Introduction

T. K. Lim¹✉

(1) Canberra, Aust Capital Terr, Australia

This book continues as volume nine of a multi-compendium on *Edible Medicinal and Non Medicinal Plants*. It covers such plants with edible modified storage subterranean stems (corms, rhizomes, stem tubers) and unmodified subterranean stem stolons, above-ground swollen stems and hypocotyls, storage roots (taproot, lateral roots, root tubers) and bulbs that are eaten as conventional or functional food as vegetables and spices, as herbal teas, and may provide a source of food additive or nutraceuticals. A list of such edible plant species from families: Acanthaceae to Zygophyllaceae are presented in a tabular form (Table 1) and 32 such edible species from the families Alismataceae, Amaryllidaceae, Apiaceae, Araceae, Araliaceae, Asparagaceae, Asteraceae, Basellaceae, Brassicaceae and Campanulaceae are covered in detail in separate chapters. Other such edible species in the families: Amaranthaceae, Cannaceae, Cibotiaceae, Convolvulaceae, Cyperaceae, Dioscoreaceae, Euphorbiaceae, Fabaceae, Iridaceae, Lamiaceae, Marantaceae, Nelumbonaceae, Nyctaginaceae, Nymphaeaceae, Onagraceae, Orchidaceae, Oxalidaceae, Piperaceae, Poaceae, Rubiaceae, Simaroubaceae, Solanaceae, Tropaeolaceae, Typhaceae and Zingiberaceae will be covered in detail in the next volume. Many plants with such edible plant parts that are better known for their edible fruits or flowers have been covered in earlier volumes and for those better known for other nonreproductive plant parts will be covered in latter volumes.

Table 1 Plants with edible modified stems, roots and bulbs

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Abelmoschus crinitus</i> Wall.	Malvaceae	Hairy Okra	Tuberous taproots are edible	Groen et al. (1996)
<i>Abelmoschus ficulneus</i> (L.) Wight & Arn.	Malvaceae	White Wild Musk Mallow, Native Rosella	Underground taproot is eaten	Cribb and Cribb (1987) and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Abelmoschus manihot</i> (L.) Med.	Malvaceae	Sunset Muskmallow, Sunset Hibiscus, Hibiscus Manihot, Aibika; Qiu kui (Chinese)	Taproots are boiled with pork in broth	Hu (2005)
<i>Abelmoschus moschatus</i> Medik.	Malvaceae	Bush Carrot	Underground taproot is eaten	Cribb and Cribb (1982, 1987) and Facciola (1990)
<i>Abronia latifolia</i> Eschsch.	Nyctaginaceae	Yellow Sand Verbena	Root is edible	Yanovsky (1936) and Facciola (1990)
<i>Abuta platyphylla</i> , Mart. ex Eichler	Menispermaceae	Videira Silvestre, Uva Do Apa, Parreira Brava	Brazil (northeast): a flour is extracted from the root starch	De Castro (1952)
<i>Acacia bidwillii</i> Benth.	Fabaceae	Corkwood Wattle	Young roots are cooked as food by the aborigines	Cribb and Cribb (1982, 1987)
<i>Acacia crassicaarpa</i> Benth.	Fabaceae	Northern Wattle, Thick-Podded Salwood, Brown Salwood, Papua New Guinea Red Wattle, Red Wattle	As above	Cribb and Cribb (1982, 1987)
<i>Acacia holosericea</i> G. Don	Fabaceae	Silver Leaf Wattle	As above	Cribb and Cribb (1987)
<i>Achasma loroglossum</i> (Gagnep) K. Larsen	Zingiberaceae	Karphul, Gandh Tora (Assamese)	Aromatic rhizomes are eaten fresh or with betel nut or as masticatory. Small bits are added in curries for flavour	Patiri and Borah (2007)
<i>Acianthus collinus</i> D.L. Jones = <i>Acianthus fornicatus</i> R. Br.	Orchidaceae	Mountain Giant Orchid	Tuber is edible	Harden (1993)
<i>Acianthus apprimus</i> D.L. Jones = <i>Acianthus fornicatus</i> R. Br.	Orchidaceae	Pixie Caps, Mosquito Orchid, Mayfly Orchids	Tuber is edible	Harden (1993)
<i>Acianthus exsertus</i> R. Br.	Orchidaceae	Mosquito Orchid	Tuber is edible	Harden (1993)
<i>Acianthus fornicatus</i> R. Br.	Orchidaceae	Pixie Caps, Mosquito Orchid, Mayfly Orchids	Tuber is edible	Harden (1993)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Acianthus pusillus</i> D.L. Jones = <i>Acianthus</i> <i>exsertus</i> R. Br.	Orchidaceae	Gnat Orchid, Mosquito Orchid	Tuber is edible	Harden (1993)
<i>Acianthus</i> sp.	Orchidaceae	Pixie Caps	Tubers are eaten by aborigines	Cribb and Cribb (1987)
<i>Aciphylla</i> <i>squarrosa</i> J.R. Forst. & G. Forst.	Apiaceae	Common Speargrass	Roots are edible	Facciola (1990)
<i>Aconitum</i> <i>carmichaelii</i> Debeaux	Ranunculaceae	Sichuan Aconite, Bai Fu Pian (Chinese)	Young tubers are used as tonic in broth with chicken especially for the elderly	Hu (2005)
<i>Acorus calamus</i> L.	Araceae	Calamus, Sweet Flag, Sweet Myrtle, Myrtle Sedge, Sweet Root, Beewort	Starch-rich rhizome is peeled and washed to remove acrid element before consumption; rootstock is candied, chewed as ginger substitute and to sweeten the breath	Read (1946), Burkill (1966), Uphof (1968), Morton (1976), Gibbons and Tucker (1979), Fernald et al. (1958), and Facciola (1990)
<i>Acorus gramineus</i> Aiton	Araceae	Grass-Leaved Sweet Flag, Japanese Sweet Flag, Japanese Rush	Rhizome after peeling and washing is eaten fried or oil roasted, also used as flavouring	Hedrick (1972), Tanaka (1976), and Facciola (1990)
<i>Acrostichum</i> <i>speciosum</i> Willd.	Pteridaceae	Mangrove Fern	Starch-rich underground stem is eaten	Cribb and Cribb (1987) and Low (1989)
<i>Adansonia</i> <i>digitata</i> L.	Malvaceae	Baobab, Dead-Rat Tree, Bottle Tree, Monkey-Bread Tree Baobab	Tuberous roots are edible	Facciola (1990), Sidibe and Williams (2002), and Lim (2012a)
<i>Adansonia</i> <i>gregorii</i> F. Muell.	Malvaceae	Baobab, Bottle Tree, Monkey Fruit Tree, Cream of Tartar Tree, Sour Gourd Tree and Upside-Down Tree	Tuberous roots are edible	Johnson et al. (2002, 2006) and Lim (2012a)
<i>Adenochilus</i> <i>nortonii</i> Fitzg.	Orchidaceae	Creeping Fairy Orchid	Tubers are edible	Harden (1993)
<i>Adenophora</i> <i>polymorpha</i> var. <i>latifolia</i> (Fisch.) Herder	Campanulaceae	Bluebell	In China, root is boiled in two changes of water and eaten	Read (1946)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Adenophora remotiflora</i> (Siebold & Zucc.) Miq.	Campanulaceae	Panicked Lady Bells	As above	Read (1946)
<i>Adenophora stricta</i> Miq.	Campanulaceae	Sha Shen (Chinese), Ladybells	As above	Read (1946)
<i>Adenophora tetraphylla</i> (Thunb.) Fisch. = <i>Adenophora triphylla</i> (Thunb.) A. DC.	Campanulaceae	Ladybell Root, Nan Sha Shen (Chinese)	Fusiform taproot is dried, used with Chinese jujubes, lotus rhizome and pork chops with bones for soup	Hu (2005)
<i>Adenophora triphylla</i> (Thunb.) A.DC.	Campanulaceae	Ladybell Root	As above	Codex (2014)
<i>Adenophora verticillata</i> Fisch. = <i>Adenophora triphylla</i> (Thunb.) A.DC.	Campanulaceae	As above	As above	Read (1946) and Uphof (1968)
<i>Adhatoda zeylanica</i> Medik. = <i>Justicia adhatoda</i> L.	Acanthaceae	Jok An Kelok (Assamese)	Root is eaten in Karbi, Assam	Kar and Borthakur (2008)
<i>Agave utahensis</i> Engelm.	Asparagaceae	Utah Agave	Roots are edible	Gibbons and Tucker (1979) and Facciola (1990)
<i>Agropyron repens</i> (L.) P. Beauv. = <i>Elymus repens</i> (L.) Gould	Poaceae	English Couch, Quick Grass	Roots are ground into a meal and used to make bread	Cribb and Cribb (1987)
<i>Alisma plantago-aquatica</i> L.	Alismataceae	European Water Plantain, Water Plantain, Deil's Spoons, Devil's Spoons	Roots are edible	Gibbons and Tucker (1979), Fernald et al. (1958), and Facciola (1990)
<i>Allium altaicum</i> Pall.	Amaryllidaceae	Altai Onion	Bulb is used as spice	Seidemann (2005)
<i>Allium ampeloprasum</i> cv. group Leek		Leek	Pseudostem/bulb is eaten, boiled, braised or blanched	Sulistiorini and van der Meer (1994)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Allium ampeloprasum</i> L.	Amaryllidaceae	Leek	Pseudostem/bulb is eaten, boiled, braised or blanched and served with a white sauce or cheese dressing	Hu (2005), Seidemann (2005), and van Wyk (2006)
<i>Allium angolense</i> Baker = <i>Allium cepa</i> L.	Amaryllidaceae	African Onion, African Shallot	Bulb is used as spice	Seidemann (2005)
<i>Allium angulosum</i> L.	Amaryllidaceae	Edged Garlic	Bulb is used as spice	Seidemann (2005)
<i>Allium ascalonium</i> L.	Amaryllidaceae	Shallot	Bulbs are eaten	Hu (2005), Seidemann (2005), and Walter and Lebot (2007)
<i>Allium canadense</i> L.	Amaryllidaceae	Canada Onion, American Wild Onion	Bulb is used as spice	Seidemann (2005)
<i>Allium carinatum</i> L.	Amaryllidaceae	Keeled Garlic	Bulb is used as spice	Seidmann (2005)
<i>Allium cepa</i> L.	Amaryllidaceae	Onion, Common Onion	Bulbs are eaten chopped, sliced dice, fresh or cooked, sautéed, stewed, fried and roasted or in soups, sauces, curries, sauces or with meat dishes	Phillips and Rix (1993), Hu (2005), Seidemann (2005), van Wyk (2006), Walter and Lebot (2007), and Santich et al. (2008)
<i>Allium cepa</i> L. cv. group Common Onion	Amaryllidaceae	Onion, Common Onion	As above	Van der meer and Leong (1994)
<i>Allium cepa</i> L. cv. group Aggregatum	Amaryllidaceae	Shallots, Multiplier Onion, Echalote	Bulb is used as food, spice and seasoning	Permadi and van der Meer (1994)
<i>Allium chinense</i> G. Don	Amaryllidaceae	Chinese Shallot, Rakyok Lokyo	Bulb is eaten, pickled or served as salted sour preserves or sweets	van der meer and Agustina (1994), Hu (2005), and Seidemann (2005)
<i>Allium chrysanthum</i> Regel	Amaryllidaceae	Wild Onion, Tain Cong (Chinese)	Whole plant including the oblong cylindrical bulb is eaten	Hu (2005)
<i>Allium consanguineum</i> Kunth	Amaryllidaceae	None	Bulb is used as spice	Seidemann (2005)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Allium fistulosum</i> L.	Amaryllidaceae	Welsh Onion, Bunching Onion, Scallion	Pseudostem and leaves are used in Asian cooking, in salads, stir-fries, noodles, soups, spring rolls and salads	Phillips and Rix (1993), Oyen and Soenoeadi (1994), Hu (2005), van Wyk (2006), and Santich et al. (2008)
<i>Allium hookeri</i> Thwaites	Amaryllidaceae	Broad-Leaved Leek, Kuan Ye Jiu (Chinese)	Fleshy roots are eaten in Yunnan	Hu (2005)
<i>Allium ledebourianum</i> Schult. & Schult.f.	Amaryllidaceae	Tartar Scallion, Xiao Cong (Chinese)	Whole plant including ovoid bulb is eaten	Hu (2005)
<i>Allium lineare</i> L.	Amaryllidaceae	Northern Leek, Thread Onion, Bei Jiu (Chinese)	Young plant with small bulb is eaten	Hu (2005)
<i>Allium macrostemon</i> Bunge	Amaryllidaceae	Chinese Field Garlic, Xiao Suan (Chinese)	Young plant with fleshy subglobose or ovoid bulb is eaten	Hu (2005)
<i>Allium moly</i> L.	Amaryllidaceae	Lily Leek, Moly, Yellow Onion	Bulb is used as spice	Seidemann (2005)
<i>Allium mongolicum</i> Regel	Amaryllidaceae	Mongolian Leek, She Cong (Chinese)	Young plant with bulb is eaten	Hu (2005)
<i>Allium neapolitanum</i> Cirillo	Amaryllidaceae	Daffodil Garlic, Naples Garlic, False Garlic, Neapolitan Garlic	Bulb is used as spice/condiment	Seidemann (2005)
<i>Allium obliquum</i> L.	Amaryllidaceae	Oblique Garlic	Bulb is used as spice	Seidemann (2005)
<i>Allium oleraceum</i> L.	Amaryllidaceae	Field Garlic	Bulb is used as spice	Seidemann (2005)
<i>Allium oschaninii</i> O. Fedtsch.	Amaryllidaceae	Oschanin-Zwiebel (German)	Bulb is used as spice	Seidemann (2005)
<i>Allium paradoxum</i> (M. Bieb.) G. Don	Amaryllidaceae	Few-Flowered Leek	Bulb is used as spice	Seidemann (2005)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Allium porrum</i> L.	Amaryllidaceae	Leek	When braised or slow roasted, the white bulb takes on a buttery texture, excellent additions to meat and chicken, also excellent in stir-fries with seafood and in soups	Phillips and Rix (1993), Seidemann (2005), and Santich et al. (2008)
<i>Allium x proliferum</i> (Moench) Schrad. ex Willd.	Amaryllidaceae	Egyptians, Catawissa Onion, Top Onion, Tree Onion	Bulb is used as spice	Seidemann (2005)
<i>Allium pskemense</i> B. Fedtsch.	Amaryllidaceae	Pskemense-Zwiebel (German)	Bulb is used as spice	Seidemann (2005)
<i>Allium sativum</i> L.	Amaryllidaceae	Garlic	Bulbs are eaten raw in dressings, salads, marinades and sauces. Pickled garlic is used as condiments and as ingredient for other dishes. Cooked garlic is used as flavouring agent in soups, stir-fries, stews, vegetables, meat and seafood dishes and noodles	Phillips and Rix (1993), van der Meer and Permadi (1994), Hu (2005), van Wyk (2006), Walter and Lebot (2007), and Santich et al. (2008)
<i>Allium sativum</i> L. var. <i>ophioscorodon</i> (Link) Döll = <i>Allium sativum</i> L.	Amaryllidaceae	Rocambole, Giant Garlic, Serpent Garlic	Bulb is used as spice	Seidemann (2005)
<i>Allium schoenoprasum</i> L.	Amaryllidaceae	Garden Chives	Narrow bulbs and leaves are edible	Phillips and Rix (1993) and van Wyk (2006)
<i>Allium senescens</i> L.	Amaryllidaceae	German Garlic	Young bulb and leaves are eaten	Hu (2005)
<i>Allium tricoccum</i> Aiton	Amaryllidaceae	Wild Leek	Young bulbs are sweet and flavoursome, eaten raw or cooked by native Indians	Saunders (1920)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Allium tuberosum</i> Rottler ex Sprengel	Amaryllidaceae	Chinese Leek	Insignificant small bulbs are seldom used; leaves and flower buds and stalks are commonly used	Phillips and Rix (1993), van der meer (1994), Hu (2005), and van Wyk (2006)
<i>Allium victorialis</i> L.	Amaryllidaceae	Wild Onion, Ge Cong (Chinese)	Leaves and cylindrical bulbs are eaten	Hu (2005)
<i>Alocasia acuminata</i> Schott	Araceae	Kochu (Assamese), Thaso (Bodo), Ange (Mishing)	Young shoots, tender leaves and corms are eaten, cooked mostly with acidic fruit	Patiri and Borah (2007)
<i>Alocasia cucullata</i> (Lour.) G. Don	Araceae	Panchamukhi Kochu, Boga Kachu (Assamese)	Corm, cormel and stem are eaten as vegetable. Chips can also be prepared from it	Burkill (1966), Groen et al. (1996), and Patiri and Borah (2007)
<i>Alocasia fornicata</i> (Roxb.) Schott	Araceae	Bez Kachu, Bees Kachu (Assamese and Bengali)	Petioles and corms are eaten cooked with much acidic fruit like 'Thekera' or tamarind	Patiri and Borah (2007)
<i>Alocasia indica</i> (Lour.) Spach = <i>Alocasia macrorrhiza</i> (L.) G. Don	Araceae	Giant Alocasia Kachu (Assamese and Bengali)	Corm and shoots are eaten cooked by many communities with acidic fruits in Assam. It can also be preserved by slicing and drying for later use	Patiri and Borah (2007) and Codex (2014)
<i>Alocasia macrorrhiza</i> (L.) G. Don	Araceae	Alocasia, Cunjevoi, Henchala (Assamese)	Stem and corm are baked and pounded by aborigines in Australia. Corm is eaten in Karbi, Assam	Cribb and Cribb (1982, 1987), Low (1989), Phillips and Rix (1993), Groen et al. (1996), Walter and Lebot (2007), Kar and Borthakur (2008), and Codex (2014)
<i>Alocasia portei</i> Schott	Araceae	Elephant Ear, Badiang (Bikol, Philippines)	Corm, cormel and petiole are eaten as vegetable	Groen et al. (1996)
<i>Alpinia calcarata</i> (Haw.) Roscoe	Zingiberaceae	Indian Ginger, Snap Ginger	Rhizome is used as galangal substitute	Seidemann (2005)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Alpinia caerulea</i> (R. Br.) Benth.	Zingiberaceae	Australian Blue Ginger, Native Ginger	Young rhizome is eaten raw or cooked	Cribb and Cribb (1987), Facciola (1990), Seidemann (2005)
<i>Alpinia conchigera</i> Griff.	Zingiberaceae	Lesser Alpinia, Mussel Galangal; Lengkuas Ranting (Malay); Riềng Rừng (Vietnamese)	Rhizome is used as food flavouring and flavouring of alcoholic drinks	Perry (1980), Wong et al. (2005), Seidemann (2005), and Faridah et al. (2010)
<i>Alpinia galanga</i> (Linn) Willd.	Zingiberaceae	Galangal, Greater Galangal; Languas, Lenguas (Indonesia, Malaysia); Phrikgnak (Assamese); Riềng Nếp (Vietnamese)	Rhizomes are used as spice fresh or cooked in everyday cooking, in curries and meat dishes. Essential oil extract from rhizome is used to flavour liqueurs, ice cream, pastry, etc. Rhizome is eaten in Karbi, Assam, India. In Indonesia, young rhizomes are sliced and used in side dishes as sayur or sambal, and the juice is used in the preparation of <i>dengdeng</i>	Watt (1908), Ochse and van den Brink (1980), Scheffer and Jansen (1999), Seidemann (2005), van Wyk (2006), and Kar and Borthakur (2008)
<i>Alpinia latilabris</i> Ridl.	Zingiberaceae	Ry (Vietnamese)	Rhizome is used as food flavouring. In Vietnam, bitter rhizome is used as spice	Wong et al. (2005) and Tanaka and Nguyen (2007)
<i>Alpinia malaccensis</i> (Burm.f.) Roscoe	Zingiberaceae	Malacca Galangal; Riềng Malacca (Vietnamese)	Rhizome is used as spice	Burkill (1966), Kashio and Johnson (2001), Seidemann (2005), and Sirat et al. (2011)
<i>Alpinia nigra</i> (Gaertn.) Burt	Zingiberaceae	Tora (Assamese), Tareng (Mishing), Tharai (Bodo)	Young shoots and rhizomes are eaten either raw or cooked	Patiri and Borah (2007)
<i>Alpinia officinarum</i> Hance	Zingiberaceae	Lesser Galangal, Smaller Galangal, Chinese Ginger; Riềng Thuoc (Vietnamese)	Rhizome is used as spice for flavouring	Ly et al. (2003) and Seidemann (2005)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Alpinia zerumbet</i> (Pers.) B.L. Burtt & R.M. Sm.	Zingiberaceae	Bright Ginger, Pink Porcelain Lily, Light Ginger; Riềng Đẹp, Riềng ẩm (Vietnamese)	Rhizome is edible, used as spice for flavouring	Seidemann (2005)
<i>Alstonia acuminata</i> Miq. = <i>Alstonia macrophylla</i> Wall. ex G. Don	Apocynaceae	Ajooras, Poole Batoo	Root is used to add bitterness to palm toddy	Burkill (1966) and Seidemann (2005)
<i>Althaea officinalis</i> L.	Malvaceae	Marshmallow, Marsh Mallow, Common Marshmallow	Roots are boiled, sliced and fried with onion. Root decoction is used as substitute for egg white in meringue or chiffon pies	Uphof (1968), Hedrick (1972), Gibbons and Tucker (1979), and Facciola (1990)
<i>Ammobroma sonora</i> Torr. ex A. Gray = <i>Pholisma sonora</i> (Torr. ex A. Gray) Yatsk.	Boraginaceae	Sand Food, Camote De Los Medanos	The subterranean stem is tender, juicy and sweet – a refreshing and luscious morsel, meat and drink in one	Saunders (1920)
<i>Amorphophallus campanulatus</i> Decne. = <i>Amorphophallus paeoniifolius</i> (Dennst.) Nicolson	Araceae	Elephant Foot Yam; Kurrana Kalungu (Tamil); Konda, Muncha Kunda (Telugu)	Corms are eaten after being cooked or baked in India (Madras Presidency)	Shortt (1887–1888), Burkill (1966), Facciola (1990), Phillips and Rix (1993), Walter and Lebot (2007), and Codex (2014)
<i>Amorphophallus aphyllus</i> (Hook.) Hutch.	Araceae	Bombole (Kissi, Guinea), Baga (Mandingo–Bambara, Mali)	Sudan (western): corms are dried and then boiled to remove the acrid element, eaten in times of scarcity by the Wolof people of the Cayor region	Irvine (1952)
<i>Amorphophallus bulbifer</i> (Roxb.) Blume	Araceae	Hen Salku (Assamese)	Corm is eaten in Karbi, Assam	Kar and Borthakur (2008)
<i>Amorphophallus consimilis</i> Blume	Araceae	Apaty (Basari), Gingi (Bedik)	In Senegal and Guinea, corms are eaten	Ferry et al. (1974)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Amorphophallus dracontoides</i> (Engl.) N.E. Br.	Araceae	Kinciya (Hausa)	Africa (west): corms are eaten after being cut up, repeatedly washed and boiled for 1 or 2 days. Nigeria (Kano State, northern): tuber is eaten, requires 2-day boiling to detoxify	Irvine (1952) and Mortimore (1989)
<i>Amorphophallus galbra</i> F.M. Bailey	Araceae	Cheeky Yam, Queensland Yellow Lily Yam, Sweet Snakeskin Lily	Corms are grated, pounded, soaked and baked	Cribb and Cribb (1987) and Low (1989)
<i>Amorphophallus glabra</i> F.M. Bailey = <i>Amorphophallus galbra</i> F.M. Bailey	Araceae	As above	Corms are eaten	Roth (1901)
<i>Amorphophallus konjac</i> K. Koch	Araceae	Elephant Foot Yam	Corms are eaten	Jansen et al. (1996) and Codex (2014)
<i>Amorphophallus mairei</i> H. Lev. = <i>Amorphophallus konjac</i> K. Koch	Araceae	Elephant Foot Yam	Corms are eaten in Yunnan and Laos	Hu (2005)
<i>Amorphophallus muelleri</i> Blume	Araceae	Elephant Foot Yam	Corms are edible	Jansen et al. (1996)
<i>Amorphophallus paeoniifolius</i> (Dennst.) Nicolson	Araceae	Elephant Foot Yam	Corms are edible	Wightman and Andrews (1989, 1991), Jansen et al. (1996), and Codex (2014)
<i>Amorphophallus rivieri</i> Durand ex Carrière = <i>Amorphophallus konjac</i> K. Koch	Araceae	Devil's Tongue, Leopard Palm, Snake Palm, Mo Yu (Chinese)	China: corm is ground and processed into a rich starch used for making a jelly-like food	Hu (2005)
<i>Amorphophallus sylvaticus</i> Kunth	Araceae	Elephant Foot Yam	In India (Deccan), corms and leaves are eaten	Watt (1908)
<i>Amorphophallus variabilis</i> Blume	Araceae	Elephant Foot Yam	Corms are eaten	Cribb and Cribb (1987), Burkill (1966), Facciola (1990), and Jansen et al. (1996)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Ampelocissus acetosa</i> (F. Muell.) Planch.	Vitaceae	Native Grape	Underground root is eaten	Cribb and Cribb (1987)
<i>Aneilema siliculosum</i> R. Br.	Commelinaceae	Djnj (Abor., Australia)	Roots are eaten raw and roasted	Cribb and Cribb (1987)
<i>Anemarrhena asphodeloides</i> Bunge	Asparagaceae	Zhi Mu (Chinese)	China: root is eaten	Read (1946)
<i>Angelica atropurpurea</i> L.	Apiaceae	Great Angelica, Purple-Stem Angelica	Roots are candied	Morton (1976), Fernald et al. (1958), and Facciola (1990)
<i>Angelica sinensis</i> (Oliv.) Diels	Apiaceae	Chinese Angelica, Dang Gui (Chinese)	Root slices are used in broth, soups with Chinese dates, goji berries, laminaria and chicken or pork as health food especially for women	Hu (2005)
<i>Angiopteris esculenta</i> Ching	Marattiaceae	Shi Yong Lian Zuo Jue (Chinese)	Starch extracted from rhizome is made into cakes or mixed with other foods	Cui (1998), Dai et al. (2003), and Cao et al. (2007)
<i>Angiopteris fokiensis</i> Hieron.	Marattiaceae	Fu Jian Lian Zuo Jue (Chinese)	As above	Cui (1998), Dai et al. (2003), Cao et al. (2007), and Yun et al. (2009a)
<i>Anigozanthos flavidus</i> DC.	Haemodoraceae	Kangaroo Paw	Rhizomes are edible	Cribb and Cribb (1987)
<i>Anigozanthos</i> spp.	Haemodoraceae	Kangaroo Paws	Rhizomes are edible	Cribb and Cribb (1987) and Low (1989)
<i>Anredera baselloides</i> (Kunth) Baill.	Basellaceae	Madeira Vine, Luo Kui Shu (Chinese)	Fresh tubers are eaten	Hu (2005) and Codex (2014)
<i>Anredera cordifolia</i> (Ten.) Steenis	Basellaceae	Madeira Vine, Lamb's Tail	Tubers are eaten boiled like potatoes	Uphof (1968), Tanaka (1976), Cribb and Cribb (1987), Facciola (1990), and Codex (2014)
<i>Anthriscus cerefolium</i> (L.) Hoffm.	Apiaceae	Chervil, Garden Chervil	Roots are eaten	Hedrick (1972), Morton (1976), and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Anthriscus nemorosa</i> (M. Bieb.) Spreng.	Apiaceae	Woodland Chervil, Lin Di-E-Shen (Chinese)	Roots are used as pickles by Chinese-Koreans	Hu (2005)
<i>Anthriscus sylvestris</i> (L.) Hoffm.	Apiaceae	Cow Parsley, Wild Chervil, Wild Beaked Parsley	Roots are eaten	Facciola (1990)
<i>Antigonon leptopus</i> (Hook. & Arm.)	Polygonaceae	Coral Vine, Honolulu Creeper, Mexican Creeper, Bride's Tears, Chain-Of-Love, Hearts On A Chain, Love-Vine	Tubers are cooked and eaten	Uphof (1968), Williams (1981), Pongpangan and Poobrasert (1985), Facciola (1990), and Lim (2014)
<i>Antiotrema dunnianum</i> (Diels) Handel-Mazz.	Boraginaceae	Chang Rui Ban Zhong Cao (Chinese)	Roots are eaten by mountain people in Yunnan	Hu (2005)
<i>Apios americana</i> Medik.	Fabaceae (Leguminosae)	American Potato Bean	Tuberous roots are eaten raw or cooked	Facciola (1990), Phillips and Rix (1993), and Codex (2014)
<i>Apios fortunei</i> Maxim.	Fabaceae	Potato Bean, Groundnut	Thick tubers are eaten as emergency food in China	Read (1946) and Hu (2005)
<i>Apios tuberosa</i> Moench = <i>Apios americana</i> Medik.	Fabaceae	Groundnut, Wild Bean, Potato Bean, American Potato Bean, Indian Potato	Starchy tuber is eaten	Saunders (1920)
<i>Apium graveolens</i> Rapaceum Group	Apiaceae	Celeriac	Roots are sliced or grated and eaten raw in salads, braised, pureed, marinated, baked, mashed, cooked as vegetable and used in stews, fritters, soups and stuffings	Uphof (1968), Hedrick (1972), Halpin (1978), Facciola (1990), and Santich et al. (2008)
<i>Apium graveolens</i> L. var. <i>rapaceum</i> (Mill.) Gaudin	Apiaceae	Celeriac	As above	Codex (2014)
<i>Aplectrum hyemale</i> (Muhl. ex Willd.) Nutt.	Orchidaceae	Putty Root, Adam and Eve	Corm is boiled served with butter	Facciola (1990)
<i>Aponogeton distachyos</i> L.f.	Aponogetonaceae	Cape Asparagus, Water Onion, Water Hawthorn	Starchy root is eaten roasted in southern Africa	Hedrick (1972), Fox et al. (1982), and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Aponogeton elongatus</i> F. Muell. ex Benth.	Aponogetonaceae	Queensland Lace Plant	Tuber is eaten cooked	Cribb and Cribb (1987)
<i>Aponogeton fenestralis</i> (Pers.) Hook.f. = <i>Aponogeton madagascariensis</i> (Mirb.) H. Bruggen	Aponogetonaceae	Madagascar Lace Leaf	Starchy tuber is eaten	Burkill (1966)
<i>Aponogeton lakhonensis</i> A. Camus	Aponogetonaceae	Sbai Mung (Kampuchean), Phakphuap (Thai)	Starchy tuberous rhizomes are eaten during famine	Groen et al. (1996)
<i>Aponogeton monostachyon</i> L.f. = <i>Aponogeton natans</i> (L.) Engl. & K. Krause	Aponogetonaceae	Kotee Kalungu (Tamil), Nama (Telugu)	In India (Madras Presidency), tubers are eaten after boiling	Shortt (1887–1888)
<i>Aponogeton queenslandicus</i> H. Bruggen	Aponogetonaceae	Laceleaf	Tuber is cooked	Cribb and Cribb (1987)
<i>Aponogeton undulatus</i> Roxb.	Aponogetonaceae	Undulated Leaf <i>Aponogeton</i>	Starchy tuberous rhizomes are eaten during famine	Groen et al. (1996)
<i>Aralia cordata</i> Thunb.	Araliaceae	Udo, Japanese Spikenard, Mountain Asparagus, Tu Dang Gui (Chinese)	Roots are eaten as parsnips	Hu (2005)
<i>Aralia racemosa</i> L.	Araliaceae	American Spikenard, Petty Morel	Roots are used as an ingredient of root beer. Menomonic Indians used roots in a dish with wild onion, wild gooseberry and sugar	Fernald et al. (1958) and Facciola (1990)
<i>Araucaria bidwillii</i> Hook.	Araucariaceae	Bunya Pine	Germinated seed produces an underground earthnut which has a coconut flavour	Menninger (1977), Cribb and Cribb (1987), and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Arctium lappa</i> L.	Asteraceae	Great Burdock, Edible Burdock, Burdock, Gobo	China: roots and leaves are eaten. It may be eaten raw. France: starch of root is recommended for extending bread flour, after removal of bitter element. Grated root is added to soups and stews; slices or slivers are used in stir-fries	Read (1946), Facciola (1990), Phillips and Rix (1993), Van den Bergh (1994), Hu (2005), van Wyk (2006), and Codex (2014)
<i>Argyrolobium marginatum</i> Bolus	Fabaceae	Izi Ntondo (Zulu)	In Zululand (Ubombo district), roots are eaten cooked or uncooked	Hely-Hutchinson (1898)
<i>Arisaema curvatum</i> (Roxb.) Kunth = <i>Arisaema tortuosum</i> (Wall.) Schott	Araceae	Curved-Hood Cobra Lily	India: corms are eaten	Watt (1908)
<i>Arisaema concinnum</i> Schott	Araceae	Chinese Cobra Lily	Starchy corms are eaten	Burkill (1966) and Groen et al. 1996
<i>Arisaema murrayi</i> (J. Graham) Hook.	Araceae	Baddha, Dhudha, Diwa (Bombay)	In India (Bombay Presidency), corms are cooked in water and mixed with salt and chilli peppers	Gammie (1902)
<i>Arisaema speciosum</i> (Wall.) Mart.	Araceae	Cobra Lily	Starchy corms are eaten	Burkill (1966) and Groen et al. (1996)
<i>Arisaema tortuosum</i> (Wall.) Schott	Araceae	Curved-Hood Cobra Lily	India: corms are cooked in water and mixed with salt and chilli peppers. Corms are eaten in Karbi, Assam	Gammie (1902) and Kar and Borthakur (2008)
<i>Arisaema triphyllum</i> Torr. = <i>Arisaema triphyllum</i> (L.) Schott	Araceae	Jack-in-the-Pulpit	Small, turnip-shaped corm is eaten after thorough processing	Saunders (1920) and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Arisarum simorrhinum</i> Durieu	Araceae	Ouden El-Fil, Cebot El-Ghoula, Kelb El-Beqouqa, Rejel El Begra (Berber); Tioughda, Tiqqenousine, Quaba, Abbouq, Taourza, Airni, Hierni, Idjened Tikilmout (Arabic, Tunisia)	In Tunisia, rootstock is gathered, dried, pulverised and mixed with the flour of barley or wheat	Bouquet (1939)
<i>Arisarum vulgare</i> O. Targ. Tozz.	Araceae	Friar's Cowl	As above	Bouquet (1939)
<i>Aristolochia rotunda</i> L.	Aristolochiaceae	Snakeroot, Smearwort, Round-Leaved Birthwort, English Mercury, Mercury Goosefoot	In France, starch of root is recommended as a famine food for extending bread flour, after removal of acrid elements	Parmentier (1781) (cited by Freedman 2009)
<i>Armoracia rusticana</i> P. Gaertn., B. Mey. & Scherb.	Brassicaceae	Horseradish	Roots with sharp mustard flavour, used as condiment with fish, sausages, poached chicken, egg salad, potato salad, dips, mustards, relishes, sauces, marinades, salad dressings and drinks, go well with beetroots, also dried, ground and mixed with vinegar, milk and seasoning to make horseradish sauce often used with beef	Facciola (1990), Phillips and Rix (1993), Nicols and Jansen (1999), Hu (2005), van Wyk (2006), Santich et al. (2008), and Codex (2014)
<i>Arracacia xanthorrhiza</i> Bancroft	Apiaceae	Arracacha, White Carrot, Peruvian Parsnip	Secondary tuber, starchy and sweet, is eaten boiled or fried	Facciola (1990), Groen et al. (1996), Hermann and Heller (1997), and Codex (2014)
<i>Artemisa brachyloba</i> Franch.	Asteraceae	Mongolian Sagebrush, Yan Hao (Chinese)	Roots are used in tea in Inner Mongolia	Hu (2005)
<i>Arthropodium milleflorum</i> (Dc.) J.F. Macbr.	Asparagaceae	Pale Vanilla Lily	Sweet-bitter tubers are eaten by aborigines	Cribb and Cribb (1987), Low (1991), and Harden (1993)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Arthropodium minus</i> R. Br.	Asparagaceae	Vanilla Lilies	As above	Low (1991)
<i>Arum dracunculus</i> L. = <i>Dracunculus vulgaris</i> Schott	Araceae	Dragon Arum	France: starch of root is recommended as a famine food for extending bread flour, after removal of acrid element	Parmentier (1781) (cited by Freedman 2009)
<i>Arum incurvatum</i> Lam. = <i>Arisarum vulgare</i> subsp. <i>vulgare</i>	Araceae	Friar's Cowl, Larus	France: starch of root is recommended as a famine food for extending bread flour, after removal of acrid element	Parmentier (1781) (cited by Freedman 2009)
<i>Arum italicum</i> Mill.	Araceae	Italian Arum	Eaten in Tunisia (as for <i>Arisarum simorrhinum</i>)	Bouquet (1939)
<i>Arum lyratum</i> Roxb. = <i>Amorphophallus lyratus</i> (Roxb.) Kunth	Araceae	Kondai Rakis (Tamil), Konda Rakis (Telugu)	India (Madras Presidency): roots are eaten after careful boiling	Shortt (1887–1888) (cited by Freedman 2009)
<i>Arum maculatum</i> L.	Araceae	Snakeshead, Adder's Root, Arum, Wild Arum	Tunisia: as for <i>Arisarum simorrhinum</i>	Bouquet (1939)
<i>Arum vulgare</i> Lam. = <i>Arum maculatum</i> L.	Araceae	As above	France: starch of root is recommended as a famine food for extending bread flour, after removal of acrid element	Parmentier (1781) (cited by Freedman 2009)
<i>Asarum canadense</i> L.	Aristolochiaceae	Woodland Ginger, Ginger Root, Heart Snakeroot, Indian Ginger, American Wild Ginger	Rootstock is used as flavouring, boiled in syrup to form candied wild ginger. Syrup is used on ice cream and other desserts	Gibbons and Tucker (1979), Fernald et al. (1958), and Facciola (1990)
<i>Asarum caudatum</i> Lindl.	Aristolochiaceae	Long-Tailed Wild Ginger	Rootstock is used as ginger substitute	Uphof (1968) and Facciola 1990
<i>Asclepias speciosa</i> Torr.	Apocynaceae	Showy Milkweed	Roots are edible cooked	Fernald et al. (1958), Harrington (1974), and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Asclepias tuberosa</i> L.	Apocynaceae	Butterfly Weed, Canada Root, Chieger Flower, Chiggerflower, Fluxroot, Indian Paintbrush	Tubers are said to be edible; some say they are poisonous	Yanovsky (1936), Hedrick (1972), Fernald et al. (1958), Harrington (1974), and Facciola (1990)
<i>Asparagus cochinchinensis</i> (Lour.) Merr.	Asparagaceae	Chinese Asparagus Root, Tumpeang (Kampuchean)	Tubers are eaten candied	Tanaka (1976), Facciola (1990), and Groen et al. (1996)
<i>Asparagus pauli-guilelmi</i> Solms-Laub. = <i>Asparagus flagellaris</i> (Kunth) Baker	Asparagaceae	Hyena Thorn, Gi'e Fowru (Fulade)	Africa (west): the tubers of this wild variety are boiled and then eaten	Irvine (1952) and Uphof (1968)
<i>Asparagus racemosus</i> Willd.	Asparagaceae	Shatavari, Wild Asparagus, Sparrow Grass	India (Rajasthan, western): fasciculated roots are eaten as vegetable; tuberous roots are eaten candied in Indonesia and made into conserve in India	Gupta (1962), Gupta and Kanodia (1968a, b), and Groen et al. (1996)
<i>Asparagus sarmentosus</i> L.	Asparagaceae	Challa-Gaddalu, Kilavari, Pappakilangu (India)	Fleshy roots are eaten in India and Sri Lanka. In China they are candied	Watt (1908), Hedrick (1972), and Facciola (1990)
<i>Asphodeline lutea</i> (L.) Rchb.	Xanthorrhoeaceae	Asphodel, Flower of the Dead	Roots are roasted and eaten like potatoes	Hedrick (1972) and Facciola (1990)
<i>Asphodelus albus</i> Mill.	Xanthorrhoeaceae	White Asphodel	In France, root is recommended as a famine food. After cooking and reducing to a pulp, it is suggested it be blended into a confection with barley and buckwheat flour	Parmentier (1781) (cited by Freedman 2009)
<i>Asphodelus fistulosus</i> L.	Xanthorrhoeaceae	Onion Weed, Pink Asphodel	France: root is recommended as a famine food. Prepared as above. India: tubers are eaten	Parmentier (1781) (cited by Freedman 2009); WATT

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Asplenium bulbiferum</i> G. Forst.	Aspleniaceae	Hen and Chicken Fern, Pikopiko	Roots are eaten	Kunkel (1984) and Facciola (1990)
<i>Asplenium unilaterale</i> Lam.	Aspleniaceae	Pamohe	Rhizome is used fresh in snacks and salads	Yun et al. (2009b)
<i>Astragalus fraxinifolius</i> DC.	Fabaceae	Astragal Yasenelistnyi (Russian)	Starch of root is recommended as a famine food for extending bread flour, after removal of bitter element	Parmentier (1781) (cited by Freedman 2009)
<i>Astragalus membranaceus</i> (Fisch.) Bunge = <i>Astragalus propinquus</i> Schischkin	Fabaceae	Astragalus, Huangchoy (Chinese)	Dried root slices are used in combination with <i>Codonopsis</i> (dang shen) goji berries for a tonic soup with spare ribs	Hu (2005)
<i>Atamasco atamasco</i> (L.) Greene = <i>Zephyranthes atamasco</i> (L.) Herb.	Amaryllidaceae	<i>Atamasco</i> Lily, Rain Lily, Zephyr Lily	In North America, bulbous roots are eaten by Creek tribe in times of scarcity	Yanovsky (1936) and Hedrick (1972)
<i>Athamanta sicula</i> L.	Apiaceae	Spignel; Spaccapietre (Sicilian)	Roots are eaten	Facciola (1990)
<i>Athyrium brevifrons</i> Nakai ex Kitag.	Athyriaceae		Rhizome starch is used for cakes and noodles	Freedman (2009), Fox et al. (1982), and Gade (1975)
<i>Athyrium filix-femina</i> (L.) Roth	Athyriaceae	Lady Fern	Underground rootstock and stem are eaten after being peeled and roasting, or starch is extracted for making pastries, also used for wine making	Schofield (2003)
<i>Atylosia reticulata</i> (Dryand.) Taubert ex Ewart & Davies = <i>Cantharospermum reticulatum</i> (Dryand.) Taubert ex Ewart & Davies	Fabaceae	Not found (NF)	Roots are roasted	Cribb and Cribb (1987)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Balsamorhiza hookeri</i> (Hook.) Nutt.	Asteraceae	Balsam Root, Hooker's Balsamroot, Hairy Balsamroot	Roots are eaten raw or cooked	Yanovsky (1936), Hedrick (1972), and Facciola (1990)
<i>Balsamorhiza sagittata</i> (Pursh) Nutt.	Asteraceae	Oregon Sunflower, Arrowleaf Balsamroot	Roots are eaten raw or cooked, roasted or used as coffee substitute	Yanovsky (1936), Hedrick (1972), Kunkel (1984), and Facciola (1990)
<i>Bambusa pallida</i> Munro	Poaceae	Mokal Bah (Assamese); Mai Phiu, Phai Song Kham (Thai)	Young rhizomes are eaten as vegetable after processing	Patiri and Borah (2007)
<i>Bambusa tulda</i> Roxb.	Poaceae	Spineless Indian Bamboo, Calcutta Cane; Jati Bah (Assamese)	As above	Patiri and Borah (2007)
<i>Bauhinia hupehana</i> Craib = <i>Bauhinia glauca</i> subsp. <i>hupehana</i> (Craib) T. Chen	Fabaceae	Shen Zi Ye, Hubei Yang Ti Jia (Chinese)	Root and stem are stewed with pro kidneys and intestines or cooked with pork as special health food in Huber and Sichuan	Hu (2005)
<i>Begonia fagoproides</i> DC.	Begoniaceae	Anchan Karay (Quechua)	Peru (Vilcanota Valley): rhizome is used	Gade (1975)
<i>Beta vulgaris</i> Cicla Group	Amaranthaceae	Swiss Chard, Spinach Beet, Foliage Beet, Seakale Beet	Some cultivars of Swiss chard have edible root	Facciola (1990)
<i>Beta vulgaris</i> cv. Crassa Group	Amaranthaceae	Beet, Beet Root, Sugar Beet, Mungel Wurzel	Globose root is boiled or cooked as vegetables. Fermented beetroot juice is commercially available. Sugar beets are source of sugar, syrup and molasses	Larkcom (1984) and Facciola (1990)
<i>Beta vulgaris</i> cv. Group Garden Beet	Amaranthaceae	Beet Root, Garden Beet, Field Beet	As above	Oyen and Soenoeadi (1994)
<i>Beta vulgaris</i> cv. Group Spinach Beet	Amaranthaceae	Foliage Beet, Leaf Beet	As above	Oyen and Soenoeadi (1994)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Beta vulgaris</i> L.	Amaranthaceae	Beet, Beetroot, Garden Beet	Globose root is boiled or cooked as vegetables	Oyen and Soenoeadi (1994)
<i>Beta vulgaris</i> L. var. <i>saccharifera</i> = <i>Beta vulgaris</i> L.	Amaranthaceae	Sugar Beet	Swollen, fleshy globose root is processed for sugar	Codex (2014)
<i>Beta vulgaris</i> L. var. <i>conditiva</i> = <i>Beta vulgaris</i> L.	Amaranthaceae	Beetroot	As above	Codex (2014)
<i>Beta vulgaris</i> var. <i>esculenta</i> = <i>Beta vulgaris</i> L.	Amaranthaceae	Beet Root, Garden Beet, Field Beet	Peeled and cooked before eating, can be roasted, added to soups and pickled. Pickled beet roots are used in salads as side dish or as a condiment; slices are used in hamburgers	Facciola (1990), van Wyk (2006), Santich et al. (2008), and Phillips and Rix (1993)
<i>Beta vulgaris</i> var. <i>rapa</i> Dumont	Amaranthaceae	Garden Beet, Beet Root	As above	Hu (2005)
<i>Beta vulgaris</i> var. <i>vulgaris</i> = <i>Beta vulgaris</i> L.	Amaranthaceae	Beet, Garden Beet	Swollen, fleshy globose root is processed for sugar	Phillips and Rix (1993)
<i>Blechnum indicum</i> Burm.f. = <i>Blechnum serrulatum</i> Rich.	Blechnaceae	Bungwall Fern	Starchy rhizomes are eaten after roasting	Cribb and Cribb (1987) and Low (1989)
<i>Blechnum orientale</i> L.	Blechnaceae	Centipede Fern; Paku Lipan (Malay)	Starchy rhizomes are eaten after roasting	Cribb and Cribb (1987)
<i>Boehmeria nivea</i> (L.) Gaudich.	Urticaceae	China Grass, Ramie	China: root is eaten after boiling and peeling	Read (1946)
<i>Boerhavia coccinea</i> Mill.	Nyctaginaceae	Tar Vine, Hog Weed	Bland fibrous taproot is eaten	Cribb and Cribb (1987) and Harden (1990)
<i>Boerhavia diffusa</i> L.	Nyctaginaceae	Hog Weed, Horse Purslane; Zhu Er Yan, Huang Xi Xin (Chinese)	Fleshy portion of thick roots is roasted and eaten, sweetish and nutritious	Hu (2005)
<i>Boerhavia</i> spp.	Nyctaginaceae	Tar Vines	Bland fibrous taproot is eaten	Low (1991)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Boesenbergia pandurata</i> (Roxb.) = <i>Boesenbergia rotunda</i> (L.) Mansfield	Zingiberaceae	See below	As for <i>Boesenbergia rotunda</i>	Facciola (1990)
<i>Boesenbergia rotunda</i> (L.) Mansfield	Zingiberaceae	Chinese Keys, Temu Kunci (Indonesia, Malaysia), Krachai (Thai)	Widely used as a spice in cooking traditional Malay, Indonesian, Laotian and Thai cuisine – mixed vegetable dishes, fish curries, soups and pickles. Aromatic rhizome is used in <i>ulam</i> (raw vegetable salad) in Malaysia and in salads in Thailand.	Ibrahim and Nugroho (1999), Saidin (2000), and van Wyk (2006)
<i>Bolboschoenus caldwellii</i> (V.J.) Soják	Cyperaceae	Sea Club-Rush	Grape-sized, sweet, fibrous tubers are eaten	Low (1989, 1991)
<i>Bolboschoenus fluviatilis</i> (Torr.) Soják	Cyperaceae	Marsh Club-Rush	As above	Low (1991)
<i>Bolboschoenus maritimus</i> (L.) Palla	Cyperaceae	Sea Club-Rush	Tubers are eaten after treatment	Cribb and Cribb (1987)
<i>Bombax ceiba</i> L.	Malvaceae	Sémul (India)	Succulent young roots are roasted and eaten after peeling off the skin cut into pieces, mixed with spices and eaten or boiled and eaten raw with salt	Gupta and Kanodia (1968a) and Shankarnarayan and Saxena (1987)
<i>Bombax malabaricum</i> DC. = <i>Bombax ceiba</i> L.	Malvaceae	Silk Cotton; Sawar, Savri, Shimla (Bombay)	As above	Darlington and Janaki Ammal (1945), Gammie (1902), and Gupta (1962)
<i>Bongardia chrysogonum</i> (L.) Spach	Berberidaceae	Ladies Nightcap	Roots are eaten boiled or roasted as food in Iran	Hedrick (1972) and Facciola (1990)
<i>Boscia albitrunca</i> (Burch.) Gilg & Benedict	Capparaceae	Shepherd's Tree, Witgat (Afrikaans)	Roots are source of meal and syrup in southern Africa	Uphof (1968), Fox et al. (1982), and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Bowenia spectabilis</i> Hook.	Zamiaceae	Zamia Fern	Roots are eaten by aborigines	Cribb and Cribb (1987)
<i>Brachychiton australis</i> (Schott & Endl.) A. Terracc.	Malvaceae	Broad Leaf Bottle Tree	As above	Cribb and Cribb (1987)
<i>Brachychiton populneus</i> (Schott & Endl.) R. Br	Malvaceae	Black Kurrajong, Bottletree, Kurrajong, Kurrajong Bottle Tree	As above	Cribb and Cribb (1987)
<i>Brachychiton diversifolius</i> R. Br.	Malvaceae	Northern Kurrajong, Kurrajong		Facciola (1990)
<i>Brachychiton rupestris</i> (T. Mitch. ex Lindl.) K. Schum.	Malvaceae	Queensland Bottle Tree	Young roots are cooked as food by the aborigines	Cribb and Cribb (1987)
<i>Brachystelma bingeri</i> Chev. = <i>Raphionacme bingeri</i> (A. Chev.) J.-P. Lebrun & Stork	Apocynaceae	NF	In West Africa (Niger River region), tubers are eaten, after removal of resinous outer layer. It comprises largely of carbohydrate	Irvine (1952) and Uphof (1968)
<i>Brasenia schreberi</i> J.F. Gmel.	Cabombaceae	Water-Shield	Root is edible	Facciola (1990)
<i>Brassica juncea</i> (L.) Czern.	Brassicaceae	Root Mustard	Inflated, fleshy cylindrical taproot	Facciola (1990) and Opena (1994)
<i>Brassica juncea</i> (L.) Czern. subsp. <i>napiformis</i> (Pailleux & Bois) Gladis	Brassicaceae	Tuberous Rooted Chinese Mustard	Root is edible	Codex (2014)
<i>Brassica napobrassica</i> Mill.	Brassicaceae	Rutabaga, Swedish Turnip, Swede	Enlarged swollen root is eaten boiled, steamed, baked, fried, mashed, etc.	Phillips and Rix (1993), Hu (2005), and Santich et al. (2008)
<i>Brassica napus</i> cv. Group Rutabaga	Brassicaceae	As above	As above	Van den Bergh (1994)
<i>Brassica napus</i> L. var. <i>napobrassica</i> (L.) Reichenbach	Brassicaceae	As above	As above	Codex (2014)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Brassica napus</i> Napobrassica Group	Brassicaceae	As above	As above	Facciola (1990)
<i>Brassica oleracea</i> var. <i>gongylodes</i> L. = <i>Brassica oleracea</i> L.	Brassicaceae	Kohlrabi, Cabbage Turnip	Young kohlrabi is used raw in salad; mature ones are peeled, cooked in soups and braised, can also be roasted, can be grated or cut into sticks for dips	Phillips and Rix (1993), Jansen et al. (1994), van Wyk (2006), and Santich et al. (2008)
<i>Brassica rapa</i> cv. Group Vegetable Turnip	Brassicaceae	Turnip	Roots are edible	Phillips and Rix (1993) and Toxopeus (1994)
<i>Brassica rapa</i> L. var. <i>rapa</i> = <i>Brassica rapa</i> subsp. <i>rapa</i>	Brassicaceae	Garden Turnip	Root is edible, eaten raw, grated, glazed, sautéed in butter or cooked in cream, used in soups and stews	Phillips and Rix (1993), van Wyk (2006), and Codex (2014)
<i>Brassica rapa</i> Perviridis Group	Brassicaceae	Mustard Spinach, Komatsuna	Thick tuberous roots of some cultivars are pickled and eaten	Tanaka (1976), Larkcom (1984), and Facciola (1990)
<i>Brassica rapa</i> Rapifera Group	Brassicaceae	Turnip, Fodder Turnip, Neeps	Roots are eaten raw, pickled, pureed, braised or used in stews, casseroles, soups, etc.	Facciola (1990) and van Wyk (2006)
<i>Brodiaea capitata</i> Benth. = <i>Dichelostemma capitatum</i> (Benth.) Alph. Wood	Asparagaceae	California Hyacinth, Grassnut, Wild Onion	Bulbs are eaten raw or boiled	Saunders (1920)
<i>Brodiaea douglasii</i> S. Watson = <i>Triteleia grandiflora</i> Lindl.	Asparagaceae	Clusterlily, Brodiaea, Grassnut, Fire-Cracker Flower, Blue Dicks	Corms are edible raw, fried, boiled and roasted	Facciola (1990)
<i>Brodiaea grandiflora</i> Smith = <i>Brodiaea coronaria</i> subsp. <i>coronaria</i>	Asparagaceae	Largeflower Triplelily, Wild Hyacinth	Bulbs are best cooked as by slow roasting in hot ashes which develops the sweetness	Saunders (1920)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Brodiaea pulchella</i> (Salisb.) Greene = <i>Dichelostemma congestum</i> (Sm.) Kunth	Asparagaceae	Wild Hyacinth, Common Saita, Common Brodiaea, Blue Dicks	Bulbs are eaten raw or boiled	Facciola (1990)
<i>Bromelia caratas</i> Hill = <i>Bromelia karatas</i> L.	Bromeliaceae	Camburito, Chigüichigüe, Curibijil, Quiribijil, Curujujul (Spanish)	In Brazil (northeast), bulbs are cooked and then sun-dried. Bulb is then pulverised and reduced to a flour	De Castro (1952)
<i>Bromelia laciniosa</i> Mart. ex Schult.f.	Bromeliaceae	Macambira (Spanish)	As above	De Castro (1952)
<i>Bruguiera cylindrica</i> (L.) Blume	Rhizophoraceae	White Burma Mangrove, Reflexed Orange Mangrove	Young radicals are eaten	Burkill (1966)
<i>Brunoniella acaulis</i> (R. Br.) Bremek.	Acanthaceae	Blue Yam	Roots are eaten	Cribb and Cribb (1987)
<i>Brunoniella australis</i> (Cav.) Bremek.	Acanthaceae	Blue Trumpet	Root is eaten after some preparation	Harden (1992)
<i>Bryonia alba</i> L.	Cucurbitaceae	Wild Bryony, Wild Hop, English Mandrake	France: starch of root is recommended as a famine food for extending bread flour after removing acrid element	Parmentier (1781) (cited by Freedman 2009)
<i>Bulbine bulbosa</i> (R. Br.) Haw.	Xanthorrhoeaceae	Bulbine Lily, Golden Lily	Bland starchy bulb is eaten by aborigines	Cribb and Cribb (1987), Low (1989, 1991), and Harden (1993)
<i>Bunium alpinum</i> Waldst. & Kit.	Apiaceae	NF	Tunisia: as for <i>Bunium chaberti</i>	Bouquet (1939)
<i>Bunium bulbocastanum</i> L.	Apiaceae	Earth Chestnut	In France, root is recommended as a famine food eaten raw or roasted	Facciola (1990) and Parmentier (1781) (cited by Freedman 2009)
<i>Bunium chaberti</i> (Batt.) Batt.	Apiaceae	NF	In Tunisia, tuberous roots are roasted being eaten. It is also boiled in salt water and seasoned with oil and spices	Bouquet (1939)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Bunium incrassatum</i> (Boiss.) Amo = <i>Bunium pachypodium</i> P.W. Ball	Apiaceae	Alrhouda, Belbous, Aktsir, Ouetsir, Akser, Akoutsar (Arabic)	Tunisia: as for <i>Bunium chaberti</i>	Bouquet (1939)
<i>Bunium macuca</i> Boiss. = <i>Bunium alpinum</i> subsp. <i>atlanticum</i> Maire,	Apiaceae	NF	Tunisia: as for <i>Bunium chaberti</i>	Bouquet (1939)
<i>Bunium persicum</i> (Boiss.) B. Fedtsch.	Apiaceae	Cumin Black Root, Caraway Black Root	Tuberous roots are edible	Codex (2014)
<i>Bupleurum falcatum</i> L.	Apiaceae	Chai Hu, Hare's Ear Root	Himalayas (area unspecified): roots are eaten	Read (1946)
<i>Burchardia umbellata</i> R. Br.	Colchicaceae	Milkmaids	Crisp starchy tubers	Low (1989, 1991)
<i>Butea frondosa</i> Roxb. = <i>Butea monosperma</i> (Lam.) Taub.	Fabaceae	Dangs (Bombay)	In India, roots are toasted and eaten	Gammie (1902) and Watt (1908)
<i>Butea monosperma</i> (Lam.) Taub.	Fabaceae	Dhak, Pala (Rajasthan, Western India)	Succulent young roots are roasted or boiled and eaten with salt	Gupta and Kanodia (1968a) and Shankarnarayan and Saxena (1987)
<i>Butomus umbellatus</i> L.	Butomaceae	Flowering Rush	In China, steamed roots are eaten. Root may also be sun-dried, after which root is baked or made into a flour and steamed. In the Soviet Union (unspecified areas), root is reported to be eaten	Read (1946) and Uphof (1968)
<i>Caesia alpina</i> Hook.f.	Xanthorrhoeaceae	Alpine Grass Lily	Roots are eaten by aborigines	Harden (1993)
<i>Caesia calliantha</i> R.J.F. Hend.	Xanthorrhoeaceae	Pale Grass Lily	Roots are eaten by aborigines	Low (1991) and Harden (1993)
<i>Caesia parviflora</i> R. Br.	Xanthorrhoeaceae	Pale Grass Lily	Roots are eaten by aborigines	Low (1991) and Harden (1993)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Caesia setifera</i> Baker	Xanthorrhoeaceae	Hairy Grass Lily	Roots are eaten by aborigines	Cribb and Cribb (1987) and Low (1989)
<i>Caesia vittata</i> R. Br. = <i>Caesia parviflora</i> var. <i>vittata</i> (R. Br.) R.J.F. Hend.	Xanthorrhoeaceae	Pale Grass Lily	Roots are eaten by aborigines	Low (1989) and Harden (1993)
<i>Cakile edentula</i> (Bigel.) Hook.	Brassicaceae	Sea Rocket	Canada: root is pounded and mixed with flour by native people in time of scarcity	Yanovsky (1936) and Hedrick (1972)
<i>Cakile maritima</i> Scop.	Brassicaceae	European Sea Rocket	Roots are edible	Facciola (1990)
<i>Caladenia filamentosa</i> R. Br.	Orchidaceae	Daddy Long Legs, Spider Orchids	Tubers are watery sweetish	Harden (1993)
<i>Caladenia gracilis</i> R. Br.	Orchidaceae	Musky Caladenia, Musky Finger Orchid	Tubers are edible	Harden (1993)
<i>Caladenia caerulea</i> (R. Br.) Hopper & A.P. Br.	Orchidaceae	Blue Fairy Orchid, Blue Caladenia, Parson-in-the-Pulpit	Tubers are eaten by aborigines	Harden (1993)
<i>Caladenia carnea</i> R. Br.	Orchidaceae	Pink Fingers, Pink Finger Orchid	Tubers are edible	Low (1989, 1991) and Harden (1993)
<i>Caladenia fuscata</i> (Rchb.f.) M.A. Clem. & D.L. Jones	Orchidaceae	Dusky Fingers	Tubers are edible	Harden (1993)
<i>Caladenia quadrifaria</i> (R.S. Rogers) D.L. Jones	Orchidaceae	Large Pink Fingers Orchid	Tubers are edible	Harden (1993)
<i>Caladenia</i> spp.	Orchidaceae	Pink Fingers	Tubers are edible	Cribb and Cribb (1987)
<i>Caladenia tentaculata</i> Schltdl.	Orchidaceae	Green Comb Spider Orchid, Fringed Spider Orchid	Tubers are edible	Harden (1993)
<i>Calamus rotang</i> L.	Arecaceae	Rattan Palm; Pri (Assamese)	Rhizome is eaten in Karbi, Assam	Kar and Borthakur (2008)
<i>Calathea allouia</i> (Aublet) Lindl.	Marantaceae	Guinea Arrowroot, Leren, Sweet Corn Tuber	Root tubers are boiled and eaten like potato	Facciola (1990), Groen et al. (1996), and Codex (2014)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Caleana major</i> R. Br.	Orchidaceae	Large Duck Orchid, Flying Duck Orchid	Tubers are edible	Harden (1993)
<i>Caleana minor</i> R. Br. = <i>Paracaleana minor</i> (R. Br.) Blaxell	Orchidaceae	Small Duck Orchid	As above	Harden (1993)
<i>Calla palustris</i> L.	Araceae	Marsh Calla, Water Arum, Water Dragon	In France, starch of root is recommended as a famine food for extending bread flour, after removal of acrid element. Rootstock can be dried and ground into an unpalatable but nutritious flour	Parmentier (1781) (cited by Freedman 2009) Facciola (1990) and Schofield (2003)
<i>Callicarpa rubella</i> Lindl.	Lamiaceae	Gopura Esing (Mishing), Bonmala (Assamese)	Bark and roots are chewed like betel nut; roots are eaten in Meghalaya	Patiri and Borah (2007) and Sawian et al. (2007)
<i>Callicarpa vestita</i> Wall. ex C.B. Clarke	Lamiaceae	Yarpo Esing (Mishing)	Bark and roots are chewed like betel nut	Patiri and Borah (2007)
<i>Callirhoe involucrata</i> (Torr. & A. Gray) A. Gray	Malvaceae	Purple Poppy Mallow	Sweet starchy roots are cooked and eaten	Hedrick (1972) and Facciola (1990)
<i>Calochilus campestris</i> R. Br.	Orchidaceae	Copper Beard Orchid	Tubers are eaten	Harden (1993)
<i>Calochilus gracillimus</i> Rupp	Orchidaceae	Slender Beard Orchid, Late Beard Orchid	As above	Harden (1993)
<i>Calochilus robertsonii</i> Benth.	Orchidaceae	Purple Beard Orchid	As above	Harden (1993)
<i>Calochilus</i> spp.	Orchidaceae	Bearded Orchid	Tubers are starchy bitter	Low (1991)
<i>Calochortus nuttallii</i> Torr.	Liliaceae	Sego Lily, Mariposa Lily, Sago Lily	Highly esteemed for its sweet corms. The cooking may be done by roasting in hot ashes or by steaming in pits. In North America, bulb is boiled and roasted and then made into flour by some native groups	Saunders (1920), Carr (1943), Uphof (1968), and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Calochortus venustus</i> Douglas ex Benth.	Liliaceae	Mariposa Lily	As above	Saunders (1920)
<i>Calochortus gunnisonii</i> S. Watson	Liliaceae	Mariposa Lily, Gunnison's Mariposa Lily	As above	Saunders (1920)
<i>Caltha leptosepala</i> DC.	Ranunculaceae	Western Marsh Marigold, White Marsh Marigold	Boiled roots are eaten	Schofield (2003)
<i>Caltha natans</i> Pall.	Ranunculaceae	Floating Marsh Marigold	As above	Schofield (2003)
<i>Caltha biflora</i> DC. = <i>Caltha leptosepala</i> var. <i>howellii</i> Huth	Ranunculaceae	Alpine White Marsh Marigold, Two-Flowered Marsh Marigold	As above	Schofield (2003)
<i>Caltha palustris</i> L.	Ranunculaceae	Yellow Marsh Marigold	As above	Facciola (1990) and Schofield (2003)
<i>Caltha palustris</i> var. <i>barthei</i> Hance	Ranunculaceae	Kong Jing Lu Ti Cao (Chinese)	As above	Facciola (1990)
<i>Calystegia japonica</i> (Thunb.) Choisy = <i>Calystegia pubescens</i> Lindl.	Convolvulaceae	California Rose	In China, leafy shoots and roots are eaten. Roots are reported to be purgative	Read (1946)
<i>Calystegia sepium</i> (L.) R. Br.	Convolvulaceae	Large Bindweed, Hedge Bindweed	In China, root is washed and steamed or sun-dried and then broken into fragments, eaten with rice or ground into a meal and steamed in the form of cakes	Read (1946)
<i>Camassia leichtlinii</i> (Baker) S. Watson	Asparagaceae	Camas, Quamash, Indian Hyacinth, Camash, Wild Hyacinth	Bulbs are eaten raw, boiled, baked, fried, used in pies	Saunders (1920), Hedrick (1972), and Facciola (1990)
<i>Camassia esculenta</i> (Nutt.) Lindl. = <i>Camassia quamash</i> (Pursh) Greene	Asparagaceae	Camas, Quamash	When boiled this little root is palatable and somewhat resembles the taste of the common potato	Saunders (1920)
<i>Camassia quamash</i> (Pursh) Greene	Asparagaceae	Camas, Small Camas, Common Camas	As for <i>C. leichtlinii</i>	Harrington (1974), Gibbons and Tucker (1979), and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Campanula pyramidalis</i> L.	Campanulaceae	Chimney Bellflower	In France, cooked root is recommended as famine food	Parmentier (1781) (cited by Freedman 2009)
<i>Campanula rapunculoides</i> L.	Campanulaceae	Creeping Bellflower, Rampion Bellflower	Roots are eaten raw in salads or boiled and served with butter or cream sauce	Harrington (1974), Gibbons and Tucker (1979), and Facciola (1990)
<i>Campanula rapunculus</i> L.	Campanulaceae	Rampion Bellflower, Rampion, Rover Bellflower	Roots are eaten raw, boiled as vegetable or used in soups or stews	Facciola (1990), Santich et al. (2008), and Codex (2014)
<i>Campanula urticaefolia</i> All.	Campanulaceae	Bellflower	In France, cooked root is recommended as famine food	Parmentier (1781) (cited by Freedman 2009)
<i>Canarina canariensis</i> (L.) Vatke	Campanulaceae	Canary Island Bellflower	Roots are edible	Hedrick (1972), Kunkel (1984), and Facciola (1990)
<i>Calandrinia eremaea</i> Ewart	Portulacaceae	Small Purslane	Roots are eaten raw or cooked	Harden (1990)
<i>Canna achiras</i> Gill. = <i>Canna indica</i> L.	Cannaceae	Indian Shot, Canna	Rhizome is eaten, source of Indian arrowroot called <i>rous le mois</i> in Chile and Argentina	Hedrick (1972) and Facciola (1990)
<i>Canna bidentata</i> Bertol. = <i>Canna indica</i> L.	Cannaceae	Indian Shot, Balisier	In West Africa, starchy rhizome is eaten	Irvine (1952) and Uphof (1968)
<i>Canna edulis</i> Ker Gawl.	Cannaceae	Edible Canna, Queensland Arrowroot; Achira; Gruya, Par Baul Fauk, Nung Gum (Assamese)	Starch obtained from rhizome is used to make translucent noodles in Vietnam. Rhizome is eaten in Assam	Burkill (1966), Facciola (1990), Flores et al. (2003), Santich et al. (2008), Medhi and Borthakur (2012), and Codex (2014)
<i>Canna indica</i> L.	Cannaceae	Indian Shot	As above	Ong and Siemonsma (1996)
<i>Canna lutea</i> Mill. = <i>Canna indica</i> L.	Cannaceae	K 'Uuwaap (Teenek)	In Yucatan, rhizome is eaten as a famine food by the Huastec Maya	Alcorn (1984)
<i>Canna orientalis</i> Rosc. = <i>Canna indica</i> L.	Cannaceae	Indian Shot	Rhizome is cooked and eaten as food	Burkill (1966)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Capsella bursa-pastoris</i> (L.) Medik.	Brassicaceae	Shepherd's Purse	Plant with roots is a delicacy in northern and eastern China. Ground or chopped roots are used as ginger substitute	Facciola (1990), Schofield (2003), and Hu (2005)
<i>Cardamine flexuosa</i> With.	Brassicaceae	Wavy Bittercress	Roots are eaten	Facciola (1990)
<i>Cardiocrinum giganteum</i> (Wall.) Makino var. <i>yunnanense</i> (Leicht. ex Elwes) Stearn	Liliaceae	Yunnan Cardio Crinum; Bai He Qi (Chinese)	Rural people in mountains of central and western China extract starch from the bulbs	Hu (2005)
<i>Carex</i> spp.	Cyperaceae	Ware Sedge	Sweet, enlarged underground stem is eaten	Schofield (2003)
<i>Carludovica palmata</i> Ruiz & Pav.	Cyclanthaceae	Panama Hat Plant, Hat Palm	Rhizomes are used as salads and herb in Latin America	Kunkel (1984) and Facciola (1990)
<i>Cartonema parviflorum</i> Hassk.	Commelinaceae	Arda	Starchy tubers are eaten by aborigines	Cribb and Cribb (1987) and Low (1989, 1991)
<i>Cartonema spicatum</i> R. Br.	Commelinaceae	Arda	As above	Cribb and Cribb (1987) and Low (1989, 1991)
<i>Carum carvi</i> L.	Apiaceae	Caraway, Persian Cumin	Roots are edible, used in soups	Uphof (1968), Hedrick (1972), and Facciola (1990)
<i>Carum gairdneri</i> (Hook. & Arn.) A. Gray	Apiaceae	Yamp	Clustered, spindle-shaped tuberous root is eaten raw, has an agreeable, nutty taste, with a considerable sugar content	Saunders (1920)
<i>Carum kelloggii</i> A. Gray	Apiaceae	Wild Anise	Roots are eaten	Saunders (1920)
<i>Cayratia clematidea</i> (F. Muell.) Domin	Vitaceae	Native Grape	Root tubers are eaten after baking	Cribb and Cribb (1987)
<i>Cayratia trifolia</i> (L.) Domin	Vitaceae	Three Leaf Cayratia, Bush Grape, Native Grape	As above	Cribb and Cribb (1987)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Ceropegia bulbosa</i> Roxb.	Apocynaceae	Dúdha Malida Kand, Malode (Bombay); Hedulo, Khapparkadu (western Rajasthan)	Tubers and leaves are eaten uncooked or boiled	Gammie (1902), Watt (1908), Gupta and Kanodia (1968a), Saxena (1979), and Facciola (1990)
<i>Ceropegia cumingiana</i> Decne.	Apocynaceae	Anareata	Fleshy rhizome is edible	Cribb and Cribb (1987) and Groen et al. (1996)
<i>Ceropegia tuberosa</i> Roxb. = <i>Ceropegia candelabrum</i> L.	Apocynaceae	Hadula (western Rajasthan)	Tubers are eaten raw or roasted	Shankarnarayan and Saxena (1987)
<i>Chaerophyllum bulbosum</i> L.	Apiaceae	Turnip-Rooted Chervil	Roots are eaten as vegetables	Facciola (1990) and Codex (2014)
<i>Chaerophyllum bulbosum</i> subsp. <i>prescottii</i> (DC.) Nyman	Apiaceae	Bulbous Chervil	As above	Facciola (1990)
<i>Chamaescilla corymbosa</i> (R. Br.) F. Muell. ex Benth.	Asparagaceae	Blue Star, Blue Squill	Tubers are pleasantly starchy	Low (1991)
<i>Chiloglottis diphylla</i> R. Br.	Orchidaceae	Common Ant Orchid	Tubers are edible	Harden (1993)
<i>Chiloglottis formicifera</i> Fitzg.	Orchidaceae	Ant Orchid	As above	Harden (1993)
<i>Chiloglottis palachila</i> D.L. Jones & M.A. Clem.	Orchidaceae	Clubbed Ant Orchid	As above	Harden (1993)
<i>Chiloglottis platyptera</i> D.L. Jones	Orchidaceae	Barrington Tops Ant Orchid	As above	Harden (1993)
<i>Chiloglottis pluricallata</i> D.L. Jones	Orchidaceae	Brown Bird Orchid	As above	Harden (1993)
<i>Chiloglottis sphyrnoides</i> D.L. Jones	Orchidaceae	Ornate Ant Orchid	As above	Harden (1993)
<i>Chiloglottis trapeziformis</i> Fitzg.	Orchidaceae	Erect Ant Orchid	As above	Harden (1993)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Chiloglottis trilabra</i> Fitzg. = <i>Chiloglottis reflexa</i> (Labill.) Druce	Orchidaceae	Long-Clubbed Wasp Orchid	As above	Harden (1993)
<i>Chlorogalum pomeridianum</i> (DC.) Kunth	Asparagaceae	Wavy-Leafed Soap Plant, California Soaproot	Roots are edible	Facciola (1990)
<i>Chlorophytum tuberosum</i> (Roxb.) Baker	Asparagaceae	Safed Mosali, Kolu Sevni (Bombay); Safed Musli (western Rajasthan)	India (Bombay Presidency): bulbs and leaves are eaten. Bulbs and leaves are dried and pounded into flour for bread	Gammie (1902)
<i>Christella parasitica</i> H. Lev.	Thelypteridaceae	Bihlongoni (Assamese)	Young frond and rhizomes are eaten cooked by Mishings and prepared as a special soup with chicken and given to the mother who has recently given birth and to the weak convalescents	Patiri and Borah (2007)
<i>Chrysopogon zizanioides</i> (L.) Roberty	Poaceae	Vetiver Grass, Khas Kahs, Khus Grass	Vetiver is used domestically in cooking; it is infused in tea and also used in baking	Balasankar et al. (2013)
<i>Cibotium barometz</i> (L.) J. Sm.	Cibotiaceae	Woolly Fern, Golden Chicken Fern, Golden Moss	Roots are eaten	Cui (1998), Dai et al. (2003), Cao et al. (2007), Yun et al. (2009a), and Liu et al. (2012)
<i>Cichorium intybus</i> L.	Asteraceae	Chicory	Roots are roasted and used as coffee substitute. Tubers are rich source of inulin and sugar	Facciola (1990), Hu (2005), Cabezas et al. (2002), and Codex (2014)
<i>Cirsium arvense</i> (L.) Scop.	Asteraceae	Creeping Thistle, Canada Thistle	Roots are eaten raw or cooked	Uphof (1968), Launert (1981), and Facciola (1990)
<i>Cirsium oleraceum</i> (L.) Scop.	Asteraceae	Cabbage Thistle, Meadow Cabbage	Swollen rootstock is edible	Uphof (1968), Hedrick (1972), and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Cirsium tanakae</i> Matsum.	Asteraceae	Nohara Azami (Japanese)	Roots in pieces are steeped in water and preserved in miso	Tanaka (1976) and Facciola (1990)
<i>Cirsium vulgare</i> (Savi) Ten.	Asteraceae	Bull Thistle, Common Thistle, Spear Thistle	Roots are boiled and eaten as vegetable	Harrington (1974), Fernald et al. (1958), and Facciola (1990)
<i>Cissus opaca</i> F. Muell. = <i>Clematicissus opaca</i> (F. Muell.) Jackes & Rossetto	Vitaceae	Pepper Vine	Large tuber is eaten by aborigines	Cribb and Cribb (1987)
<i>Claytonia acutifolia</i> Pall. ex Schult.	Montiaceae	Bering Sea Spring Beauty	Fleshy taproot is used as potato substitute, raw, boiled, baked or stir-fried	Schofield (2003)
<i>Claytonia caroliniana</i> Michx.	Montiaceae	Broad-Leaved Spring Beauty, Carolina Spring Beauty	Roots are eaten raw or cooked like potatoes	Hedrick (1972), Uphof (1968), and Facciola (1990)
<i>Claytonia megarhiza</i> (A. Gray) Parry ex S. Watson	Montiaceae	Alpine Spring Beauty	Root is eaten raw or cooked, peeled than boiled or baked	Yanovsky (1936), Hedrick (1972), and Facciola (1990)
<i>Claytonia tuberosa</i> Pall. ex Schult.	Montiaceae	Tuberous Spring Beauty	Corm is used as potato substitute, raw, boiled, baked or stir-fried	Schofield (2003)
<i>Claytonia virginica</i> L.	Montiaceae	Spring Beauty	Small, deep-seated, round tuber of starchy composition and nutty flavour, which might serve at a pinch to stave off starvation and has indeed so served the aborigines	Saunders (1920) and Facciola (1990)
<i>Clerodendrum fragrans</i> (Vent.) R. Br. = <i>Clerodendrum chinense</i> (Osbeck) Mabb.	Lamiaceae	Fragrant Glorybower, Chou Mo Li, Chou Mu Dan (Chinese)	Roots are dried, cooked with pork to strengthen elderly people and to remove pain and stiffness of muscles and joints	Hu (2005)
<i>Clerodendrum serratum</i> (L.) Moon. = <i>Rotheca serrata</i> (L.) Steane & Mabb.	Lamiaceae	Phelang Riho (Assamese)	Roots are eaten in Karbi, Assam	Kar and Borthakur (2008)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Cnicus japonicus</i> (Fish. ex DC.) Maxim. = <i>Cirsium japonicum</i> (Thunb.) Fish. ex DC.	Asteraceae	Cat Thistle	China: young leaves and roots are eaten	Read (1946)
<i>Cochlospermum</i> sp.	Bixaceae		Root is baked	Cribb and Cribb (1987)
<i>Codonocarpus attenuatus</i> (Hook.) H. Walter	Gyrostemonaceae	Bell Fruit Tree	Sappy roots are used as food	Harden (1990)
<i>Codonocarpus cotinifolius</i> (Desf.) F. Muell.	Gyrostemonaceae	Bell Fruit, Native Poplar	Sappy roots are used as food	Cribb and Cribb (1987)
<i>Codonopsis pilosula</i> (Franch.) Nannf.	Campanulaceae	Tang Shen, Dang Shen (Chinese)	Dried root slices are used in combination with astragalus root, goji berries, red dates, sliced Chinese yam with spare ribs for a tonifying soup	Hu (2005)
<i>Codonopsis javanica</i> (Blume) Hook.f. & Thomson	Campanulaceae	Dang Shen (Chinese), Dang Sam (Vietnamese)	As above	Anonymous (2013)
<i>Codonopsis lanceolata</i> (Sieb. & Zucc.) Benth. & Hook.f.	Campanulaceae	Yang Ru (Chinese)	Root fresh or dried is cooked with pig feet for a dish for nursing mothers	Hu (2005) and Kim et al. (2006)
<i>Codonopsis lancifolia</i> (Roxb.) Moeliono = <i>Cyclocodon lancifolius</i> (Roxb.) Kurz	Campanulaceae	Gordang-Gordang (Indonesia), Mayom-Kaeo (Thai)	Starchy rhizome is cooked as food and vegetables during famine	Groen et al. (1996)
<i>Codonopsis tangshen</i> Oliver = <i>Codonopsis pilosula</i> subsp. <i>tangshen</i> (Oliver) D.Y. Hong	Campanulaceae	Sichuan Tangshen	As for dang shen	Hu (2005)
<i>Colchicum commune</i> Neck. = <i>Colchicum autumnale</i> L.	Colchicaceae	Autumn Crocus	In France, starch of root is recommended as a famine food for extending bread flour, after removal of bitter element	Parmentier (1781) (cited by Freedman 2009)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Coleus blumei</i> Benth. = <i>Plectranthus scutellarioides</i> (L.) R. Br.	Lamiaceae	Coleus, Painted Nettle, Sayabana, Jacob's Coat	Tubers are eaten	Burkill (1966) and Facciola (1990)
<i>Coleus dazo</i> A. Chev. = <i>Plectranthus esculentus</i> N.E. Br.	Lamiaceae	Daju, Rizuka	Starchy root is peeled, boiled, served and eaten or pickled	Tanaka (1976) and Facciola (1990)
<i>Coleus parviflorus</i> Benth. = <i>Plectranthus rotundifolius</i> (Poir.) Spreng.	Lamiaceae	African Potato, Country Potato	Tubers are eaten like potatoes	Tanaka (1976), Ochse and van den Brink (1980), and Facciola (1990)
<i>Coleus tuberosus</i> (Blume) Benth. = <i>Plectranthus rotundifolius</i> (Poir.) Spreng.	Lamiaceae	African Potato, Country Potato	Tubers are usually eaten steamed or cooked with rice in Indonesia	Ochse and van den Brink (1980)
<i>Colocasia affinis</i> Schott	Araceae	Black Princess Taro, Black-Leaved Taro, Purple-Leaved Taro	Roots are eaten in Meghalaya	Sawian et al. (2007)
<i>Colocasia esculenta</i> (L.) Schott	Araceae	Taro, Kola, Kalo Kochu/Kolia Kochu (Assamese)	Tender leaves and corms and cormels are eaten as vegetable, specially with acidic fruit in various form in Assam. Roots are eaten in Meghalaya China: corms and cormels are boiled, cooked with meat or seafood, in soups or stews, and prepared for dessert. Hawaiian poi is made from cooked taro paste, also used as filling for Asian pastries cakes and buns and also in taro ice cream	Burkill (1966), Patiri and Borah (2007), Cribb and Cribb (1987), Facciola (1990), Sawian et al. (2007), Walter and Lebot (2007), Hu (2005), Brassicaceae Santich et al. (2008), Phillips and Rix (1993), Wilson and Siemonsma (1996), and Ochse and van den Brink (1980), codex
<i>Colocasia esculenta</i> (L.) var. <i>antiquorum</i> (Schott) Hubbard & Rehder	Araceae	Eddoes, Taro	As above	Codex (2014)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Colocasia esculenta</i> (L.) var. <i>globifera</i> Engl. & Krause = <i>Colocasia esculenta</i> (L.) var. <i>antiquorum</i> (Schott) Hubbard & Rehder	Araceae	Eddoes, Taro	As above	Codex (2014)
<i>Colocasia himalensis</i> Royle = <i>Colocasia esculenta</i> (L.) Schott	Araceae	Dhakol (Kumaon region, western Himalayas)	Rhizomes are either boiled and cooked or roasted in ashes	Bhargava (1960) and Gupta (1962)
<i>Colocasia nymphaeifolia</i> (Vent.) Kunth = <i>Colocasia esculenta</i> (L.) Schott	Araceae	Karunai Kizhangu (Tamil), Kanda Gadda (Telugu)	Tubers are cooked and eaten	Shott (1887–1888) (cited by Freedman 2009)
<i>Commiphora caerulea</i> Burt	Burseraceae	Wému (Sandawe)	In central Tanzania, young roots are chewed for juices	Newman (1975)
<i>Commiphora neglecta</i> Verd.	Burseraceae	Mu-Kerenju (Kikuyu)	In Kenya (Mbeere division, Embu district), leaves and roots are eaten. Root bark is peeled off; root is chewed like sugar cane	Riley and Brokensha (1988)
<i>Conopodium majus</i> (Gouan) Loret	Apiaceae	Pignut	Tubers are edible	Hedrick (1972), Facciola (1990), and Codex (2014)
<i>Coniogramme emeiensis</i> Ching & K.H. Shing	Pteridaceae	Golden Zebra, E Mei Feng Liao Jue (Chinese)	Rhizome starch is used for noodles	Dai et al. (2003) and Yun et al. (2009b)
<i>Coniogramme intermedia</i> Hieron.	Pteridaceae	Pu Tong Feng Liao Jue (Chinese)	As above	Dai et al. (2003) and Yun et al. (2009b)
<i>Coniogramme intermedia</i> var. <i>glabra</i> Ching	Pteridaceae	Wu Mao Feng Liao Jue (Chinese)	As above	Dai et al. (2003) and Yun et al. (2009b)
<i>Coniogramme japonica</i> (Thunb.) Diels	Pteridaceae	Feng Liao Jue (Chinese)	As above	Dai et al. (2003) and Yun et al. (2009b)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Coniogramme jinggangshanensis</i> Ching & K.H. Shing	Pteridaceae	Jing Gang Shan Feng Liao Jue (Chinese)	As above	Dai et al. (2003) and Yun et al. (2009b)
<i>Coniogramme robusta</i> Christ (Christ)	Pteridaceae	Hei Zhou Feng Liao Jue (Chinese)	As above	Dai et al. (2003) and Yun et al. (2009b)
<i>Coniogramme rosthornii</i> Hieron.	Pteridaceae	Ru Tou Feng Liao Jue (Chinese)	As above	Dai et al. (2003) and Yun et al. (2009b)
<i>Coniogramme simillima</i> Ching ex K.H. Shing	Pteridaceae	NF	As above	Dai et al. (2003) and Yun et al. (2009b)
<i>Coniogramme taipaishanensis</i> Ching & Y.T. Hsieh	Pteridaceae	Taibai Shan Feng Ya Jue (Chinese)	As above	Dai et al. (2003) and Yun et al. (2009b)
<i>Conopholis americana</i> (L.) Wallr.	Orobanchaceae	Squaw Root, Bear Corn, Indian Corn, American Cancer Root	Roots are edible cooked	Kaldy et al. (1980)
<i>Consolida major</i> Gilib.	Ranunculaceae	Larkspur	In France, root is recommended as a famine food. It may be cooked in the manner of <i>salisfy</i> or reduced to a pulp and blended into a confection as recommended for <i>Asphodelus albus</i>	Parmentier (1781) (cited by Freedman 2009)
<i>Convolvulus chinensis</i> Ker Gawl. = <i>Convolvulus arvensis</i> L.	<i>Convolvulaceae</i>	Chinese Bindweed; Fu-Fu-Miao, Tian Xuan Hua (Chinese)	Rhizomes are eaten in a gruel	Hu (2005)
<i>Convolvulus erubescens</i> Sims	<i>Convolvulaceae</i>	Australian Bindweed	Fibrous and not especially tasty roots	Low (1989, 1991)
<i>Cordyline australis</i> (G. Forst.) Endl.	Asparagaceae	Cabbage Tree, Ti Kouka	Roots are eaten or brewed into an intoxicating drink	Tanaka (1976) and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Cordyline fruticosa</i> (L.) A. Chev.	Asparagaceae	Ti, Ti Plant, La'i, Good Luck Plant	Roasted root is fermented in water and distilled into an alcoholic beverage. Root is rich in sugars, and when baked, the confection is eaten or used to sweeten puddings and other foods	Hedrick (1972), Ochse and van den Brink (1980), and Facciola (1990)
<i>Cordyline</i> sp.	Asparagaceae	Palm Lily	Underground stem is eaten as emergency food	Cribb and Cribb (1987)
<i>Cordyline terminalis</i> (L.) Kunth = <i>Cordyline fruticosa</i> (L.) A. Chev.	Asparagaceae	As for <i>C. Fruticosa</i>	Tuber is cooked as famine food. Puree from grated tuber is mixed with coconut milk and used to prepare small <i>lap-laps</i> which after cooking are crushed in the hand and eaten in Oceania	Walter and Lebot (2007)
<i>Corybas fimbriatus</i> (R. Br.) Rchb.f.	Orchidaceae	Fringed Helmet-Orchid	Tubers are edible	Harden (1993)
<i>Corybas hispidus</i> D.L. Jones	Orchidaceae	Bristly Helmet-Orchid	Tubers are edible	Harden (1993)
<i>Corybas montanus</i> D.L. Jones	Orchidaceae	Mt Maroon Helmet-Orchid	Tubers are edible	Harden (1993)
<i>Corybas</i> species A	Orchidaceae	Sphagnum Helmet-Orchid	Tubers are edible	Harden (1993)
<i>Costus speciosus</i> (J. König) Sm. = <i>Cheilocostus speciosus</i> (J. König) C. Specht	Costaceae	Crepe Ginger, Malay Ginger, Wild Ginger	Tuberous rhizomes are used as food and spice	Facciola (1990), Groen et al. (1996), Hu (2005), and Codex (2014)
<i>Crambe cordifolia</i> Steven	Brassicaceae	Colewort	Roots are edible	Hedrick (1972) and Kunkel (1984)
<i>Crambe orientalis</i> L.	Brassicaceae	Oriental Sea Kale	Roots are used as horseradish substitute	Hedrick (1972) and Tanaka (1976)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Crambe tatarica</i> Sebeok	Brassicaceae	Tartar Bread Plant	Root is eaten raw in salads or cooked as a vegetable. It can be dried, grounded into powder and mixed with cereal flours when making bread	Hedrick (1972) and Tanaka (1976)
<i>Crinum defixum</i> Ker Gawl. = <i>Crinum viviparum</i> (Lam.) R. Ansari & V.J. Nair.	Amaryllidaceae	River Crinum Lily	India: root is eaten	Watt (1908)
<i>Crinum flaccidum</i> Herb.	Amaryllidaceae	Darling Lily, Murray Lily, Macquarie Crinum, Inland Crinum	Bulb is used as a source of arrowroot	Cribb and Cribb (1987) and Harden (1993)
<i>Crocus sativus</i> L.	Iridaceae	Saffron, Asian Saffron, Persian	Root is eaten roasted	Facciola (1990) and Lim (2014)
<i>Cryptostylis erecta</i> R. Br.	Orchidaceae	Tartan Tongue-Orchid, Turban Orchid	Fleshy starchy tubers are eaten by aborigines	Harden (1993)
<i>Cryptostylis hunteriana</i> Nicholls	Orchidaceae	Leafless Tongue-Orchid	Fleshy starchy tubers are eaten by aborigines	Harden (1993)
<i>Cryptostylis leptochila</i> F. Muell. ex Benth.	Orchidaceae	Small Tongue-Orchid, Red Tongue-Orchid	Fleshy starchy tubers are eaten by aborigines	Harden (1993)
<i>Cryptostylis</i> sp.	Orchidaceae	Tongue Orchids	Fleshy starchy tubers are eaten by aborigines	Cribb and Cribb (1987)
<i>Cryptostylis subulata</i> (Labill.) Rchb.f.	Orchidaceae	Large Tongue-Orchid, Cowslip Orchid	Fleshy starchy tubers are eaten by aborigines	Harden (1993)
<i>Cryptotaenia canadensis</i> (L.) DC.	Apiaceae	Honewort, Wild Chervil	Root is boiled in salt water and served with butter and sprinkle of parsley or cream sauce	Fernald et al. (1958) and Facciola (1990)
<i>Cryptotaenia japonica</i> Hassk.	Apiaceae	Mitsuba, Japanese Parsley, Japanese Honewort	Blanched roots are sautéed with sesame oil or boiled together with parsnip	Tanaka (1976), Morton (1976), Larkcom (1984), and Facciola (1990)
<i>Cucurbita foetidissima</i> Kunth	Cucurbitaceae	Buffalo Gourd	Starch is obtained from roots	Hu (2005)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Curculigo ensifolia</i> R. Br.	Hypoxidaceae	Grass Potato	Slender taproots are eaten by aborigines	Cribb and Cribb (1987) and Low (1989, 1991)
<i>Curcuma aeruginosa</i> Roxb.	Zingiberaceae	Pink And Blue Ginger, Dark Blue Temu	Rhizome is used as spice	Burkill (1966)
<i>Curcuma amada</i> Roxb.	Zingiberaceae	Tharmit Tharve Am Haladhi, Am-Ada (Assamese)	Rhizome is eaten in Karbi, Assam. Rhizome is used to prepare salad or chutney or eaten raw. It is also used as medicinal for its zedoary content	Patiri and Borah (2007) and Kar and Borthakur (2008)
<i>Curcuma angustifolia</i> Roxb.	Zingiberaceae	Indian Arrowroot	Rhizome has edible starch	Ibrahim and Jansen (1996a)
<i>Curcuma aromatica</i> Salisb.	Zingiberaceae	Wild Turmeric, Yellow Zedoary	Rhizome is used as spice, source of starch	Ibrahim and Jansen (1996a) and Hu (2005)
<i>Curcuma australasica</i> Hook.f.	Zingiberaceae	Native Ginger	Tuberous roots are roasted and eaten by aborigines	Cribb and Cribb (1987)
<i>Curcuma caulina</i> J. Graham = <i>Hitchenia caulina</i> (J. Graham) Baker	Zingiberaceae	Chavar	In India (Deccan), tuberous root is eaten	Watt (1908)
<i>Curcuma domestica</i> Valetton = <i>Curcuma longa</i> L.	Zingiberaceae	Turmeric	Rhizome is used as spice	Phillips and Rix (1993) and Hu (2005)
<i>Curcuma longa</i> L.	Zingiberaceae	Turmeric, Kunyit, Temu Kunyit (Malaysia), Khamin (Thai)	Rhizome is used as culinary spice in Asian dishes, curries. Ground turmeric is used in food industry as colouring agent in processed sauces, curry pastes and sauces; turmeric oil and oleoresins are similarly used. Roots are eaten in Meghalaya	Burkill (1966), Morton (1976), Ochse and van den Brink (1980), Facciola (1990), Dahal and Idris (1999), Saidin (2000), Hu (2005), Sawian et al. (2007), and Walter and Lebot (2007)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Curcuma mangga</i> Valeton & Zijp	Zingiberaceae	Mango Ginger; Temu Pauh, Temu Mangga (Malaysia); Khamin Khao (Thai)	Rhizome is used as spice	Burkill (1966), Morton (1976), Ochse and van den Brink (1980), Facciola (1990), Saidin (2000), and Van den Bergh (1994)
<i>Curcuma phaeocaulis</i> Valeton	Zingiberaceae	E Zhu (Chinese)	Rhizome is used as spice	Lu et al. (2013)
<i>Curcuma pierreana</i> Gagnep.	Zingiberaceae	NF	Rhizome is highly aromatic, source of starch	Ibrahim and Jansen (1996a)
<i>Curcuma pseudomontana</i> R. Grah.	Zingiberaceae	Hill Turmeric	In India (Deccan), rhizomes are eaten	Watt (1908)
<i>Curcuma purpurascens</i> Blume	Zingiberaceae	Temu Tis, Koneng Pinggang, Kunir Tinggang (Indonesia)	Rhizome is edible	Ochse and van den Brink (1980)
<i>Curcuma zanthorrhiza</i> Roxb.	Zingiberaceae	Temulawak (Malaysia)	Rhizome is used as spice or eaten raw	Burkill (1966), Ochse and van den Brink (1980), Facciola (1990), Jansen (1996a), and Saidin (2000)
<i>Curcuma zedoaria</i> (Christm.) Roscoe	Zingiberaceae	Zedoary, Temu Kuning (Malaysia)	Rhizome is used as spice; young rhizome is added to salads	Burkill (1966), Morton (1976), Ochse and van den Brink (1980), Facciola (1990), Ibrahim and Jansen (1996a, b), and Saidin (2000)
<i>Cyclosorus interruptus</i> (Willd.) H. Ito = <i>Thelypteris interrupta</i> (Willd.) K. Iwats.	Thelypteridaceae	Willdenow's Maiden Fern	Roots are edible roasted	Cribb and Cribb (1987)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Cymbidium canaliculatum</i> R. Br.	Orchidaceae	Tiger Orchid, Channeled Cymbidium, Inland Tree Orchid	The pseudobulbs are rich in starch and while recorded as being used cooked or raw are mucilaginous and insipid. The 'arrowroot' may be removed by washing out the pounded starch and allowing it to settle. Tubers and stems are eaten	Maiden (1889) and Harden (1993)
<i>Cynanchum bungei</i> Decne.	Apocynaceae	Bai Shou Wu (Chinese)	Starch from fleshy roots is used with sugar as health food	Hu (2005)
<i>Cynanchum caudatum</i> (Miq.) Maxim.	Apocynaceae	NF	China: leaves and roots are eaten. The root is peeled, sliced, boiled in several changes of water to remove the acrid element, washed and boiled again until it is very thoroughly cooked	Read (1946), Tanaka (1976), and Kunkel (1984)
<i>Cynanchum forrestii</i> Schlechter	Apocynaceae	Da Li Bai Qian (Chinese)	Rootstock and wiry roots are dried, used in soup and tasty beverage in Yunnan	Hu (2005)
<i>Cynanchum otophyllum</i> C.K. Schneid.	Apocynaceae	Qing Yang Shen (Chinese)	Roots are boiled with pork or spare ribs in a special dish	Hu (2005)
<i>Cynanchum wilfordii</i> (Maxim.) Hemsl.	Apocynaceae	Ge Shan Xiao (Chinese)	Roots are used to extract starch	Hu (2005)
<i>Cynara cardunculus</i> L.	Asteraceae	Cardoon	Roots are cooked like carrot or parsnip	Hedrick (1972), Halpin (1978), and Facciola (1990)
<i>Cyperus bifax</i> C.B. Clarke = <i>Cyperus rotundus</i> L.	Cyperaceae	Downs Nutgrass	Tubers produced on rhizomes are dried, coat removed, shaken with hot ashes, eaten raw or rubbed to a powder and eaten as porridge	Cribb and Cribb (1987) and Harden (1993)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Cyperus bulbosus</i> Vahl	Cyperaceae	Nalgoo (Australia)	Tubers are pleasantly starchy. In India (Bombay Presidency), bulbs are dried and pulverised and then mixed with <i>jowar</i> , <i>bajrai</i> (millet) or wheat flour to make bread	Gammie (1902), Paton and Dunlop (1904), Irvine (1957), Burkill (1966), Gupta and Kanodia (1968a), Saxena (1979), Low (1991), and Jansen and Aguilar (1996)
<i>Cyperus esculentus</i> L.	Cyperaceae	Chufa, Tiger Nut, Yellow Nutgrass	Chufa's hard tubers are sweet and tasty. In Zimbabwe, tubers are eaten raw or cooked	Saunders (1920), Burkill (1966), Cribb and Cribb (1987), Zinyama et al. (1990), Jansen and Aguilar (1996), and Codex (2014)
<i>Cyperus esculentus</i> L. var. <i>sativus</i> Boeckeler = <i>Cyperus esculentus</i> L.	Cyperaceae	Yellow Nut Grass, Chufa; You Sha Cao (Chinese)	Tubers are eaten in China	Hu (2005)
<i>Cyperus jemicus</i> Rottb.	Cyperaceae	NF	In India, tubers are ground into flour	Watt (1908)
<i>Cyperus papyrus</i> L.	Cyperaceae	Egyptian Reed, Paper Reed	Starchy rhizomes and culms are edible	Mahr (2011)
<i>Cyperus rotundus</i> L.	Cyperaceae	Nutgrass, Purple Nutgrass; Mothee, Motha (Rajasthan)	In France, root is recommended as famine food, can be eaten raw or cooked, can be dried and reduced to a flour. In India (Jaisalmer district, Rajasthan), fibre and cuticle of root are removed; root is dried, ground and made into bread and sometimes mixed with other flours; in western Rajasthan, tubers are roasted, also boiled, outer skin peeled off, and the starchy rhizome eaten with spices	Parmentier (1781) (cited by Freedman (2009), Saunders (1920), Burkill (1966), Saxena (1979), Cribb and Cribb (1987), Harden (1993), and Jansen and Aguilar (1996)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Cyrtosperma chamissonis</i> Schott = <i>Cyrtosperma merkusii</i> (Hassk.) Schott	Araceae	Giant Swamp Taro, Swamp Taro	Corm is sliced, boiled or cooked or baked	Burkill (1966), Facciola (1990), Phillips and Rix (1993), and Walter and Lebot (2007)
<i>Cyrtosperma edule</i> Schott = <i>Cyrtosperma merkusii</i> (Hassk.) Schott	Araceae	Giant Swamp Taro, Swamp Taro	As above	Burkill (1966)
<i>Cyrtosperma merkusii</i> (Hassk.) Schott	Araceae	Giant Swamp Taro, Swamp Taro	As above	Evangelio (1996)
<i>Cyrtostylis reniformis</i> R. Br.	Orchidaceae	Gnat Orchid	Tubers can be eaten	Harden (1993)
<i>Dalea candida</i> (Michx.) Willd.	Fabaceae	White Prairie Clover	Root is eaten raw or chewed, eaten as delicacy by children	Yanovsky (1936), Tanaka (1976), and Facciola (1990)
<i>Dalea gattingeri</i> (A. Heller) Barneby	Fabaceae	Purple Tassels	Root is eaten raw or chewed	Yanovsky (1936), Uphof (1968), and Tanaka (1976)
<i>Dalea purpurea</i> Vent	Fabaceae	Purple Prairie Clover	Root is eaten raw or chewed	Facciola (1990)
<i>Dahlia pinnata</i> Cav.	Asteraceae	Garden Dahlia	Sweet tuber extract is used as a beverage or flavouring. It is mixed with hot or cold water or milk or sprinkled on ice cream	Uphof (1968), Hedrick (1972), Facciola (1990), and Lim (2014)
<i>Daucus carota</i> L.	Apiaceae	Carrot, Queen Anne's Lace	Carrot can be eaten raw; as a solo dish it can be served steamed, boiled, with dill, honey and butter or baked or roasted; they can be sautéed, used in soups, stocks, stews, braised dishes. They can be used as accompanying vegetable in many dishes. Carrot can be grated and used in carrot cakes	Facciola (1990), Phillips and Rix (1993), van der vossen and Sambas (1994), Walter and Lebot (2007), Santich et al. (2008), and Codex (2014)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Daucus carota</i> Sativus Group	Apiaceae	As above	As above	Facciola (1990)
<i>Daucus pusillus</i> Michx.	Apiaceae	American Carrot, Rattlesnake Weed	Navajo Indians eat the root raw or cooked	Yanovsky (1936) and Facciola (1990)
<i>Daucus vulgaris</i> Neck. = <i>Daucus</i> <i>carota</i> L.	Apiaceae	Wild Carrot	France: root is recommended as a famine food	Parmentier (1781) (cited by Freedman 2009)
<i>Dentaria diphylla</i> Michx. = <i>Cardamine</i> <i>diphylla</i> (Michx.) Alph. Wood.	Brassicaceae	Two-Leaved Toothwort, Pepper- Root, Crinkleroot	Crisp white rootstock is eaten as popular nibble, having flavour of horseradish; it is also added to green salads and sandwiches with salt or grated and prepared like horseradish	Fernald et al. (1958), Gibbons and Tucker (1979), and Facciola (1990)
<i>Dentaria laciniata</i> Muhl. ex Willd. = <i>Cardamine</i> <i>concatenata</i> (Michx.) O. Schwarz.	Brassicaceae	Cut-Leaved Toothwort	Crisped, peppery root is chopped and added to salads or use for preparation of spices and sauces. It goes well with sandwiches with luncheon meat	Gibbons and Tucker (1979) and Facciola (1990)
<i>Dichelostemma</i> <i>pulchellum</i> var. <i>pauciflorum</i> (Torr.) Hoover = <i>Dichelostemma</i> <i>capitatum</i> subsp. <i>pauciflorum</i> (Torr.) Keator	Asparagaceae	Blue Dick	North America (Arizona): tuber is eaten by Native American Papago group	Castetter and Bell (1942)
<i>Dichopogon</i> <i>fimbriatus</i> (R. Br.) J.F. Macbr.	Asparagaceae	Nodding Chocolate Lily	Translucent, bitter, tuberous roots are used as food	Low (1989, 1991) and Harden (1993)
<i>Dichopogon</i> <i>strictus</i>	Asparagaceae	Chocolate Lily	Translucent, bitter, tuberous roots are used as food	Low (1989, 1991)
<i>Dioscorea</i> <i>aculeata</i> Balb. ex Kunth = <i>Dioscorea</i> <i>cayennensis</i> Lam.	Dioscoreaceae	Fancy Yam, Potato Yam, Lesser Yam, Lesser Asiatic Yam, Ighame; Man-Alu (Kumaon region, western Himalayas)	Roots are cut and boiled prior to eating	Bhargava (1960) and Ochse and van den Brink (1980)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Dioscorea alata</i> L.	Dioscoreaceae	Purple Yam, Greater Yam, Winged Yam, Water Yam, White Yam; Kath Alu (Assamese); Yams Kalung (Tamil); Niluva Pandalum (Telugu)	Tubers are eaten cooked as vegetable. In China, tubers are used in soups. In Oceania, tuber is cut into pieces and baked or roasted whole or boiled in marmite or grated and used for <i>lap-lap</i>	Burkill (1966), Ochse and van den Brink (1980), Low (1991), Onwueme and Ganga (1996), Onwueme (1996a), Hu (2005), Patiri and Borah (2007), Walter and Lebot (2007), and Codex (2014)
<i>Dioscorea anguina</i> Roxb. = <i>Dioscorea pubera</i> Blume	Dioscoreaceae	Kakalu (Bengali), Savida Dumpa (Telugu)	Tuber is eaten in India	Watt (1908)
<i>Dioscorea belophylla</i> (Prain) Voigt ex Haines	Dioscoreaceae	Spear-Leaved Yam	In India (Garhwal Himalayas), tuber is eaten after repeated boiling, washing and baking	Gupta (1962)
<i>Dioscorea bulbifera</i> L.	Dioscoreaceae	Aerial Yam, Air Potato, Air Yam, Bitter Yam, Cheeky Yam, Potato Yam, Wild Yam; Gosh Alu (Assamese); Ho (Hawaiian); Genth (Kumaon region, western Himalayas); Kapuang (Thai Sakai)	Root tubers are eaten cooked as vegetable during winter in India (Kumaon region, western Himalayas): axillary tubers are cut into pieces, steeped in water and boiled prior to eating. Hawaii: aerial bulbils are eaten. Yams are baked and boiled, or fried slices of tuber or pureed tuber may be added to soups, stew, soufflés, fritter and various sweet dishes	Patiri and Borah (2007), Cribb and Cribb (1987), Wightman and Andrews (1989), Low (1989), Facciola (1990), Bhargava (1960), Handy (1940), Neal (1965), Sturtevant, Burkill (1966), Hu (2005), Onwueme (1996a), and Walter and Lebot (2007)
<i>Dioscorea calcicola</i> Prain & Burkill	Dioscoreaceae	Bayae (Thai Sakai)	Tuber is the main source of carbohydrate for the Sakai tribe in peninsular Thailand	Maneenoon et al. (2008)
<i>Dioscorea cayenensis</i> Lam.	Dioscoreaceae	Yellow Guinea Yam, Yellow Yam, White Yan	Yams are used to make fufu, may also be used in the same way as potatoes or sweet potatoes	Burkill (1966), Facciola (1990), van Wyk (2006), and Codex (2014)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Dioscorea cumingii</i> Prain & Burkill	Dioscoreaceae	Lima-Lima (Tagalog), Kasi (Igorot), Pari (Bagobo)	Tuber is used as food in Luzon (Philippines)	Groen et al. (1996)
<i>Dioscorea daunea</i> Prain & Burkill	Dioscoreaceae	Suna (Thai Sakai)	Tuber is used as substitute for <i>Dioscorea</i> food species during famine	Maneenoon et al. (2008)
<i>Dioscorea deltoidea</i> Wall. ex Griseb.	Dioscoreaceae	Nepal Yam; Gun (Kumaon region, western Himalayas)	Tubers are cut into pieces, steeped in water and boiled and/or baked prior to eating	Bhargava (1960) and Gupta (1962)
<i>Dioscorea divaricata</i> Blanco	Dioscoreaceae	Pakit, Kiroi (Tagalog), Sulian (Iloko), Baklaiakang (Bisaya)	Tuber is used as food in the Philippines, baked, boiled or fried	Groen et al. (1996)
<i>Dioscorea dumetorum</i> Kunth (Pax)	Dioscoreaceae	Cluster Yam; Ma-Nyeny, E-Dyeny (Bedik, Gold Coast); Rogon Biri (Hausa Nigeria)	In Gold Coast, tuber is used as a famine food. The tuber is boiled, peeled, sliced, pounded and steeped in running (preferably salt) water	Irvine (1952), Burkill (1966), Ferry et al (1974), and Mortimore (1989)
<i>Dioscorea esculenta</i> (Lour.) Burkill	Dioscoreaceae	Lesser Asiatic Yam, Sweet Yam, Potato Yam; Ruipheng Selu (Assamese)	Tuber is eaten in Karbi, Assam Yams are baked and boiled, or fried slices of tuber or pureed tuber may be added to soups, stew, soufflés, fritter and various sweet dishes	Burkill (1966), Ochse and van den Brink (1980), Facciola (1990), Onwueme (1996a, b), Hu (2005), van Wyk (2006), Walter and Lebot (2007), Kar and Borthakur (2008), and Codex (2014)
<i>Dioscorea esculenta</i> (Lour.) Burkill var. <i>fasciculata</i> (Roxb.) Prain & Burkill = <i>Dioscorea esculenta</i> (Lour.) Burkill	Dioscoreaceae	Moa Alu (Assamese)	Tubers are used as vegetable	Patiri and Borah (2007)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Dioscorea filiformis</i> Blume	Dioscoreaceae	Wauh (Malaysia), Aroi Huwi Curuk (Sumatra), Dudung (Java), Balun (Thai Sakai)	Tubers are boiled and eaten in Malaysia. Tuber is the main source of carbohydrate for the Sakai tribe in peninsular Thailand	Groen et al. (1996) and Maneenoon et al. (2008)
<i>Dioscorea gibbiflora</i> Hook.f. = <i>Dioscorea filiformis</i> Blume	Dioscoreaceae	Wild Yam	Tuber is eaten	Burkill (1966)
<i>Dioscorea glabra</i> Roxb.	Dioscoreaceae	Mandong (Thai), Luntak (Thai Sakai)	Tubers (glutinous and starchy) are used as food in peninsular Malaysia and Andaman islands. Tuber is the main source of carbohydrate for the Sakai tribe in peninsular Thailand	Groen et al. (1996) and Maneenoon et al. (2008)
<i>Dioscorea hastifolia</i> Nees	Dioscoreaceae	Warrine	Tuber is eaten	Low (1989)
<i>Dioscorea hemsleyi</i> Prain & Burkill	Dioscoreaceae	Glutinous; Nian Shan Yao (Chinese)	Tuber is eaten	Hu (2005)
<i>Dioscorea hirtiflora</i> Benth.	Dioscoreaceae	Mng'oko (Tanzania)	Sierra Leone, Nigeria (northern): eaten as a famine food	Irvine (1952)
<i>Dioscorea hispida</i> Dennst.	Dioscoreaceae	Intoxicating Yam, Asiatic Bitter Yam; Gadog, Gadong, Gadong Lilin, Gadong Mabuk, Gadung (Malay)	Tuber is eaten	Burkill (1966), Onwueme (1996c), Ochse and van den Brink (1980), and Codex (2014)
<i>Dioscorea japonica</i> Thunb.	Dioscoreaceae	Glutinous Yam, Chinese Yam, Japanese Yam, Taiwanese Yam, Yama-No-Imo	Tuber is eaten in China	Read; Facciola (1990), Burkill (1966), Hu (2005), and Codex (2014)
<i>Dioscorea laurifolia</i> Wall. ex Hook.f.	Dioscoreaceae	Clangporn (Thai Sakai)	Tubers are eaten in peninsular Malaysia	Burkill (1966) and Groen et al. (1996)
<i>Dioscorea luzonensis</i> Schauer	Dioscoreaceae	Pakit, Mayabang (Tagalog) Kamangeg (Iloko)	Tubers are used for food	Groen et al. (1996)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Dioscorea macrostachya</i> Benth. = <i>Dioscorea mexicana</i> Scheidw.	Dioscoreaceae	Panil Book	Tuber is cooked and eaten in Mexico	Alcorn (1984), Kunkel (1984), and Facciola (1990)
<i>Dioscorea macroura</i> Harms = <i>Dioscorea sansibarensis</i> Pax	Dioscoreaceae	Zanzibar Yam	Tropical Africa: eaten as a famine food	Irvine (1952) and Uphof (1968)
<i>Dioscorea membranacea</i>	Dioscoreaceae	Chatong (Thai Sakai)	Tuber is used as substitute for <i>Dioscorea</i> food species during famine	Maneenoon et al. (2008)
<i>Dioscorea minutiflora</i> Engl.	Dioscoreaceae	Aha Bayere (Twi, Gold Coast); Magoraza, Hazara (Hausa, Nigeria)	Gold Coast: eaten as a famine food. Nigeria (Kano State, northern): tuber is eaten	Irvine (1952) and Mortimore (1989)
<i>Dioscorea nummularia</i> Lam.	Dioscoreaceae	Prickly Yam	Tubers are eaten	Low (1991), Onwueme (1996a), and Walter and Lebot (2007)
<i>Dioscorea opposita</i> Thunb = <i>Dioscorea oppositifolia</i> L.	Dioscoreaceae	Chinese Yam, Korean Yam, Japanese Mountain Yam, Nagaimo, Yamaimo	Tuber is eaten	Burkill (1966), Facciola (1990), Hu (2005), van Wyk (2006), and Codex (2014)
<i>Dioscorea oppositifolia</i> L.	Dioscoreaceae	As above	India (Deccan): tuber is eaten	Watt (1908) and Facciola (1990)
<i>Dioscorea orbiculata</i> Hook.f.	Dioscoreaceae	Ubi Garam (Indonesia); Takob, Ubi Garam (Malaysia); Man Tayong (Thai); Takob (Thai Sakai)	Tubers are eaten in peninsular Malaysia. Tuber is the main source of carbohydrate for the Sakai tribe in peninsular Thailand	Burkill (1966), Groen et al. (1996), and Maneenoon et al. (2008)
<i>Dioscorea owenii</i> Prain & Burkill	Dioscoreaceae	NF	Tubers are eaten	Burkill (1966)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Dioscorea pentaphylla</i> L.	Dioscoreaceae	Fiveleaf Yam; Pi‘A (Hawaiian); Ser (Thai Sakai); Pachpotia Alu, Ruipheng (Assamese); Chai, Chavi, Alshi, Shahada, Kala Kand, Jaglia Che Kand, Kadu Kand (Bombay Presidency); Taigun, Takuli (Kumaon region, western Himalayas); Kanta-Alu (western Rajasthan)	In India, tubers are cut into pieces, steeped in water and boiled or baked prior to eating. In Hawaii, tuber is steamed and eaten warm. In Oceania, tubers are boiled baked or used in <i>lap-lap</i> . In peninsular Thailand, tubers are the main source of carbohydrate for the Sakai	Gammie (1902), Watt (1908), Handy (1940), Bhargava (1960), Gupta (1962), Gupta and Neal (1965), Burkill (1966), Gupta and Kanodia (1968a), Low (1989), Onwueme (1996a), Patiri and Borah (2007), Walter and Lebot (2007), Ochse and van den Brink (1980), Maneenoon et al. (2008), and Kar and Borthakur (2008)
<i>Dioscorea persimilis</i> Prain & Burkill = <i>Dioscorea hamiltonii</i> Hook.f.	Dioscoreaceae	Khoai Mai, Ciu Mai (Vietnamese)	Tuber is eaten, boiled in soups	Tanaka and Nguyen (2007)
<i>Dioscorea piscatorum</i> Prain & Burkill	Dioscoreaceae	Fish Poison Yam, Tuba Gunjo (Indonesia), Tuba Ubi (Malaysia), Kiyak (Thai Sakai)	Tubers are eaten boiled, baked or roasted. Tuber is used as substitute for <i>Dioscorea</i> food species during famine in peninsular Thailand	Burkill (1966), Groen et al. (1996), and Maneenoon et al. (2008)
<i>Dioscorea polyclados</i> Hook.f.	Dioscoreaceae	Kedut (Sumatra), Kedut (Malaysia)	Tubers are eaten after several boilings or baked in peninsular Malaysia	Burkill (1966) and Groen et al. (1996)
<i>Dioscorea polystachya</i> Turcz.	Dioscoreaceae	Chinese Yam	Tubers are eaten	Codex (2014)
<i>Dioscorea prainiana</i> R. Kunth	Dioscoreaceae	Ubi Kelonak, Kelunoh, Kelana (Malaysia)	Tubers are eaten in peninsular Malaysia	Burkill (1966)
<i>Dioscorea prazeri</i> Prain & Burkill	Dioscoreaceae	Sehod (Thai Sakai)	Tubers are used as substitute for <i>Dioscorea</i> food species during famine in peninsular Thailand	Maneenoon et al. (2008)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Dioscorea preussii</i> Pax	Dioscoreaceae	Preuss' Dioscorea	In tropical, central Africa, tuber is eaten in times of famine	Irvine (1952)
<i>Dioscorea pubera</i> Blume	Dioscoreaceae	Rui-Chilong	Bulbs and tubers are eaten in Karbi, Assam	Groen et al. (1996) and Kar and Borthakur (2008)
<i>Dioscorea pyrifolia</i> Kunth	Dioscoreaceae	Ubi Babi, Badak, Akar Kemnyan Paya, Huwi Upas (Sundanese), Ilus (Javanese), Hngo (Thai Sakai)	Tubers are eaten after several boilings or baked in peninsular Malaysia. Tuber is the main source of carbohydrate for the Sakai tribe in peninsular Thailand	Burkill (1966), Groen et al. (1996), and Maneenoon et al. (2008)
<i>Dioscorea quinata</i> Walter = <i>Dioscorea villosa</i> L.	Dioscoreaceae	Magiya, Munia (Kumaon region, western Himalayas, India)	Tubers are cut into pieces, steeped in water and boiled, prior to eating	Bhargava (1960)
<i>Dioscorea rotundata</i> Poir. = <i>Dioscorea cayennensis</i> subsp. <i>rotundata</i> (Poir.) J. Miegé	Dioscoreaceae	Eight-Month Yam, Round White Yam, White Yam, White Guinea Yam	Yams are used to make fufu, may also be used in the same way as potatoes or sweet potatoes	Akinwande et al. (2007) and Codex (2014)
<i>Dioscorea sagittata</i> Poir.	Dioscoreaceae	Fiveleaf Yam, Tarur (Kumaon region, western Himalayas, India)	Axillary tubers are cut into pieces, steeped in water and boiled prior to eating	Bhargava (1960)
<i>Dioscorea sativa</i> L. = <i>Dioscorea villosa</i> L.	Dioscoreaceae	Kath Alu (Assamese); Kadia Kand, Mano Kand, Vaj Kand, Kadawa Kand, Kedvo Kand (Bombay Presidency)	Tubers are eaten cooked as vegetable by boiling or toasting. After neutralising toxic substances, the tuber may be mixed with <i>konda</i> or some other flours and then eaten	Gammie (1902) and Patiri and Borah (2007)
<i>Dioscorea schimperiana</i> Hochst. ex Kunth	Dioscoreaceae	Yagniat (Kipsigis, Kenya)	Root tubers are eaten	Kabuye (1986)
<i>Dioscorea stemonoides</i> Prain & Burkill	Dioscoreaceae	Kungkwad (Thai Sakai)	Tuber is the main source of carbohydrate for the Sakai tribe in peninsular Thailand	Maneenoon et al. (2008)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Dioscorea transversa</i> R. Br.	Dioscoreaceae	Long Yam	Tuber is eaten raw or roasted, also aerial bulbils	Cribb and Cribb (1987), Wightman and Andrews (1989), Low (1989), and Harden (1993)
<i>Dioscorea trifida</i> L.f.	Dioscoreaceae	Indian Yam, Cush-Cush and Yampee	Tubers are eaten boiled, baked	Facciola (1990), Walter and Lebot (2007), and Codex (2014)
<i>Dioscorea triphylla</i> L. = <i>Dioscorea pentaphylla</i> L.	Dioscoreaceae	See <i>D. Pentaphylla</i>	Tubers are eaten in India (Deccan)	Watt (1908)
<i>Dioscorea tuberosa</i> Vell. = <i>Dioscorea cinnamomifolia</i> Hook.	Dioscoreaceae	NF	India (Garhwal Himalayas): tuber is eaten after repeated boiling, washing and baking	Gupta (1962)
<i>Dioscorea wallichii</i> Hook.f.	Dioscoreaceae	Rui Nihang (Assamese), Yarex (Thai Sakai)	Tuber is the main source of carbohydrate for the Sakai tribe in peninsular Thailand	Maneenoon et al. (2008)
<i>Dioscoreophyllum cumminsii</i> (Stapf) Diels	Menispermaceae	Guinea Potato, African Serendipity Berry,	Tubers are eaten like potato	Jansen (1999)
<i>Dipcadi erythraeum</i> Webb & Berthel.	Asparagaceae	Askanda	Bulb is rich in starch, source of vegetables for nomads	Gupta and Kanodia (1968b)
<i>Dipodium atropurpureum</i> D.L. Jones	Orchidaceae	Purple Hyacinth Orchid	Fleshy, starchy, thick roots are eaten	Harden (1993)
<i>Dipodium hamiltonianum</i> F.M. Bailey	Orchidaceae	Green Hyacinth Orchid	Fleshy, starchy, thick roots are eaten	Harden (1993)
<i>Dipodium pulchellum</i> D.L. Jones & M.A. Clem.	Orchidaceae	Dark Hyacinth Orchid	Fleshy, starchy, thick roots are eaten by aborigines	Harden (1993)
<i>Dipodium punctatum</i> (Sm.) R. Br. = <i>Dipodium squamatum</i> (G. Forst.) R. Br.	Orchidaceae	Hyacinth Orchid	Fleshy, starchy, thick roots are eaten by aborigines	Low (1989, 1991) and Harden (1993)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Dipodium roseum</i> D.L. Jones & M.A. Clem.	Orchidaceae	Pink Hyacinth Orchid	Fleshy, starchy, thick roots are eaten	Harden (1993)
<i>Dipodium</i> spp.	Orchidaceae	Hyacinth Orchids	Fleshy, starchy, thick roots are eaten by aborigines	Cribb and Cribb (1987)
<i>Dipodium variegatum</i> M.A. Clem. & D.L. Jones	Orchidaceae	Spotted Hyacinth Orchid	Fleshy, starchy, thick roots are eaten	Harden (1993)
<i>Disporopsis aspersa</i> (Hua) Engler ex Krause	Asparagaceae	Golden Hematinic, Mottled False Disporum, Huang Jin Qi (Chinese)	Rhizomes are cooked with pork in central China	Hu (2005)
<i>Disporopsis pernyi</i> (Hua) Diels	Asparagaceae	Bamboo-Root Hematinic, Zhu Gen Qi (Chinese)	Rhizomes are cooked with chicken given as a special food for postpartum mothers in Guizhou	Hu (2005)
<i>Diuris abbreviata</i> F. Muell. ex Benth.	Orchidaceae	Lemon Doubletail	Fleshy, starchy, bland, glutinous, tubers are eaten	Harden (1993)
<i>Diuris alba</i> R. Br.	Orchidaceae	White Donkey Orchid	As above	Harden (1993)
<i>Diuris aurea</i> Sm.	Orchidaceae	Golden Donkey	Fleshy, starchy, bland, glutinous tubers are eaten	Low (1991)
<i>Diuris chrysantha</i> D.L. Jones & M.A. Clem.	Orchidaceae	Yellow Donkey Orchid	As above	Harden (1993)
<i>Diuris dendrobioides</i> Fitzg. = <i>Diuris punctata</i> Sm.	Orchidaceae	Purple Donkey Orchid	As above	Harden (1993)
<i>Diuris goonooensis</i> Rupp = <i>Diuris platichila</i> Fitzg.	Orchidaceae	Western Donkey Orchid	As above	Harden (1993)
<i>Diuris lanceolata</i> Lindl.	Orchidaceae	Snake Orchid, Golden Moths	As above	Harden (1993)
<i>Diuris maculata</i> Sm.	Orchidaceae	Leopard Orchid	Tubers are bland and glutinous	Low (1989, 1991)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Diuris pedunculata</i> R. Br.	Orchidaceae	Golden Moths, Small Snake Orchid	As above	Harden (1993)
<i>Diuris punctata</i> Sm.	Orchidaceae	Purple Donkey Orchid	As above	Harden (1993)
<i>Diuris striata</i> Rupp	Orchidaceae	NF	As above	Harden (1993)
<i>Diuris sulphurea</i> R. Br.	Orchidaceae	Tiger Orchid, Hornet Orchid	As above	Harden (1993)
<i>Diuris tricolor</i> Fitzg.	Orchidaceae	Tricolor Donkey Orchid	As above	Harden (1993)
<i>Diuris venosa</i> Rupp	Orchidaceae	Veined Doubletail, Veined Donkey Orchid, Goat Orchid	As above	Harden (1993)
<i>Dolichos biflorus</i> L. = <i>Vigna unguilata</i> (L.) Walp.	Fabaceae	Horse Gram	In Australia (North Queensland), rootstock is roasted and eaten	Watt (1908) and Irvine (1957)
<i>Doryanthes excelsa</i> Corrêa	Doryanthaceae	Gymea Lily	Hefty roots are eaten	Low (1989) and Lim (2014)
<i>Dracontium polyphyllum</i> L.	Araceae	Kaat Curna (Tamil), Adiva Kanda (Telugu)	Cooked tubers are eaten	Watt (1908)
<i>Drosera auriculata</i> Backh. ex Planch.	Droseraceae	Climbing Sundew	Tubers may be edible	Harden (1990)
<i>Drynaria baronii</i> (Christ) Diels = <i>Drynaria sinica</i> Diels	Polypodiaceae	Qin Ling Hu Jue (Chinese)	Rhizome is source of starch	Dai et al. (2003) and Cao et al. (2007)
<i>Drynaria fortunei</i> (Kunze ex Mett.) J. Sm. = <i>Drynaria roosii</i> Nakaike	Polypodiaceae	Hu Jue (Chinese)	Rhizome starch is used for cakes and liquor	Dai et al. (2003), Cao et al. (2007), and Yun et al. (2009b)
<i>Dryopteris dilatata</i> (Hoffm.) A. Gray	Dryopteridaceae	Shield Fern	Root is eaten	Schofield (2003)
<i>Echinophora spinosa</i> L.	Apiaceae	Prickly Samphire, Sea Parsnip	Roots are edible with a parsnip flavour	Hedrick (1972) and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Eleocharis dulcis</i> (Burm.f.) Trinius ex Henscel	Cyperaceae	Water Chestnut, Ground Chestnut	Corms are eaten raw or fresh or from canned material, used in salad or as snack and as a condiment and pickled and also baked, go well in soups, stir-fries, dumplings or as garnish for vegetable dishes. Starch obtained from tubers for domestic use, mixed with sugar to prepare a refreshing morning drink as well as for pastry	Cribb and Cribb (1987), Low (1989), Facciola (1990), Phillips and Rix (1993), Paisooksantivatana (1966), Hu (2005), van Wyk (2006), Santich et al. (2008), and Codex (2014)
<i>Eleocharis kuroguwai</i> Ohwi	Cyperaceae	Kuro Gawai (Japanese)	Corm is edible	Codex (2014)
<i>Eleusine indica</i> (L.) Gaertn.	Poaceae	Indian Goosegrass, Wiregrass, Crowfootgrass	Roots are edible raw	Kunkel (1984)
<i>Eleutherococcus senticosus</i> (Rupr. & Maxim.) Harms	Araliaceae	Eleuthero Root, Siberian Ginseng, Ci Wu Jia (Chinese)	Root and stem are used for tea	Hu (2005)
<i>Emex spinosa</i> (L.) Campd.	Polygonaceae	Devil's Thorn	Roots are eaten raw or cooked	Kunkel (1984) and Facciola (1990)
<i>Ensete superbum</i> (Roxb.) Cheesman	Musaceae	Dwarf Banana, Red Dwarf Banana, Cliff Banana, Lobong Ken-Tong (Assamese)	Rhizome is eaten in Karbi, Assam	Kar and Borthakur (2008)
<i>Ensete ventricosum</i> (Welw.) Cheesman	Musaceae	Abyssinian Banana	Rhizome is eaten	Codex (2014)
<i>Epilobium angustifolium</i> L.	Onagraceae	Fireweed	Norway: a flour is obtained from the roots which is baked into flat cakes	Sayce (1953) and Uphof (1968)
<i>Eriochilus cucullatus</i> (Labill.) Rehb.f.	Orchidaceae	Smooth Leaf Parson's Bands, Large Parson's Bands	Egg-shaped tubers are eaten	Low (1991) and Harden (1993)
<i>Eriophorum gracile</i> Koch	Cyperaceae	Mousenuts, Alaska Cotton, Swamp Cotton	Rootstock is used raw or cooked	Schofield (2003)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Eriophyton wallichii</i> Benth. ex Wall.	Lamiaceae	Mian Shen (Chinese)	Roots are used in food in northwestern Yunnan	Hu (2005)
<i>Eriosema chinense</i> Vogel	Fabaceae	Chinese Eriosoma, Katil (Indonesia)	Tubers are eaten cooked; enlarged fleshy tuberous roots are used in tonifying broth with pork	Cribb and Cribb (1987), Groen et al. (1996), and Hu (2005)
<i>Erodium crinitum</i> Carolin	Geraniaceae	Smooth Leaf Parson's Bands, Large Parson's Bands	Rhizomes are edible cooked	Cribb and Cribb (1987) and Harden (1992)
<i>Eryngium campestre</i> L.	Apiaceae	Snakeroot	Roots are cooked as vegetables. Candied roots are eaten in England and France	Uphof (1968), Tanaka (1976), and Facciola (1990)
<i>Eryngium maritimum</i> L.	Apiaceae	Sea Holly, Sea Eryngo	Roots boiled or roasted resembled chestnuts or parsnips in taste. Roots are candied	Grieve (1971), Hedrick (1972), and Facciola (1990)
<i>Erythrina vespertilio</i> Benth.	Fabaceae	Bat's Wing Coral Tree	Roots are eaten raw by aborigines	Cribb and Cribb (1987)
<i>Erythronium americanum</i> Ker Gawl.	Liliaceae	Trout Lily, Yellow Adder's Tongue	Bulbs are eaten raw, boiled or roasted	Harrington (1974), Gibbons and Tucker (1979), and Facciola (1990)
<i>Erythronium albidum</i> Nutt.	Liliaceae	White Trout Lily	Bulbs are eaten boiled	Gibbons and Tucker (1979) and Facciola (1990)
<i>Erythronium dens-canis</i> L.	Liliaceae	Dog's Tooth Violet	Roots are eaten with reindeer or cow's milk in Siberia and Mongolia. Also a source of starch used in vermicelli and cakes	Hedrick (1972), Uphof (1968), and Facciola (1990)
<i>Erythronium japonicum</i> Decne.	Liliaceae	Katakuri	Bulbs are source of starch used in dumplings, confectionery, fritters to thicken soups or as dietetic food	Tanaka (1976) and Facciola (1990)
<i>Erythronium oregonum</i> Applegate	Liliaceae	Fawn Lily, White Fawn Lily	Bulb is eaten raw, boiled or roasted	Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Eucalyptus caesia</i> Benth.	Myrtaceae	Caesia, Gungurru, Silver Princes	Bark of young roots is eaten	Cribb and Cribb (1987)
<i>Eucalyptus dumosa</i> A. Cunn. ex Oxley	Myrtaceae	Water Mallee, Congoo Mallee, White Mallee	As above	Cribb and Cribb (1987) and Facciola (1990)
<i>Eucalyptus loxophleba</i> Benth.	Myrtaceae	Smooth-Barked York Gum, York	Root bark is eaten	Low (1989)
<i>Euryale ferox</i> Salisb.	Nymphaeaceae	Chicken Head, Fox Nut	In China, roots and seeds are eaten	Read (1946) and Facciola (1990)
<i>Eurycoma longifolia</i> Jack	Simaroubaceae	Tongkat Ali (Malay)	Traditional users of tongkat ali brew tea from the dried chips of the tree's root. Tea, coffee and carbonated beverages, premixed with the root extract, are available commercially for the improvement of general health and libido in Malaysia	Low et al. (2013)
<i>Eustrephus latifolius</i> R. Br.	Asparagaceae	Wombat Berry	Root tuber crisp is eaten raw	Cribb and Cribb (1987)
<i>Eutrema wasabi</i> Maxim. = <i>Eutrema japonicum</i> (Miq.) Koidz.	Brassicaceae	Wasabi, Asian Horseradish	Root is used as spice	Facciola (1990) and Hu (2005)
<i>Farfugium japonicum</i> var. <i>formosanum</i> (Hayata) Kitamura	Asteraceae	Leopard Plant, Green Leopard Plant, Gao Wu (Chinese)	Roots are eaten in Taiwan	Hu (2005)
<i>Ferula assa-foetida</i> L.	Apiaceae	Asafoetida	Gum extracted from stem and roots is used as condiment in food and has a garlic flavour	Facciola (1990) and Jansen (1999)
<i>Fimbristylis kysoor</i> (Roxb.) Dalz. & Gibbs	Cyperaceae	NF	Root is eaten in India	Watt (1908)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Fimbristylis subbispicata</i> Nees = <i>Fimbristylis tristachya</i> var. <i>subbispicata</i> (Nees) T. Koyama	Cyperaceae	Sedge, Pond Onion	Shoots and roots are eaten in China	Read (1946)
<i>Flemingia procumbens</i> Roxb.	Fabaceae	Sohplong (India)	Starch rib tubers are eaten raw	Groen et al. (1996)
<i>Flemingia vestita</i> Baker = <i>Flemingia procumbens</i> Roxb.	Fabaceae	Soh Phlang	Tuber is eaten in Meghalaya	Sawian et al. (2007)
<i>Fockea angustifolia</i> K. Schum.	Apocyanaceae	Water Root, Khoa	Swollen rootstock is eaten raw when young or used for making jam and preserved in South Africa	Fox et al. (1982) and Facciola (1990)
<i>Fockea edulis</i> (Thunb.) K. Schum.	Apocyanaceae	Kambro	Large tuber is used to make a konfyt as an alternative to watermelon	Fox et al. (1982) and Facciola (1990)
<i>Foeniculum azoricum</i> Mill. = <i>Foeniculum vulgare</i> Mill.	Apiaceae	Florentine, Florence	Swollen bulbs of leaf bases are eaten raw as accompaniment to cheese or cooked	Phillips and Rix (1993)
<i>Foeniculum vulgare</i> Mill.	Apiaceae	Fennel	Thick roots of young plants are cooked and eaten	Facciola (1990) and Phillips and Rix (1993)
<i>Fritillaria camschatcensis</i> (L.) Ker Gawl.	Liliaceae	Indian Rice, Black Lily, Kamchatka Fritillary, Chocolate Lily, Rice-of-the-Earth	Bulbs are eaten raw or cooked, steamed with garlic butter or a spicy sauce, boiled, mashed, stir-fried and top with butter, brown sugar, herbs or sauces and added to casseroles. Bulbs are also made into soups or a meal in itself. Bulb is dried and ground for flour. Bulblets are eaten as food	Facciola (1990), Schofield (2003), and Hu (2005)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Fritillaria lanceolata</i> Torr. = <i>Fritillaria biflora</i> var. <i>biflora</i>	Liliaceae	Mission Bells	As above	Schofield (2003)
<i>Fritillaria pudica</i> (Pursh) Spreng.	Liliaceae	Yellow Bells	As above	Schofield (2003)
<i>Fritillaria verticillata</i> Willd.	Liliaceae	Baimo	Bulbs are eaten fried or candied in China	Tanaka (1976) and Facciola (1990)
<i>Fumaria bulbosa</i> L. = <i>Corydalis solida</i> (L.) Clairv.	Papaveraceae	NF	In France, starch of root is recommended as famine food for extending bread flour, after removal of bitter element	Parmentier (1781) (cited by Freedman 2009)
<i>Galactia tenuiflora</i> (Willd.) Wight & Arn.	Fabaceae	Florida Hammock Milkpea	Root is eaten after treatment	Cribb and Cribb (1987)
<i>Gastrodia elata</i> Blume	Orchidaceae	Gastrodia Tuber, Tian Ma (Chinese)	Fleshy potato-like tuber is boiled in water for tea or with chicken in soup	Hu (2005) and Codex (2014)
<i>Gastrodia procera</i> G.W. Carr	Orchidaceae	Large Potato Orchid, Large Cinnamon Bells	Tuber is edible and reportedly formed as mainstay diet for the Tasmanian aborigines. The cooked tuber is described as 'like beetroot'	Harden (1993)
<i>Gastrodia sesamoides</i> R. Br.	Orchidaceae	Potato Orchid, Cinnamon Bells	As above	Cribb and Cribb (1987) and Low (1989, 1991)
<i>Genoplesium archeri</i> (Hook.f.) D.L. Jones & M.A. Clem.	Orchidaceae	Variable Midge Orchid	Tubers are edible	Harden (1993)
<i>Genoplesium filiforme</i> (Fitzg.) D.L. Jones & M.A. Clem	Orchidaceae	Glandular Midge Orchid	Tubers are edible	Harden (1993)
<i>Genoplesium fimbriatum</i> (R. Br.) D.L. Jones & M.A. Clem.	Orchidaceae	Fringed Midge Orchid	Tubers are edible	Harden (1993)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Genoplesium nudiscapum</i> (Hook.f.) D.L. Jones & M.A. Clem.	Orchidaceae	Dense Midge Orchid	Tubers are edible	Harden (1993)
<i>Genoplesium nudum</i> (Hook.f.) D.L. Jones & M.A. Clem.	Orchidaceae	Tiny Midge Orchid	Tubers are edible	Harden (1993)
<i>Genoplesium pedersonii</i> D.L. Jones	Orchidaceae	Red Midge Orchid	Tubers are edible	Harden (1993)
<i>Genoplesium rufum</i> (R. Br.) D.L. Jones & M.A. Clem.	Orchidaceae	Red Midge Orchid	Tubers are edible	Harden (1993)
<i>Geodorum</i> sp.	Orchidaceae	Ground Gem Orchid	Tubers are eaten by aborigines	Cribb and Cribb (1987)
<i>Geranium solanderi</i> Carolin	Geraniaceae	Native Cranebills, Native Geranium	Starchy taproots eaten after roasting have a turnip flavour	Cribb and Cribb (1987), Low (1989, 1991), and Harden (1992)
<i>Gladiolus byzantinus</i> Mill. = <i>Gladiolus communis</i> L.	Iridaceae	Byzantine Gladiolus	In France, starch of root is recommended as a famine food for extending bread flour, after removal of bitter element	Parmentier (1781) (cited by Freedman 2009)
<i>Glossodia major</i> R. Br.	Orchidaceae	Common Wax Lip	Tubers are watery and bittersweet when eaten	Low (1991) and Harden (1993)
<i>Glossodia</i> sp.	Orchidaceae	Waxlip Orchids	Tubers are eaten by aborigines	Cribb and Cribb (1987)
<i>Glottiphyllum linguiforme</i> (L.) N.E. Br.	Aizoaceae	Tongue Leaf Plant	Roots are used in Transvaal for making a fermented beer	Fox et al. (1982) and Facciola (1990)
<i>Glycyrrhiza glabra</i> L.	Fabaceae	Licorice, Liquorice	Pieces of rhizomes are used as flavourant or sweetener, can be chewed as sweet snack used in confectionery, sweets, drinks, dark beers (stouts) and liqueurs	van Wyk (2006)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Glycyrrhiza lepidota</i> Pursh	Fabaceae	American Licorice	Roots are chewed, added to other foods for flavouring or dried and brewed in tea	Uphof (1968), Fernald et al. (1958), and Facciola (1990)
<i>Gynura bicolor</i> (Roxb. ex Willd.) DC.	Asteraceae	Red Groundsel, Di Huang Cai (Chinese)	Roots are cooked with sliced pork	Hu (2005)
<i>Gypsophila davurica</i> Turcz. ex Fenzl	Caryophyllaceae	Cao Yuan Shi Tou Hua (Chinese)	In Manchuria (eastern forests), root is eaten after thorough processing. Contains toxic saponin	Baranov (1967)
<i>Habenaria conopsea</i> Rchb.f.	Orchidaceae	Fragrant Orchid, Shou Shen (Chinese)	Tuber is used in soup with meat	Hu (2005)
<i>Habenaria delavayi</i> Finet	Orchidaceae	Ji Zhu Shen, Chi Chua Shen (Chinese)	Tubers are eaten by ethnic group in Yunnan	Hu (2005)
<i>Habenaria multipartite</i> Blume ex Kraenzl.	Orchidaceae	Toothed Habenaria	Tubers are used as emergency food	Groen et al. (1996)
<i>Habenaria rumphii</i> (Brong.) Lindl.	Orchidaceae	NF	Tubers are used as emergency food	Groen et al. (1996)
<i>Habenaria sparsiflora</i> S. Watson = <i>Platanthera sparsiflora</i> (S. Watson) Schltr.	Orchidaceae	Bog Orchid	North America (New Mexico): bulb is used by Native American San Felipe Pueblo group in times of food shortage	Yanovsky (1936) and Castetter and Bell (1942)
<i>Haemodorum corymbosum</i> Vahl	Haemodoraceae	Bloodroot	Bulb is eaten after roasting	Cribb and Cribb (1987)
<i>Haemodorum</i> sp.	Haemodoraceae	Bloodroot	Roots are pounded and cooked	Low (1989)
<i>Halopegia blumei</i> (Körn.) K. Schum.	Marantaceae	Jelantir (Javanese), Patat (Sundanese), Dong Nam (Vietnam)	Tubers are eaten cooked or roasted	Groen et al. (1996) and Ochse and van den Brink (1980)
<i>Hardenbergia retusa</i> Benth. = <i>Vandasina retusa</i> (Benth.) Rauschert	Fabaceae	Sarsaparilla Vine	Roots are roasted	Cribb and Cribb (1987)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Hedychium coronarium</i> J. Koenig	Zingiberaceae	White Ginger Lily	Tubers are eaten in India (Deccan)	Watt (1908) and Lim (2014)
<i>Hedysarum boreale</i> Nutt.	Fabaceae	Licorice Root, Sweet Root	Young sweet roots have a licorice flavour and are eaten raw, boiled, baked or added in soups	Uphof (1968), Gibbons and Tucker (1979), Fernald et al. (1958), and Facciola (1990)
<i>Hedysarum mackenzii</i> Richardson = <i>Hedysarum boreale</i> subsp. <i>mackenzii</i> (Richardson) S.L. Welsh	Fabaceae	Licorice Root, Sweet Broom	Young sweet roots have a licorice flavour and are eaten	Uphof (1968), Hedrick (1972), Fernald et al. (1958), and Facciola (1990)
<i>Hedysarum occidentale</i> Greene	Fabaceae	Licorice Root, Sweet Vetch	As above	Facciola (1990)
<i>Helianthus annuus</i> L.	Asteraceae	Sunflower, Xiang Ri Kui (Chinese)	Root is used for tea	Hu (2005)
<i>Helianthus maximiliani</i> Schrad.	Asteraceae	Maximilian Sunflower	Tubers may be eaten raw, boiled or roasted	Yanovsky (1936) and Facciola (1990)
<i>Helianthus strumosus</i> L. = <i>Helianthus hirsutus</i> Raf.	Asteraceae	Paleleaf Woodland Sunflower	Used raw or cooked like the Jerusalem artichoke	Kunkel (1984)
<i>Helianthus tuberosus</i> L.	Asteraceae	Jerusalem Artichoke, Girosole	Tubers are boiled and used as vegetables – raw in salads or lightly cooked in stir-fries or as a vegetable served with cream, butter or a sauce. Sliced rhizomes are fried as fritter and made into soufflés or purees. Tubers are rich source of inulin and sugar	Saunders (1920), Kaldy et al. (1980), Facciola (1990), Phillips and Rix (1993), Vervelde (1996), Cabezas et al. (2002), Hu (2005), van Wyk (2006), Santich et al. (2008), and Codex (2014)
<i>Helianthus x laetiflorus</i> Pers.	Asteraceae	Showy Sunflower	Tubers are edible	Gibbons and Tucker (1979) and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Helleborus niger</i> L.	Ranunculaceae	Christmas Rose, Black Hellebore	In France, starch of root is recommended for extending bread flour, after removal of bitter element	Parmentier (1781) (cited by Freedman 2009)
<i>Hemerocallis fulva</i> (L.) L.	Xanthorrhoeaceae	Orange Day Lily, Tawny Daylily, Shina-Kanzo (Japanese)	In China, flowers, leaves, shoots and roots are eaten. Root can be prepared into flour from which cakes are made. Bulbs are boiled and creamed, baked eaten raw, mashed or made into fritters	Read (1946), Harrington (1974), Tanaka (1976), Facciola (1990), and Lim (2014)
<i>Hemerocallis lilioasphodelus</i> L.	Xanthorrhoeaceae	Yellow Day Lily, Lemon Lily, Wasuregusa (Japanese)	Fleshy root boiled in salt water tastes like blend of sweet corn and salsify	Fernald et al. (1958), Facciola (1990), and Lim (2014)
<i>Hemerocallis minor</i> Mill.	Xanthorrhoeaceae	Grassleaf Daylily, Hosoba-Kisuge (Japanese)	Bulbs are baked, steamed, roasted or stir-fried in Japan and China	Hedrick (1972), Tanaka (1976), and Facciola (1990)
<i>Heracleum lanatum</i> Michx.	Apiaceae	Cow Parsnip	Cooked root has a flavour like rutabaga	Facciola (1990)
<i>Heracleum sphondylium</i> subsp. <i>montanum</i> (Schleich. ex Gaudin) Briq.	Apiaceae	American Cow Parsnip		Harrington (1974), Gibbons and Tucker (1979), Fernald et al. (1958), and Facciola (1990)
<i>Heuchera glabra</i> Willd. ex Roem. & Schult.	Saxifragaceae	Alpine Heuchera, Smooth Heuchera	Roots are edible and chopped and added to soups and vegetable pies	Schofield (2003)
<i>Heuchera micrantha</i> Douglas ex Lindl.	Saxifragaceae	Small-Flowered Alum Root	As above	Schofield (2003)
<i>Hibiscus divaricatus</i> Graham	Malvaceae	Native Hibiscus	In Australia (South Australia, northeast; Queensland, north), roots and buds of young plants are eaten raw	Irvine (1957)
<i>Hibiscus diversifolius</i> Jacq.	Malvaceae	Swamp Hibiscus	Young starchy roots are eaten	Cribb and Cribb (1987)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Hibiscus heterophyllus</i> Vent.	Malvaceae	Native Rosella Queensland Sorrel, Green Kurrajong, Batham; New South Wales, Dtharang- Gange	Young starchy roots are eaten in Australia	Maiden (1889), Cribb and Cribb (1987), and Harden (1990)
<i>Hibiscus sturtii</i> Hook.	Malvaceae	Hill Hibiscus	As above	Harden (1990)
<i>Hibiscus tiliaceus</i> L.	Malvaceae	Beach Hibiscus, Cuan Bast, Huang Jin (Chinese)	Roots are eaten by fishing community along the coast of South China Sea	Hu (2005)
<i>Hibiscus trionum</i> L.	Malvaceae	Flower-of-an-Hour, Bladder Hibiscus, Bladder Ketmia, Bladder Weed	Starchy root is eaten	Harden (1990)
<i>Homalomena aromatica</i> (Spreng.) Schott	Araceae	Ok Hi Atehang; Tharem, Thagong- Yungsa (Assamese)	Tuber is eaten in Karbi, Assam	Kar and Borthakur (2008) and Medhi and Borthakur (2012)
<i>Hordeum bulbosum</i> L.	Poaceae	Abu Suwaif	Bulbous roots are chewed and eaten occasionally	Tanaka (1976) and Facciola (1990)
<i>Hornstedtia scottiana</i> (F. Muell.) K. Schum.	Zingiberaceae	Jiddo, Scotts Ginger	Tuberous root is eaten edible	Wikipedia (2014)
<i>Hosta plantaginea</i> (Lam.) Asch.	Asparagaceae	Plantain Lily, Yu Zan (Chinese)	Root is cooked with meat in Hubei	Hu (2005)
<i>Houttuynia cordata</i> Thunb.	Saururaceae	Heart-Leaved Houttuynia, Fishwort; Masundari, Mosondoi (Assamese); Maisundri (Bodo)	Roots are edible, eaten as chutney. It is used in various Assamese dishes	Uphof (1968), Tanaka (1976), Facciola (1990), and Patiri and Borah (2007)
<i>Humulus lupulus</i> L.	Cannabaceae	Hops	Fleshy rhizomes are sometimes eaten	Uphof (1968), Kunkel (1984), and Facciola (1990)
<i>Humulus lupulus</i> var. <i>cordifolius</i> (Miq.) Maxim. ex Franch. & Sav. = <i>Humulus lupulus</i> L.	Cannabaceae	Hops	Fleshy rhizomes are sometimes eaten	Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Hydrophyllum canadense</i> L.	Boraginaceae	John's Cabbage, Bluntleaf Waterleaf	Root is eaten in times of famine	Yanovsky (1936) and Hedrick (1972)
<i>Hyoscyamus vulgaris</i> Neck.	Solanaceae	NF	In France, starch of root is recommended as famine food for extending bread flour, after removal of bitter element	Parmentier (1781) (cited by Freedman 2009)
<i>Hypoxis hygrometrica</i> Labill.	Hypoxidaceae	Golden Stars, Star Grass, Golden Weather-Glass	Roasted minute tubers are eaten by aborigines	Cribb and Cribb (1987) and Low (1991)
<i>Hypoxis nervosa</i> R.J.F. Hend.	Hypoxidaceae	Golden Stars, Star Grass	As above	Low (1991)
<i>Hypoxis filiformis</i> Baker	Hypoxidaceae	Isinongwe (Zulu)	In Zululand (Ubombo district), roots are boiled and eaten	Hely-Hutchinson (1898)
<i>Hypoxis marginata</i> R. Br.	Hypoxidaceae	Golden Stars, Star Grass	Roots are boiled and eaten	Low (1989)
<i>Hypoxis pratensis</i> R. Br.	Hypoxidaceae	Golden Stars, Star Grass	As above	Low (1991)
<i>Icacina mannii</i> Oliver	Icacinaceae	Mutuo (Akan-Twi, Ghana), Akin (Kyama, Ivory Coast), Ututo Ogiri (Igbo, Nigeria)	Tubers are eaten after detoxification in Africa (area not specified)	Irvine (1952), Uphof (1968), and Ferry et al. (1974)
<i>Icacina senegalensis</i> Juss. = <i>Icacina oliviformis</i> (Poir.) J. Raynal	Icacinaceae	False African Yam	West Africa as above	Irvine (1952), Uphof (1968), Kay (1973), and Ferry et al. (1974)
<i>Imperata cylindrica</i> L.	Poaceae	Blady Grass, Alang-Alang, Lalang Wooly Grass	Aboriginal children sucked the roots, underground shoots like sugar cane, used as survival food; a kind of beer is made from the roots in peninsular Malaysia. China: fresh rhizome is chewed by rural people for the sweet juice	Burkill (1966), Cribb and Cribb (1987), Low (1991), and Hu (2005)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Imperatoria major</i> Gray	Apiaceae	NF	France: starch of root is recommended for extending bread flour, after removal of bitter element	Parmentier (1781) (cited by Freedman 2009)
<i>Ipomoea graminea</i> R. Br.	Convolvulaceae	Bush Potato	Large tubers are roasted and eaten	Cribb and Cribb (1987)
<i>Ipomoea racemosa</i> Poir. = <i>Turbina racemosa</i> (Poir.) D.F. Austin	Convolvulaceae	Soh Lah	Tuber is eaten in Meghalaya	Sawian et al. (2007)
<i>Ipomoea aquatica</i> Forsk.	Convolvulaceae	Water Spinach, Kangkong, River Spinach, Water Morning Glory	Roots are occasionally cooked and eaten	Facciola (1990)
<i>Ipomoea batatas</i> (Linn.) Lam	Convolvulaceae	Sweet Potato, Phan Karo (Meghalaya), Ruidok (Assam)	Tuber is eaten in Meghalaya and in Karbi, Assam; sweet potatoes are always eaten cooked, boiled, baked, roasted or fried and work well in stews, soups and braised dishes	Burkill (1966), Facciola (1990), Phillips and Rix (1993), Takagi et al. (1996), Hu (2005), van Wyk (2006), Sawian et al. (2007), Walter and Lebot (2007), Kar and Borthakur (2008), Santich et al. (2008), and Codex (2014)
<i>Ipomoea cairica</i> (L.) Sweet	Convolvulaceae	Morning Glory, Mile-a-Minute Vine, Messina Creeper, Cairo Morning Glory, Coast Morning Glory; Wu Zhao Jin Long (Chinese)	Roots are used to extract starch in Yunnan	Hu (2005)
<i>Ipomoea calobra</i> F. Muell.	Convolvulaceae	Bush Potato, Goolabura	Large tubers are roasted and eaten	Cribb and Cribb (1987) and Low (1991)
<i>Ipomoea costata</i> F. Muell. ex Benth.	Convolvulaceae	Bush Potato, Desert Yam	As above	Low (1991)
<i>Ipomoea digitata</i> L. = <i>Ipomoea cheirophylla</i> O'Donell	Convolvulaceae	Spanish Woodbine	Oblong tubers are eaten like sweet potatoes	Hedrick (1972), Tanaka (1976), and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Ipomoea eriocarpa</i> R. Br.	Convolvulaceae	Tiny Morning Glory; Buta (Hindi); Mulli Balli (Kannada)	Large tubers are roasted and eaten	Cribb and Cribb (1987)
<i>Ipomoea gracilis</i> R. Br.	Convolvulaceae	Almor-Ira	Large tubers are roasted and eaten	Cribb and Cribb (1987)
<i>Ipomoea mauritiana</i> Jacq.	Convolvulaceae	Giant Potato, Qi Zhao Long (Chinese)	Roots are used to extract starch	Hu (2005)
<i>Ipomoea pandurata</i> (L.) G. Meyer	Convolvulaceae	Wild Potato Vine, Man-of-the-Earth	Huge, tuberous root weighing sometimes 20 lb	Saunders (1920)
<i>Ipomoea pes-caprae</i> subsp. <i>brasiliensis</i>	Convolvulaceae	Goatsfoot Convolvulus, Beach Morning Glory	Fleshy taproot is eaten after baking and pounding	Cribb and Cribb (1987)
<i>Ipomoea polpha</i> R.W. Johnson	Convolvulaceae	Bush Potato, Weir Vine	Large tubers are roasted and eaten	Low (1991)
<i>Ipomoea polymorpha</i> Roem. & Schult.	Convolvulaceae	Silky Cow Vine	Large tubers are roasted and eaten	Cribb and Cribb (1987)
<i>Ipomoea staphylina</i> Roem. & Schult.	Convolvulaceae	Lesser Glory, Hai Nan Shu (Chinese)	Fleshy tubers are eaten in Hainan island	Hu (2005)
<i>Ipomoea velutina</i> R. Br.	Convolvulaceae	Velvet Morning Glory	Large tubers are roasted and eaten	Cribb and Cribb (1987)
<i>Ipomoea violacea</i> L.	Convolvulaceae	Beach Moonflower, Sea Moonflower	Large tubers are roasted and eaten	Cribb and Cribb (1987)
<i>Iris foetidissima</i> L.	Iridaceae	Stinking Iris	France: starch of root is recommended as a famine food for extending bread flour, after removal of the bitter element	Parmentier (1781) (cited by Freedman 2009)
<i>Iris lutea</i> Lam. = <i>Iris pseudacorus</i> L.	Iridaceae	Yellow Flag, Yellow Iris, Water Flag Iris, Yellow Water Flag	As above	Parmentier (1781) (cited by Freedman 2009)
<i>Iris pallida</i> Lam.	Iridaceae	Sweet Iris	Dried rhizomes give an essential oil, orris oil, used to flavour soft drinks, candy and chewing gum. It is also chewed to sweeten the breath	Morton (1976) and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Iris setosa</i> Pall. ex Link	Iridaceae	Beachhead Iris, Canada Beachhead Iris, Wild Flag	Rhizomes are eaten or used as source of starch	Uphof (1968), Hedrick (1972), Tanaka (1976), and Facciola (1990)
<i>Iris vulgaris</i> Pohl = <i>Iris x germanica</i> L.	Iridaceae	German Iris	As above	Parmentier (1781) (cited by Freedman 2009)
<i>Iris x germanica</i> L.	Iridaceae	German Iris	Rhizomes are dried and used as flavouring or sometimes they are chewed	Uphof (1968), Morton (1976), and Facciola (1990)
<i>Ixeris chinensis</i> (Thunb. ex Thunb.) Nakai	Asteraceae	Shan Ku Mai, Nai Jiang Cai (Chinese)	Root is eaten in northwestern China	Hu (2005)
<i>Ixora subsessilis</i> Wall. ex G. Don	Rubiaceae	Dieng Jowat (Meghalaya), Nang Guo Long Chuan Hua (Chinese)	Flower, shoot and root are eaten in Meghalaya	Sawian et al. (2007)
<i>Jaltomata procumbens</i> (Cav.) J.L. Gentry	Solanaceae	Creeping False Holly, Jaltomate	Roots are eaten raw or boiled	Altschul (1973) and Facciola (1990)
<i>Kaempferia galanga</i> L.	Zingiberaceae	Cekur, Kencur	Rhizome is eaten as spice to flavour food	Burkill (1966), Ochse and van den Brink (1980), and Facciola (1990)
<i>Kaempferia pandurata</i> Roxb. = <i>Boesenbergia rotunda</i> (L.) Mansf.	Zingiberaceae	Kencur, Temu Putri, Kunir Putih, Ardong, Kunci Pepet	Rhizome is eaten as spice to flavour food in Java	Ochse and van den Brink (1980)
<i>Kaempferia rotunda</i> L.	Zingiberaceae	Round-Rooted Galangal Kencur, Temu Putri, Kunir Putih, Ardong, Kunci Pepet	Rhizome is eaten as spice to flavour food in Java	Burkill (1966), Ochse and van den Brink (1980), and Facciola (1990)
<i>Khadia acutipetala</i> (N.E. Br.) N.E. Br.	Aizoaceae	Khadi root, Khadiwortel (Afrikaans)	Roots are used by natives of Transvaal to prepare a fermented liquor called khadi	Fox et al. (1982) and Facciola (1990)
<i>Labichea buettneriana</i> F. Muell.	Fabaceae	NF	Roots are roasted	Cribb and Cribb (1987)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Lablab purpureus</i> (L.) Sweet	Fabaceae	Bonavista Bean, Hyacinth Bean, Dolichos Bean, Seim Bean, Lablab Bean	Large, starchy root is edible	Hedrick (1972) and Facciola (1990)
<i>Languas galanga</i> (L.) Stuntz	Zingiberaceae	Greater Galangal, False Galangal Lengkuas, Languas	Rhizome is used as a spice	Burkill (1966), Morton (1976), and Phillips and Rix (1993)
<i>Languas javanica</i> (Blume) Burkill = <i>Alpinia javanica</i> Blume	Zingiberaceae	Puar Putih, Tepus Putih, Kantan Hutan	Rhizome is used as food, scentless and bitter	Burkill (1966)
<i>Lapathum alpinum</i> Lam.	Polygonaceae	Monk's Rhubarb	France: starch of root is recommended as a famine food, for extending bread flour, after removal of toxic element	Parmentier (1781) (cited by Freedman 2009)
<i>Lapathum aquaticum</i> Garsault = <i>Rumex hydrolapathum</i> Huds.	Polygonaceae	Great Water Dock	As above	Parmentier (1781) (cited by Freedman 2009)
<i>Lapathum sylvestre</i> Lam. = <i>Rumex obtusifolius</i> L.	Polygonaceae	Broad-Leaved Dock, Bitter Dock	As above	Parmentier (1781) (cited by Freedman 2009)
<i>Lasia spinosa</i> (L.) Thwaites	Araceae	Lasia; Phak Naam (Thai); Henru Ehong, Chusot (Assamese)	Tuber is eaten in Karbi, Assam	Van den Bergh (1994) and Kar and Borthakur (2008)
<i>Lathyrus tuberosus</i> L.	Fabaceae	Earthnut Pea, Tuberous Pea	France: root tuber is recommended as a famine food cooked or dried and reduced to flour for use in baking bread	Parmentier (1781) (cited by Freedman 2009), Hedrick (1972), Fernald et al. (1958), Facciola (1990), and Codex (2014)
<i>Lavatera plebeia</i> Sims	Malvaceae	Australian Hollyhock	Slender roots are eaten	Cribb and Cribb (1987) and Low (1989)
<i>Leichardtia australis</i> R. Br. = <i>Marsdenia australis</i> (R. Br.) Druce	Apocynaceae	Doubah	Roots are edible	Cribb and Cribb (1987) and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Leonurus sibiricus</i> L.	Lamiaceae	Siberian Motherwort	In China, the roots are cooked with pork	Burkill (1966), Altschul (1973), Tanaka (1976), and Facciola (1990)
<i>Leopoldia comosa</i> (L.) Parl.	Asparagaceae	Grape Hyacinth, Cippolini (Italian)	Bulbs are eaten boiled with vinegar, pickled or added to omelette. Cooked bulbs are preserved in oil used in antipasto or as relish	Uphof (1968), Bianchini and Corbetta (1976), and Facciola (1990)
<i>Lepidium latifolium</i> L.	Brassicaceae	Dittander	Hot pungent root is used as horseradish substitute	Uphof (1968) and Facciola (1990)
<i>Lepidium meyenii</i> Walp.	Brassicaceae	Maca	Dried maca is cooked in water or milk and used to prepare a kind of sweet and aromatic porridge, <i>mazamorra</i> . The dried roots are eaten after boiling in water or milk and are sometimes mixed with honey and fruit for preparation of juices and addition of sugar cane rum for cocktails and other alcoholic beverages. Flour is also prepared from the dried roots for making bread and cookies	León (1964), Johns (1981), Tello et al.(1992), Hermann and Heller (1997), Ochoa (2001), Flores et al. (2003), and Codex (2014)
<i>Lepironia articulata</i> (Retz.) Domin	Cyperaceae	Grey Sedge	Underground stem is eaten. Rhizome is edible	Cribb and Cribb (1987) and Low (1989)
<i>Levisticum officinale</i> W.D.J. Koch	Apiaceae	Lovage	Roots are the source of oil of lovage, used for flavouring. Roots can be chopped and preserved in honey	Grieve (1971), Hedrick (1972), Morton (1976), and Facciola (1990)
<i>Levisticum vulgare</i> Reichb.	Apiaceae	NF	France: root is recommended as a famine food after cooking ‘a grande eau’	Parmentier (1781) (cited by Freedman 2009)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Lewisia rediviva</i> Pursh	Montiaceae	Bitterroot	Boiling has the effect of dissipating the bitterness; and the white heart of the root, which is starchy and mucilaginous, is certainly nutritious	Saunders (1920), Harrington (1974), Gibbons and Tucker (1979), and Facciola (1990)
<i>Ligusticum scoticum</i> L.	Apiaceae	Scotch Lovage	Roots are chewed	Hedrick (1972), Fernald et al. (1958), Gibbons and Tucker (1979), and Facciola (1990)
<i>Ligusticum sinense</i> Oliver	Apiaceae	Chinese Lovage, Shan Yuan Sui (Chinese)	Root is used for tea	Hu (2005)
<i>Ligusticum wallichii</i> Franch. = <i>Ligusticum striatum</i> DC.	Apiaceae	Sichuan Lovage, Chuan Xiong (Chinese)	Thin slices of dried root are used in bupin mixtures	Hu (2005)
<i>Lilium amabile</i> Palib.	Liliaceae	Friendly Lily, Koma Yuri (Japanese)	Bulbs are cooked and eaten as vegetable in Korea	Tanaka (1976) and Facciola (1990)
<i>Lilium auratum</i> Lindl.	Liliaceae	Goldband Lily, Yama-Yuri (Japanese)	Mucilaginous bulb is boiled, sweetened, powdered and used in dumplings or in a Japanese dish with eggs	Hedrick (1972), Altschul (1973), Tanaka (1976), and Facciola (1990)
<i>Lilium auratum</i> var. <i>platyphyllum</i> Baker	Liliaceae	Saku-Yuri (Japanese)	As above	Tanaka (1976)
<i>Lilium brownii</i> F.E. Br. ex Mieliez	Liliaceae	White Lily, Hong Kong Lily, Paak-Hop (Chinese)	Bulbs are used fresh or dried; starch is obtained from the bulbs. Bulbs are also eaten baked or grated and added to thicken soup. In China, bulbs are eaten boiled in honey or dried and made into flour	Uphof (1968), Phillips and Rix (1993), Facciola (1990), and Hu (2005)
<i>Lilium davidii</i> Duch. ex Elwes	Liliaceae	David's Lily	Bulbs are eaten	Phillips and Rix (1993)
<i>Lilium japonicum</i> Thunb.	Liliaceae	Bamboo Lily	China: bulb is eaten	Read (1946)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Lilium lancifolium</i> Thunb.	Liliaceae	Tiger Lily, Pai Ho (Chinese), Oniyuri (Japanese)	Fleshy scales of bulb are eaten fresh or dried	Facciola (1990), Hu (2005), and Phillips and Rix (1993)
<i>Lilium longiflorum</i> Thunb.	Liliaceae	White Trumpet Lily, Regal Lily, Teppo Yuri (Japanese)	Starch is obtained from the bulb	Tanaka (1976) and Facciola (1990)
<i>Lilium superbum</i> L.	Liliaceae	American Turk's-Cap Lily	Fleshy bulb is eaten cooked, also used for thickening soup	Hedrick (1972) and Facciola (1990)
<i>Liriope spicata</i> Lour.	Asparagaceae	Black Leek	China: mucilaginous tuber is eaten	Read (1947)
<i>Litsea cubeba</i> (Lour.) Pers.	Lauraceae	Mountain Pepper, May Chang (Chinese)	Roots are cooked with pork	Altschul (1973), Morton (1976), and Facciola (1990)
<i>Lomatium californicum</i> (Nutt.) Mathias & Constance	Apiaceae	Wild Celery Parsley	Aromatic roots are eaten by American Indians	Facciola (1990)
<i>Lomatium dissectum</i> (Nutt.) Mathias & Constance	Apiaceae	Fern-Leaved Biscuit Root	Roots are dried and cooked	Yanovsky (1936) and Facciola (1990)
<i>Lomatium macrocarpum</i> (Hook. & Arn.) J.M. Coult. & Rose = <i>Lomatium hallii</i> (S. Watson) J.M. Coult. & Rose	Apiaceae	Large-Fruited Biscuit Root	Roots eaten raw or dried and ground into flour to make cakes	Yanovsky (1936) and Facciola (1990)
<i>Lomatium nudicaule</i> (Pursh) J.M. Coult. & Rose = <i>Cogswellia nudicaulis</i> M.E. Jones	Apiaceae	Cow Parsley, Smyrnium	Roots are sometimes cooked and eaten	Yanovsky (1936), Hedrick (1972), and Facciola (1990)
<i>Lotus siloquosus</i> L.	Fabaceae	NF	France: farinaceous root is recommended as a famine food	Parmentier (1781) (cited by Freedman 2009)
<i>Lunaria annua</i> L.	Brassicaceae	Honesty	Roots can be eaten raw in salads	Uphof (1968), Hedrick (1972), and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Lupinus arcticus</i> S. Watson	Fabaceae	Arctic Lupine	Roots are used as survival food after roasting	Schofield (2003)
<i>Lupinus nootkatensis</i> Sims	Fabaceae	Nootka Lupin	As above	Schofield (2003)
<i>Lycopus europaeus</i> L.	Lamiaceae	Gypsywort, Water Horehound	China: root is eaten. Manchuria: starchy tubers are eaten	Read (1946) and Baranov (1967)
<i>Lycopus lucidus</i> Turcz. ex Benth.	Lamiaceae	Lycopus, Bugleweed, Di Gua Er Miao (Chinese)	Underground rhizomes are eaten in northern China and Yunnan	Hu (2005)
<i>Lycopus uniflorus</i> Michx.	Lamiaceae	Northern Bugleweed	White tubers are eaten raw in salads, boiled, pickled or added to soups and stews	Fernald et al. (1958) and Facciola (1990)
<i>Lycoris aurea</i> (L'Hér.) Herb.	Amaryllidaceae	Lycoris	Roots are eaten in China	Read (1946)
<i>Lycoris radiata</i> (L'Hér.) Herb.	Amaryllidaceae	Red Spider Lily, Red Magic Lily	As above	Read (1946)
<i>Lygodium microphyllum</i> (Cav.) R. Br.	Lygodiaceae	Climbing Maidenhair	Slender fleshy underground stem is eaten	Cribb and Cribb (1987)
<i>Lyperanthus</i> sp.	Orchidaceae	Brown Beaks	Tubers are eaten by aborigines	Cribb and Cribb (1987)
<i>Lyperanthus suaveolens</i> R. Br.	Orchidaceae	Brown Beaks	Tubers are juicy fragrant	Low (1991)
<i>Macrotyloma uniflorum</i> (Lam.) Verd.	Fabaceae	Madras Gram, Horse Gram	Fleshy root is roasted and eaten by aborigines in Australia	Cribb and Cribb (1987) and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Manihot esculenta</i> Crantz	Euphorbiaceae	Cassava, Manioc, Tapioca, Yuca	Tuberous roots are eaten boiled, fried, baked, roasted and processed into flour, farina, sweetmeats, bread, syrup, pasties, fufu, chips, pastries and cakes. Flour is also used for thickening soups and sauces. Root sap is boiled to make the condiment cassareep or fermented into chicha and other alcoholic beverages	Burkill (1966), Uphof (1968), Hedrick (1972), Tanaka (1976), Ochse and van den Brink (1980), Facciola (1990), Veltkamp and De Bruijn (1996), and Hu (2005)
<i>Manihot glaziovii</i> Müll. Arg. = <i>Manihot carthaginensis</i> subsp. <i>glaziovii</i> (Müll. Arg.) Allem	Euphorbiaceae	Manicoba, Mandioca Brava, Ceara Rubber	Tubers are eaten sometimes, also a source of starch	Tanaka (1976) and Facciola (1990)
<i>Manihot utilissima</i> Pohl = <i>Manihot esculenta</i> Crantz	Euphorbiaceae	Cassava, Bitter Cassava; Ingwese, Aloti (Gabon); Bafra (Arabic, Sudan)	As for <i>M. esculenta</i>	Ochse and van den Brink (1980), Abdelmuti (1991), Burkill (1966), and Codex (2014)
<i>Maranta arundinacea</i> L.	Marantaceae	Arrowroot, Tora Alu (Assamese), Khaita Alu (Boro) Nginti Ali (Mishing) Arrowroot, Tha Lairusa, Hnathel, Hpogimbai	Rhizomes are source of arrowroot, eaten cooked or raw. Tuber is eaten both raw and boiled; starch is from rhizome	Ochse and van den Brink (1980), Facciola (1990), Villamayor and Jukema (1996), Hu (2005), Patiri and Borah (2007), Medhi and Borthakur (2012), and Codex (2014)
<i>Maranta dichotoma</i> (Roxb.) Wall. = <i>Schumannianthus dichotomus</i> (Roxb.) Gagnep.	Marantaceae	Mohtra Reed, Sitalpati Plant; Tha Lairu, Hnathel, Hpogimbai (Assamese)	Tuber is eaten both raw and boiled	Medhi and Borthakur (2012)
<i>Marattia salicina</i> Sm. = <i>Ptisana salicina</i> (Sm.) Murdock	Marattiaceae	Giant Fern, King Fern	Roots are edible	Cribb and Cribb (1987)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Mariscus sieberianus</i> Nees ex C.B. Clarke = <i>Cyperus cyperoides</i> (L.) Kuntze	Cyperaceae	Tall Sedge	In China, roots and seeds are made into flour	Read (1946)
<i>Marsdenia flavescens</i> A. Cunn. = <i>Pergularia flavescens</i> (A. Cunn.) Hook.f. ex D. Dietr.	Apocyanaceae	Yellow Milk Vine, Native Potato	Tuberous root is eaten after preparation	Cribb and Cribb (1987) and Harden (1992)
<i>Marsdenia viridiflora</i> R. Br. = <i>Pergularia viridiflora</i> (R. Br.) Spreng.	Apocyanaceae	Bush Banana	Juicy insipid tubers are eaten	Low (1991) and Harden (1992)
<i>Matteuccia pennsylvanica</i> (Willd.) Raymond = <i>Matteuccia struthiopteris</i> (L.) Tod.	Onocleaceae	Ostrich Fern	Rootstock is eaten boiled or roasted	Gibbons and Tucker (1979), Fernald et al. (1958), and Facciola (1990)
<i>Matteuccia struthiopteris</i> (L.) Tod.	Onocleaceae	Ostrich Fern, Jia Guo Jue (Chinese)	As above. In China, rhizome starch is used for noodle making	Cui (1998), Dai et al. (2003), Schofield (2003), and Cao et al. (2007)
<i>Medeola virginiana</i> L.	Liliaceae	Indian Cucumber Roots	Crisp, white rhizome is eaten raw as nibble, boiled and served with butter and mixed into tossed salads dressed with oil and vinegar or made into dill pickles	Gibbons and Tucker (1979), Fernald et al. (1958), and Facciola (1990)
<i>Melampyrum roseum</i> Maxim.	Orobanchaceae	Asian Cow Wheat, Shan Luo Huo (Chinese)	Roots are used for tea in northwestern China	Hu (2005)
<i>Melilotus albus</i> Medik.	Fabaceae	Sweet Clover	Roots are prized as food by some native groups in North America	Schofield (2003)
<i>Melilotus officinalis</i> (L.) Pall.	Fabaceae	Yellow Sweet Clover	As above	Facciola (1990) and Schofield (2003)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Menyanthes palustris</i> S.F. Gray	Menyanthaceae	Bog Grass	France: root is recommended as a famine food after cooking and seasoning	Parmentier (1781) (cited by Freedman 2009)
<i>Menyanthes trifoliata</i> L.	Menyanthaceae	Buckbean, Marsh Clover, Marsh Trefoil, Bitter Worm, Water Shamrock	Great Britain, Norway: roots are leached to remove bitter element and then ground to a flour. Bitter rhizome is cooked as emergency food	Sayce. (1953), Facciola (1990), and Schofield (2003)
<i>Merremia hungaiensis</i> (Lingelsh. & Borza) R.C. Fang	Convolvulaceae	Huang Hua Tu Gua, Shan Tu Gua (Chinese)	Enlarged root is eaten in Yunnan	Hu (2005)
<i>Mertensia maritima</i> (L.) Gray	Boraginaceae	Sea Bugloss, Oyster Plant	Rhizomes are eaten by Eskimos in Alaska	Uphof (1968) and Facciola (1990)
<i>Meum athamanticum</i> Jacq.	Apiaceae	Spignel, Meu, Baldmoney	Roots are eaten like parsnip in Scotland	Uphof (1968), Grieve (1971), Launert (1981), and Facciola (1990)
<i>Microseris lanceolata</i> (Walp.) Sch. Bip.	Asteraceae	Yam Daisy, Murnong, Native Yam	Tubers are eaten after roasting	Cribb and Cribb (1987)
<i>Microseris scapigera</i> (Sol. ex A. Cunn.) Sch. Bip.	Asteraceae	Yam Daisy, Murnong, Native Dandelion	Tubers are eaten after roasting	Cribb and Cribb (1987), Low (1989), and Codex (2014)
<i>Microstemma tuberosum</i> R. Br.	Apocyanaceae	White Turnip	Tubers are eaten raw or roasted	Cribb and Cribb (1987)
<i>Microtis parviflora</i> R. Br. = <i>Microtis unifolia</i> (G. Forst.) Rchb.f.	Orchidaceae	Slender Onion Orchid	As above	Harden (1993)
<i>Microtis</i> sp.	Orchidaceae	Onion Orchid	Tubers are bland starchy eaten by aborigines	Cribb and Cribb (1987) and Low (1991)
<i>Microtis unifolia</i> (G. Forst.) Rchb.f.	Orchidaceae	Common Onion Orchid	As above	Harden (1993)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Millettia speciosa</i> Champ. ex Benth.	Fabaceae	Showy Millettia, Shan Lian Ou (Chinese)	Root fresh or dried is boiled with pork for soup that strengthens bones used in southern China and Hong Kong	Hu (2005)
<i>Mirabilis expansa</i> (Ruiz & Pav.) Standl.	Nyctaginaceae	Mauka, Chago	Tuber is dried, boiled or fried, eaten as vegetable	Tanaka (1976), Popenoe et al. (1989), Facciola (1990), Bermejo and Leon (1994), and Codex (2014)
<i>Moghania philippinensis</i> (Merr. & Rolfe) Li = <i>Flemingia prostrata</i> Roxb.	Fabaceae	Southern Astragalus, Qian Jin Ba (Chinese)	Sliced roots are cooked with pig's feet in water and cooking wine, a special southern Chinese cuisine	Hu (2005)
<i>Monochoria vaginalis</i> (Burm.f.) C. Presl	Pontederiaceae	Duck Tongue Herb, Ya She Cao (Chinese)	China: young rhizome is eaten	Hu (2005)
<i>Montia perfoliata</i> (Donn ex Willd.) Howell = <i>Claytonia perfoliata</i> Donn ex Willd.	Montiaceae	Miner' Lettuce, Winter Purslane, Cuban Spinach	Roots are edible raw or boiled	Harrington (1974), Larkcom (1984), and Facciola (1990)
<i>Moraea fugax</i> (D. Delaroché) Jacq.	Iridaceae	Uintjie	Bulbous root is eaten roasted, boiled or stewed with milk in southern Africa	Hedrick (1972), Fox et al. (1982), and Facciola (1990)
<i>Moringa oleifera</i> Lam.	Moringaceae	Horse Radish Tree, Drumstick, Zogale (Huasa), La Mu (Chinese)	Root is used as condiment in China. In Nigeria (Kano State, northern), leaves, roots, young pods and seed oil are eaten	Mortimore (1989) and Hu (2005)
<i>Moringa pterygosperma</i> Gaertn. = <i>Moringa oleifera</i> Lam.	Moringaceae	Horse Radish Tree, Drumstick, Shekta (Bombay Presidency, Surat district)	India (Bombay Presidency): roots, leaves, flowers and fruits are eaten cooked in water and mixed with salt and chilli peppers	Gammie (1902)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Mucuna glabra</i> (Reinecke) Wilmot-Dear	Fabaceae	Tupe	Brazil (northeast): flour is made from both the seeds and roots. The flour or starch thus obtained is made into a variety of Brazilian foods including <i>farofa</i> , in which the meal is sautéed and mixed with bits of meat, crisp fat, chopped egg, etc.; <i>boijus</i> , which are small, sweet cakes; and <i>angus</i> , which are dumplings, the flour being merely boiled in water	De Castro (1952)
<i>Murdannia graminea</i> (R. Br.) G. Bruckn.	Commelinaceae	Pink Swamp Lily	Bland, fibrous tubers are eaten raw	Cribb and Cribb (1987), Low (1989, 1991), and Harden (1993)
<i>Musa ornata</i> Roxb.	Musaceae	Flowering Banana, Ornamental Banana, Bronze Banana	In India (Deccan), root is eaten	Watt (1908)
<i>Musa paradisiaca</i> L.	Musaceae	It' Ath (Teenek, Yucatan)	In Yucatan, corm is eaten as a famine food by the Huastec Maya	Alcorn (1984)
<i>Musa rosacea</i> Jacq. = <i>Musa balbisiana</i> var. <i>balbisiana</i>	Musaceae	Mauritius Plantain Tree	In India, rhizomes and shoots are eaten	Gammie (1902)
<i>Musa superba</i> Roxb. = <i>Ensete superbum</i> (Roxb.) Cheesman	Musaceae	Dwarf Banana, Red Dwarf Banana; Kardai, Kawdar, Rankele (Bombay Presidency)	Roots of wild plantains are dried and pounded, and the flour is used for making bread	Gammie (1902) and Watt (1908)
<i>Muscari neglectum</i> Guss. ex Ten.	Asparagaceae	Musk Hyacinth, Nutmeg Hyacinth	Bulbs are edible	Hedrick (1972) and Facciola (1990)
<i>Myrrhis odorata</i> Scop.	Arecaceae	Sweet Cicely	Roots are boiled, served with oil and vinegar or candied	Grieve (1971), Hedrick (1972), Morton (1976), Launert (1981), and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Narcissus x albus</i> Mill. = <i>Narcissus x medioluteus</i> Mill.	Amaryllidaceae	Double Daffodil	France: root is recommended as a famine food, boiled, dried or reduced to a flour and cooked as a porridge	Parmentier (1781) (cited by Freedman 2009)
<i>Nelumbium speciosum</i> Willd.	Nelumbonaceae	Pink Water Lily	India: root and seeds are eaten	Gammie (1902) and Watt (1908)
<i>Nelumbo lutea</i> Pers.	Nelumbonaceae	American Lotus, Water Chinquapin	Large tubers, when baked, are sweet and mealy with a flavour somewhat like a sweet potato	Facciola (1990) and Saunders (1920)
<i>Nelumbo nucifera</i> Gaertn.	Nelumbonaceae	Lotus, Lotus Root	Root is eaten raw or cooked; sliced used in stir-fries, soups and stews; or fried as a garnish or side dish. Sliced pieces can be candied or pickled. Lotus root flour is starch and can be used to make desserts	Burkill (1966), Cribb and Cribb (1987), Facciola (1990), Phillips and Rix (1993), Ong (1996), Hu (2005), Santich et al. (2008), van Wyk (2006), and Codex (2014)
<i>Neowerdermannia vorwerkii</i> Frič	Cactaceae	Achacana	Large root is used as food in Bolivia	Gupta and Kanodia (1968b)
<i>Nephrolepis auriculata</i> (L.) Trimen.	Davalliaceae	Tuber Ladder Fern, Tuberous Sword Fern, Sword	Sweet tuber is eaten as snack	Dai et al. (2003), Cao et al. (2007), and Yun et al. (2009b)
<i>Nephrolepis cordifolia</i> (L.) C. Presl	Davalliaceae	Tuber Ladder Fern, Erect Sword Fern, Qiu Jue (Chinese)	China: tuber is used fresh or dried for preparing a broth with chicken or pork	Hu (2005)
<i>Nervilia fordii</i> (Hance) Schltr.	Orchidaceae	Taro Orchid, Qing Tian Kui (Chinese)	Whole plant plus rhizome are used for tea or cooked with pork in broth	Hu (2005)
<i>Nothoscordum andicola</i> Kunth	Amaryllidaceae	False Garlic, Chullkus (Quechua)	Peru (Vilcanota Valley, hills of Canchis): bulbs are boiled, reported to have a 'garlicky' taste and liked for its flavour	Gade (1975)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Nuphar advena</i> R. Br.	Nymphaeaceae	Common Spatterdock	Rootstock is eaten raw, roasted or cooked with meat	Uphof (1968), Hedrick (1972), and Facciola (1990)
<i>Nuphar luteum</i> Sibth. & Sm.	Nymphaeaceae	Yellow Water Lily	Rootstock is boiled as vegetable	Hedrick (1972), Fernald et al. (1958), and Facciola (1990)
<i>Nuphar polysepala</i> Engelm. = <i>Nuphar lutea</i> subsp. <i>polysepala</i> (Engelm.) E.O. Beal.	Nymphaeaceae	Cow Lily, Spatterdock, Pond Collard	Rich starchy rhizome is used as survival food, after boiling, roasting or baked and skin is removed	Schofield (2003)
<i>Nuphar pumilum</i> (Timm.) DC.	Nymphaeaceae	Yellow Pond Lily, Ping Peng Cao (Chinese)	Young tender rhizomes are used as potherb in Yunnan and Hubei	Hu (2005)
<i>Nuytsia floribunda</i> R. Br.	Loranthaceae	Christmas Tree	Roots are eaten by aborigines, roasted and made into cakes	Low (1989)
<i>Nymphaea lotus</i> L.	Nymphaeaceae	Egyptian Lotus, White Lotus	Tubers are edible	Tanaka (1976), Kunkel (1984), and Facciola (1990)
<i>Nymphaea stellata</i> Willd. = <i>Nymphaea nouchali</i> Burm.f.	Nymphaeaceae	Blue Lotus of India	Rhizomes are eaten raw or roasted	Uphof (1968), Hedrick (1972), Tanaka (1976), and Facciola (1990)
<i>Nymphaea alba</i> L.	Nymphaeaceae	White Lotus, European White Waterlily	In France, root is recommended as a famine food after cooking in water and being flavoured	Parmentier (1781) (cited by Freedman 2009)
<i>Nymphaea caerulea</i> Savigny = <i>Nymphaea nouchali</i> var. <i>caerulea</i> (Savigny) Verdc.	Nymphaeaceae	Blue Lotus of Egypt, Blue Water Lily	Starchy tubers are eaten boiled or roasted	Tanaka (1976), Fox et al. (1982), and Facciola (1990)
<i>Nymphaea edulis</i> DC.	Nymphaeaceae	Red Water Lily; Shunguneer Pushpum (Tamil); Koteka, Kalharamu (Telugu)	In India (Madras Presidency), roots and seeds are cooked and eaten	Shortt (1887–1888)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Nymphaea gigantea</i> Hook.	Nymphaeaceae	Giant Water Lily	Tuberous rootstock is eaten	Cribb and Cribb (1987)
<i>Nymphaea lotus</i> var. <i>pubescens</i> (Willd) Hook.f. & Thomson = <i>Nymphaea pubescens</i> Willd.	Nymphaeaceae	Red Water Lily	Root is eaten baked or boiled with salt added	Paton and Dunlop (1904)
<i>Nymphaea lotus</i> L.	Nymphaeaceae	Egyptian Lotus, White Lotus, Bado (Hausa), Dambi (Kanuri)	In upper Guinea, Africa, root is used as a famine food, being either roasted in ashes or dried before being ground into flour. In Nigeria (Kano State, northern): rhizome and seeds are eaten. In India (Bombay Presidency), roots and seeds are eaten	Gammie (1902), Watt (1908), Irvine (1952), Uphof (1968), Hedrick (1972), Tanaka (1976), Pongpangan and Poobrasert (1985), Mortimore (1989), and Facciola (1990)
<i>Nymphaea nouchali</i> Burm.f.	Nymphaeaceae	Boga Bhet, Seluk (Assamese)	Rhizomes/roots are eaten raw or cooked as vegetable in Assam	Van den Bergh (1994) and Patiri and Borah (2007)
<i>Nymphaea odorata</i> Aiton	Nymphaeaceae	Fragrant Water Lily	Tubers are edible	Tanaka (1976), Kunkel (1984), and Facciola (1990)
<i>Nymphaea rubra</i> Roxb. ex Andrews	Nymphaeaceae	Ronga Bhet, Mokua, Seluk (Assamese)	As above	Patiri and Borah (2007)
<i>Nymphaea</i> spp.	Nymphaeaceae	Waterlilies	Fibrous tubers are edible	Cribb and Cribb (1987) and Low (1989)
<i>Nymphaea stellata</i> Willd. = <i>Nymphaea nouchali</i> Burm.f.	Nymphaeaceae	Izibo (Zulu)	In Zululand (Ubombo district), tuber is boiled and eaten. In India, roots and seeds are eaten	Hely-Hutchinson (1898), Gammie (1902), Watt (1908), and Uphof (1968)
<i>Nymphaea tetragona</i> Georgi	Nymphaeaceae	Four-Angled Water Lily, Shui Lian (Chinese)	Rhizomes are used as food in northwestern China	Hu (2005)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Nymphaea tuberosa</i> Paine = <i>Nymphaea odorata</i> subsp. <i>tuberosa</i> (Paine) Wiersema & Hellq.	Nymphaeaceae	Tuberous Water Lily, White Water Lily	Tubers are occasionally eaten	Gibbons and Tucker (1979), Fernald et al. (1958), and Facciola (1990)
<i>Nymphoides crenata</i> (F. Muell.) Kuntze	Menyanthaceae	Wavy Marshwort	Tubers are eaten	Cribb and Cribb (1987) and Harden (1992)
<i>Nymphoides geminata</i> (R. Br.) Kuntze	Menyanthaceae	Entire Marshwort	Tubers are eaten by aborigines	Cribb and Cribb (1987) and Harden (1992)
<i>Oenanthe pimpinelloides</i> L.	Apiaceae	Meadow Parsley	Roots are prized as food in certain areas in Europe	Grieve (1971), Hedrick (1972), and Facciola (1990)
<i>Oenanthe apiifolia</i> Brot.	Apiaceae	Water Dropwort	In France, starch of root is recommended for extending bread flour, after removal of toxic element	Parmentier (1781) (cited by Freedman 2009)
<i>Oenanthe javanica</i> (Blume) DC.	Apiaceae	Water Dropwort, Seri	Roots are esteemed for cooking	Tanaka (1976) and Facciola (1990)
<i>Oenanthe sarmentosa</i> C. Presl. ex DC.	Apiaceae	Pacific Dropwort, Water Parsley	Black tubers are esteemed by native Indians, when boiled has a parsley flavour	Yanovsky (1936), Hedrick (1972), and Facciola (1990)
<i>Oenothera biennis</i> L.	Onagraceae	Evening Primrose, German Rampion	Roots are boiled, fried, scalloped, au gratin, or added to stews and soups	Gibbons and Tucker (1979), Fernald et al. (1958), and Facciola (1990)
<i>Oenothera erythrosepala</i> Borbás = <i>Oenothera glazioviana</i> Micheli	Onagraceae	Large Evening Primrose	Edible roots	Cribb and Cribb (1987)
<i>Oenothera hookeri</i> Torr. & A. Gray = <i>Oenothera elata</i> Kunth	Onagraceae	Hooker's Evening Primrose	Roots are cooked like parsnip	Harrington (1974) and Facciola (1990)
<i>Onoclea sensibilis</i> L.	Woodsiaceae	Sensitive Fern	Rootstock is used as food	Yanovsky (1936) and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Ondinea purpurea</i> Hartog	Nymphaeaceae	NF	Corms are eaten by Australian aborigines	Les (2003)
<i>Ophiopogon japonicus</i> (Thunb.) Ker Gawl.	Asparagaceae	Mondo Grass	In China, tubers are eaten	Read (1946)
<i>Orchis mascula</i> (L.) L.	Orchidaceae	Male Orchis, Early Purple Orchid	Dried root is cooked and eaten, also a source of salep, bassorine or sahlab, a fine, yellowish-white powder used as food	Watt (1908), Uphof (1968), Hedrick (1972), and Facciola (1990)
<i>Orchis militaria</i> L.	Orchidaceae	Military Orchid	In France, bulbs are recommended as a source of edible starch (salep), after processing and drying	Parmentier (1781) (cited by Freedman 2009) Facciola (1990)
<i>Orchis morio</i> L. = <i>Anacamptis morio</i> (L.) R.M. Bateman, Pridgeon & M.W. Chase	Orchidaceae	Green-Winged Orchid, Gandergoose	As for <i>O. mascula</i>	Grieve (1971), Hedrick (1972), and Facciola (1990)
<i>Orchis palmata</i> Gilib. = <i>Dactylorhiza incarnata</i> subsp. <i>incarnata</i>	Orchidaceae	Palm Orchid	In France, bulbs are recommended as a source of edible starch (salep), after processing and drying	Parmentier (1781) (cited by Freedman 2009)
<i>Orchis pyramidalis</i> L. = <i>Anacamptis pyramidalis</i> (L.) Rich.	Orchidaceae	Pyramidal Orchid	As above	Parmentier (1781) (cited by Freedman 2009)
<i>Ornithogalum gramineum</i> Sims = <i>Nothoscordum bivalve</i> var. <i>bivalve</i>	Asparagaceae	False Garlic, Crowpoison	In France, root is recommended as a famine food, boiled in water, roasted or sliced and fried	Parmentier (1781) (cited by Freedman 2009)
<i>Ornithogalum luteum</i> L. = <i>Gagea lutea</i> (L.) Ker Gawl.	Asparagaceae	Yellow Star-of-Bethlehem	As above	Parmentier (1781) (cited by Freedman 2009)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Ornithogalum umbellatum</i> L.	Asparagaceae	Star-of-Bethlehem, Dove's Dung, Pigeon's Dung, Bird's Milk	Middle East: when in famine, food bulbs were ground up after numerous boilings, to eliminate the poisonous principles and then mixed with cereal flour to make bread	Calcott (1842), Moldenke (1954), and Facciola (1990)
<i>Orobancha cernua</i> Loebl.	Orobanchaceae	Tarthuth	Roots are roasted and eaten	Facciola (1990)
<i>Orobis tuberosus</i> L. = <i>Lathyrus linifolius</i> (Reichard) Bassler	Fabaceae	Tuberous Bitter Vetch	In France, boiled root is eaten as a famine food	Parmentier (1781) (cited by Freedman 2009)
<i>Orontium aquaticum</i> L.	Araceae	Golden Club	Bulbous rootstock is eaten cooked	Saunders (1920)
<i>Orthoceras strictum</i> R. Br.	Orchidaceae	Horned Orchid, Bird's-Mouth Orchid	Tubers are fragrant, starchy and edible	Low (1989) and Harden (1993)
<i>Osmorhiza aristata</i> (Thunb.) Rydb.	Apiaceae	Longstyle Sweetroot, Smooth Sweet Cicely, Yabu Ninjin	In China, roots are peeled, washed and eaten raw	Read (1946), Tanaka (1976), and Facciola (1990)
<i>Osmorhiza claytonia</i> (Michx.) C.B. Clarke = <i>Osmorhiza aristata</i> var. <i>aristata</i>	Apiaceae	Anise, Sweet Cicely	Roots are used for its anise-like flavouring	Yanovsky (1936), Facciola (1990), and Seidemann (2005)
<i>Osmorhiza japonica</i> Sieb. & Zucc.	Apiaceae	Japanese Sweet Cicely	In China, roots are peeled, washed, and eaten raw	Read (1946)
<i>Osmorhiza longistylis</i> (Torr.) DC.	Apiaceae	Aniseroot, Smooth Sweet Cicely, Sweet Myrrh	Tea has anise-like flavour, chewed, used in tea or for flavouring	Tanaka (1976) and Facciola (1990)
<i>Osmorhiza occidentalis</i> (Nutt.) Torr.	Apiaceae	Western Sweetroot, Western Sweet Cicely	Tea has anise-like flavour used for flavouring cookies and other foods	Harrington (1974) and Facciola (1990)
<i>Osmunda japonica</i> Thunb.	Osmundaceae	Japanese Cinnamon Fern, Zenmai (Japanese)	Rhizome starch is used for noodles and liquor	Flores et al. (2003), Freedman (2009), Fox et al. (1982), and Gade (1975)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Oxalis corymbosa</i> DC. = <i>Oxalis debilis</i> var. <i>corymbosa</i> (DC.) Lourteig	Oxalidaceae	Pink Shamrock	Sweet crisp swollen taproot is eaten	Cribb and Cribb (1987)
<i>Oxalis deppei</i> Lodd. ex Sweet	Oxalidaceae	Orach, Deppei Wood Sorrel	Fleshy root is eaten boiled in Mexico	Fernald et al. (1958) and Facciola (1990)
<i>Oxalis perennans</i> Haw.	Oxalidaceae	Grassland Wood Sorrel	Small taproots are eaten by aborigines	Low (1991)
<i>Oxalis radicata</i> A. Rich. = <i>Oxalis corniculata</i> L.	Oxalidaceae	Dwarf Wood Sorrel	Small taproots eaten by aborigines	Low (1991)
<i>Oxalis</i> sp.	Oxalidaceae	Wood Sorrel	Small taproots are eaten by aborigines	Low (1991)
<i>Oxalis stricta</i> L.	Oxalidaceae	Yellow Wood Sorrel	Roots are edible	Yanovsky (1936), Uphof (1968), and Facciola (1990)
<i>Oxalis tuberosa</i> Molina	Oxalidaceae	Oca	Tubers are eaten boiled, roasted or candied, one of the principal food crops of the Indians in the Andes, second to potato; tubers can be eaten unpeeled, raw, in salads, pickled, boiled, fried or in soups and stews, also can be dried in the sun to sweeten up	Facciola (1990), Groen et al. (1996), Flores et al. (2003), van Wyk (2006), and Santich et al. (2008)
<i>Oxalis violacea</i> L. = <i>Oxalis debilis</i> var. <i>corymbosa</i> (DC.) Lourteig	Oxalidaceae	Violet Wood Sorrel	Roots are edible	Yanovsky (1936) and Facciola (1990)
<i>Pachyrhizus ahipa</i> (Wedd.) Parodi	Fabaceae	Ahipa, Yam Bean	The roots are sweet and crispy; when eaten raw it can be peeled like banana or eaten as snacks or in green and fruit salads or prepared as juice	Popenoe et al. (1989), Sørensen et al. (1997), Hermann and Heller (1997), and Codex (2014)
<i>Pachyrhizus angulatus</i> Rich. ex DC. = <i>Pachyrhizus erosus</i> (L.) Urb.	Fabaceae	As below	In India, root is eaten	Watt (1908)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Pachyrhizus erosus</i> (L.) Urban	Fabaceae	Yam Bean, Jicama, Sengkuang, Bangkwaun	Sweetish, subglobose tuberous root is eaten fresh raw as a snack or cooked, stir-fried, stewed and in other dishes	Burkill (1966), Facciola (1990), Sørensen (1996), Sørensen and van Hoof (1966), Santich et al. (2008), van Wyk (2006), and Codex (2014)
<i>Pachyrhizus tuberosus</i> (Lam.) Spreng.	Fabaceae	Amazonian Yam Bean, Jicama, Jactupe	As above	Hedrick (1972) and Sørensen (1996)
<i>Paederia foetida</i> L.	Rubiaceae	Rekang Nemthu	Roots are eaten in Karbi, Assam	Kar and Borthakur (2008)
<i>Paederia stenobotrya</i> Merr.	Rubiaceae	White Paederia	Root is ground with soaked soybean for milk, cooked and given to people with jaundice	Hu (2005)
<i>Paeonia foemina</i> Mill. = <i>Paeonia officinalis</i> L.	Paeoniaceae	Peony	In France, starch of root is used as a famine food for extending bread flour, after removing bitter element	Parmentier (1781) (cited by Freedman 2009)
<i>Paeonia lactiflora</i> Pallas	Paeoniaceae	Peony	Root with bark is removed, dried and used to prepare health food	Facciola (1990), Hu (2005), and Lim (2014)
<i>Panax bipinnatifidus</i> Seem.	Araliaceae	Pearl Gisang, Ge Da Qi (Chinese)	As below	Codex (2014)
<i>Panax ginseng</i> C.A. Meyer	Araliaceae	Ginseng, Chinese Ginseng, Korean Ginseng, Asian Ginseng; Ren Shen, Jen Shen (Chinese)	Roots are eaten fresh in same amount like carrot or used in soups, chicken broth, noodles and other meat dishes and health foods by the Chinese in Asia and Koreans	Hu (2005), van Wyk (2006), and Codex (2014)
<i>Panax japonicus</i> (T. Nees) C.A. Mey.	Araliaceae	Japanese Ginseng	As above	Codex (2014)
<i>Panax quinquefolius</i> L.	Araliaceae	American Ginseng	As true ginseng substitute	Facciola (1990), Hu (2005), and Codex (2014)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Panax vietnamensis</i> Ha & Grusshv.	Araliaceae	Vietnamese Ginseng	As above	Codex (2014)
<i>Panax wangianus</i> S.C. Sun	Araliaceae	Sanchi Ginseng; Sanchi, San Qi (Chinese)	As for ginseng and in a special chicken sanchi dish	Hu (2005)
<i>Passiflora quadrangularis</i> L.	Passifloraceae	Giant Granadilla	Roots are baked, roasted and eaten like yams	Uphof (1968), Morton (1976), Facciola (1990), and Lim (2012c)
<i>Pastinaca sativa</i> L.	Apiaceae	Parsnip	Swollen root is eaten after cooking, lends itself to slow cooking such as simmering, slow roasting and braising, goes well in soups and stewed and stock, pairs well with salty foods like cod and bacon. The high sugar content was exploited to produce jams, sweet flour for cakes and even parsnip wine; candied parsnip is a popular snack in North America	Burkill (1966), Facciola (1990), Hu (2005), Santich et al. (2008), van Wyk (2006), Phillips and Rix (1993), and Codex (2014)
<i>Pastinaca sylvestris</i> Mill. = <i>Pastinaca sativa</i> L.	Apiaceae	Parsnip	In France, root is eaten as a famine food. The cooked root can be eaten with butter and salt	Parmentier (1781) (cited by Freedman 2009)
<i>Pedicularis carnos</i> a Wall.	Orobanchaceae	Entire Leaf Lousewort, Sam Thapar	Roots are eaten in Meghalaya	Sawian et al. (2007)
<i>Pedicularis kanei</i> Dur. = <i>Pedicularis lanata</i> Cham. & Schlecht.	Orobanchaceae	Arctic Lousewort, Fernweed, Bumblebee Plant	Roots are nibbled raw or served boiled, baked or stir-fried, use in soups and stew or candy roots like yam or steam like carrots	Schofield (2003)
<i>Pediomelum cuspidatum</i> (Pursh) Rydb. = <i>Psoralea cuspidata</i> Pursh	Fabaceae	Indian Turnip, Largebract Indian Breadroot	As for <i>P. esculenta</i>	Yanovsky (1936) and Harrington (1974)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Pedimelum esculentum</i> (Pursh) Rydb. = <i>Psoralea esculenta</i> Pursh	Fabaceae	Prairie Turnip, Indian Breadroot, Tipsin, Scurfpea, Timpsula	Tuber is edible, eaten raw or in stews, ground to flour for soups and bread	Yanovsky (1936) and Kaldy et al. (1980)
<i>Pedimelum hypogaeum</i> var. <i>hypogaeum</i> (Nutt.) Rydb. = <i>Psoralea hypogaea</i> Torr. & A. Gray	Fabaceae	Little Indian Breadroot, Subterranean Indian Breadroot	As above	Yanovsky (1936) and Harrington (1974)
<i>Pedimelum tenuiflorum</i> (Pursh) A.N. Egan	Fabaceae	Slimflower Scurfpea	As above	Yanovsky (1936)
<i>Pedimelum subacaule</i> (Torr. & A. Gray) Rydb.	Fabaceae	Whiterim Scurfpea	As above	Yanovsky (1936)
<i>Pelargonium australe</i> J. Jacq.	Geraniaceae	Native Storksbill, Wild Geranium	Taproot is eaten	Low (1991)
<i>Peltandra alba</i> Raf. = <i>Peltandra sagittifolia</i> (Michx.) Morong	Araceae	White Arrow Arum	Fleshy rootstock dried and thoroughly cooked can be eaten	Saunders (1920)
<i>Peltandra virginica</i> (L.) Schott	Araceae	Arrow Arum, Virginia Tuckahoe	As above	Saunders (1920)
<i>Peniocereus greggii</i> (Engelm.) Britton & Rose	Cactaceae	Deerhorn Cactus	Tubers are parboiled, dipped in batter and made into fritters	Hedrick (1972), Kunkel (1984), and Facciola (1990)
<i>Perideridia gairdneri</i> (Hook. & Arn.) Mathias	Apiaceae	Common Yampah, Gardner's Yampah	Roots are edible	Kaldy et al. (1980)
<i>Perideridia</i> sp.	Apiaceae	Yampa, Squawroot, False Caraway	Fleshy root is eaten raw, boiled, baked or preserved for later used	Yanovsky (1936), Hedrick (1972), Harrington (1974), and Facciola (1990)
<i>Petalostemon candidum</i> (Willd.) Michx. = <i>Dalea candida</i> Willd.	Fabaceae	White Prairie Clover	Roots are eaten or chewed for the sweet flavour	Yanovsky (1936), Uphof (1968), and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Petasites frigidus</i> (L.) Fr.	Asteraceae	Sweet Coltsfoot	Roasted roots are eaten	Uphof (1968), Kunkel (1984), Facciola (1990), and Schofield (2003)
<i>Petroselinum crispum</i> (Mill.) Nyman ex A.W. Hill. Radicosum Group	Apiaceae	Turnip-Rooted Parsley, Hamburg Parsley	Swollen taproot cultivars are eaten as aromatic vegetable, slow cooking methods, roasted or simmered as vegetables, added to stock, soups, stews and braised dishes	Facciola (1990), Phillips and Rix (1993), Ipor and Oyen (1999), Santich et al. (2008), and Codex (2014)
<i>Peucedanum ambiguum</i> (Nutt.) Nutt. ex Torr. & A. Gray = <i>Eulophus ambiguous</i> Nutt.	Apiaceae	Biscuit-Root	Tubers has a celery flavour and may be consumed raw	Saunders (1920)
<i>Peucedanum canbyi</i> J.M. Coult. & Rose = <i>Cogswellia canbyi</i> M.E. Jones	Apiaceae	Biscuit-Root, Chuklusa (Spokane Indians)	Tubers may be consumed raw or mixed with water, flattened into cakes and dried in the sun or baked	Saunders (1920)
<i>Peucedanum cous</i> S. Watson = <i>Cogswellia cous</i> M.E. Jones	Apiaceae	Cow-As (Indians)	Tubers have a celery flavour and may be consumed raw	Saunders (1920)
<i>Peucedanum eurycarpum</i> J.M. Coult. & Rose	Apiaceae	Biscuit-Root	As above	Saunders (1920)
<i>Peucedanum geyeri</i> S. Watson = <i>Cogswellia geyeri</i> M.E. Jones.	Apiaceae	Biscuit-Root	As above	Saunders (1920)
<i>Phaseolus adenanthus</i> G. Mey. = <i>Vigna adenantha</i> (G. Mey.) Marechal & al.	Fabaceae	Adzuki Bean, Moth Bean, Wild Pea Adzuki Bean, Moth Bean, Wild Pea	In India, root is eaten cooked	Watt (1908), Hedrick (1972), and Facciola (1990)
<i>Phaseolus coccineus</i> L.	Fabaceae	Runner Bean, Scarlet Runner Bean, Dutch Runner Bean	Starchy tuberous root is eaten	Popenoe et al. (1989) and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Phaseolus rostratus</i> Wall. = <i>Vigna adenantha</i> (G. Mey.) Marechal & al.	Fabaceae	Karalsona (Tamil); Karalasana, Karu Alachandra (Telugu)	In India (Madras Presidency), tuberous roots are eaten cooked	Shott (1887–1888) (cited by Freedman 2009)
<i>Phlomis tuberosa</i> L.	Lamiaceae	Tuberous Jerusalem Sage, Bodmon Sok	Roots are eaten by the Kalmucks in Eurasia	Hedrick (1972)
<i>Phragmites australis</i> (Cav.) Trin. ex Steud.	Poaceae	Common Reed Grass	Rhizomes are cooked like potatoes	Tanaka (1976), Fernald et al. (1958), and Facciola (1990)
<i>Phrynium capitatum</i> Willd. = <i>Phrynium pubinerve</i> Blume	Marantaceae	Packing Leaf	Root tuber is eaten in Meghalaya	Sawian et al. (2007)
<i>Phyteuma orbiculare</i> L.	Campanulaceae	Round-Headed Rampion	Fleshy roots are consumed in salads and cooked as vegetables in Europe	Uphof (1968) and Facciola (1990)
<i>Phyteuma spicatum</i> L.	Campanulaceae	Spiked Rampion	As above	Hedrick (1972) and Facciola (1990)
<i>Phytolacca acinosa</i> Roxb.	Phytolaccaceae	Poke Root, Indian Pokeberry	In China, root is eaten after boiling and a few changes with water	Darlington and Janaki Ammal (1945) and Read (1946)
<i>Phytolacca acinosa</i> var. <i>esculenta</i> Maxim.	Phytolaccaceae	Yama Gobo (Japanese)	Roots are edible	Tanaka (1976) and Facciola (1990)
<i>Picris echioides</i> L. = <i>Helminthotheca echioides</i> (L.) Holub	Asteraceae	Bristly Ox-Tongue	In France, root is eaten as a famine food	Parmentier (1781) (cited by Freedman 2009)
<i>Picris evae</i> Lack	Asteraceae	Native Hawkweed	Slender carrot root baked and eaten by aborigines	Cribb and Cribb (1987) and Harden (1992)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Piper methysticum</i> L.f.	Piperaceae	Kava, Kava-Kava, Awa, Kava Pepper	The root and rhizome (underground stem) of kava are used to prepare beverages, extracts, capsules, tablets and topical solutions. Kava is widely and commonly consumed as a social beverage to establish kinship in the Pacific island communities	McDonald and Jowitt (2000) and NCAM (2006)
<i>Plantago major</i> L.	Plantaginaceae	Common Plantain, Greater Plantain	Roots are edible	Fernald et al. (1958) and Facciola (1990)
<i>Platanthera delavayi</i> Schltr. = <i>Platanthera mandarinorum</i> Rchb.f.	Orchidaceae	Mandarin Platanthera, Ji Zhua Shen (Chinese)	Fleshy root is cooked	Hu (2005)
<i>Platycodon grandiflorus</i> (Jacq.) A. DC.	Campanulaceae	Chinese Balloon Flower, Jie Geng (Chinese), Doraji (Korean), Kikyo (Japanese)	Dried root is used for soup or tea	Hu (2005), Read (1946), and Codex (2014)
<i>Plectranthus barbatus</i> Andrews	Lamiaceae	Indian Coleus	Tubers are eaten	Jansen (1996b)
<i>Plectranthus edulis</i> Agnew	Lamiaceae	Gala Potato	Tubers are eaten	Jansen (1996b)
<i>Plectranthus esculentus</i> N.E. Br.	Lamiaceae	Livingstone Potato, Kaffir Potato	Stem tubers are eaten, eaten raw or boiled and eaten as vegetables	Jansen (1996b), Phillips and Rix (1993), van Wyk (2006), and Codex (2014)
<i>Plectranthus madagascariensis</i> (Pers.) Benth.	Lamiaceae	Madagascar Spur Flower	Tubers are eaten in Madagascar	Tanaka (1976) and Facciola (1990)
<i>Plectranthus rotundifolius</i> (Poir.) Spreng.	Lamiaceae	Chinese Potato, Coleus Potato, Hausa Potato	Young aromatic tubers are used in soup and vegetable dishes	Jansen (1996b) and Codex (2014)
<i>Podolepis jaceoides</i> (Sims) Voss	Asteraceae	Showy Podolepis	Thickened roots are eaten	Cribb and Cribb (1987)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Polygala japonica</i> Houtt. = <i>Polygala sibirica</i> L.	Polygalaceae	Chinese Senega Root, Yuan Zhi (Chinese)	Root is thoroughly washed and boiled several times before consumption	Read (1946)
<i>Polygala tenuifolia</i> Willd.	Polygalaceae	Chinese Senega	As above	Read (1946)
<i>Polygonatum biflorum</i> (Walter) Elliot	Asparagaceae	Small Solomon's Seal	Rootstock is soaked in lye, parboiled and eaten like potatoes or pickled	Hedrick (1972), Gibbons and Tucker (1979), and Facciola (1990)
<i>Polygonatum falcatum</i> A. Gray	Asparagaceae	Deer Bamboo	China: shoot and root are eaten. Root is steamed and sun-dried nine times must be fully grown when processed; otherwise, it stings the throat	Read (1946)
<i>Polygonatum multiflorum</i> (L.) All.	Asparagaceae	Common Solomon's Seal, David's Harp, Ladder-to-Heaven, Eurasian Solomon's Seal	In China, rhizome is eaten	Read (1946)
<i>Polygonatum odoratum</i> (Mill.) Druce	Asparagaceae	Angular Solomon's Seal, Scented Solomon's Seal, Yu Zhu (Chinese)	Rhizome is parboiled and dried, sliced and dried repeatedly and mixed with other Chinese herbs in a refreshing health beverage, used to make tea in Korea and in traditional medicines	Hu (2005)
<i>Polygonatum officinale</i> Allen = <i>Polygonatum odoratum</i> var. <i>odoratum</i>	Asparagaceae	Solomon's Seal	In China, leaves and rhizomes are milled and eaten	Read (1946)
<i>Polygonatum sibiricum</i> F. Delaroche	Asparagaceae	Siberian Dogwood, Huang Jing (Chinese)	Rhizome contains starch and sugars used for pastries, is steamed, dried repeatedly with sugar or honey, eaten as candy and used in traditional Chinese medicine	Hu (2005)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Polygonatum vulgare</i> Desf. = <i>Polygonatum odoratum</i> var. <i>odoratum</i>	Asparagaceae	Solomon's Seal	China (northern): rhizome is eaten	Read (1946)
<i>Polygonum bistorta</i> L. = <i>Persicaria bistorta</i> (L.) Samp.	Polygonaceae	Bistort, Pink Plumes, Snakeweed	Rhizomes are eaten after roasting or sliced for stir-fries or added to soups and stews	Hedrick (1972), Grieve (1971), Facciola (1990), and Schofield (2003)
<i>Polygonum bistortoides</i> Pursh = <i>Bistorta bistortoides</i> (Pursh) Small	Polygonaceae	American Bistort	As above	Yanovsky (1936), Harrington (1974), Launert (1981), and Facciola (1990)
<i>Polygonum multiflorum</i> Thunb. = <i>Fallopia multiflora</i> (Thunb.) Haraldson	Polygonaceae	Flowery Knotweed; He Shou Wu, Ye Jiao Teng (Chinese)	China: roots are boiled in changes of water to remove the bitter principle and then eaten. Rhizome is used as famine and health food	Read (1946) and Hu (2005)
<i>Polygonum viviparum</i> L. = <i>Persicaria vivipara</i> (L.) Ronse Decr.	Polygonaceae	Alpine Bistort	Rhizomes are eaten after roasting or sliced for stir-fries or added to soups and stews	Harrington (1974), Fernald et al. (1958), Facciola (1990), and Schofield (2003)
<i>Polymnia sonchifolia</i> Poepp. = <i>Smallanthus sonchifolius</i> (Poepp.) H. Rob.	Asteraceae	Yacon, Llacon, Strawberry Jicama, Bolivian Sunroot	In yacon-producing countries, products made from yacon root include flour, dehydrated products, slice or chips, juices, purees, sweeteners in the form of syrup or tea with high fructooligosaccharide (FOS)	Popenoe et al. (1989), Facciola (1990), and Hermann and Heller (1997)
<i>Polypodium vulgare</i> L.	Polypodiaceae	Oakfern, Tree-Fern	Norway: roots are used to obtain flour for bread or porridge	Sayce (1953)
<i>Portulaca australis</i> Endl.	Portulacaceae	Portulaca	Tuberous roots are eaten after roasting	Cribb and Cribb (1987)
<i>Portulaca intraterranea</i> J.M. Black.	Portulacaceae	Large Pigweed	Australia: root is edible only when cooked	Irvine (1957)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Portulaca tuberosa</i> Roxb.	Portulacaceae	Safed Musli (Rajasthan)	India (Rajasthan, western): roots are eaten raw	Saxena (1979)
<i>Potamogeton crispus</i> L.	Potamogetonaceae	Curly Pond Weed	China: leaves and roots are eaten	Read (1946)
<i>Potentilla anserina</i> L.	Rosaceae	Silverweed, Jue Ma (Chinese)	Roots add a nutty texture to salads and sandwiches. In China, root tuber is dried, boiled with rice in a tonic soup	Cribb and Cribb (1987), Facciola (1990), Schofield (2003), and Hu (2005)
<i>Potentilla discolor</i> Bunge	Rosaceae	Cinquefoil, Fan Bai Cao (Chinese)	China: root is eaten boiled, or raw roots are eaten in northern China	Read (1946) and Hu (2005)
<i>Potentilla egedii</i> Wormsk.	Rosaceae	Silverweed	Roots add a nutty texture to salads and sandwiches	Schofield (2003)
<i>Pouzolzia tuberosa</i> Wight	Urticaceae	NF	India: tuberous roots are eaten	Watt (1908)
<i>Pouzolzia viminea</i> (Blume) Wedd. = <i>Pouzolzia sanguinea</i> var. <i>sanguinea</i>	Urticaceae	Lipe (Nepal); Mosilo, Ut-Kra (India)	India (Garhwal Himalayas): bark is dried and powdered and then eaten	Gupta (1962)
<i>Prasophyllum brevilabre</i> (Lindl.) Hook.f.	Orchidaceae	Short-Lipped Leek-Orchid	Tubers are eaten by aborigines	Harden (1993)
<i>Prasophyllum campestre</i> R.J. Bates & D.L. Jones	Orchidaceae	Starry Leek-Orchid, Ben Lomond Leek-Orchid	As above	Harden (1993)
<i>Prasophyllum caudiculum</i> D.L. Jones	Orchidaceae	NF	As above	Harden (1993)
<i>Prasophyllum dosseum</i> R.J. Bates & D.L. Jones	Orchidaceae	Tall Leek-Orchid, Piano Orchid	As above	Harden (1993)
<i>Prasophyllum elatum</i> R. Br.	Orchidaceae	Yellow Leek-Orchid	As above	Harden (1993)
<i>Prasophyllum flavum</i> R. Br.	Orchidaceae	Scented Leek-Orchid, Sweet Leek-Orchid	As above	Harden (1993)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Prasophyllum odoratum</i> R.S. Rogers	Orchidaceae	Broad-Lipped Leek-Orchid	As above	Harden (1993)
<i>Prasophyllum patens</i> R. Br.	Orchidaceae	Marsh Leek-Orchid	As above	Harden (1993)
<i>Prasophyllum rogersii</i> Rupp	Orchidaceae	Summer Leek-Orchid	As above	Harden (1993)
<i>Prasophyllum solstitium</i> D.L. Jones	Orchidaceae	NF	As above	Harden (1993)
<i>Prasophyllum</i> sp.	Orchidaceae	Leek Orchids	As above	Cribb and Cribb (1987)
<i>Pseudostellaria heterophylla</i> (Miq.) Pax	Caryophyllaceae	Prince Ginseng, Tai Zhi Shen (Chinese)	Roots are used for soup	Hu (2005)
<i>Psidium guajava</i> L.	Myrtaceae	Guava	Roots are said to be used in soups	Uphof (1968) and Facciola (1990)
<i>Psophocarpus palustris</i> Desv.	Fabaceae	African Winged Bean	Tuberous root is eaten in some parts of Africa	Dalziel (1955), Uphof (1968), and Facciola (1990)
<i>Psophocarpus tetragonolobus</i> (L.) DC.	Fabaceae	Winged Bean Root, Asparagus Bean Root, Goa Bean Root	Tuberous root is eaten	Hu (2005), Facciola (1990), Khan (1994), Lim (2012b), and Codex (2014)
<i>Psoralea badocana</i> (Blanco) Benth. = <i>Cullen badocanum</i> (Blanco) Verdc.	Fabaceae	NF	Roots are eaten roasted	Cribb and Cribb (1987)
<i>Psoralea argophylla</i> Pursh	Fabaceae	Silverleaf Scurf Pea, Silverleaf Indian Breadroot	Root is edible raw or cooked in stews, ground into flour for thick soups and bread	Yanovsky (1936) and Tanaka (1976)
<i>Psoralea canescens</i> Michx.	Fabaceae	Buckroot	As above	Yanovsky (1936), Hedrick (1972), and Tanaka (1976)
<i>Psoralea cuspidata</i> Pursh	Fabaceae	Indian Breadroot, Largebract Indian Breadroot	As above	Tanaka (1976) and Fernald et al. (1958)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Psoralea esculenta</i> Pursh	Fabaceae	Breadroot, Prairie Turnip, Prairie Potato	Fresh tubers may be eaten raw with a dressing of oil, vinegar and salt, or they may be boiled or roasted	Saunders (1920), Yanovsky (1936), Uphof (1968), Hedrick (1972), Kaldy et al. (1980), Facciola (1990), and Groen et al. (1996)
<i>Psoralea hypogaea</i> Torr. & A. Gray	Fabaceae	Small Indian Breadroot	As above	Saunders (1920)
<i>Psoralea tenuiflora</i> Pursh	Fabaceae	Slender Scurfy Pea, Slimflower Scurfpea	Root is edible raw or cooked in stews, ground into flour for thick soups and bread	Yanovsky (1936) and Tanaka (1976)
<i>Pteridium aquilinum</i> (L.) Kuhn	Dennstaedtiaceae	Bracken, Brake or Common Bracken; Okang Oing (Mishing); Jue Fen, Jue Tai Cai (Chinese)	In China, rhizomatous roots are eaten as a famine food in Chaotung, southern Szechuan, on the Yunnan border; starch is also extracted from the rhizomes. In Australia, starchy rhizomes are eaten raw or roasted. In India, rhizomes are eaten sometimes as vegetable by Mishing people	Maiden (1889), Irvine (1957), Watt (1908), Sutton (1974), Hu (2005), and Patiri and Borah (2007)
<i>Pteridium aquilinum</i> L. var. <i>latiusculum</i> (Desv.) Underw. ex A. Heller	Dennstaedtiaceae	Eastern Bracken	Rhizome starch is used to make noodles, liquor, cakes and other products	Cui (1998), Dai et al. (2003), Cao et al. (2007), and Yun et al. (2009a)
<i>Pteridium esculentum</i> (G. Forst.) Nakai	Dennstaedtiaceae	Bracken Fern, Jue (Chinese)	Rhizome is roasted and chewed for the bland white starch	Low (1989)
<i>Pteridium revolutum</i> (Bl.) Nakai	Dennstaedtiaceae	Mao Zhou Jue (Chinese)	Rhizome starch is used to make noodles, liquor, cakes and other products	Cui (1998), Dai et al. (2003), Cao et al. (2007), and Yun et al. (2009a)
<i>Pterostylis abrupta</i> D.L. Jones	Orchidaceae	Abrupt Greenhood, Drooping Greenhood	Tubers are edible	Harden (1993)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Pterostylis alata</i> (Labill.) Rchb.f.	Orchidaceae		Tubers are edible	Harden (1993)
<i>Pterostylis bicolor</i> M.A. Clem. & D.L. Jones	Orchidaceae	Two-Colour Greenhood	Tubers are edible	Harden (1993)
<i>Pterostylis boormanii</i> Rupp	Orchidaceae	Boorman's Ruddyhood	Tubers are edible	Harden (1993)
<i>Pterostylis chaetophora</i> M.A. Clem. & D.L. Jones	Orchidaceae	Hair-Lip Ruddyhood	Tubers are edible	Harden (1993)
<i>Pterostylis coccinea</i> Fitzg.	Orchidaceae	Alpen Greenhood	Tubers are edible	Harden (1993)
<i>Pterostylis curta</i> R. Br.	Orchidaceae	Blunt Greenhood	Tubers are edible	Harden (1993)
<i>Pterostylis cynocephala</i> Fitzg.	Orchidaceae	Swan Greenhood	Tubers are edible	Harden (1993)
<i>Pterostylis daintreana</i> F. Muell. ex Benth.	Orchidaceae	Daintree's Green Hood	Tubers are edible	Harden (1993)
<i>Pterostylis decurva</i> R.S. Rogers	Orchidaceae	Summer Greenhood	Tubers are edible	Harden (1993)
<i>Pterostylis fischii</i> Nicholls	Orchidaceae	Fisch's Greenhood	Tubers are edible	Harden (1993)
<i>Pterostylis hamata</i> Blackmore & Clemesha	Orchidaceae	Hooked Greenhood	Tubers are edible	Harden (1993)
<i>Pterostylis hildae</i> Nicholls	Orchidaceae	Rainforest Greenhood	Tubers are edible	Harden (1993)
<i>Pterostylis laxa</i> Blackmore	Orchidaceae	Antelope Greenhood	Tubers are edible	Harden (1993)
<i>Pterostylis longicurva</i> Rupp	Orchidaceae	Long-Tongued Greenhood	Tubers are edible	Harden (1993)
<i>Pterostylis longifolia</i> R. Br.	Orchidaceae	Tall Greenhood	Tubers are edible, watery and sweetish	Low (1989) and Harden (1993)
<i>Pterostylis longipetala</i> Rupp	Orchidaceae	Curved Greenhood	Tubers are edible	Harden (1993)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Pterostylis mutica</i> R. Br.	Orchidaceae	Midget Greenhood	Tubers are edible	Harden (1993)

<i>Pueraria lobata</i> (Willd.) Ohwi var. <i>thomsonii</i> (Benth.) van der Maesen = <i>Pueraria montana</i> var. <i>chinensis</i> (Ohwi) Sanjappa & Pradeep	Fabaceae	Kudzu, Thomson Kudzu	Tubers are edible	Groen et al. (1996)
<i>Pueraria lobata</i> (Willd.) Ohwi var. <i>montana</i> (Lour.) van der Maesen = <i>Pueraria montana</i> var. <i>montana</i> (Lour.) Merr.	Fabaceae	Kudzu, Taiwan Kudzu	Tubers are edible	Groen et al. (1996)
<i>Pueraria edulis</i> Pamp.	Fabaceae	Edible Kudzu, Ge Gen Fen (Chinese)	Starch from enlarged root is extracted for noodles	Hu (2005)
<i>Pueraria hirsuta</i> Kurz = <i>Pueraria stricta</i> Kurz	Fabaceae	Cudzú-Tropical (Portuguese, Brazil)	China: root is steamed and eaten. Japan: processed into flour during the period of scarcity immediately following World War II	Read (1946) and Uphof (1968)
<i>Pueraria montana</i> (Lour.) Merr.	Fabaceae	Ge Ma Mu (Chinese)	Starch is obtained from roots	Hu (2005)
<i>Pueraria phaseoloides</i> (Roxb.) Benth.	Fabaceae	Pani Alu (Assamese)	Tuber is fleshy and tasty; it is often eaten raw	Facciola (1990) and Patiri and Borah (2007)
<i>Pueraria thomsonii</i> Benth. = <i>Pueraria montana</i> var. <i>chinensis</i> (Ohwi) Sanjappa & Pradeep	Fabaceae	Sweet Kudzu; Pani Alu (Assamese); Gang E Teng (Chinese)	Roots sliced used in soup with pork chops in China. In Assam, tuberous roots are eaten cooked	Hu (2005) and Patiri and Borah (2007)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Pueraria thunbergiana</i> (Siebold & Zucc.) Benth. = <i>Pueraria montana</i> var. <i>lobata</i> (Willd.) Sanjappa & Pradeep	Fabaceae	Kudzu	Fleshy tuber eaten	Read (1946)
<i>Pueraria tuberosa</i> (Willd.) DC.	Fabaceae	Indian Kudzu, Nepalese Kudzu; Urahi Alu, Pani Alu (Assamese); Bilai-Kand, Biralu, Birali Panwa, Sural (Kumaon region, western Himalayas)	Tuberous roots are eaten	Bhargava (1960), Gupta (1962), and Patiri and Borah (2007)
<i>Ranunculus ficaria</i> L. = <i>Ficaria verna</i> Huds.	Ranunculaceae	Pilewort, Lesser Celandine	Roots are cooked and served with meat	Uphof (1968), Launert (1981), and Facciola (1990)
<i>Raphanus raphanistrum</i> subsp. <i>maritimus</i> (Sm.) Thell. = <i>Raphanus raphanistrum</i> subsp. <i>landra</i> (Moretti ex DC.) Bonnier & Layens	Brassicaceae	Sea Radish, Spanish Radish	Taproot is eaten as potherb	Hedrick (1972) and Facciola (1990)
<i>Raphanus sativus</i> L. var. <i>longipinnatus</i> L.H. Bailey = <i>Raphanus raphanistrum</i> subsp. <i>sativus</i> (L.) Domin	Brassicaceae	Japanese Radish	As below	Codex (2014)
<i>Raphanus sativus</i> Caudatus Group	Brassicaceae	Rat Tail Radish, Monkey Tail Radish	As below	Burkill (1966), Tanaka (1976), and Facciola (1990)
<i>Raphanus sativus</i> Longipinnatus Group	Brassicaceae	Oriental Radish, Lobak, Daikon	As below	Facciola (1990) and van Wyk (2006)
<i>Raphanus sativus</i> cv. group Chinese radish			As below	Piluek and Beltran (1994)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Raphanus sativus</i> cv. small radish group	Brassicaceae		As below	Piluek and Beltran (1994) and van Wyk (2006)
<i>Raphanus sativus</i> L. = <i>Raphanus raphanistrum</i> subsp. <i>sativus</i> (L.) Domin	Brassicaceae	Radish, European Radish	Swollen fleshy root is eaten as vegetable fresh or dried or pickled or added to soups, stews, stir-fries	Facciola (1990), Phillips and Rix (1993), Piluek and Beltran (1994), Hu (2005), van Wyk (2006), Walter and Lebot (2007), and Santich et al. (2008)
<i>Raphanus sativus</i> L. var. <i>niger</i> (Mill.) J. Kern. = <i>Raphanus raphanistrum</i> subsp. <i>sativus</i> (L.) Domin	Brassicaceae	Black Radish	Taproot is edible	Codex (2014)
<i>Raphionacme brownii</i> Scott-Elliott	Apocyanaceae	Raphionacme; Rujiya (Hausa); Katakirri (Kanuri)	Nigeria (Kano State, northern): tuber is eaten	Mortimore (1989)
<i>Raphionacme daronii</i> Berhaut = <i>Raphionacme splendens</i> subsp. <i>bingeri</i> (A. Chev.) Venter	Apocyanaceae	A-Ndekap (Bassari), Gamkbuhrongal (Bedik)	Senegal/Guinea: children among the Bedik eat the root and fruits during famine	Ferry et al. (1974)
<i>Rapunculus esculentus</i> Steud. = <i>Campanula rotundifolia</i> L.	Campanulaceae	Common Harebell, Bluebell, Blawort Cuckoo Shoe	Root is recommended as famine food. It can be eaten raw in salads	Parmentier (1781) (cited by Freedman 2009)
<i>Rapunculus spicatus</i> (L.) Mill. = <i>Phyteuma spicatum</i> L.	Campanulaceae	Spiked Rampion	In France, root is used as a famine food	Parmentier (1781) (cited by Freedman 2009)
<i>Rehmannia glutinosa</i> (Gaertn.) DC.	Plantaginaceae	Chinese Foxglove, Di Huang (Chinese)	Root is used for bupin in China: the leaves either are boiled or may be powdered and mixed with juice from the root and cooked. The root is steamed and sun-dried nine times	Read (1946) and Hu (2005)
<i>Rehmannia lutea</i> Maxim.	Plantaginaceae	Rehmania	As above	Read (1946)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Reichardia picroides</i> (L.) Roth	Asteraceae	French Scorzonera	Roots are eaten	Hedrick (1972) and Facciola (1990)
<i>Reynoutria japonica</i> Houtt.	Polygonaceae	Japanese Knotweed	Rhizomes are edible	Gibbons and Tucker (1979), Fernald et al. (1958), and Facciola (1990)
<i>Rhamnus prinoides</i> L'Hér.	Rhamnaceae	Mofifi Buckthorn	Roots are used in soup	Fox et al. (1982) and Facciola (1990)
<i>Rheum nanum</i> Siev. ex Pall.	Polygonaceae	Small Rhubarb, Ai Da Huang (Chinese)	Starch is obtained from caudex and root is used as food in the steppes in northwestern China, Inner Mongolia and Xinjiang	Hu (2005)
<i>Rhexia virginica</i> L.	Melastomataceae	Meadow Beauty, Deer Grass	Tubers are chopped and added to salads or eaten as nibble	Gibbons and Tucker (1979), Fernald et al. (1958), and Facciola (1990)
<i>Rhizophora mangle</i> L.	Rhizophoraceae	American Red Mangrove	Roots are used as emergency food	Tanaka (1976) and Facciola (1990)
<i>Rhodiola rosea</i> L. = <i>Sedum roseum</i> (L.) Scop.	Crassulaceae	Roseroot	Roots are boiled, seasoned with butter and served with meat or fish	Gibbons and Tucker (1979), Fernald et al. (1958), and Facciola (1990)
<i>Rhus glabra</i> L.	Anacardiaceae	Smooth Sumac, Scarlet Sumac	Roots are peeled and eaten raw	Gibbons and Tucker (1979), Fernald et al. (1958), and Facciola (1990)
<i>Romulea bulbocodium</i> (L.) Sebast. & Mauri	Iridaceae	Rocus-Leaved Romulea, Violet Romulea	Bulbous root is eaten by shepherds in northern Africa	Facciola (1990)
<i>Rosa laevigata</i> Michx.	Rosaceae	Cherokee Rose, Jin-Ying Zhi (Chinese)	Sliced roots are used for health tea	Hu (2005)
<i>Rumex acetosella</i> L.	Polygonaceae	Sheep Sorrel	Roots are edible	Harrington (1974), Gibbons and Tucker (1979), Fernald et al. (1958), and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Rhynchosia comosa</i> Baker = <i>Pseudeminia comosa</i> (Baker) Verdc.	Fabaceae	L'Indo (Sandawe)	In central Tanzania, roots are chewed for juices	Newman (1975)
<i>Saccharum spontaneum</i> L.	Poaceae	Wild Cane, Wild Sugarcane, Fodder Cane; Khagori (Assamese); Mojora (Mishing)	Young shoots and rhizomes are eaten as sugar cane, sweet in taste	Patiri and Borah (2007)
<i>Sagittaria variabilis</i> Engelm. = <i>Sagittaria latifolia</i> Willd.	Alismataceae	Arrowhead, Duck Potato	Roasted or boiled, the corms become soft, palatable and digestible	Saunders (1920)
<i>Sagittaria japonica</i> H. Vilm. = <i>Sagittaria trifolia</i> L.	Alismataceae	Arrowhead, Arrow Weed, Swamp Potato	Corms are edible	
<i>Sagittaria latifolia</i> Willd.	Alismataceae	Arrowhead, Duck Potato, Wapato	Corms are eaten boiled, creamed, fried and roasted	Gibbons and Tucker (1979), Fernald et al. (1958), Facciola (1990), and Codex (2014)
<i>Sagittaria rigida</i> Pursh	Alismataceae	Sessile-Fruited Arrowhead	Corms are eaten	Facciola (1990)
<i>Sagittaria sagittifolia</i> L.	Alismataceae	Old World Arrowhead, Swamp Potato, Sagittaria	Corms are cooked and eaten	Tanaka (1976), Facciola (1990), Hu (2005), and Codex (2014)
<i>Sagittaria sinensis</i> Sims = <i>Sagittaria trifolia</i> L.	Alismataceae	Chinese Arrowhead, Chee Koo, Kuwai	Roasted or boiled, the corms become soft, palatable and digestible	Saunders (1920), Facciola (1990), and Phillips and Rix (1993)
<i>Sagittaria trifolia</i> L.	Alismataceae	Arrowhead, Arrow Weed, Swamp Potato	Corms are consumed boiled	Harrington (1974), Facciola (1990), and Groen et al. (1996)
<i>Salix daphnoides</i> Vill.	Salicaceae	Arctic Willow	Rhizomes are peeled eaten raw or cooked	Uphof (1968), Gibbons and Tucker (1979), and Facciola (1990)
<i>Sambucus javanica</i> Blume	Adoxaceae	Chinese Elderberry, Chieh-Ku-Ts'ao (Chinese)	Roots are parboiled and eaten	Uphof (1968), Tanaka (1976), and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Santalum murrayanum</i> C.A. Gardner	Santalaceae	Bitter Quandong	Bark of roots is roasted	Cribb and Cribb (1987)
<i>Sauromatum guttatum</i> Schott = <i>Sauromatum venosum</i> (Dryand. ex Aiton) Kunth	Araceae	Voodoo Lily	India: as for <i>Dioscorea sativa</i>	Gammie (1902)
<i>Scabiosa japonica</i> Miq.	Caprifoliaceae	Pincushion Flower	In China, roots are eaten	Read (1946)
<i>Schismatoglottis calyptrata</i> (Roxb.) Zoll. & Morit.	Araceae	Guang Xi Luo Yan (Chinese), Nyampon (Indonesia), Alapayi (Philippines)	Stolons are eaten cooked	Ochse and van den Brink (1980) and Van den Bergh (1994)
<i>Schismatoglottis wallichii</i> Hook.f.	Araceae	Arum	Rhizomes are edible	Groen et al. (1996)
<i>Schoenoplectus litoralis</i> (Schrad.) Palla	Cyperaceae	Daly River Club Rush	Edible roots	Cribb and Cribb (1987)
<i>Scilla chinensis</i> Benth. = <i>Barnardia japonica</i> (Thunb.) Schult. & Schult.f.	Asparagaceae	Squill	In China, bulb is eaten after thorough soaking and boiling	Read (1946)
<i>Scilla japonica</i> Baker = <i>Barnardia japonica</i> (Thunb.) Schult. & Schult.f.	Asparagaceae	As below	As above	Read (1946)
<i>Scilla scilloides</i> (Lindl.) Druce = <i>Barnardia japonica</i> (Thunb.) Schult. & Schult.f.	Asparagaceae	Chinese Jacinth, Chinese Squill; Jin Zao Er (Chinese)	Bulb containing starch and sugars, soaked cooked and eaten during famine times	Hu (2005)
<i>Scirpus americanus</i> Pers. = <i>Schoenoplectus americanus</i> (Pers.) Volkart	Cyperaceae	Bulrush	Rootstock is eaten raw, boiled, baked or roasted, also pounded into flour	Schofield (2003)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Scirpus californicus</i> (C.A. Mey.) Steud. = <i>Schoenoplectus californicus</i> (C.A. Mey.) Soják	Cyperaceae	California Bulrush, Totora	Rhizomes are peeled, baked and eaten	Facciola (1990)
<i>Scirpus grossus</i> L.f. = <i>Actinoscirpus grossus</i> (L.f.) Goetgh. & D.A. Simpson	Cyperaceae	Giant Bulrush, Greater Club-Rush	In India and Kumaon region, western Himalayas, roots are burnt and then ground into flour from which bread is prepared	Paton and Dunlop (1904) and Bhargava (1960)
<i>Scirpus lacustris</i> L. = <i>Schoenoplectus lacustris</i> (L.) Palla	Cyperaceae	Tule, Greatbulrush	In China, shoots and roots are eaten. Rootstock can be processed into syrup or flour	Saunders (1920), Read (1946), Uphof (1968), Harrington (1974), Gibbons and Tucker (1979), and Facciola (1990)
<i>Scirpus microcarpus</i> J. Presl & C. Presl	Cyperaceae	Bulrush	Rootstock is eaten raw, boiled, baked or roasted	Schofield (2003)
<i>Scirpus paludosus</i> A. Nelson = <i>Bolboschoenus maritimus</i> subsp. <i>paludosus</i> (A. Nelson) T. Koyama	Cyperaceae	Alkali Bulrush, Nutgrass	Rhizome is eaten raw or made into flour for bread	Uphof (1968), Fernald et al. (1958), and Facciola (1990)
<i>Scirpus subterminalis</i> Torr. = <i>Schoenoplectus subterminalis</i> (Torr.) Soják	Cyperaceae	Bulrush	Rootstock is eaten raw, boiled, baked or roasted	Schofield (2003)
<i>Scirpus tuberosus</i> Roxb. (illeg.) = <i>Eleocharis dulcis</i> (Burm.f.) Trin. ex Hensch.	Cyperaceae	Chechur (Assamese), Khitro (Bodo)	Root tubers are sweet and eaten fresh especially in Upper Assam, also can be cooked as vegetable with potato and chicken	Patiri and Borah (2007)
<i>Scirpus validus</i> Vahl = <i>Schoenoplectus tabernaemontani</i> (C.C. Gmel.) Palla	Cyperaceae	Bulrush, Tule, River Club-Rush	White underground shoots after boiling are of excellent flavour; roots are eaten cooked or preserved in rice bran	Tanaka (1976), Cribb and Cribb (1987), Fernald et al. (1958), Facciola (1990), and Schofield (2003)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Scolymus hispanicus</i> L.	Asteraceae	Golden Thistle	Fleshy roots are eaten boiled, mashed, baked or used as substitute for coffee	Hedrick (1972), Tanaka (1976), Kunkel (1984), and Facciola (1990)
<i>Scolymus maculatus</i> L.	Asteraceae	Spotted Golden Thistle, Spanish Salsify, Spanish Oyster Plant	Roots are boiled and eaten	Hedrick (1972), Kunkel (1984), and Facciola (1990)
<i>Scorzonera glabra</i> Rupr.	Asteraceae	Serpent Root, Ya Cong (Chinese)	Roots are eaten as emergency food in northern China	Hu (2005)
<i>Scorzonera hispanica</i> L.	Asteraceae	Black Salsify, Mock Oyster, Coconut Root	Root is peeled after cooking, usually boiled and served along with other vegetables as a side dish or in salads, or cooked in soups and stews. Battered in flour and make into fritters, roasted roots used as coffee substitute	Facciola (1990), Phillips and Rix (1993), Van den Bergh (1994), van Wyk (2006), Santich et al. (2008), and Codex (2014)
<i>Scorzonera humilis</i> L.	Asteraceae	Viper's Grass	In France, root is used as a famine food	Parmentier (1781) (cited by Freedman 2009)
<i>Scrophularia nodosa</i> L.	Scrophulariaceae	Figwort, Woodland Figwort, Common Figwort	In France, starch of root is recommended as famine food for extending bread flour, after removal of bitter element	Parmentier (1781) (cited by Freedman 2009)
<i>Sechium edule</i> (Jacq.) Swartz	Cucurbitaceae	Chayote, Vegetable Pear	Roots are eaten boiled, baked, fried or candied in syrup	Facciola (1990) and Codex (2014)
<i>Silybum marianum</i> (L.) Gaertn.	Asteraceae	Milk Thistle	Roots are eaten raw or cooked	Uphof (1968), Grieve (1971), Larkcom (1984), and Facciola (1990)
<i>Sisarum germanorum</i> Schur	Apiaceae	Chervil	In France, root is recommended as a famine food, eaten with milk or broth	Parmentier (1781) (cited by Freedman 2009)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Sison amomum</i> L.	Apiaceae	Bastard Stone Parsley	Roots are edible	Uphof (1968), Hedrick (1972), and Facciola (1990)
<i>Sium cicutifolium</i> Schrenk = <i>Sium suave</i> Walter	Apiaceae	Water Parsnip	Roots are used as food by some Indian tribes in North America	Uphof (1968), Fernald et al. (1958), and Facciola (1990)
<i>Sium sisarum</i> L.	Apiaceae	Skirret	Roots are consumed, used fresh in salad or cooked in stews or soups, also boiled and roasted as a vegetable	Facciola (1990), Phillips and Rix (1993), Hu (2005), Santich et al. (2008), and Codex (2014)
<i>Smallanthus sonchifolius</i> (Poepp.) H. Rob.	Asteraceae	Yacon	See <i>Polymnia sonchifolia</i>	Popenoe et al. (1989), Facciola (1990), Hermann and Heller (1997), and Codex (2014)
<i>Smilacina racemosa</i> (L.) Desf. = <i>Maianthemum racemosum</i> (L.) Link	Asparagaceae	False Solomon's Seal, Treacle Berry	Rootstock is soaked in lye, parboiled and eaten like potatoes or pickled	Hedrick (1972), Fernald et al. (1958), and Facciola (1990)
<i>Smilax china</i> L.	Smilacaceae	China Root, Ma Chia, Thassap, Susni, Reuchu (Assamese)	Roots are edible, eaten in Assam	Tanaka (1976), Facciola (1990), and Medhi and Borthakur (2012)
<i>Smilax macrophylla</i> Roxb. = <i>Smilax ovalifolia</i> Roxb. ex D. Don	Smilacaceae	Kumarika; Tamboli (Bombay)	In India, roots and leaves are eaten	Gammie (1902)
<i>Smilax megacarpa</i> A. DC.	Smilacaceae	Akar Kelona (Malaysia)	Red rhizome is edible	Van den Bergh (1994)
<i>Smilax ovalifolia</i> Roxb. ex D. Don	Smilacaceae	Kumarika	Roots are eaten	Watt (1908)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Smilax pseudochina</i> L.	Smilacaceae	China Brier	Starchy, tuberous roots are chopped, pounded and mixed with water to make a nutritious meal, mixed with fine corn flour, and frying in bear grease gives good hotcakes or fritters	Saunders (1920)
<i>Smilax zeylanica</i> L.	Smilacaceae	Kayu China Hutan (Moluccas), Asihe Tunj (Ambon)	Young roots are boiled and eaten during famine	Groen et al. (1996)
<i>Smyrniolobos</i> L.	Apiaceae	Alexanders, Black Lovage	Roots are boiled and served with oil and vinegar or used in soups	Uphof (1968), Hedrick (1972), Larkcom (1984), and Facciola (1990)
<i>Solanum ajanhuiri</i> Juz. & Bukasov	Solanaceae	Ajanhuri	Root tuber is edible	Codex (2014)
<i>Solanum berthaultii</i> Hawkes	Solanaceae	Wild Potato	Tubers are used like the cultivated potato	Gupta and Kanodia (1968b)
<i>Solanum candolleanum</i> Berthault	Solanaceae	Gentil Achochil Chocke	Tubers are used like the cultivated potato	Gupta and Kanodia (1968b)
<i>Solanum curtilobum</i> Juz. & Bukasov	Solanaceae	Ckaisal, Bitter Potatoes	Root tuber is edible	Arbizu and Tapia (1994)
<i>Solanum demissum</i> Lindl.	Solanaceae	Papa Cimarrona, Papa Del Monte	Tubers are cooked and eaten	Facciola (1990)
<i>Solanum fendleri</i> A. Gray	Solanaceae	Fendler Potato, Wild Potato	In southwestern United States, root tuber is eaten raw or boiled with clay, by Native American Keresan Pueblo groups	Yanovsky (1936), White (1944), Hedrick (1972), Gibbons and Tucker (1979), and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Solanum jamesii</i> Torr.	Solanaceae	Colorado Wild Potato	In southwestern United States, tuber is eaten raw or boiled with clay, by Native American Keresan Pueblo group and also eaten by Navajo Indians. Tubers are also baked or ground into flour	Saunders (1920), Yanovsky (1936), White (1944), Harrington (1974), and Facciola (1990)
<i>Solanum paucijugum</i> Bitter	Solanaceae	Sacha Pappa	Root tuber is edible	Facciola (1990)
<i>Solanum tuberosum</i> L. var. <i>boreale</i> A. Gray	Solanaceae	Wild Potato	Root tubers are quite edible when cooked and eaten by Navajo and other Indians	Saunders (1920)
<i>Solanum tuberosum</i> L.	Solanaceae	Potato, Irish Potato	Russet or baking potato is best for roasting, frying or baking; all-purpose potatoes are used for soups, stews and mashing; red and newer cultivars are best for boiling, creaming and in cold salads	Facciola (1990), Phillips and Rix (1993), Wagih and Wiersema (1996), Hu (2005), van Wyk (2006), and Santich et al. (2008)
<i>Solanum tuberosum</i> L. subsp. <i>andigenum</i> (Juz. & Bukasov) Hawkes	Solanaceae	Andigena	Root tuber is edible	Codex (2014)
<i>Solanum verrucosum</i> Schltdl.	Solanaceae	Papa Morda	Root tuber is edible	Facciola (1990)
<i>Solanum juzepczukii</i> Bukasov	Solanaceae	Bitter Potatoes	Root tuber is edible	Arbizu and Tapia (1994)
<i>Solenostemon rotundifolius</i> (Poir.) J.K. Morton. = <i>Plectranthus rotundifolius</i> (Poir.) Spreng.	Lamiaceae	Hausa Potato, Frafra Potato; Tumuku, Tamaka (Hausa)	Nigeria (Kano State, northern): tuber is eaten like potato	Dalziel (1955), Fox et al. (1982), Mortimore (1989), Facciola (1990), and Codex (2014)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Sonchus oleraceus</i> (L.) L.	Asteraceae	Common Sowthistle	Roots are eaten	Grieve (1971), Fox et al. (1982), Cribb and Cribb (1987), and Facciola (1990)
<i>Spathium chinense</i> Lour. = <i>Saururus chinensis</i> (Lour.) Baill.	Saururaceae	Chinese Lizard's Tail	India: tubers are boiled and eaten	Watt (1908)
<i>Spathyema foetida</i> (L.) Rafin. = <i>Symplocarpus foetidus</i> (L.) Salisb. ex W.P.C. Barton	Araceae	Skunk Cabbage	Native American: rootstock is used as an emergency food, dried or baked, to improve the taste	Yanovsky (1936), Uphof (1968), Usher (1974), and Harris (1995)
<i>Sphaeralcea coccinea</i> (Nutt.) Rydb.	Malvaceae	Globemallow	North America (Arizona): root is eaten by Native American Navajo group	Elmore (1944)
<i>Sphenostylis stenocarpa</i> (A. Rich.) Harms	Fabaceae	Africa Yam Bean	Tuber is eaten raw or cooked like potato	Kay (1973), Popenoe et al. (1989), and Facciola (1990)
<i>Spiranthes sinensis</i> (Pers.) Ames	Orchidaceae	Ladies Tresses, Chinese Spiranthes	Egg-shaped tubers are edible and eaten	Low (1991) and Harden (1993)
<i>Spondias tuberosa</i> Arruda	Anacardiaceae	Brazil Plum, Umbu or Imbu	Brazil (northeast): roots, in the form of aqueous bulbs, are eaten	De Castro (1952)
<i>Spiranthes lancea</i> (Thunb. ex Sw.) Bakh.f. & Steenis = <i>Herminium lanceum</i> (Thunb. ex Sw.) Vuijk	Orchidaceae	Pan Long Shen (Chinese), Mukago-Sou (Japanese)	Fleshy root is cooked with chicken or meat	Hu (2005)
<i>Stachys adulterina</i> Hemsl.	Lamiaceae	Hubei Artichoke, Di Can Zi (Chinese)	Root tubers are used as vegetables, cooked or pickled	Hu (2005)
<i>Stachys affinis</i> Bunge	Lamiaceae	Chinese Artichoke, Cao Shi Can (Chinese)	As above	Phillips and Rix (1993), Hu (2005), and Codex (2014)
<i>Stachys chinensis</i> Bunge ex Benth.	Lamiaceae	Hyssopleaf Hedgenettle	Manchuria: rhizome is eaten	Baranov (1967)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Stachys sieboldii</i> Miq.	Lamiaceae	Crosnes, Chinese Artichoke, Japanese Artichoke	Japan: tubers are salted or preserved in plum vinegar	Read (1946), Facciola (1990), Van den Bergh (1996), and Codex (2014)
<i>Stellaria jamesiana</i> Torr. = <i>Pseudostellaria jamesiana</i> (Torr.) W.A. Weber & R.L. Hartm.	Caryophyllaceae	Tuber Starwort	Roots are eaten raw or cooked	Harrington (1974)
<i>Stemona australiana</i> (Benth.) C.H. Wright	Stemonaceae	NF	Fleshy subterranean tubers are edible	Cribb and Cribb (1987)
<i>Stemona tuberosa</i> Lour.	Stemonaceae	Wild Asparagus, Sessile Stemona Root, Japanese Stemona Root, Tuber Stemona Root; Bai Bu (Chinese); Thagdi, Barhtlum (Assamese)	Tuberous root is eaten in Assam	Medhi and Borthakur (2012)
<i>Sterculia foetida</i> L.	Malvaceae	Java Olive	Rootstock can be eaten raw	Kunkel (1984), Pongpangan and Poobrasert (1985), and Facciola (1990)
<i>Sterculia urens</i> Roxb. = <i>Kavalama urens</i> (Roxb.) Raf.	Malvaceae	Indian Gum Tragacanth, Gum Karaya; Kadhai (Bombay)	In Bombay, India, the tender roots are chopped, boiled and mixed with either spices or sugar	Gammie (1902)
<i>Sterculia villosa</i> Roxb.	Malvaceae	Elephant Rope Tree, Udal, Vakenar	Roots are edible	Burkill (1966), Tanaka (1976), and Facciola (1990)
<i>Streptopus amplexifolius</i> (L.) DC.	Asparagaceae	Liver Berry, Claspig-Leaved Twisted Stalk, Wild Cucumber	Roots are sometimes used in salads	Gibbons and Tucker (1979) and Facciola (1990)
<i>Stylochiton lancifolium</i> Kotschy & Peyr.	Araceae	Gwandai (Huasa, Plant); Kinciyar, Ngurra (Kanuri)	In Nigeria (Kano State, northern), leaves and rhizome are eaten after repeated boiling of young leaves and rhizome to detoxify	Mortimore (1989)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Stylochiton warneckii</i> Engl.	Araceae	A-Nyé! Ewùrè (Senegal Basari), Tabal (Senegal, Wolof)	Africa (west): the thickened rhizome is repeatedly washed in ashes and lye to leach out toxic saponins and raphides	Irvine (1952), Uphof (1968), and Burkill (1985)
<i>Swertia bimaculata</i> Hook.f. & Thomas ex C.B. Clarke	Gentianaceae	Double-Spotted Swertia, Chinese Chirata	In China, root is eaten	Read (1946)
<i>Symphytum officinale</i> L.	Boraginaceae	Comfrey	Roasted roots are mixed with chicory roots used as coffee substitute	Grieve (1971), Hedrick (1972), and Facciola (1990)
<i>Synantherias sylvatica</i> (Roxb.) Schott = <i>Amorphophallus sylvaticus</i> (Roxb.) Kunth	Araceae	Kuttukaranai (Tamil), Vanakanda (Telugu)	Roots are eaten in India	Watt (1908)
<i>Tacca involucrata</i> Schumach. & Thonn. = <i>Tacca leontopetaloides</i> (L.) O. Kuntze	Dioscoreaceae	See below	In Nigeria, the Munshi first boils the tuber to remove the toxic element. A coarse flour, called <i>amara</i> , is prepared from it	Irvine (1952)
<i>Tacca leontopetaloides</i> (L.) O. Kuntze	Dioscoreaceae	Polynesian Arrowroot, East Indian Arrowroot, Salep	Root tuber is grated, pounded, soaked and baked	Cribb and Cribb (1987), Wightman and Andrews (1989), Low (1989, 1991), Facciola (1990), Jukema and Paisooksantivatana (1966), Hu (2005), and Codex (2014)
<i>Tacca pinnatifida</i> J.R. Forst & G. Forst. = <i>Tacca leontopetaloides</i> (L.) O. Kuntze	Dioscoreaceae	See above	Tubers are usually eaten after preparation, bitter when raw	Burkill (1966)
<i>Taraxacum albidum</i> Dahlst.	Asteraceae	White Dandelion	Roots are edible after parboiling	Tanaka (1976) and Facciola (1990)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Taraxacum officinale</i> Webb	Asteraceae	Dandelion Root	Roots are boiled as vegetable or baked, added to soups and stir-fries. Roasted roots afford a hearty coffee-flavoured beverage free of caffeine	Harrington (1974), Cribb and Cribb (1987), Facciola (1990), Phillips and Rix (1993), Van den Bergh (1994), Schofield (2003), and Codex (2014)
<i>Telosma cordata</i> (Burm.f.) Merr.	Apocynaceae	Fragrant Telosma, Tonkin Creeper, Cowslip Creeper, Pakalana Vine	Fleshy roots are made into sweetmeat by the Chinese in Java	Burkill (1966), Tanaka (1976), and Facciola (1990)
<i>Tetrapanax papyrifer</i> (Hook.) K. Koch	Araliaceae	Rice Paper Plant	Roots are edible	Tanaka (1976) and Kunkel (1984)
<i>Thalia geniculata</i> L.	Marantaceae	Swamp Lily	Rhizomes are baked and eaten or made into a kind of arrowroot	Tanaka (1976) and Facciola (1990)
<i>Thelymitra carnea</i> R. Br.	Orchidaceae	Tiny Sun Orchid, Pink Sun Orchid	Root tubers are edible	Harden (1993)
<i>Thelymitra circumsepta</i> Fitzg.	Orchidaceae	Naked Sun Orchid	Root tubers are edible	Harden (1993)
<i>Thelymitra cyanea</i> (Lindl.) Benth.	Orchidaceae	Veined Sun Orchid	Root tubers are edible	Harden (1993)
<i>Thelymitra fragrans</i> D.L. Jones & M.A. Clem.	Orchidaceae	Frahrant Sun Orchid	Root tubers edible	Harden (1993)
<i>Thelymitra ixioides</i> Sw.	Orchidaceae	Spotted Sun Orchid	Root tubers are bland and glutinous	Low (1991)
<i>Thelymitra megacalyptra</i> Fitzg.	Orchidaceae	Scented Sun Orchid	Root tubers are edible	Harden (1993)
<i>Thelymitra nuda</i> R. Br.	Orchidaceae	Plain Sun Orchid	Root tubers are edible	Low (1989) and Harden (1993)
<i>Thelymitra pauciflora</i> R. Br.	Orchidaceae	Slender Sun Orchid	Root tubers are edible	Harden (1993)
<i>Thelymitra</i> spp.	Orchidaceae	Sun Orchids	Root tubers are eaten by aborigines	Cribb and Cribb (1987)

Scientific name	Family	Common/vernacular names	Edible part use	Reference
<i>Thilachium africanum</i> Scott-Elliot = <i>Thilachium panduriforme</i> (Lam.) Juss.	Capparaceae	Mutungu (Sandawe), Raa-Wa-Mburi (Kikuya), Mtungu (Kamba), Lolmugi (Samburu), Matanuyu (Masai)	In Tanzania (central), roots are boiled and eaten. In Kenya (Mbeere division, Embu district), after the root bark is removed, the cortex is pounded, soaked, strained and boiled for many hours and used as a porridge	Newman (1975), Kabuye (1986), and Riley and Brokensha (1988)
<i>Thysanotus banksii</i> R. Br.	Asparagaceae	Fringed Lily	Roots are eaten by aborigines	Low (1989)
<i>Thysanotus baueri</i> R. Br.	Asparagaceae	Malee Fringe-Lily	Slender tubers are eaten	Low (1989)

NF = Not Found

As in the preceding eight volumes, topics covered include taxonomy (botanical name and synonyms), common English and vernacular names, origin and distribution, agro-ecological requirements, edible plant part and uses, plant botany, nutritive and medicinal/pharmacological properties with up-to-date research findings, traditional medicinal uses, other non-edible uses and selected/cited references for further reading.

A corm or bulbotuber is defined as a short, vertical, swollen, underground plant stem that serves as a storage organ used by some plants to survive unfavourable adverse periods. It bears membranous or scaly leaves and buds. Some examples of plants with edible corms are found in *Amorphophallus* spp., *Colocasia esculenta* (taro), *Eleocharis dulcis* (Chinese water chestnut), *Sagittaria* spp. (arrowhead or wapato) and *Xanthosoma* spp. (cocoyam or tannia). Corms often give rise to many small secondary corms or cormlet called cormels at the end of very short stolons.

Rhizome is a modified subterranean stem of a plant that is usually found underground, producing roots and shoots. It is used by the plant as storage organ, and whole rhizome or pieces of the rhizome serve as vegetative propagules to give rise to new plants. Examples of plants with edible rhizomes include gingers (*Zingiber* spp.), turmeric (*Cucurma longa*), greater galangal (*Alpinia galanga*), lesser galangal (*Alpinia officinarum*), sand ginger or kencur (*Kaempferia galanga*), lotus root (*Nelumbo nucifera*), *Typha* spp., fingerroot (*Boesenbergia rotunda*) and arrowroot (*Maranta arundinacea*).

A stem tuber is a modified plant storage organ that is formed from thickened rhizome or stolon. The tops or sides of the tuber produce shoots that grow into typical stems and leaves and the undersides produce roots. The stem tuber has all the parts of a normal stem, including nodes (eyes) and internodes. A stem tuber may start off as an enlargement of the hypocotyls of the seedling and may include the

epicotyl or upper section of the root as is in the case of maca (*Lepidium meyenii*). More commonly as in *Plectranthus esculentus* in the Lamiaceae family, numerous tubers are formed on short stolons that arise from the base of the stem, or as in potatoes tubers are formed as enlarged stolons thickened and enlarged into storage organs. In some *Cyperus* species, e.g. tigernut or chufa (*C. esculentus*), the stolons end with the growth of tubers that can give rise to new plants. Other striking examples of plants with stem tubers include hog potato or groundnut (*Apios americana*), Jerusalem artichoke or sunchoke (*Helianthus tuberosus*), earthnut pea (*Lathyrus tuberosus*), oca or New Zealand yam (*Oxalis tuberosa*), Chinese artichoke or crosne (*Stachys affinis*), mashua or añu (*Tropaeolum tuberosum*) and ulluco (*Ullucus tuberosus*). In botany, a stolon is a horizontal modified stem arising from the base of a plant that produces new plants from buds at its tip or nodes and forms adventitious roots at the nodes; it can be creeping above the ground surface or underground. An example of a plant with edible stolon is *Imperata cylindrica*. However, some botanists used the term stolons for stem branches that arise from the base of the stem that creeps above the ground and those that creeps horizontally underground as rhizomes. An example of a plant with swollen, above-ground storage stem is the kohlrabi.

Taproot is the true main root of the plant, and in some species the taproot is modified and fleshy, rich in stored nutrients; they may or may not be fused with the hypocotyl or basal stem tissues and may be napiform, globose, conical, fusiform or cylindrical in shape. Notable examples of plants with edible taproots are *Abelmoschus* spp., beet (*Beta vulgaris*), rutabaga, turnip, *Bunium persicum*, burdock, carrot, radish and daikon, celeriac, jicama and ahipa (*Pachyrhizus* spp.), parsnips, parsley, skirret (*Sium sisarum*), bush potato (*Vigna lanceolata*), salsify (*Tragopogon porrifolius*), black salsify (*Scorzonera hispanica*), tongkat ali (*Eurycoma longifolia*) and many others. Notable examples of plants with edible root tubers or tuberous roots with enlarged root and lateral roots that function as storage organs, lacking nodes, internodes and adventitious buds include pignut or earthnut (*Conopodium majus*); sweet potato (*Ipomoea batatas*); desert yam (*Ipomoea costata*); cassava or yuca or manioc (*Manihot esculenta*); yams (*Dioscorea* spp.); mauka or chago (*Mirabilis expansa*); breadroot, tipsin or prairie turnip (*Psoralea esculenta*); and yacón (*Smallanthus sonchifolius*).

Bulb is a much reduced underground stem bearing at its apex a growing or floral primordium surrounded by thick, fleshy modified scale leaves or leaf bases that serve as food storage organs during dormancy and enable the plant to survive through adverse periods. The fleshy leaves are arranged in a concentric manner. Bulbs can be tunicate, i.e. with membranous papery covering (scale leaves), or tunic that protects

the inner fleshy scale leaves from drying and mechanical injury. Examples of tunicate bulbs are the *Allium* onions, leeks, hyacinth and tulips. In imbricate or non-tunicate bulbs, the fleshy scale leaves are not in concentric rings but are loosely arranged or spreading, overlapping one another at the margin. Such a bulb is not a compact body and not usually covered by a common tunic. Examples are the garlic (*Allium sativum*) and some *Lilium* lilies.

Origin/Distribution

Sagittaria trifolia is widespread from south European Russia to Japan and Malaysia as well as in several provinces of China and is indigenous to Afghanistan; Cambodia; China (Anhui, Beijing, Chongqing, Fujian, Gansu, Guangdong, Guangxi, Guizhou, Hainan, Hebei, Heilongjiang, Henan, Hubei, Hunan, Jiangsu, Jiangxi, Jilin, Liaoning, Nei Mongol, Ningxia, Qinghai, Shaanxi, Shandong, Shanghai, Shanxi, Sichuan, Tianjin, Xinjiang, Yunnan, Zhejiang); Hong Kong; India (Assam); Indonesia (Sulawesi, Sumatera); Iran, Islamic Republic of; Japan; Kazakhstan; Kyrgyzstan; Lao People's Democratic Republic; Macao; Malaysia; Myanmar; Nepal; Philippines; Russian Federation (Amur, Buryatiya, Chita, Khabarovsk, Krasnoyarsk); Taiwan, Province of China; Thailand; Turkmenistan; Uzbekistan; and Vietnam (Zhuang 2011).

Agroecology

Being an aquatic herb, it can be found growing in ponds, lakes, marshes, paddy fields and water channels. It prefers shallow, still or slowly flowing water up to 30–60 cm deep although it will grow in a moist or wet loamy soil in a sunny position. It grows best in warm weather and require at least a 6-month growing season in order to produce a crop and is fairly cold tolerant surviving temperatures down to at least -10°C , though the top growth is damaged once temperatures fall below zero.

Edible Plant Parts and Uses

The petioles and the starchy corms are cooked and eaten in Manipur and Southeast Asia. In Vietnam young petiole leaf and corms are used for soups (Tanaka and Nguyen 2007). The plant is cultivated in China and Japan for starch-containing corms which have been used in a variety of cooked and fresh dishes for centuries. The corms are eaten on its own after boiling, baking, cooking or roasting. The corms can also be dried and ground into a powder, and the powder can be used as gruel and porridge or be added to cereal flours and used in making bread. Young leaves are eaten as vegetables.

Botany

Aquatic, acaulescent, glabrous perennial herb (Plate 1) with fleshy rootstock giving rise to numerous thick, axillary stolons bearing somewhat subglobose corms (Plate 3) (tubers) 3–6 cm by 2–5 cm at the tips. Leaves in a radical rosette, mostly emerged, upright, up to 40 cm long by 15 cm wide, sagittate or somewhat hastate, blade ovate or linear-lanceolate, with acute, basal lobes triangular or linear-lanceolate, often longer than the blade, sharply acute (Plate 2); petiole 60–75 cm long, triangular. Inflorescence an unbranched scapose terminal raceme, 30–50 cm long. Flowers in 2–6 whorls of 3 flowers each, unisexual, 1–2 cm across, white; pedicels 8–15 mm long, staminate flowers above, pistillate ones below; sepals and petals 3, petals white, suborbicular, unguiculate, stamens 20 with yellow anthers. Fruit an oblate head, 1 cm diameter consisting of numerous triangularly obovate achenes 3–5 mm by 1.5–3 mm with laterally bent beak and subcrenate to entire wings.

Plate 2 Arrowhead leaf close-up

Plate 3 Arrowhead corms

Nutritive/Medicinal Properties

Proximate food value of the raw corm per 100 g edible portion was reported as energy 107 cal, moisture 70.6 %, protein 5 g, fat 0.3 g, total carbohydrate 22.4 g, fibre 0.9 g, ash 1.7 g, Ca 13 mg, P 165 mg, Fe 2.6 mg, K 729 mg, thiamine 0.16 mg, riboflavin 0.04 mg, niacin 1.4 mg and ascorbic acid 5 mg (Leung et al. 1972). The corm starch contained a high level of amylose (25.6 %) and 53 ppm of organic phosphorus and showed Ca X-ray diffraction pattern (Suzuki et al. 1993). Starch granules were oval, deformed sphere or potato tuber-like with about 15 µm in length on average. The number-average degree of polymerisation and apparent degree of polymerisation and distribution of amylose were 2,840, 7,080, and 570–21,300, respectively. The chain length (ratio of total carbohydrate/non-reducing residue) of amylose and amylopectin were 420 and 20.2, respectively. Arrowhead starch showed a little lower pasting temperature and higher breakdown than sweet potato starch. The retrogradation tendency of the aqueous paste showed also similar to that of sweet potato starch. Sugimoto et al. (2001) found that the amylose content of three cultivars of Chinese arrowhead tuber starches determined by amperometric iodotitrimetry were in a range of 28.2–29.9 % and 26.6–31.3 % by gel permeation chromatography of isoamylase-debranched starches. The starches had unique amylopectin short-chain length distributions of increased amounts of chains with DP (degree of polymerisation) 6 and 7 and decreased amounts of chains with DP 9 compared with waxy maize amylopectin. The X-ray diffractograms of the starches showed A-type patterns. Zhao et al. (2011) found that as *S. trifolia* corm enlarged to about 90 days, the sugar content increased to 28.05 mg/g (Zhao et al. 2011). Fructose and glucose also increased and then decreased. Total starch, amylose and amylopectin content increased, and changes of amylopectin/amylose ratio were always less than 1.

D-raffinose, D-stachyose, D-verbascose, D-fructose, D-galactose and glucose, asparagine and vitamin B were reported by Li (2008).

From *S. trifolia* tubers, four bioactive diterpene ketones, trifoliones A, B, C and D; two diterpene glucosides, sagittariosides a and b; and a nitroethylphenol glycoside, arabinothalictoside were isolated, together with six known diterpenes: isoabienol, 13-episclareol, *ent*-13-epimanoyl oxide (6-deoxyandalusol), *ent*-19-hydroxy-13-epimanoyl oxide, *ent*-kaur-16-en-19-ol and *ent*-kaur-16-en-19-oic acid (Yoshikawa et al. 1993, 1996). A terpenoid, sandaracopimaric acid was isolated from the methanol extract (Yuan et al. 1993). From the methanol extract of the plant ergosterol peroxide, icariside D₂, thalictoside and 4-nitrophenyl β-D-glucopyranoside were isolated (Kim et al. 1998). Seven new ent-rosane diterpenoids, sagittines A–G (1–7), together with one new labdane diterpene, 13-epimanoyl oxide-19-*O*-α-L-2',5'-diacetoxyarabinofuranoside (8), were isolated from the whole plant (Liu et al. 2006). Ten diterpenoids were isolated including new compounds sagittine H, sclareol and 19-β-L-3'-acetoxyarabinofuranosyl- *ent*-kaur-16-ene-19-oate (Liu et al. 2009).

Starch from the corm of *Sagittaria trifolia* L. var. *sinensis* Makino (arrowhead) contained 31.65 % of amylose and 0.0897 mg/g of phosphorus (Chang 1988). It had a gelatinization temperature range of 56.1–61.7–64.9 °C, a mixed type of Brabender viscosity pattern, a one-stage swelling pattern, 99.6 % water binding capacity, low solubility in dimethyl sulfoxide and high α-amylase susceptibility. The amylose was found to be a branched molecule of DP 2,202 and was hydrolyzed 86.6 % with β-amylase. Its amylopectin had an average chain length of 24.5 and was hydrolyzed 65.5 % with β-amylase.

Sagittariol a new diterpene was isolated from *S. sagittifolia* and characterised as labda-7,14-dien-13(*S*),17-diol (Sharma et al. 1975). Later, sagittariol was considered to be 17-hydroxymanool, as it possessed an A-B *cis* clerodane skeleton (Sharma et al. 1984).

Twenty-eight compounds were identified in the essential oil of *Sagittaria trifolia*; the major components were found hexahydrofanesyl acetone (62.3 %), tetramethylhexadecenone

(5.8 %), myristaldehyde (4.7 %), *n*-pentadecane (2.9 %) and 2-hexyldecanol (2.9 %) (Zheng et al. 2006). Other minor compounds were *n*-pentylfuran 0.3 %, *n*-decaldehyde 0.4 %, *n*-tetradecane 0.4 %, isocaryophyllene 0.9 %, longifolene 1.2 %, caryophyllene 0.8 %, *trans*-geranylacetone 0.7 %, methyl pentadecane (2.1 %), β -caryophyllene 0.6 %, dimethylundecenol 1.4 %, *n*-cetane 1.1 %, caryophyllene 0.9 %, tridecyl aldehyde 0.6 %, *n*-heptadecane 1.3 %, tetramethylpentadecane 0.6 %, myristic acid 2.1 %, *n*-octadecane 0.6 %, tetramethyl pentadecanol 0.8 %, 2-hexyl-1-decanol 1.2 %, *n*-nonadecane and phenanthrenol 0.8 %.

Diuretic Activity

The alcoholic extract of *S. sagittifolia* was reported to show diuretic activity (Sharma et al. 1975).

Immunomodulatory Activity

A terpenoid, sandaracopimaric acid isolated from the plant exhibited good immunosuppressive activity (Yaun et al. 1993). Several diterpenes trifoliones A, B, C and D exhibited inhibitory effects on the histamine release from rat mast cells induced by compound 48/80 or calcium ionophore A-23187 (Yoshikawa et al. 1993, 1996).

Antimicrobial Activity

The antimicrobial activity of the essential oil was evaluated against seven microorganisms. Studies showed that *S. trifolia* oil had a significant antimicrobial effect on several microorganisms (Zheng et al. 2006). This antimicrobial activity can partly explain why the oil is used medicinally during childbirth and for skin diseases in Chinese traditional medicine. Another study reported that four ent-rosane diterpenoids, sagittines A–D, isolated from the whole plant, exhibited antibacterial activity against the oral pathogens, *Streptococcus mutans* and *Actinomyces naeslundii*, with MIC values between 62.5 and 125 μ g/mL (Liu et al. 2006). Sagittine E was active against only *A. naeslundii*, with an

MIC value of 62.5 µg/mL. Sagittine H, a new *ent*-rosane glycoside, demonstrated antibacterial activity against *Streptococcus mutans* and *Actinomyces naeslundii*s with MIC of 62.5 µg/mL (Liu et al. 2009). The other diterpenoid, 19-β-L-3'-acetoxyarabinofuranosyl-*ent*-kaur-16-ene-19-oate, exhibited strong activity against *S. mutans* and *A. naeslundii*s with MIC of 15.6 µg/mL.

Proteinase Inhibitory Activity

Arrowhead was reported to contain double-headed and multifunctional proteinase inhibitors APIA and APIB consisting of 179 amino acid residues with three disulfide bonds (Yang et al. 1992; Xu et al. 1993; Luo et al. 1997). Earlier studies by Chi et al. (1985) found that APIB consisted of 141 amino acid residues; 20 pairs amino acid residues were repeated in the molecule of this inhibitor. Three of these pairs even occurred three times, suggesting that this arrowhead inhibitor may belong to a new family. Inhibitor APIA inhibited an equimolar amount of trypsin and chymotrypsin simultaneously and weakly inhibited kallikrein, while inhibitor APIB inhibited two molecules of trypsin simultaneously and inhibited kallikrein more strongly than did inhibitor APIA (Yang et al. 1992). Both inhibitors consisted of 150 amino acid residues with three disulfide bonds (Cys 43-Cys 89, Cys 110-Cys 119, and Cys 112-Cys 115) and share 90 % sequence identity, with 13 different residues. Both inhibitors were found having the same cDNA sequence and genomic structures. Though they share 91 % homology, they are different in inhibitory activities (Xie et al. 1997). Lys-44 and Arg-76 were found to be the reactive site of APIB and Ser-82 and Leu-87 for APIA. Studies by Li et al. (2002b) confirmed that Arg-76 and Arg-87 but not Lys-44 were definitely the reactive sites of APIB and Leu-87 in APIA. Subsequent studies by Li et al. (2002a) found that the inhibitory specificity of arrowhead protease inhibitors A and B (APIA and APIB) were modulated by conformation around tryptophan residues. Jiang et al. (2008) reported that arrowhead protease inhibitor A (API-A), a member of the serine protease inhibitor family, could inhibit two trypsin molecules simultaneously. Further studies by Bao

et al. (2009) found that the ternary structure revealed that the two trypsins bind on opposite sides of API-A and were 34 Å apart. The two P1 residues were unambiguously assigned as Leu(87) and Lys(145), and their identities were further confirmed by site-directed mutagenesis.

Traditional Medicinal Uses

The plant is antiscorbutic, laxative, tonic and diuretic. The leaf is used to treat a range of skin problems (Duke and Ayensu 1985). The tuber is regarded as discutient and galactagogue and may induce premature birth. *S. trifolia* essential oil is used medicinally during childbirth and for skin diseases in Chinese traditional medicine (Zheng et al. 2006). In Vietnam, the plant is used to treat dizziness or to apply on pimples (Tanaka and Nguyen 2007).

Other Uses

Aerial parts of Chinese arrowhead are fed to cattle in parts of India and Southeast Asia and also to pigs.

Comments

Most specimens determined as *Sagittaria sagittifolia* are, in fact, this taxon (Wang et al. [2010](#)).

Origin/Distribution

Allium ampeloprasum sensu lato consist of a cohort of wild ecotypes and cultivated plants, originating from an area extending from Iran to Portugal and Northern Africa. Bulbous leek has been long cultivated by ancient Egyptians, Greeks and Romans. Bulbous and non-bulbous leek is cultivated nowadays on all continents throughout the world. Leek is cultivated in many European countries, especially in Western Europe, and in North America and Australia, more seldom elsewhere in the world.

Agroecology

In its native range, leek (Plate 1) occurs in open disturbed areas and roadsides. Its optimum temperature range is 20–30 °C with night temperature of 22 °C and day temperature of 30 °C. A cool season of at least 4 months is needed for good growth of leek. Leek is cultivated in the higher altitude above 1,000 m in the tropics. Leek cultivation in hot humid lowlands below 500 m is rarely successful. It grows on any soil types but does best in friable, deep, well-drained soils rich in organic matter and with pH above 5.6.

Plate 1 Leek plant in situ

Weibe (1994) found that leek may have an obligatory vernalisation requirement, whereas the effects of day length were quantitative only. Optimum vernalisation temperature was determined at 5 °C and the inductive temperature ranging

between 0 and 18 °C. Temperatures above 18 °C caused devernalisation, and bolting was promoted by short days during and long days after vernalisation.

Edible Plant Parts and Uses

The non-bulbous (Plate 2) and bulbous (Plate 3) pseudostem and lower blades of foliage leaves and the green leaves are consumed as vegetables. They can be used sliced and eaten raw in salads or as flavouring or pickled but are usually cooked in soups or stir-fried. In Asia, leek is usually eaten cooked in soups or with noodles or stir-fried with meat or seafood. The flowers are also edible but are seldom produced. Leeks are an ingredient of cock-a-leekie soup, leek and potato soup and *vichyssoise*, as well as plain leek soup. One of the most popular uses is for adding flavour to stock. The dark green portion is usually discarded because it has a tough texture, but it can be sautéed or added to stock. Leeks are much relished in Turkish cuisine. Some popular dishes are *Zeytinyağlı pırasa* (leek with olive oil), *Ekşili pırasa* (sour leek), *Etli pırasa* (leek with meat), *Pırasa Musakka* (leek musakka), *Pırasalı börek* (börek with leek) and *Pırasa köftesi* (cooked leek meatball). The bulbils have a mild garlic flavour and make a nice flavouring in salads and cooked foods but are too fiddly to use because of their small size. Leeks are also extensively used in Welsh cuisine.

Plate 2 Leeks with swollen non-bulbous pseudostem

Plate 3 Leek with bulbous pseudostem

Allium porrum has been widely used in Persian foods as a flavour component (Movahedian et al. 2006). Persian leek is commonly used in soups, pottage and hash (Rojhan 1981). Fermentation of leek afforded opportunities in view of biomass valorisation and product diversification (Wouters et al. 2013). A preliminary sensory analysis revealed that the spontaneously fermented leek and the one obtained with the mixed starter culture were preferred by consumers, emphasising again the importance of microbial successions in vegetable fermentations. The mixed starter culture of *Lactobacillus plantarum* IMDO 788 and *Lactobacillus mesenteroides* IMDO 1,347 was most promising, as its application resulted in fermented leek of good microbiological quality and in a more extensive carbohydrate consumption, whereby diverse end metabolites were produced.

Botany

A biennial, robust, odorous, erect herb growing to 60–100 cm high (Plates 1 and 5). The true stem consisting only of a basal plate or disc, with little or no bulb formation (Plate 2) or with bulbs producing two kinds of cloves, small stiped ones and larger sessile ones, and with adventitious roots (Plate 4). The bulb is solitary, cylindrical ovoid to subglobose (Plate 3), sometimes bearing bulbels; covered by a white, membranous entire coat. Leaves 6–9, distichously alternate; sheath tubular, forming a pseudostem up to 60 cm long; blade linear to linear-lanceolate, flat, up to 50 cm × 7 cm, keeled, V-shaped in cross-section. Inflorescence a globose umbel, 4–12 cm across, compact, consisting of several hundreds of flowers (Plate 6), on a solid, terete scape up to 100 cm long; umbel subtended by a single, long-beaked spathe shed at flowering. Flowers bisexual, campanulate; pedicel 1–5 cm long; tepals 6, in 2 whorls, free, ovate-oblong, 4–6 mm long, pink, purple or white; stamens 6, the inner ones tricuspid; ovary ovoid-globose, superior, 3 celled with transversely convex nectaries near middle of septa. Linear style exerted with capitate stigma. Fruit a depressed globose to ovoid capsule 2–4 mm across, with up to six seeds. Seeds small, 2–3 mm × 2 mm, black.

Plate 6 Leek inflorescence

Nutritive/Medicinal Properties

The nutrient composition of raw leek bulb and lower leaf portion per 100 g edible portion minus the top, root ends and skin (USDA-ARS 2014) was reported as: water 83 g, energy kcal 61 (255 kJ), protein 1.50 g, total fat 0.30 g, ash 1.05 g, carbohydrate 14.15 g, total dietary fibre 1.8 g, total sugars 3.90 g, Ca 59 mg, Fe 2.10 mg, Mg 28 mg, P 35 mg, K 180 mg, Na 20 mg, Zn 0.12 mg, Cu 0.120 mg, Mn 0.481 mg, Se 1.0 µg, vitamin C 12 mg, thiamine 0.060 mg, riboflavin 0.030 mg, niacin 0.400 mg, pantothenic acid, 0.140 mg, vitamin B6 0.233 mg, folate 64 µg, choline 9.5 mg, β-carotene 1,000 µg, lutein + zeaxanthin 1,900 µg, vitamin A 1,667 IU, vitamin A 83 µg RAE, total vitamin E (α-tocopherol) 0.92 mg and vitamin K (phylloquinone) 47.0 µg; total saturated fatty acids 0.040 g, 16:0 (palmitic acid) 0.038 g and 18:0 (stearic acid) 0.002 g; total monounsaturated fatty acids 0.004 g, 18:1 undifferentiated (oleic acid) 0.004 g; total polyunsaturated fatty acids 0.166 g, 18:2 undifferentiated (linoleic acid) 0.067 g and 18:3 undifferentiated (linolenic acid) 0.099 g; and tryptophan 0.012 g, threonine 0.063 g, isoleucine 0.052 g, leucine 0.096 g, lysine 0.078 g, methionine 0.018 g, cystine 0.025 g, phenylalanine 0.055 g, tyrosine 0.041 g, valine 0.056 g, arginine 0.078 g, histidine 0.025 g, alanine 0.074 g, aspartic acid 0.140 g, glutamic acid 0.226 g, glycine 0.069 g, proline 0.066 g and serine 0.092 g. Eighty per cent of the total lipids of *Allium cepa*, *Allium sativum* and *Allium porrum* were found to consist of four fatty acids: linoleic (46–53 %), palmitic (20–23 %), oleic (4–13 %) and α-linolenic acid (3–7 %) (Tsiaganis et al. 2006). In leek, 50 fatty acids were determined, 12 of that above 0.4 % and 4 above 2.5 %. Phospholipids consisted of a limited number of specific fatty acids, while neutral lipids contained a wide range including some unusual fatty acids.

Green leaves of leek mainly contained kaempferol glycosides, predominated by mono- and diglycosides such as kaempferol-3-β-D-glucoside and kaempferol-3-xylosyl-β-D-glucoside (Starke and Herrmann 1976). In leek glucose was dominant as sugar component compared to xylose. Traces of

quercetin-3-glucoside were identified, but no spiraeoside (quercetin-4'-glucoside) was detected. Leek bulb only few milligramme of glycosides of kaempferol and quercetin per kg fresh weight. Flavonols kaempferol 2.7 mg, myricetin 0.2 mg and quercetin 0 mg were found in leeks (Hertog et al. 1992; Lugasi and Hovari 2000; Keveres et al. 2007). Five flavonoid glycosides based on the kaempferol aglycone were isolated from leek bulbs, and two of them were new compounds and identified as kaempferol 3-*O*-[2-*O*-(*trans*-3-methoxy-4-hydroxycinnamoyl)- β -D-galactopyranosyl]-(1 $\rightarrow$ 4)-*O*- β -D-glucopyranoside and kaempferol 3-*O*-[2-*O*-(*trans*-3-methoxy-4-hydroxycinnamoyl)- β -D-glucopyranosyl]-(1 $\rightarrow$ 6)-*O*- β -D-glucopyranoside (Fattorusso et al. 2001). A set of secondary metabolites was identified from the aerial part of *Allium porrum*: mono-hexose, dihexose and coumaroyl, feruloyl and caffeoyl acylated dihexose derivatives of kaempferol (Donna et al. 2014). The total concentration of carbohydrates (glucose, fructose, kestose/nystose and sucrose) and nine amino acids (glutamine, arginine, alanine, threonine, valine, leucine, lysine, phenylalanine, tyrosine) varied by fourfold in leek juice from different cultivars, while the total concentrations of four organic acids (pyruvic acid, malic acid, fumaric acid, α -hydroxybutyrate) were similar in all cultivars (Soininen et al. 2014). All the quantified flavonols were kaempferol derivatives or quercetin derivatives; the most abundant were kaempferol derivatives (including kaempferol hexose, kaempferol dihexose, kaempferol trihexose), but quercetin-malonyl-dihexose, kaempferol-malonyl-dihexose 1 and 2 and kaempferol-malonyl-hexose were also detected.

Fructans were the only nonstructural carbohydrates detected apart from glucose, fructose and sucrose in *A. porrum* (Darbyshire and Henry 1981). The maximum DP (degree of polymerisation) detected was 12. No starch or members of the raffinose series of oligosaccharides were detected. The trisaccharides, 1^F-fructosylsucrose and 6^G-fructosylsucrose were also detected. Fructan-type oligosaccharide (FTO) 3–10 g/100 g FW was found in leek bulb and the chain length distribution in comprised, DP (degree of polymerisation) 3–5 = 50 %, 6–12 DP = 50 % (Muir et al. 2007; Judprasong et al.

2011). Leek contained large amounts of FTO with DP ranging from 3 to 12 (up to 10 % FW) and a fructan profile similar to onions. The four FTO series, namely, 1-kestose type, an inulin series with the general formula $G-1, 2 \rightarrow 1, n(2 \rightarrow F-1)$, 2-F(G-1, 2-F = sucrose); 6-kestose type, a neokestose-based series with chain elongation only at the glucose end of the original sucrose molecule F-2_m (1-F-2), 1-F-2, 6-G-1, 2-F; mixed type a neokestose-based series with elongation from both sides of the sucrose F-2_m (1-F-2), 1-F-2, 6-G-1, 2-F-1, $n(2-F-1)$, 2-F; and neoseries, an inulo-*n*-ose series without a terminal glucose F-1, (2-F-1)_n, 2-F were present in leek although neoseries were dominant (Ernst et al. 1998).

Total concentrations of S-alk(en)yl-L-cysteine sulfoxide (ACSO), namely, methyl cysteine sulfoxide (MCSO), 2-propenyl cysteine sulfoxide (2-PeCSO), 1-propenyl cysteine sulfoxide (1-PeCSO) and propyl cysteine sulfoxide (PCSO), in leek pseudostems, roots and leaves were 0.31, 0.39 and 0.36, respectively (Hovius et al. 2005). The most abundant ACSO in leek tissues was 1-PeCSO and MCSO. The concentration of 1-PeCSO in leek pseudostems, roots and leaves was 0.14, 0.10 and 0.14, respectively. Fritsch and Keusgen (2006) found that pearl onion and leek (*A. ampeloprasum*) had higher relative amounts of cysteine sulfoxides methiin and propiin, respectively. The content of S-alk(en)ylcysteine-S-oxides in *Allium* species (leek, garlic and onion) varied between 0.59 and 12.3 mg/g fresh weight (Kubec and Dadáková 2008). Whereas alliin was found only in garlic, isoalliin was the major S-alk(en)ylcysteine-S-oxide in onion, leek, chive and shallot. A detailed analysis of leek cultivar “Tadorna” leaves showed that total S-alk(en)yl-L-cysteine sulfoxides (RCSOs) concentrations decreased acropetally (Doran et al. 2007). Profiles were composed of (±)-methyl-L-cysteine sulfoxide, (±)-ethyl-L-cysteine sulfoxide, (+)-propyl-L-cysteine sulfoxide and (+)-1-propenyl-L-cysteine sulfoxide (MCSO, ECSO, PCSO and 1-PeCSO, respectively). (+)-PCSO was the most prominent in green (2.4 mg/g FW), yellow (5.5 mg/g FW) and white (3.8 mg/g FW) tissues. The prop(en)yl-L-cysteine sulfoxide derivatives were dominant in tissues that had photosynthetic capacity. The (+)-MCSO levels were high in

the bulb (3.6 mg/g FW). Detectable levels of (±)-ECSO were determined in the leaves (approximately 0.5 mg/g FW). RCSO profiles of the different tissue regions were similar, but more (+)-PCSO and (+)-1-PeCSO were detected in the bulb. In general, mature upper leaf tissues had lower levels of total RCSOs. A detailed analysis of leek cultivar “Tadorna” leaves showed that total S-alk(en)yl-L-cysteine sulfoxides (RCSOs) concentrations decreased acropetally (Doran et al. 2007).

Profiles were composed of (±)-methyl-L-cysteine sulfoxide, (±)-ethyl-L-cysteine sulfoxide, (+)-propyl-L-cysteine sulfoxide and (+)-1-propenyl-L-cysteine sulfoxide (MCSO, ECSO, PCSO, and 1-PeCSO respectively). (+)-PCSO was the most prominent in green (2.4 mg/g FW), yellow (5.5 mg/g FW) and white (3.8 mg/g FW) tissues. The prop(en)yl-L-cysteine sulfoxide derivatives were dominant in tissues that had photosynthetic capacity. The (+)-MCSO levels were high in the bulb (3.6 mg/g FW). Detectable levels of (±)-ECSO were determined in the leaves (approximately 0.5 mg/g FW). RCSO profiles of the different tissue regions were similar, but more (+)-PCSO and (+)-1-PeCSO were detected in the bulb. In general, mature upper leaf tissues had lower levels of total RCSOs. The phenolic compounds (mg/kg DW) found in fresh, cut green leek leaves in order of importance were kaempferol 3-*O*-glucoside 31.92 mg, ferulic acid 27.07 mg, quercetin 3-*O*-galactoside 21.73 mg, sinapinic acid 3.76 mg, quercetin 2.67 mg, propyl gallate 2.09 mg, caffeic acid 0.93 mg, kaempferol 0.85 mg and luteolin 0.74 mg (Bernaert et al. 2013a).

Fermentation of the green leek leaves increased the number and amount of several phenolic compounds. The phenolic compounds (mg/kg DW) found in green leek leaves after 21 days fermentation in order of importance were kaempferol 3-*O*-glucoside 50.25 mg, ferulic acid 37.70 mg, quercetin 3-*O*-galactoside 22.56 mg, hydroferulic acid 37.70 mg, quercetin 2.71 mg, propyl gallate 2.10 mg, quercetin 3-*O*-rutinoside 1.60 mg, caffeic acid 0.83 mg, kaempferol 0.79 mg, luteolin 0.84 mg, dihydroquercetin 0.73 mg, quercetin 3-*O*-arabinoside 0.55 mg and naringenin 0.23 mg, and sinapinic acid was not detected. The phenolic compounds (mg/kg DW) found in fresh, cut white shaft of leek in order of importance were ferulic acid 29.71 mg, quercetin 3-*O*-galactoside 23.23 mg,

kaempferol 3-*O*-glucoside 3.50 mg, quercetin 2.63 mg, propyl gallate 2.11 mg, caffeic acid 1.03 mg, kaempferol 0.77 mg, luteolin 0.71 mg and naringenin 0.16 mg, and sinapinic acid, hydroferulic acid, quercetin 3-*O*-arabinoside, quercetin 3-*O*-rutinoside and dihydroquercetin were not detected. The phenolic compounds (mg/kg DW) found in leek white shaft after 21 days fermentation in order of importance were ferulic acid 45.05 mg, quercetin 3-*O*-galactoside 22.99 mg, hydroferulic acid 20.79 mg, kaempferol 3-*O*-glucoside 7.47 mg, quercetin 2.62 mg, propyl gallate 2.07 mg, caffeic acid 0.83 mg, kaempferol 0.71 mg, luteolin 0.71 mg and naringenin 0.23 mg, and sinapinic acid, quercetin 3-*O*-arabinoside, quercetin 3-*O*-rutinoside and dihydroquercetin were not detected. Tamping was responsible for great losses in polyphenol content. Total phenolic content in the green leaves at the end of fermentation was significantly higher compared with tamped samples. The contents of ferulic acid, astragalin and luteolin increased significantly by 39 %, 57 % and 13 %, respectively, after leek fermentation process for 3 weeks. Compared with initial concentration, the tamping process also caused a significant decline in methiin and isoalliin contents of green leaves (62 and 32 %, respectively) and a decrease of 48 % and 32 %, respectively, in the white shaft. Three weeks of fermentation caused a decrease of 93 % of methiin and 100 % of isoalliin in the green leaves compared with fresh samples, while a reduction of 91 % of methiin and 100 % of isoalliin was found in the white shaft. White shaft is used in many culinary preparations, while the leaves deemed inferior are used for soups. Leek cultivar and tissue had an effect on the S-alk(en)yl-L-cysteine sulfoxides, i.e. isoalliin and methiin amounts (Bernaert et al. [2012b](#)). Cultivars Artico and Apollo F1 rated highest for the mean isoalliin and methiin concentration, respectively. The isoalliin concentration of the white shaft and green leaves of the 31 leek cultivars varied from 15 to 53 mg/g dry weight (DW) and from 9 to 45 mg/g DW, respectively, whereas the methiin concentration varied from 3 to 16 mg/g DW and from 1 to 10 mg/g DW, respectively.

Apocarotenoids made up of cyclohexenone derivatives of mono- and diglycosides of 13-hydroxyblumenol C and

blumenol C acylated with 3-hydroxy-3-methyl-glutaric and/or malonic acid that accumulated in the mycorrhizal roots of leek were: 13-hydroxyblumenol C-di-9,13-*O*- β -glucopyranoside; 13-hydroxyblumenol C-9-*O*- β -glucopyranoside; 13-hydroxyblumenol C-9-*O*-[3'-*O*-(3''-hydroxy-3''-methylglutaryl)- β -glucopyranoside], 13-hydroxyblumenol C derivative; mixture of 13-hydroxyblumenol C and blumenol C derivatives; blumenol C 9-*O*-(6'-*O*- α -arabinopyransoyl- β -glucopyranoside); blumenol C 9-*O*-(4'-*O*-glucosyl- β -glucopyranoside); 13-hydroxyblumenol C 9-*O*-[3'-(3''-hydroxy-3''-methylglutaryl)-6'-*O*-malonyl- β -glucopyranoside]; blumenol C 9-*O*-[3'-(3''-hydroxy-3''-methylglutaryl)- β -glucopyranoside]; blumenol C 9-*O*-(6'-*O*-malonyl- β -glucopyranoside); and isomer of blumenol C 9-*O*-[3'-(3''-hydroxy-3''-methylglutaryl)- β -glucopyranoside (Schliemann et al. 2008). The content of mycorradicin derivatives remained low in the roots. Antifungal *N*-feruloyl amides *N*-feruloyltyrosine and *N*-feruloyl-tyramine were isolated from *A. porrum* roots (Fattorusso et al. 1999). A cinnamic imide (1*Z*,2*E*)-methyl 3-(-*p*-hydroxy-*m*-methoxyphenyl)-*N*-(-*p*-hydroxyphenethyl) acrylimide, named persicoimide, and two cinnamic acid derivatives, *N*-feruloyl tyramine and *N*-caffeoyl tyramine, were isolated and characterised from bulbs and seeds of Persian leek, *Allium ampeloprasum* subsp. *persicum* (Sadeghi et al. 2013a).

Non-fertilised leek contained 20.4 g/kg of dry weight (DW) of *S*-alk(en)yl-L-cysteine sulfoxides (ACSOs) and 1.57 g/kg of DW ascorbic acid (Lundegårdh et al. 2008). The ACSOs comprised 92–96 % isoalliin, the rest being methiin. Alliin was identified in only 1 of 72 samples. The ACSO level was increased by 37 % by the mineral fertiliser. Whereas direct incorporation of red clover, mulch and red clover biodigestate had no influence on the ACSO level, the highest dose of compost increased the ACSO level by 55 %. Ascorbic acid levels were not influenced by the mineral treatment. Green manures increased ascorbic acid levels only on a dry weight basis. A high correlation between the content of sulfur and ACSO indicated that delivering capacity of sulfur from the

manure to the plant strongly affected the ASCO content of the leek.

Allium species including *A. ampeloprasum* were reported to produce asymmetric aliphatic disulfides: methyl-allyl, methyl-*n*-propyl and allyl-*n* propyl disulfides (Jacobsen et al. 1964). Studies by Bernhard et al. (1964) confirmed that *Allium ampeloprasum* and *A. sativum* produced allyl monosulfide and allyl alcohol. A volatile compound 3, 4-dimethyl-2, 5-dioxo-2, 5-dihydrothiophene was identified in leek (Albrand et al. 1980). When crushed, the leek emitted propyl propanethiosulfinate (Auger et al. 1989). Propyl propanethiosulfmate was found to be the most attractive substance for the leek moth *Acrolepiopsis assectella* but appeared to be repulsive on *Ephestia kuehniella*. Pearl onion and leek (*A. ampeloprasum*) were reported to have higher relative amounts of methiin and propiin, respectively (Fritsch and Keusgen 2006).

The potent odorant 3-mercapto-2-methylpentan-1-ol was detected in Leek (Granvogl et al. 2004). Studies by Ferary et al. (1996) found that *A. porrum* odours contained only thiopropanal *S*-oxide and thiosulfinates as sulfur volatiles. The contents of sulfides from jumbo leek (*Allium ampeloprasum*) were dimethyl disulfide (1.7 mg/kg wet wt), methyl propenyl disulfide (15.7 mg/kg), propyl propenyl disulfide (7.5 mg/kg), dimethyl trisulfide 21.5 mg/kg), methyl propyl trisulfide (10.0 mg/kg) and methyl propenyl trisulfide (14.0 mg/kg) (Uchida et al. 2009a). The composition of alk(en)yl-cysteine sulfoxide from jumbo leek was *S*-methyl cysteine sulfoxide (4.1 mg/kg wet wt), *S*-propyl cysteine sulfoxide (0.1 mg/kg) and *S*-propenyl cysteine sulfoxide (2.44 mg/kg). The total content was the same as those of *A. cepa* L. and *A. ampeloprasum* L. Moreover, *N*-(γ -glutamyl)-*S*-(*E*-1-propenyl) cysteine (Glu-PEC, 87 mg/kg wet wt), an alk(en)yl-cysteine precursor from jumbo leek, was also detected. The lower odour producing mechanism in jumbo leek was determined to be the same as that in broadleaf wild leek (*A. ampeloprasum*); the substrate precursor Glu-PEC was converted to *S*-*E*-1-propenyl cysteine by γ -glutamyl transpeptidase. Then, *S*-*E*-1-propenyl cysteine was oxidised to *S*-propenyl cysteine sulfoxide, a substrate for

alliinase. *S*-propenyl cysteine sulfoxide, another naturally present alk(en)yl-cysteine sulfoxide, was converted to *S*-alk(en)yl acid by alliinase(C-S lyase), followed by sulfide production via formation of the dialkyl thiosulfinates. The essential oils of *A. porrum* were characterised by the presence of dipropyl disulfide, dipropyl trisulfide and dipropyl tetrasulfide (Casella et al. 2013).

The steroid saponins oleanolic acid and gitogenin were found in leek (Smoczkievicz et al. 1982). From *Allium ampeloprasum* bulbs, a new spirostane-type saponin, named ampeloside Bs₁, and two new furostane-type saponins, named ampeloside-Bf₁ and ampelosid-Bf₂, were isolated along with a known spirostane-type saponin, the prosapogenin of aginoside (Morita et al. 1988). The structures of the new saponins were established as agigenin 3-*O*-β-glucopyranosyl(1→3)-β-glucopyranosyl(1→4)-β-galactopyranoside, (25*R*)-26-*O*-β-glucopyranosyl-22-hydroxy-5α-furostane-2α, 3β, 6β, 26-tetraol-3-*O*-β-glucopyranosyl(1→3)-β-glucopyranosyl-(1→4)-β-galactopyranoside and (25*R*)-26-*O*-β-glucopyranosyl-22-hydroxy-5α-furostane-2α, 3β, 6β, 26-tetraol-3-*O*-β-glucopyranosyl(1→4)-β-galactopyranoside, respectively.

Steroid glycosides found in leek included: aginoside, a diosgenin glycoside C₃₉ H₆₄ O₁₅, ampeloside B_{S1}, ampelosideB_{f1} and ampeloside B_{f2} (Kravets et al. 1990). Four sapogenins, porrigenins A and B, identified as (25*R*)-5α-spirostan-2β,3β,6β-triol and (25*R*)-2-oxo-5α-spirostan-3β,6β-diol, respectively, and neoporrigenins A and B were also isolated from *Allium porrum* (Carotenuto et al. 1997b). Additionally, the known agigenin and its 25S epimer, neoagigenin, were also identified. Two other sapogenins, 12-keto-porrigenin (1a) and 2,3-seco-porrigenin (2a), isolated from the organic leek extract were identified as (25*R*)-5α-spirostan-3β, 6β-diol-12-one (1a) and (25*R*)-5α-2,3-secospirostan-2,3-dioic acid-6β-hydroxy-3,6-γ-lactone (2a) (Carotenuto et al. 1997a). Small amounts of the 25S epimers of both sapogenins were also found in the extract. Carotenuto et al. (1999) isolated four spirostanol saponins from leek bulbs; two of them were new compounds and were identified

as (25*R*)-5 α -spirostan-3 β ,6 β -diol 3-*O*-{*O*- β -D-GLUCOPYRANOSYL-(1 $\rightarrow$ 2)-*O*-[β -D-xylopyranosyl-(1 $\rightarrow$ 3)]-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 4)- β -D-galactopyranoside} and (25*R*)-5 α -spirostan-3 β ,6 β -diol 3-*O*-{*O*- β -D-GLUCOPYRANOSYL-(1 $\rightarrow$ 3)-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 2)-*O*-[β -D-xylo pyranosyl-(1 $\rightarrow$ 3)]-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 4)- β -D-galactopyranoside}, a steroidal saponin isolated previously by Minaki et al. (1995) and F-gitonin isolated previously by Kawasaki et al. (1965). Three new steroidal saponins named yayoisaponins A–C were obtained together with the known dioscin and aginoside from elephant garlic (Sata et al. 1998). The structure of yayoisaponin A was determined as 3-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 3)- β -D-glucopyranosyl-(1 $\rightarrow$ 2)-[β -D-xylopyranosyl-(1 $\rightarrow$ 3)]- β -D-glucopyranosyl-(1 $\rightarrow$ 4)- β -D-galactopyranoside; yayoisaponin B as porrigenin B 3-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 3)- β -D-glucopyranosyl-(1 $\rightarrow$ 2)-[β -D-xylopyranosyl-(1 $\rightarrow$ 3)]- β -D-glucopyranosyl-(1 $\rightarrow$ 4)- β -D-galactopyranoside; and yayoisaponin C as agigenin 3-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 2)-[β -D-glucopyranosyl-(1 $\rightarrow$ 3)]- β -D-glucopyranosyl-(1 $\rightarrow$ 4)- β -D-galactopyranoside. A novel sapogenin named porrigenin C and its 25*S* epimer were isolated from leek, together with the previously described sapogenins and the known compounds agigenin, diosgenin, β -chlorogenin and 24-ethylcholesta-(6-acyl)-3-*O*- β -D-glucoside (Fattorusso et al. 1998). Eight saponins (1–8) were isolated from leek bulbs, four of them (5–8) being novel compounds (Fattorusso et al. 2000). Compounds 5 and 6, possessing the same tetrasaccharide moiety of compounds 1 and 3, displayed very unusual spirostane aglycones, 12-keto-porrigenin and 2,12-diketoporrigenin (named porrigenin C), respectively. Compounds 7 and 8 were rare cholestane bidesmosides possessing a di- and trisaccharide residues linked to a polyhydroxycholesterol aglycone, respectively. Compound 7 was (22*S*)-cholest-5-ene-1 β ,3 β ,16 β ,22-tetrol 1-*O*- α -L-rhamnopyranosyl 16-*O*- β -D-glucopyranoside. Seven steroidal saponins were isolated from *A. ampeloprasum* bulbs (25*R*)-5 α -spirost-5-en-3 β -ol (diosgenin); *O*- α -L-rhamnopyranosyl-(1 $\rightarrow$ 4)- β -D-glucopyranoside (dioscin), (25*R*)-5 α -spirostane-2 α ,3 β ,6 β -triol (agigenin), 3-*O*-{*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 2)-*O*-[β -D-xylopyransoyl-(1 $\rightarrow$ 3)]-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 4)-

β -D-galactopyranoside} (aginoside), agigenin 3-*O*-{*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 2)-*O*-[β -D-xyloglucopyransoyl-(1 $\rightarrow$ 3)]-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 4)- β -D-galactopyranoside} (yayoisaponin C), (25*R*)-26-*O*- β -D-glucopyranosyl-22-*O*-methyl-5 α -furostane-2 α ,3 β ,6 β , 22 α ,26-pentol 3-*O*-{*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 2)-*O*-[β -D-xylopyranosyl-(1 $\rightarrow$ 3)]-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 4)- β -D-galactopyranoside and (25*R*)-26-*O*- β -D-glucopyranosyl-22-*O*-methyl-5 α -furostane-3 β ,6 β , 22 α ,26-tetrol 3-*O*-{*O*- β -D-GLUCOPYRANOSYL-(1 $\rightarrow$ 2)-*O*-[β -D-xylopyranosyl-(1 $\rightarrow$ 3)]-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 4)- β -D-galactopyranoside (Mimaki et al. 1999). From the freeze-dried whole-bulb powder of jumbo leek, the known steroid saponin, karatavioside A was isolated (Uchida et al. 2009b).

Steroidal saponins with the following structures (3 β ,5 α ,6 β ,25*R*)-6-[(β -D-glucopyranosyl)oxy]-spirostan-3-yl *O*- β -D-glucopyranosyl-(1 $\rightarrow$ 2)-*O*-[β -D-glucopyranosyl-(1 $\rightarrow$ 3)]- β -D-galactopyranoside and 3-[(*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 3))- β -D-glucopyranosyl-(1 $\rightarrow$ 2)-*O*-[*O*- β -D-GLUCOPYRANOSYL-(1 $\rightarrow$ 3)]-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 4)- β -D-galactopyranosyl)oxy]-2,6-dihydroxy-(2 α ,3 β ,5 α ,6 β ,25*R*)-spirostane were isolated from the bulbs of *Allium ampeloprasum* var. *porrum* (Adão et al. 2011a, b). A new steroidal saponin was isolated from leek bulbs and its structure determined as (3 β ,5 α ,6 β ,25*R*)-3-{(*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 3))- β -D-glucopyranosyl-(1 $\rightarrow$ 2)-*O*-[*O*- β -D-GLUCOPYRANOSYL-(1 $\rightarrow$ 3)]-*O*- β -D-glucopyranosyl-(1 $\rightarrow$)- β -D-galactopyranosyl)oxy}-6-hydroxyspirostan-2-one (Adão et al. 2012).

Two new spirostane glycosides, persicosides A (1) and B (2); four new furostane glycosides, isolated as a couple of inseparable mixture, persicosides C1/C2 (3a/3b) and D1/D2 (4a/4b); and one cholestane glycoside, persicoside E (5), together with the furostane glycosides ceposides A1/A2 and C1/C2, tropeosides A1/A2 and B1/B2 and ascalonicoside A1/A2 were isolated from seeds of Persian leek *Allium ampeloprasum* subsp. *persicum* (Sadeghi et al. 2013b). The chemical structure of new compounds were identified as (25*S*)-spirostan-2 α ,3 β ,6 β -triol 3-*O*-[β -D-glucopyranosyl-(1 $\rightarrow$ 3)] [β -D-xylopyranosyl-(1 $\rightarrow$ 2)]- β -D-glucopyranosyl-(1 $\rightarrow$ 4)- β -D-galactopyranoside (1), (25*S*)-spirostan-2 α ,3 β ,6 β -

triol 3-*O*-[β -D-xylopyranosyl-(1 $\rightarrow$ 3)] [α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)]- β -D-glucopyranosyl-(1 $\rightarrow$ 4)-*O*- β -D-GALACTOPYRANOSIDE (2), furosta-1 β ,3 β ,22 ξ ,26-tetraol 5-en 1-*O*- β -D-glucopyranosyl (1 $\rightarrow$ 3)- β -D-glucopyranosyl (1 $\rightarrow$ 2)- β -D-galactopyranosyl 26-*O*- α -L-rhamnopyranosyl (1 $\rightarrow$ 2)- β -D-galactopyranoside (3a,3b), furosta-2 α ,3 β ,22 ξ ,26-tetraol 3-*O*- β -D-glucopyranosyl (1 $\rightarrow$ 3)- β -D-glucopyranosyl (1 $\rightarrow$ 2)- β -D-galactopyranosyl 26-*O*- β -D-glucopyranoside (4a,4b) and (22*S*)-cholesta-1 β ,3 β ,16 β ,22 β -tetraol 5-en 1-*O*- α -L-rhamnopyranosyl 16-*O*- α -L-rhamnopyranosyl (1 $\rightarrow$ 2)- β -D-galactopyranoside (5).

According to Block (1992), most of the nonprotein sulfur in *Alliums* could be found in the form of four principal ACSOs: methyl (MeCSO), 2-propenyl (2-PeCSO), 1-propenyl (1-PeCSO) and propenyl (PCSO). 1-PeCSO was found in the highest concentration in onions, and 2-PeCSO was found in the highest concentrations in garlic with only trace amounts in onions. Among three common *Allium* crops, the total ACSO concentration was generally highest in garlic, intermediate in onion and lowest in leek (Block 1992; Coley-Smith 1986). Of eight *Allium* species, garlic and giant garlic contained greatest amounts of total S-alk(en)yl-L-cysteine sulfoxides (ACSO) (5.0–11.7 mg/g); Chinese chive, dehydrator onion, leek and shallot had moderate amounts (2.0–5.0 mg/g); and Japanese bunching onion, onion (TG 1015Y) and chive leaves contained least amounts of total CSO (<2 mg/g) (Yoo and Pike 1998). AlCSO (S-allyl-L-cystine sulfoxide, alliin) was the major precursor in garlic and giant garlic (3.2–9.8 mg/g) and was also contained in chive and Chinese chive. PeCSO (S-propenyl-L-CYSTEINE sulfoxide) was the main flavour precursor in onion, green onion, leek and shallot (0.3–2.2 mg/g) but also found in chive, Chinese chive, garlic and giant garlic. MeCSO (S-methyl-L-cysteine sulfoxide) was a major precursor in chive and Chinese chive (0.68–1.85 mg/g fresh wt.) and found in all eight species examined with less amounts. S-propyl CSO, however, was not found in any of these species.

The major volatiles in leek oil were dipropyl trisulfide, dipropyl disulfide and (*E*)-propenyl propyl disulfide (Schulz et al. 1998). According to the higher amount of leek chromosomes in the cell nucleus, the percentages of the

measured sulfur volatiles in the interspecific hybrid between *Allium cepa* and *Allium porrum* material corresponded more to the leek than to the onion flavour profile.

1-propenyl-L-cysteine sulfoxide (PeCSO) was the main flavour precursor in onion, green onion, leek and shallot (0.3–2.2 mg/g) but also found in chive, Chinese chive, garlic and giant garlic (Yoo and Pike 1998). *S*-methyl cysteine sulfoxide (MeCSO) was a major precursor in chive and Chinese chive (0.68–1.85 mg/g fresh wt.) and found in garlic, onion and leek in lesser amounts. The most important aroma compounds in the freshly cut leek slices were dipropyl disulfide, methyl propenyl disulfide, pentanal, decanal and propyl propenyl disulfide in order of priority (Nielsen and Poll 2004). When stored frozen and unblanched for 12 months, the aroma composition changed, and the most important compounds became pentanal, decanal, 2,5-dimethyl furan, unknown compound I and dipropyl disulfide. Blanching before freezing prevented to some degree these changes but also reduced the perceived intensity of the aroma compounds. The most important aroma compounds in the blanched sample were dipropyl disulfide, unknown compound I, pentanal, 2,5-dimethyl furan and propyl propenyl disulfide. The aroma profile of unblanched leek slices changed from consisting of almost only sulfur compounds such as dipropyl disulfide [concentration in fresh leek (FL) = 0.197 mg/L, concentration after 12 months of frozen storage (12 M) = 0.0409 mg/L] and propyl (*E*)-propenyl disulfide (FL = 0.0437 mg/L, 12 M = 0.00452 mg/L) in the fresh leeks to being dominated by numerous saturated and unsaturated aldehydes, such as hexanal (FL = 1.53 mg/L, 12 M = 3.63 mg/L), (*E,E*)-2,4-nonadienal (FL = 0.000 mg/L, 12 M = 0.0647 mg/L) and (*E,E*)-2,4-decadienal (FL = 0.129 mg/L, 12 M = 0.594 mg/L) at the end of the storage period (Nielsen et al. 2003). The catalytic activity of lipoxygenase (LOX) diminished throughout frozen storage, but 25 % of the original activity was present after 12 months of storage. Total amount of sulfur compounds was influenced by storage time, slice thickness and atmosphere (concentration in fresh 4 mm slices = 17.8 mg/L, 4 mm 12 M (month storage) = 3.48 mg/L, fresh 15 mm slices = 2.48 mg/L, 15 mm 12 M = 0.418 mg/L and 15 mm N

12 M = 1.81 mg/L) (Nielsen et al. 2004a). The 4 mm slices significantly developed the most aldehydes after 12 M (total amount = 9.28 mg/L) compared to 15 mm 12 M (6.49 mg/L) and 15 mm N 12 M (4.33 mg/L). LOX activity was positively influenced by nitrogen packaging, and hydroperoxide lyase (HPL) activity was influenced by slice thickness, whereas alcohol dehydrogenase (ADH) was unaffected by both parameters. The total amount of sulfur compounds and the total amount of aldehydes were greatly influenced by storage time, atmosphere and blanching [concentration of sulfur compounds in fresh unblanched (UNB) slices = 1.35 mg/L, fresh blanched (B) slices = 1.09 mg/L, UNB 21 % O₂ 12 M = 0.656 mg/L, UNB 0 % O₂ 12 M = 2.11 mg/L, B 21 % O₂ 12 M = 1.14 mg/L, B 0 % O₂ 12 M = 1.59 mg/L] (Nielsen et al. 2004c). The activities of HPL and alliinase were totally lost after 12 months, and ADH showed minimal activity, whereas LOX (UNB 0 % O₂) showed 25 % of the original activity. LOX was the most and HPL the least heat-labile enzyme investigated. The catalytic activity of LOX in leek tissues showed significant difference between linolenic acid (9.43×10^{-4} katals per kg protein) and linoleic acid (2.53×10^{-4} katals per kg protein), and the pH optimum of LOX was 4.5 – 5.5 against linoleic acid (Nielsen et al. 2004b). The catalytic activity of HPL was statistically the same for 9-(S)-hydroperoxy-(10*E*,12*Z*)-octadecadienoic acid (1.01×10^{-2} katals per kg protein) and 13-(S)-hydroperoxy-(9*Z*,11*E*)-octadecadienoic acid (7.69×10^{-3} katals per kg protein). ADH showed a catalytic activity of 5.01×10^{-4} katals/kg of protein towards hexanal. Linoleic acid resulted in significantly most hexanal, heptanal, (*E*)-2-heptenal, (*E*)-2-octenal, (*E,E*)-2,4-decadienal, pentanol and hexanol, whereas linolenic acid resulted in significantly most (*E*)-2-pentenal, (*E*)-2-hexenal, (*E,Z*)-2,4-heptadienal, (*E,E*)-2,4-heptadienal and butanol. Leek LOX produced only the 13-hydroperoxide of linoleic acid and linolenic acid.

The major polysaccharides in the leek were pectic substances – 23.3 %, which had a high degree of esterification (73–74 %) and cellulose 21.7 % (Kratchanova et al. 2008).

The protein content of the leek was 24 %. Five pectic polysaccharide fractions of commensurate yields (2.4–3 %) were obtained. The obtained pectins differed in their polyuronic content (27.5–73.6), degree of esterification (12.6–76.6), neutral sugar content (18.4–71.1 %) and protein content (1.3–8.0 %). The highest polyuronic content was observed in the water- and chelate-extractable fractions. The acid- and alkaline-extractable pectic polysaccharides contained about 30 % uronic acids. In the polysaccharide fractions, a presence of glucuronic acid was observed. Its content was about 10 % of the total polyuronic acid content. Only the first two fractions had a high degree of esterification: 76.59 and 61.53 %. The first fraction had also very high protein content (8 %). In the other polysaccharides, the protein content was between 1.3 and 2.2 %. In the neutral sugar fraction, the prevailing sugar was galactose, followed by rhamnose. Extraction with diluted hydrochloric acid yielded polysaccharide with the highest neutral sugar content of 71.1 % and a low uronic acids content. The water- and chelate-extractable fractions had a lower L-rhamnose content (2.7 % and 2.9 %, respectively), and the other polysaccharide fractions from leek were characterised by a high L-rhamnose content (from 14 to 28 %). Further they reported that the water-extractable pectin had higher polyuronic content, higher protein content and lower neutral sugar content (Kratchanova et al. 2010). Next to galacturonic acid, they also contained glucuronic acid in the ratio 9:1 for the water-extractable polysaccharide and 3:1 for the acid-extractable polysaccharide. The main neutral sugar was galactose. The water-extractable pectic polysaccharide had higher molecular weight (10^6 Da) and homogeneity.

In leek seedlings, sterols were found to be present as a mixture in which (24*R*)-24-ethylcholest-5-en-3 β -ol (around 60 %) was the major component (Moreau et al. 1998). The other sterols present were cholest-5-en-3 β -ol; 24-methyl-cholest-5-en-3 β -ol; (24*S*)-24-ethylcholesta-5,22*E*-dien-3 β -ol; and stigmasta-5, 24(24(1))*Z*-dien-3 β -ol. These compounds were shown to reside mainly in the plasma membrane.

Leek leaf waxes consisted primarily of fatty acids (C16–22) and longer-chain (C26–31) derivatives (aldehydes, alkanes

and ketones) (Rhee et al. 1998). CHCl₃-extractable lipids from the lower leaf segments were primarily hexadecanoic (C16) and octadecanoic (C18) acids. Smaller amounts of eicosanoic (C20) and docosanoic (C22) acids were also detected. The level of hexadecanoic and octadecanoic acids increased almost four- and twofold, respectively, from the bottom (segment I) to the top of the leaf (segment VII). Even though C16 and C18 fatty acids were a major component (78–92 %) of the CHCl₃-extractable surface lipids in the bottom 5 cm, they were minor components (12–13 %) in the top 5 cm. Undetectable or very low levels (<5 % of the total wax load) of very long-chain alkanes, aldehydes and ketones were also observed in the bottom leaf segments. These components, however, increased dramatically in the middle region of the leaf to more than 75 % in the top 5 cm. Composition of epicuticular wax on segments of leek leaves IV (7–9 cm from leaf base) to VII (19,024 cm) consisted of hexadecanoic acid, octadecanoic acid, eicosanoic acid, docosanoic acid, hexacosanal, octacosanal, n-nonacosane, triacontanal, n-hentriacontane and hentriacontane-16-one. The following compounds were identified in leek leaves: bicyclo, hept-2-ene 0.56 %, thymol 3.68 %, 3-methyl-4-isopropylphenol 3.68 %, caryophyllene 3.63 %, naphthalene 23.27 %, copaene 2.96 %, cycloisolongofolene 4.76 %, 2-pentadecanone 1.96 %, N-hexadecanoic acid 2.49 %, phytol 3.16 % and 9,12,15-octadecatrienoic acid 0.82 % (Monemi et al. 2014). From leek callus, the following were identified: cyclotetrasiloxane 1 %, 2-methyl 5 phenol 1.44 %, ethyl α-D-glucopyranoside 13.25 %, 2-methylindene 11.64 %, 9-methyl-3,4-dihydro-2H-pyrido 2.11 %, pentadecanoic acid 4.11 %, 2H-1-benzopyran 9.19 %, 3,4-dihydro H-cyclopenta 16 %, 9,12-octadecadienoic acid 2.43 %, 1,3,5-cycloheptatriene 1.20 %, 3-morpholine 5-methyl-6-phenyl 1.18 %, benzene 16.04 % and 1,2-benzenedicarboxyl 4.33 %.

Analysis of nectar from leek flowers revealed the presence of two major polypeptide bands of 50 kDa and 13 kDa, which were identified as subunits of alliin lyase (alliinase) and mannose-binding lectin, respectively (Peumans et al. 1997).

The latter protein was particularly abundant since it accounted for about 75 % of the total nectar protein.

Antioxidant Activity

The ethanolic extract of leek leaf and stem exhibited 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical scavenging antioxidant activity with IC_{50} values of 98.90 g/mL and 61.05 g/mL, respectively (Mladenović et al. 2011). It contained high contents of phenols (69.46 mg GAE/g dry extract) and flavonoids (33.53 mg CE/g dry extract).

Green leek leaves were found to have significantly stronger antioxidant properties than the white shaft in the free radical scavenging activities against peroxy (ORAC) and 2,2-diphenyl-1-picrylhydrazyl radicals (DPPH) and their Fe^{3+} -reducing capacity (FRAP) assays (Bernaert et al. 2011, 2012a). The antioxidant of the white shaft of leek cultivars to peroxy radicals ranged from 26.91 to 88.07 μ mol TE/g DW in the oxygen radical absorbance capacity (ORAC) assay. The antioxidant reducing potential of the white shaft ranged from 154.14 to 898.04 μ M ferric reducing antioxidant power (FRAP). Correlation analysis between the total phenolic and L-ASCORBIC acid content and the antioxidant activity showed that phenolics and ascorbic acid contribute significantly to the antioxidant activity of leek. The three antioxidant activity assays were all correlated for the extracts of the white shaft of the 30 leek cultivars. The antioxidant capacity and the total content of phenolic compounds in the white shaft of the entire and packaged leek were stable during 13 days of refrigerated storage (Bernaert et al. 2013a). A significant increase in the concentration of isoalliin was observed. Significant differences could be observed in antioxidant properties of the entire and processed (green leaves removed)/packaged leek. The *S*-alk(en)yl-L-cysteine sulfoxide (ACSO) content (isoalliin and methiin) in the white shaft of packaged leek was significantly lower than the content in the white part of the entire leek. It was concluded that the minimal processing step of cutting the green leaves and roots had an influence on the levels of antioxidant properties. Application of fermentation resulted in

a higher ORAC value and polyphenol content of the leek plant, especially in the green leaves (Bernaert et al. 2013b). The oxygen radical absorbance capacity (ORAC) increased by 62 % when the green leaves were fermented for 21 days, while 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical scavenging activity did not increase significantly.

Antimicrobial Activity

Steroidal saponins isolated from leek bulbs, ampeloside Bs₁, ampeloside-Bf₁ and the prosapogenin of aginoside did not inhibit growth of *Aspergillus niger*, but the spirostanol saponins ampeloside Bs₁ and the prosapogenin of aginoside were weakly inhibitory to growth of *Candida albicans* (Morita et al. 1988). The furostanol saponin ampeloside-Bf₁ was inactive. Four spirostanol saponins isolated from leek bulb, two new compounds (25*R*)-5α-spirostan-3β,6β-diol 3-*O*-{*O*-β-D-glucopyranosyl-(1→2)-*O*-[β-D-xylopyranosyl-(1→3)]-*O*-β-D-glucopyranosyl-(1→4)-β-D-galactopyranoside} and (25*R*)-5α-spirostan-3β,6β-diol 3-*O*-{*O*-β-D-GLUCOPYRANOSYL-(1→3)-*O*-β-D-glucopyranosyl-(1→2)-*O*-[β-D-xylopyranosyl-(1→3)]-*O*-β-D-glucopyranosyl-(1→4)-β-D-galactopyranoside}, a steroidal saponin isolated previously by Minaki et al. (1995) and F-gitonin isolated previously by Kawasaki et al. (1965) exhibited antifungal activity against *Fusarium culmorum* with ED₅₀ values of 30–35 μg/mL (Carotenuto et al. 1999).

Allium ampeloprasum essential oil showed the strongest inhibitory effect against *Saccharomyces cerevisiae* at a concentration of only 1 % (Kocić-Tanackov et al. 2009). *Allium ampeloprasum* essential oil was inactive against the yeast *Candida tropicalis*, but another yeast *Rhodotorula* sp. was inhibited only by *A. ampeloprasum* essential oil. *Penicillium griseofulvum* was appreciably inhibited by *A. ampeloprasum* oil (78.3 % of inhibition, at a concentration of 10 %). The antimicrobial activity of elephant garlic (*Allium ampeloprasum* var. *ampeloprasum*) was stronger than ampicillin when used against *Escherichia coli*, *Bacillus subtilis*, *Bacillus thuringiensis*, *Staphylococcus actinomycetes*

and gray Actinomycetes. It exhibited antibacterial effect against the common bacteria *Escherichia coli* and *Staphylococcus aureus* at a very low concentration (12.5 %).

Anticancer Activity

Sapogenin compounds isolated from *A. porrum*, agigenin and porrigenins A and B exhibited cytotoxicity and high antiproliferative activity on four different tumour cell lines WEHI 164 (murine fibrosarcoma), J-774 (murine monocyte/macrophage), IGR-1 (human melanoma) and P-388 (murine leukaemia) cell lines in-vitro (Carotenuto et al. 1997b). Two other leek sapogenins 12-keto-porrigenin and 2,3-seco-porrigenin exhibited antiproliferative activity on the same four tumour cell lines (Carotenuto et al. 1997a). Porrigenin C isolated from leek showed a considerable antiproliferative activity on the four tumour cell lines in-vitro (Fattorusso et al. 1998). Yayoisoaponins A–C and aginoside, isolated from leek bulb, exhibited not only in-vitro cytotoxicity against P-388 cells at 2.1 µg/mL but also antifungal activity against *Mortierella ramanniana* at 10 µg/disc (Sata et al. 1998). Steroidal saponins from leek bulb diosgenin and a spirostanol saponin derivative exhibited appreciable cytostatic activity on human promyelocytic leukaemia HL-60 cells with IC₅₀ values of 2.1 and 3.2 µg/mL, respectively (Mimaki et al. 1999). Elephant garlic extract inhibited the growth of human osteosarcoma cells, U2OS, by preventing the transition from G1 phase to S phase (Huang and Ren 2013). It reduced osteosarcoma cell, U2OS, invasion ability and significantly increased the proportion of apoptosis.

In a meta-analysis, consumption of high levels of *Allium* vegetables (onion, garlic, leek, Chinese chive, scallion, garlic stalk and Welsh onion) reduced the risk for gastric cancer risk (odds ratio, 0.54) (Zhou et al. 2011). Specific analyses for onion, garlic, leek, Chinese chive, scallion, garlic stalk and Welsh onion yielded similar results, except for onion leaf.

Hepatoprotective Activity

Both foam powder and freeze-dried powder obtained from jumbo leek (*A. ampeloprasum*) bulb decreased the induction of hepatocyte necrosis in D-galactosamine hydrochloride (GalN)-induced acute fulminant hepatitis and prevented the occurrence of ethanol-induced chronic liver disorders in rats by inhibiting the absorption of alcohol from the stomach (Uchida et al. 2009b).

Antisteoporotic Activity

Oral administration of *Allium porrum* (250 and 500 mg/kg) had significant protective effect against osteoporosis induced by ethanol in rats (El-Shenawy et al. 2013). Administration of 20 % ethanol (3 g/kg) for 11 weeks led to a significant decrease in bone mineral density (BMD by 40 %); however, administration of leek extract (250, 500 mg/kg) and calcium (54 mg/kg) p.o. restored BMD by 31, 46 and 32 %, respectively, compared with negative control group. Leek extract also reduced the ethanol-induced elevation in serum alkaline phosphatase and malondialdehyde levels. It was concluded that protective effect of leek alcoholic extract on osteoporosis in rats may be attributed to its antioxidant capacity.

Anti-inflammatory and Gastroprotective Activities

Steroidal saponins from bulbs of leek (3 β ,5 α ,6 β ,25*R*)-6-[(β -D-glucopyranosyl)oxy]-spirostan-3-yl *O*- β -D-glucopyranosyl-(1 $\rightarrow$ 2)-*O*-[β -D-glucopyranosyl-(1 $\rightarrow$ 3)]- β -D-galactopyranoside and 3-[(*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 3))- β -D-glucopyranosyl-(1 $\rightarrow$ 2)-*O*-[*O*- β -D-GLUCOPYRANOSYL-(1 $\rightarrow$ 3)]-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 4)- β -D-galactopyranosyl)oxy]-2,6-dihydroxy-(2 α ,3 β ,5 α ,6 β ,25*R*)-spirostane showed haemolytic effects in the in-vitro assays and demonstrated anti-inflammatory activity and gastroprotective property using in-vivo models (Adão et al. 2011a, b).

Antihypercholesterolemic/Hypolipidemic Activity

Treatment of rabbits on a hypercholesterolemic diet with 250, 500 or 1,000 mg/kg of body weight of extract a hydroalcoholic extract of *A. porrum* bulbs decreased plasma total cholesterol in a dose-dependent manner (Movahedian et al. 2006).

Changes in the distribution of cholesterol in HDL or LDL were found, and LDL cholesterol decreased significantly in all of the groups treated with *A. porrum* extract with respect to the hypercholesterolemic group.

Antidiabetic Activity

Administration of ethanolic extract of leek leaves significantly reduced the serum glucose in streptozotocin-induced diabetic mice, but not in healthy mice (Eydi et al. 2007). The ethanolic extract also increased serum insulin in diabetic mice. Chronic oral administration of leek extract to STZ diabetic rats for 4 weeks significantly reduced serum glucose, cholesterol and triglyceride levels compared to control diabetic rats (Roghani and Aghaie 2007a). The scientists also showed that streptozotocin diabetic rats exhibited a higher score of pain at both phases of the formalin test and leek treatment for 1 month ameliorated this, while sodium salicylate administration significantly reduced pain score only at chronic phase of the test (Roghani and Aghaie 2007b).

Allium sativum and *Allium porrum* inhibited significantly the active transport of D-glucose across rat enterocytes in the rat everted intestinal sac experiment (Belemkar et al. 2013). Increased concentrations of both at 2.2 and 5.0 mg/mL in the mucosal solution significantly decreased absorption as well as transport across the rat intestine. D-glucose absorption along with transport was significantly inhibited at 2.5 and 5 mg/mL of garlic and leek compared to the control experiment groups. *A. porrum* showed more potent action.

Immunomodulatory Activity

The pectic polysaccharides obtained from leek exhibited good immunostimulating properties (Kratchanova et al. 2008, 2010). The highest immunostimulating activity was shown by the water- and chelate-extractable polysaccharides, which were also characterised by a high polyuronic acid content and polysaccharides with molecular mass over 10^6 Da. The water-extractable pectic polysaccharide had higher molecular weight (10^6 Da) and homogeneity. Despite the lack of antioxidant activity, the pectic polysaccharides of leek significantly decreased the production of reactive oxygen species (ROS) by human neutrophils (Nikolova et al. 2013). Polysaccharides isolated from alcohol-insoluble substances (AIS) of leek markedly activated RAW 264.7 macrophages for reactive nitrogen species production in a concentration-dependent manner. The polysaccharides extracted from AIS with water showed the ability to fix serum complement, especially through the alternative pathway. It was found that the polysaccharide exhibiting the highest complement-fixing effect was characterised by the highest content of uronic acids and the highest molecular weight. A new steroidal saponin 3 β ,5 α ,6 β ,25R)-3- $\{[(O\text{-}\beta\text{-D-GLUCOPYRANOSYL-(1\rightarrow3)-}\beta\text{-D-glucopyranosyl-(1\rightarrow2)-O-[O\text{-}\beta\text{-D-glucopyranosyl-(1\rightarrow3)]-O-}\beta\text{-D-GLUCOPYRANOSYL-(1\rightarrow4)-}\beta\text{-D-galactopyranosyl)oxy}\}-6\text{-hydroxyspirostan-2-one}$ isolated from leek bulbs exhibited haemolytic activity in the in-vitro assays and immunological adjuvant activity on the cellular immune response against ovalbumin antigen (Adão et al. 2012).

Nguansangiam et al. (2003) found that pre- and post-topical treatment of leek volatile oil could protect against trichothecene toxin-induced epidermal damage (epidermal desquamation and necrosis with oedema and inflammatory cells infiltration) in the mouse footpad rich in epidermal Langerhans cells. Langerhans cells had been reported to play a critical role in cutaneous immunological reactions (Weiss 1988).

Platelet Antiaggregation Activity

Flavonoids isolated as kaempferol aglycones from the bulbs of leek exhibited human platelet antiaggregation activity (Fattorusso et al. 2001).

Spasmolytic Activity

Studies showed that *Allium ampeloprasum* leaf hydroalcoholic extract could affect rat ileum motor activity by affecting beta adrenergic receptors and voltage-dependent calcium channels (Sedighi et al. 2012). Leek leaf extract (100, 200 and 400 mg/kg), in a dose-dependent manner, reduced ileum contractions induced by potassium chloride. The intervention of beta adrenergic receptor antagonist (propranolol, 1 M), opioid receptors (Narcan, 1 M) and nitric oxide synthase inhibitor (L-name, 100 M) in ileum showed that propranolol decreased the inhibitory effects of the extract on the contractions caused by potassium chloride significantly. Based on the results, leek leaf extract may be used to treat digestive problems.

Allergy Issues

A 26-year-old woman was presented with asthma and contact eczema on handling leek for 3 years (Cadot et al. 2001). Some months after having started this work, she began to complain of conjunctivitis, rhinitis, asthma and eczema on the hands. She could not remember having allergic reactions to any other vegetable than leek. The patch test with leek was positive. The peculiarity of the present case was that the patient did not show any sign of common inhalant allergies nor was there cross-reactivity with the closest botanically related vegetables, namely, onion and garlic. Another case of occupational rhinitis to leek was reported by Armentia et al. (2005).

Traditional Medicinal Uses

Leek bulb is regarded to be anthelmintic, antiasthmatic, anticholesterolemic, antiseptic, antispasmodic, cholagogue, diaphoretic, diuretic, expectorant, febrifuge, stimulant, stomachic, tonic and vasodilator (Grieve 1971; Holtom and

Hylton 1979; Launert 1981; Lust 1974). The crushed bulb may be applied as a poultice to ease the pain of stings and insect bites.

Allium porrum is employed as an antiatherogenic remedy in traditional Iranian medicine (Movahedian et al. 2006). In traditional Iranian medicine, Persian leek is employed for constipation, asthma, haemoptysis, gout, obesity, haemorrhoids and headache and as a diuretic, emmenagogue and aphrodisiac (Avicenna and Bakhtiar 2012). Seeds are used for chronic diarrhoea, freckle, vitiligo, neuralgia, haemorrhoids and as appetiser and aphrodisiac.

Other Uses

Allium ampeloprasum contain compounds with insecticidal and antifungal properties.

Allium porrum produced nonprotein sulfur amino acids derived from cysteine, i.e. alk(en)yl-cysteine sulfoxides precursors of volatile thiosulfinates and disulfides, as a defence mechanism against insect species including the specialist leek moth, *Acrolepiopsis assectella* (Dugravot et al. 2005). They found an increase in the production of sulfur compounds in both the sulfur precursor propylcysteine sulfoxide and volatile form, occurring only in association with intensive attacks by leek moths and not by the generalist moth, *Agrotis ipsilon*. The increase in sulfur precursors also led to an increase in the release of sulfur volatiles.

Antifungal N-feruloyl amides N-feruloyltyrosine and N-feruloyl-tyramine, isolated from *A. porrum* roots, showed antifungal activity towards *Fusarium culmorum* (Fattorusso et al. 1999). Cinnamic acid derivatives N-feruloyl-tyramine and N-caffeoyl tyramine, isolated from leek seeds and bulb, inhibited in-vitro growth of *Botrytis cinerea*, and N-feruloyl tyramine inhibited *Penicillium italicum* and *Aspergillus niger* at a low concentration (Sadeghi et al. 2013a). Persicosides A and B from leek bulbs were active in-vitro against the tested fungal phytopathogens, *Penicillium italicum*, *Aspergillus niger*, *Trichoderma harzianum* and *Botrytis cinerea*, highlighting the positive effect of the spirostane skeleton on the antifungal activity (Sadeghi et al. 2013b).

Comments

Allium ampeloprasum is a complex species. The allopolyploid origin of great headed garlic (GHG) *Allium iranicum* and *A. polyanthum* was confirmed. No signs of hybridisation in leek or kurrat were detected, but possible introgression events were identified in pearl onion and bulbous leek (Hirscheegger et al. 2010). They also clarified the previous incorrect classification of cultivated forms within *A. ampeloprasum*, by showing that leek, kurrat, pearl onion and bulbous leek should be considered separately from GHG. Recent studies on the diversity of small and wild to large and cultivated *Allium ampeloprasum* found that domesticated *A. ampeloprasum* (great headed garlic, kurrat and leek) clustered consistently within the ampeloprasum group (Guenauoui et al. 2013). A high number of single point mutations (SNPs) was recorded over the ITS1-2 spacer sequence. Most of these SNPs were heterozygous only in great headed garlic. It was inferred that heterozygosity played the major role in promoting great headed garlic domestication. Thus, great headed garlic adaptation to horticultural conditions along with its yield trait sizes was mainly associated to heterozygosity rather than to polyploidy. Vegetative, floral and chromosome morphology studies by Mousavi et al. (2006) suggested the Persian leek to be a distinct subordinate group of *A. ampeloprasum*.

Origin/Distribution

Common onion is known only in cultivation and is believed to have probably originated from wild *Allium* progenitors from Central Asia in the region comprising Afghanistan, Iran and Turkmenistan (Havey 1995). The cultivated form is often polyploid ($2n = 16, 32, 54$) and possibly of hybrid origin. It exists in numerous cultivars, a few of which form large bulbils in the umbel. The onion of commerce is widely cultivated as a biennial in North America, Europe and Asia.

The leading world producers of dry onions based on production figures are China 22,600,000 tonnes, India 16,308,990 tonnes, the United States 3,277,460 tonnes, Iran 2,260,000 tonnes, Russian Federation 2,090,814 tonnes, Egypt 2,024,881 tonnes, Turkey 1,819,000 tonnes, Pakistan 1,692,300 tonnes, Nigeria 1,350,000 tonnes, Bangladesh 1,159,259 tonnes, Brazil 1,519,022 tonnes, Netherlands 1,353,000 tonnes, Mexico 1,238,602 tonnes, Myanmar 1,140,000 tonnes, Republic of Korea 1,195,737 tonnes, Spain 1,187,100 tonnes, Ukraine 1,141,300 tonnes and Japan 1,097,000 tonnes (FAO 2013).

Agroecology

Onion is a cool season biennial that is tolerant of frost. Optimum temperatures for growth and development are between 12.8 and 20 °C. Temperatures below 10 °C initiate bolting of the onion or flowering. However, optimum temperatures for seedling growth are much narrower, with 20–25 °C being most productive.

Edible Plant Parts and Uses

Onion bulb is used as vegetable, seasoning and flavouring. The bulb is eaten raw or cooked. Eaten raw, it can be sliced up and used in salads, sandwich fillings, etc.; it can be baked or boiled as a vegetable in its own right and is also commonly used as a flavouring in soups, stews and many other cooked dishes. Some cultivars have been selected for their smaller and often hotter bulbs, and these are used for making pickles or chutneys.

A large number of processed products are made from onion and garlic, and these find their way into a wide array of processed foods. Concentrated oils are produced from steam distillation of fresh onion and garlic, and these are used to deliver onion or garlic flavour to processed foods. Dehydrated products make up a sizable portion of the onion and garlic processing industry. The resultant dried flakes can be further ground into powder and mixed with salt and calcium stearate to produce onion or garlic salt. In a number of countries, particularly in Asia, pickled onion and garlic bulbs are consumed. These are produced in a fermentation process and then bottled in vinegar and salt to make a sour pickle or vinegar and sugar to make a sweet pickle.

The leaves are also raw or cooked. There are some cultivars that have been selected for their leaves and are used in salads while still young and actively growing – the bulb is much smaller than in other cultivars and is usually eaten with the leaves.

The flowers are eaten raw and used as a garnish on salads. The flowers are somewhat dry and are less pleasant than many other species. The seeds are sprouted and eaten and impart a delicious onion flavour.

Fortification of bread with onion skin supplements influenced protein digestibility (a reduction from 78.4 % for control breads to 55 % for breads with a 4 % supplement) (Swieca et al. 2013). The interaction of onion flavonoids with proteins affected antioxidant efficacy and protein digestibility,

thus, affording multiple effects on food quality and pro-health properties of bread. Sensory evaluation studies showed that replacement of wheat flour in bread with up to 3 % onion skin powder gave satisfactory consumer acceptability (Gawlik-Dziki et al. 2013). The 2–3 % onion skin addition caused significant improvement of antioxidant abilities of the bread.

Vinegar was successfully produced from the juice of a red onion cultivar, Kurenai, by batch culture using yeast and *Acetobacter aceti* (Horiuchi et al. 1999). Nutritional analysis revealed that the potassium content of onion vinegar was extremely high, while the amount of sodium was lower than that in conventional vinegars. Also, the total amino acid and total organic acid contents of the onion vinegar were, respectively, 1.6–6.9 times and 3.5–11.5 times those in other kinds of vinegars.

Studies showed that onion brown skin and top–bottom could be potentially used as functional ingredient rich in dietary fibre, mainly in insoluble fraction, and in total phenolics and flavonoids, with high antioxidant activity (Benítez et al. 2011). Moreover, brown skin showed a high concentration of quercetin aglycone and calcium, and top–bottom showed high concentration of minerals. Outer scales could be used as source of flavonols, with good antioxidant activity and content of dietary fibre. However, inner scales could be an interesting source of fructans and alk(en)yl cysteine sulfoxides. Additionally, discarded onions (cvs Recas and Figueres) could be used as a good source of dietary fibre and cv Recas also as a source of phenolics compounds.

Ethanol could be produced from onion wastes by transforming the onion juice into onion liquor via alcoholic fermentation with the yeast *Saccharomyces cerevisiae* González-Sáiz et al. (2008a, b). The onion bioethanol produced could be later used as a favourable substrate for acetic fermentation into acetic acid and finally obtain onion vinegar. Processing of onion cv. ‘Recas’ onion wastes (residues and surpluses of onion) to obtain a paste (mixture content) and applying a mild pasteurisation were the best alternatives to obtain an interesting stabilised onion by-product

with good antioxidant properties that could be used as a functional food ingredient (Roldán et al. 2008).

Studies suggested the potential good uses of the fresh leaves of Romanian *Allium* spp. (*Allium cepa* var. 'Diamant', *Allium cepa* var. 'Rubiniu' and *Allium ursinum*) as condiment, ingredient or preservative in the food industry (Gîtin et al. 2014).

Botany

A biennial herb with adventitious, fibrous roots (Plates 7 and 11) within a radius of 30 cm from the stem and in the top 30 cm of the soil (Plates 1 and 10). Real stem is very much reduced at the base of the plant, the pseudostem, if formed by the sheathing leaf bases. Leaves 3–8 alternate, distichous, glaucous produced from the broadening stem apex, leaf lamina cylindrical later becoming hollow, up to 50 cm long, apex acute. The bulb is comprised of concentric, enlarged fleshy leaf bases, also called scales, a short distance above the stem. The outer leaf base dries and becomes scaly, thin and variously coloured yellowish brown, orangey brown, purplish, red, greyish white or white forming the protective coat (Plates 3, 4, 5, 6, 7, 8 and 9) and the inner leaf bases thicken as the bulb develops. The mature bulb is depressed globose, ovoid or elongate, varying in size from cultivar to cultivar, 5–8 × 3–10 cm. In the case of the *Aggregatum* group (shallots), bulbs are formed in clusters of 3–28 cloves from the single mother bulb. Scape persistent, solitary, erect, fistulose, inflated below middle, 30–100 cm × 3–20 mm. Umbel persistent, erect, compact, to 500-flowered, globose (Plate 2), bulbils occasionally found; spathe bracts caducous, 2–3, 3–4-veined, ovate, apex acute to acuminate. Flowers stellate to campanulate to urceolate, 3–7 mm; tepals erect to more or less spreading, white to pink with greenish midveins, withering in fruit, margins entire, apex obtuse or acute, outer ovate, inner oblong; stamens exserted; anthers white; pollen white; ovary crestless; style linear, equalling stamens; stigma capitate, unlobed; pedicel 10–50 mm. Seed coat not known.

Nutritive/Medicinal Properties

Bulb Nutrients/Phytochemicals

Although rarely used specifically as a medicinal herb, the onion has a wide range of beneficial actions on the body. It had been reported to contain many vitamins and minerals and is rich in sulfur amino acids, flavonoids and phytosterols. Onion had also been reported to contain a variety of secondary compounds, such as flavonols, anthocyanin pigments, sterols and saponins (Brewster 1994). The amino compounds identified in the phenol–water, *sec*-butanol–tert-butanol–methylethyl ketone–water and *sec*-butanol–tert-butanol–methylethyl ketone–water extracts of onion were glutathione, aspartic acid, cysteine, cystine, glutamic acid, serine, canavanine, asparagine, glycine, arginine, lysine, threonine, tyrosine, methionine sulfoxide, alanine, dihydro-alliin, S-methyl cysteine, tryptophan, methionine, valine, phenylalanine and mixed leucines (Kuon and Bernhard 1963). Suspected as present was α -L-glutamyl-S-[β -carboxy-n-propyl]-L-cysteinyl glycine. The more abundant amino acids were arginine, glutamic acid, phenylalanine, leucines, tyrosine, lysine and methionine sulfoxide. The following amino acids and γ -glutamyl peptides were isolated from onion: isomers of S-methyl-L-cysteine sulfoxide, γ -glutamyl-S-(prop-1-enyl) cysteine sulfoxide, S-(2-carboxypropyl)-glutathione, cycloalliin; isomers of S-propyl-L-cysteine sulfoxide, isomers of L-methionine sulfoxide, S-(prop-1-enyl)-L-cysteine sulfoxide, γ -glutamyl-S-methyl cysteine; aspartic acid, L-glutamyl-valine, asparagine, threonine, serine, γ -glutamyl-methionine, γ -glutamyl-isoleucine, glutamic acid, S-(2-carboxy-propyl)-L-cysteine, citrulline; proline; S-methylcysteine; glycine and unknown, alanine, γ -glutamyl-phenylalanine, S-allylcysteine, valine, pipercolic acid, methionine, S-(prop-1-enyl)-cysteine, isoleucine, leucine, tyrosine, β -alanine, phenylalanine, γ -aminobutyric acid, ethanolamine, ammonia, lysine, histidine, tryptophan, arginine and several unknowns (Matikkala and Virtanen 1967).

The proximate value per 100 g edible portion of raw onions had been reported by USDA-ARS (2014) as water 89.11 g, energy 166 kJ (40 kcal), protein 1.10 g, fat 0.10 g, carbohydrate 9.34 g, total dietary fibre 1.7 g, total sugars 4.24 g, sucrose 0.99 g, glucose 1.97 g, fructose 1.29 g, ash 0.35 g, Ca 23 mg, Mg 10 mg, P 29 mg, K 146 mg, Fe 0.21 mg, Na 4 mg, Zn 0.17 mg, Cu 0.039 mg, Mn 0.129 mg, Se 0.5 µg, vitamin C (total ascorbic acid) 7.4 mg, thiamine 0.046 mg, riboflavin 0.027 mg, niacin 0.116 mg, pantothenic acid 0.123 mg, vitamin B-6 0.120 mg, total folate 19 µg, total choline 6.1 mg, betaine 0.1 mg, vitamin A 2 IU, β-carotene 1 µg, lutein + zeaxanthin 4 µg, vitamin E (α-tocopherol) 0.02 mg, vitamin K (phylloquinone) 0.4 µg, total saturated fatty acids 0.042 g, 14:0 (myristic acid) 0.004 g, 16:0 (palmitic acid) 0.034 g, 18:0 (stearic acid) 0.0034 g; total monounsaturated fatty acids 0.013 g, 18:1 undifferentiated (oleic acid) 0.013 g; total polyunsaturated fatty acids 0.017 g, 18:2 undifferentiated (linoleic acid) 0.013 g, 18:3 undifferentiated (linolenic acid) 0.004 g; phytosterols 15 mg, and amino acids – tryptophan 0.014 g, threonine 0.021 g, isoleucine 0.014 g, leucine 0.025 g, lysine 0.039 g, methionine 0.002 g, cystine 0.004 g, phenylalanine 0.025 g, tyrosine 0.014 g, valine 0.021 g, arginine 0.104 g, histidine 0.014 g, alanine 0.021, aspartic acid 0.091 g, glutamic acid 0.258 g, glycine 0.025 g, proline 0.012 g and serine 0.021 g.

Eighty per cent of the total lipids of *Allium cepa*, *Allium sativum* and *Allium porrum* were found to consist of four fatty acids: linoleic (46–53 %), palmitic (20–23 %), oleic (4–13 %) and α-linolenic acid (3–7 %) (Tsiaganis et al. 2006). In onion, 43 fatty acids were determined, 18 of that above 0.4 % and 4 above 2.5 %. Phospholipids consisted of a limited number of specific fatty acids, while neutral lipids contained a wide range including some unusual fatty acids. Yellow onion extract contained more organic acid and free sugar than those detected in the white and red onion extract (Shon et al. 2004).

Dry matter content (dry weight basis) in five white and seven red varieties of onion varied from 10.66 to 14.80 %, total water-soluble sugars 41.50–74.00 %, reducing sugars 12.00–22.25 %, nonreducing sugars 25–62 % and total

phenols 1.75–2.95 g/100 g (Baja et al. 1980). The lachrymatory factor and pyruvic acid content ranged from 8.00–27.25 mg/100 g to 6.18–13.27 $\mu\text{mol/g}$, respectively, on a fresh wt basis, respectively. Red varieties contained a higher phenolic content than white varieties. Varieties with higher phenolic contents had greater amount of colouring matter in the dehydrated onions. Among the organic acids (glutamic, oxalic, pyruvic, malic, tartaric, citric and fumaric), in onion cultivars (Texas, Guayonje, San Juan de la Rambla, Carrizal Alto, Carrizal Bajo and Masca), glutamic acid was the most abundant organic acid (325 mg/100 g) followed by citric acid (48.5 mg/100 g) and malic acid (43.6 mg/100 g) (Rodríguez Galdón et al. 2008b). The sweetest onions with respect to low content of pyruvate and high amount of fructose and glucose ranged in pyruvate content from 2.7 to 3.6 $\mu\text{mol/mL}$ (Vågen and Slimestad 2008). These cultivars were juicy and contained low amounts of fructooligosaccharides (FOS) and total flavonols. The most pungent onions contained the highest amounts of FOS among the cultivars: 4.53, 3.80 and 5.81 g/100 g fresh weight (FW), respectively. They also had a high content of flavonols (86.6, 159.2 and 97.6 mg/100 g FW) and high dry weight content (14.6, 13.5 and 15.6 g/100 g). Excepting the lachrymatory factor (thiopropional S-oxide), frozen onion compounds were similar compared to those of fresh onion sample in terms of thiosulfinates and zwiebelanes (Mondy et al. 2002). Conversely, the other transformed (freeze-dried, sterilised) samples lost most of the initially formed compounds and produced mainly disulfides and trisulfides corresponding to the degradation of thiosulfinates and zwiebelanes. These dramatic changes underpinned the very different flavours of these manufactured products compared to fresh material.

Freeze-drying process of fresh onion maintained the concentration of S-alk(en)yl-l-cysteine sulfoxides (ACSOs), organic acids, total sugars, total protein and minerals and significantly increased vitamin C concentration (Colina-Coca et al. 2014). Regarding high-pressure processing (HPP), the concentration of ACSOs, total sugars and vitamin C of fresh onion was preserved at the three HPP assayed (200, 400, 600 MPa for 5 minutes at 25 °C); however, for some organic acids

and minerals, small decreases were found. In high-pressure-treated onion (especially for treatment at 400 MPa), freeze-drying retained the levels of the major organic acids, total sugars, total protein and minerals (Ca, Fe, Mg, K, Na, Zn, Mn and Se) and increased the content of ascorbic acid and total vitamin C. Extensive differences were detected between the sugar concentrations in onion species (Soininen et al. 2014). Yellow onion contained the highest and red onion the lowest amounts of amino acids. The main flavonol–glucosides were quercetin 3,4'-diglucoside and quercetin 4'-glucoside. In general, the levels of flavonols were higher in yellow onions than in red onions.

Invertase activity in onion bulb increased progressively after 8 weeks of storage to 0.084 and 0.092 nkatal/g fresh weight (FW) and then sharply to 0.29 and 0.35 nkatal/g FW at 20 °C and 10 °C, respectively, and remained high during 5 weeks of storage before declining abruptly to 0.039 and 0.041 nkatal/g and remained low during the last 8 weeks (Benkeblia et al. 2004). Glucose increased to 17.73 and 14.62 mg/g FW after 4 weeks at 20 °C and 10 °C, respectively, then decreased sharply between week 5 and week 7 to 4.13 and 4.91 mg/g FW, respectively, and remained rather stable ranging from 9 to 10 mg/g FW at both temperatures. Fructose showed a similar pattern. Between week 10 and week 24, fructose ranged from 5 to 6 mg/g FW and from 6 to 7 mg/g FW at 20 °C and 10 °C, respectively. Sucrose increased to 19.63 and 14.43 mg/g FW at 20 °C and 10 °C, respectively, decreased during 3 weeks and then increased randomly from 5.69 to 9.42 mg/g FW at 20 °C, but remained in a steady state at 10 °C at 5.03 mg/g FW. During the last 6 weeks, the sucrose content was higher at 20 °C than at 10 °C.

Fructans/Oligosaccharides

Fructan (polyfructosylsucrose) was reported to be an important storage carbohydrate in onions (Vijn et al. 1997).

Fructooligosaccharides (degree of polymerisation (DP) 3–c. 11) were the only nonstructural carbohydrates detected apart from glucose, fructose and sucrose in onions (Bacon 1957, 1959; di-Minac 1970; Bose and Shirivastava 1961;

Darbyshire and Henry 1978, 1981). No starch or members of the raffinose series of oligosaccharides were detected (Darbyshire and Henry 1978, 1981). Maximum carbohydrate concentration occurred in DP 5 for *A. cepa* bunching onion (Darbyshire and Henry 1981). The trisaccharides, 1^F -fructosylsucrose and 6^G -fructosylsucrose were found in *A. cepa*. *A. cepa* also contained fructan–fructan fructosyltransferases which transferred fructosyl residues from trisaccharide to form tetrasaccharide and sucrose as the major products (Darbyshire and Henry 1981). The distribution of fructooligosaccharides in onion leaf bases had been studied, and the fructooligosaccharide contents were found to be higher in younger (inner) than in older (outer) leaf bases (Bacon 1959; Darbyshire and Henry 1978). Bacon (1959) found low molecular weight fructans in onion with DP up to 5 and reported two trisaccharides: *O*- α -D-GLUCOPYRANOSYL, (1 $\rightarrow$ 2)-*O*- β -D-FRUCTOFURANOSYL-(1 $\rightarrow$ 2) β -fructofuranoside = 1^F - β -fructosylsucrose (1-kestose or 1-kestotriose) and *O*- β -D-fructofuranosyl-(2 $\rightarrow$ 6)- α -D-glucopyranosyl (1 $\rightarrow$ 2) β -D-fructofuranoside = 6^G - β -fructosylsucrose (neo-kestose or 6^G -kestotriose), which were absent outer older leaf bases and increases to a peak in the inner younger leaf bases. Both were also reported in onion bulbs by Darbyshire and Henry (1978). Di Miniac (1970) reported a similar distribution of tri-tetra- and pentasaccharides (DPs 3, 4 and 5) except that DP 3 and DP 4 were present in outer leaf bases fructans up to DP 11 were reported from onion bulbs and up to DP 9 in individual onion leaf bases (Darbyshire and Henry 1978). Nine fructooligosaccharides were isolated from onion bulbs and identified as $1^F(1\text{-}\beta\text{-D-FRUCTOFURANOSYL})_3$ sucrose [1,1,1-kestopentaose]; $6^G(1\text{-}\beta\text{-D-fructofuranosyl})_2$ sucrose [1,16G-kestopentaose] and $1^F(1\text{-}\beta\text{-D-fructofuranosyl})_m\text{-}6^G(1\text{-}\beta\text{-D-fructofuranosyl})_n$ sucrose $m = 1, n = 1; m = 2, n = 1$ and $m = 1, n = 2$ (Shiomi 1989). The fructosyltransferases purified were confirmed to be sucrose–sucrose 1^F - β -D-FRUCTOSYLTRANSFERASE [SST], $1^F(1\text{-}\beta\text{-D-FRUCTOSYL})_n$ sucrose– $1^F(1\text{-}\beta\text{-D-fructosyl})_m$ sucrose 6^G - β -D-fructosyltransferase [6^G -FT] and $1^F(1\text{-}\beta\text{-D-fructosyl})_n$ sucrose– $1^F(1\text{-}\beta\text{-D-fructosyl})_m$ sucrose 1^F - β -

D-fructosyltransferase (1^F -FT). The following fructooligosaccharides: 1-kestose (1-kestotriose), neokestose (6G-kestotriose), raffinose, 6-kestose, nystose, 1^F and 6^G -di- β -fructosylsucrose; $6^G(1-\beta\text{-fructosyl})_3$ sucrose from onion leaves on extraction were resolved from one another except for fructosylraffinose and fructosylstachyose; $1^F(1-\beta\text{-fructosyl})_2$ - 6^G - β -fructosylsucrose (1 and 1,6G-kestopentaose) and 1^F - β -fructosyl- $6^G(1-\beta\text{-fructosyl})_2$ sucrose; and 1^F - β -fructosyl- $6^G(1-\beta\text{-fructosyl})_3$ sucrose and $1^F(1-\beta\text{-fructosyl})_2$ - $6^G(1-\beta\text{-fructosyl})_2$ sucrose (Shiomi et al. 1991).

Fructan–fructan 6G-fructosyltransferase (6G-FFT) was reported as a key enzyme in the formation of the inulin neoseries, a type of fructan found in onion and other liliaceous plants (Vijn et al. 1997). The accumulation of fructooligosaccharides and the activities of fructosyltransferase (sucrose–sucrose 1^F -fructosyltransferase (SST), 1^F -fructosyltransferase (1^F -FT) and 6^G -fructosyltransferase (6^G -FT)) in the bulbs of three onion cultivars were investigated from June to September 1993 (Shiomi et al. 1997). The total fructooligosaccharide content increased from June until August and then decreased in September, except in one cultivar. The levels of neokestose and its related tetrasaccharides (1^F , 6^G -di- β -D-fructofuranosyl sucrose and $6^G(1-\beta\text{-D-FRUCTOFURANOSYL})_2$ sucrose) were higher than those of 1-kestose and nystose throughout growth of onion bulb. The activities of fructosyltransferase (sucrose–sucrose 1^F -fructosyltransferase (SST), 1^F -fructosyltransferase (1^F -FT) and 6^G -fructosyltransferase (6^G -FT)) were high in June and July and then decreased; SST activity was very low in September. The activity ratios of 6^G -FT to 1^F -FT varied between 1.86 and 2.65 over the growth period. Two trisaccharides, three tetrasaccharides and four pentasaccharides were identified, together with a mixture of hexa- and heptasaccharides. All the saccharides produced from sucrose, 1-kestose or neokestose, by the crude enzyme prepared from onion bulbs were identical to the saccharides occurring naturally in onion bulbs. A fructosyltransferase that

transfers the terminal (2→1)-β-linked D-fructosyl group of fructooligosaccharides ($1^F(1\text{-}\beta\text{-D-FRUCTOFURANOSYL})_n$ sucrose, $n \geq 1$) to HO-6 of the glucosyl residue and HO-1 of the fructosyl residue of similar saccharides ($1^F(1\text{-}\beta\text{-D-FRUCTOFURANOSYL})_m$ sucrose, $m \geq 0$) was purified from an onion bulb extract (Fujishima et al. 2005). The enzyme tentatively classified as fructan–fructan 6^G-fructosyltransferase (6G-FFT) was proposed to play an important role in the synthesis of inulin and inulin neoseries fructooligosaccharides in onion bulbs.

Benkeblia et al. (2005) found the contents of trisaccharide (Tri), fructooligosaccharide (FOS) and total FOS of onion bulbs decreased abruptly during the first 8 weeks of storage; however, at 10 °C, contents of Tri, FOS (DP 3–12) and total FOS were lower than those at 20 °C. 1-fructo-exohydrolase (1-FEH) peaked sharply after 10 weeks and seemed to be triggered by a decrease in sucrose content. 1-kestose-hydrolysing (1-KH) increased during the first 8 weeks and remained stable during the last 8 weeks of the 24-week storage.

Onion and shallot (*Allium cepa*) were reported to exhibit wide variation in bulb fructan content (Yaguchi et al. 2008). It was found that concordance between chromosome 8 localisation of sucrose phosphate synthase and elevated leaf sucrose levels conditioned by high fructan alleles at the Frc locus in onion bulb suggested that the Frc locus on chromosome 8 may condition much of this variation.

Onion cell walls comprised a range of pectic polysaccharides with varying proportions of neutral side chains (Mankarios et al. 1980). It was found that (1,4')-linked galactans and a substituted xyloglucan were probably major components. Exhaustive treatment of onion tissue with pectin lyase solubilised 89 % of the total uronides of onion cell wall pectic polysaccharides (Ishii 1982). The galacturonides released from the tissue were separated into three fractions (10.7, 5.3 and 84 %, in order of molecular weight (MW)). The low MW fraction was a mixture of oligogalacturonides. The intermediate MW fraction was a rhamnogalacturonan II type

component which contained 3- and 3,4-linked rhamnose. Methylation analysis showed that the pectic polysaccharides of onion resembled those of potato tuber. Onion cell wall materials were found to be rich in uronic acid and glucose, with smaller quantities of arabinose, galactose and xylose (Ng et al. 2000). In the fleshy scales, the lower epidermis contained relatively more galactose-rich pectic polysaccharides, whereas the upper epidermis and the papery scales contained virtually no galactose. A small but significant amount of ferulic acid was found in the walls, predominantly in the thick cuticle of the lower epidermis of fleshy scales. Alkali-labile wall-bound flavonoids were also detected.

In fresh onions, the Grano de Oro variety had low contents of total fructans and fructooligosaccharide (FOS) but high levels of reducing sugars (Jaime et al. 2001). In the other varieties, Sturon, Hysam, Durco and Caribo fructans were the main carbohydrates, the lowest polymerised FOS being the major oligomer. Storage period caused in these important varieties increased levels of free fructose attributed to fructan hydrolysis. Varieties with >16 % dry matter or 15 % soluble solids contents could be stored for 6 months at 0 °C and 60–65 % relative humidity. Brown onion skin exhibited the highest total dietary fibre (TDF) content (65.8 %) on a dry matter basis, followed by top (48.5 %) and bottom (38.6 %) and insoluble dietary fibre (IDF) being the main fraction found (Jaime et al. 2002). The soluble dietary fibre (SDF)–IDF ratio decreased from inner to outer tissues. Brown onion skin and outer leaves by-products appeared to be the most suitable sources of dietary fibre (DF) that might be used in food product supplementation. Cellulose and pectic polysaccharides were the main components of onion DF in all tissues. An increase in the uronic acids/neutral sugars ratio from inner to outer tissues was found, suggesting that the galactan side chain possessed a DF solubilisation role.

Carrizal Bajo and Carrizal Alto onion cultivars presented the highest moisture content and lowest protein, fibre, sugars and total fructans contents (Rodríguez Galdón et al. 2009). In contrast, the Texas cultivar had the highest total and insoluble fibre and glucose contents, the Masca cultivar had the highest

ash and protein contents, the Guayonje cultivar had the highest fructose and total sugar contents, and the San Juan de la Rambla had the highest Brix degree and total fructan contents. Significant differences in many of the parameters analysed were observed between the two seed origins for the Guayonje and San Juan de la Rambla cultivars. Onion-soluble nonstructural carbohydrates were reported to consist of fructose, glucose and sucrose plus fructooligosaccharides (FOS) with degrees of polymerisation (DP) in the range of 3–19 (Downes and Terry 2010). They found that a methanol-based free mobile phase method for LC-ELSD quantification of fructooligosaccharides was more efficacious at extracting sugars and FOS from onion flesh, eluting significantly higher concentrations of glucose, kestose, nystose and DP5-DP8 than the ethanol-based method. The polysaccharide fraction extracted from onion bulbs contained a mixture of galactan with short-length sugar chains, pectic polysaccharides and evident content of proteinaceous material (Golovchenko et al. 2012). Galacturonan and rhamnogalacturonan were the main constituents of the linear regions of the sugar chains of the pectic polysaccharides. The ramified regions included rhamnogalacturonan I. The side chains of the ramified region contained mainly 1,4-linked β -D-galactopyranose residues and lesser content of 1,3-linked β -D-galactopyranose and 1,5-linked α -L-arabinofuranose residues. Furthermore, the proteinaceous material was found to be partly linked to the sugar chains. The polysaccharide fraction extracted from onion bulbs was found to decrease absorption of ovalbumin (OVA) to the blood from the gut lumen (Golovchenko et al. 2012). The serum OVA level was threefold lower in mice fed with OVA mixed with the onion pectins compared with the control group, which was administered with OVA alone.

Other Phytoproteins/Peptides

Gamma-glutamyl peptidase that cleaves γ -glutamyl peptides was found in sprouting onion (Matikkala and Virtanen 1965). Extracts of commercially frozen onion, although possessing considerable peroxidase and catalase activity, were devoid of strong flavour and of L-cysteine sulfoxide lyase activity, the

enzyme considered to be responsible for the development of onion flavour (Schwimmer and Guadagni 1968). It was found that both odour and pyruvic acid may be produced via the same enzyme but that the odour was formed after the formation of pyruvic acid. From the data, it was calculated that the odour threshold value of some of the enzymatically produced odour-bearing constituents in onions may be less than one part per billion. An enzyme capable of liberating *p*-nitroaniline from γ -L-glutamyl *p*-nitroanilide was purified 800-fold from sprouted onions (Schwimmer and Austin 1971). The purified enzyme was a transpeptidase, whereas crude onion extract may, in addition, possess a true γ -glutamyl hydrolase. It was suggested that such enzymes may play a role in the disappearance of peptides in post-dormant onions and may be useful evoking the full flavour potential of onion.

Quantitative analysis of γ -glutamyl peptides in onion bulbs showed that γ -glutamyl *trans*-(+)-*S*-(1-propenyl)-L-cysteine sulfoxide (γ -glutamyl propenyl CSO) and *S*-2-carboxypropyl glutathione (2CPGTH) were absent prior to bulbing and then at bulbing accumulated to levels of 2.1 and 0.4 mg/g FW, respectively, that were maintained throughout storage (Lancaster and Shaw 1991). The hydrolytic enzyme γ -glutamyl transpeptidase exhibited minimal activity in a stored bulb, but during sprouting, activity increased ca fivefold. Levels of γ -glutamyl propenyl CSO and 2CPGTH decreased by 50 % to 0.94 and 0.14 mg/g FW. γ -Glutamyl transpeptidase that catalyses hydrolysis of γ -glutamyl linkages in γ -glutamyl peptides and transfer of the γ -glutamyl group to amino acids and peptides was purified from sprouting onion bulb (Shaw et al. 2005). It catalysed transpeptidation of methionine by the synthetic substrate γ -glutamyl-*p*-nitroanilide (GGPNA) and obtained N-terminal peptide sequence. This enzyme showed high affinity for glutathione and glutathione conjugates. The major onion γ -glutamyl peptide, γ -glutamyl *trans*-*S*-1-propenyl cysteine sulfoxide (GGPrCSO), exhibited uncompetitive inhibition of transpeptidation by GGPNA. This suggested GGPrCSO to be a poor glutamyl donor and therefore unlikely to be an in-vivo substrate for peptidase activity by this enzyme. From onion bulbs, a novel antifungal peptide, allicepin, with molecular weight of 10 K was isolated

(Wang and Ng 2004). A plant growth bioregulator was isolated from onion bulb and determined to be a peptide of molecular weight of 4,036 Da comprising 18-C-terminal amino acid sequence of 18 residues (Kulikova et al. 2011). It inhibited seedling growth and development of some vegetables.

Phenolic Compounds/Flavonoids (Flavonols, Dihydroflavonols, Anthocyanins)

Onions had been reported as a major dietary source of flavonoids (principally flavonols and dihydroflavonols and anthocyanins) (Rhodes and Price 1996; Slimestead et al. 2007). Epidemiologic evidence had correlated diets rich in flavonoid compounds with a low risk of coronary heart disease. Hertog et al. (1992) found onion to be the richest source of flavonols among 28 vegetables and fruits studied. Onions was described as one of the richest and most common source of the antioxidant flavonoid quercetin (Nemeth and Piskula 2007). The main flavonoids of onion extract were kaempferol, myricetin, quercetin and quercitrin (Hur et al. 2013). Yellow onions were found to contain 270–1,187 mg of flavonols per kilogram of fresh weight (FW), whereas red onions contain 415–1,917 mg of flavonols per kilogram of FW (Slimestead et al. 2007). At least 25 different flavonols had been characterised, and quercetin derivatives were the most important ones in all onion cultivars, while analogous derivatives of kaempferol and isorhamnetin had been identified as minor pigments. Onion peels contained abundant epicatechin and morin; their contents in the methanol extract were 1.1–4.8 times higher than those of in ethanol or acetone extracts. Other phenolics found included catechin, epigallocatechin gallate, quercitrin, myricetin, resveratrol, quercetin, naringenin, apigenin and kaempferol (Kim et al. 2013).

A general increase in the total sum of flavonoids was determined in onions during 7 months storage at ambient temperature, whereas fluctuations were observed in different onion fleshy scale layers (Sharma et al. 2013). The outer

fleshy scales contain higher water content and also highest concentration of flavonoids per dry weight. Quercetin recorded increases during the storage period, and in each scale layer, the content of quercetin 3,4'-*O*-diglucoside was higher than quercetin 4'-*O*-monoglucoside, and these ratios were maintained during the storage period. The dry matter content increased towards the inner scales of onion. High content of glucose and fructose in the middle scales was observed, whereas high content of sucrose was found in the inner scales. The contents of sugars (fructose, glucose, sucrose) in onion bulb as a whole declined after 7 months. During storage, the distribution of amino acids (phenylalanine and tryptophan) varied inconsistently in different scale layers.

Herrmann (1956, 1958) identified quercetin 4-glucoside (spiraeoside) as the main flavonol and quercetin in the pigmented scales of 'Braunschweiger Dunkelblutrote' cultivar. Koeppen and Van Der Spuy (1961) identified quercetin 4'-glucoside as the main flavonol and also detected the presence of quercetin 5-glucoside and quercetin 3-diglucoside in the cultivar 'Australian Brown'. Southport Yellow Globe, Southport White Globe and Southport Red Globe onion cultivars were found to contain quercetin 4'-glucoside, quercetin 3,4'-diglucoside, quercetin 4',7'-diglucoside and quercetin 3-glucoside (Brandwein 1965). In addition, Southport Yellow Globe contained quercetin, and Southport Red Globe contained quercetin and peonidin-3-arabinoside. Harborne (1965) found 3,4'-diglucoside and 7,4' diglucoside of quercetin in onion. Starke and Herrmann (1975) found that onion scales contained exclusively glucosides of quercetin as flavonols, while the dry outer skins contained quercetin mainly in the free state. The flavonol concentration decreased from the outer to the inner scales, with higher levels in the outer than in the inner epidermis. Tissut (1972) identified quercetin 3-glucoside (isoquercetin), kaempferol 3-glucoside (astragalin), kaempferol 4'-glucoside and isorhamnetin 4'-glucoside as minor pigments. Panisset and Tisot (1983) identified 3,7'-diglucoside, from onion bulb, quercetin 7-glucoside, kaempferol and kaempferol 7,4'-diglucoside as minor pigments. Kaempferol was detected in onion peels (Bhandari 1970). Fluorescing compounds in onion guard and

epidermal cells were identified to be 7-*O*-glucuronides of quercetin and kaempferol (Weissenböck et al. 1987). In addition to the main flavonol glycoside spiraeoside in onion bulbs, kaempferol 4'-*O*- β -glucoside was found in smaller amounts and traces of other flavonoids were also detected (Scheer and Wichtl 1987).

Four flavonol glycosides isolated from the wet scales of the deep purple onion cv. Res Creole were identified as quercetin 3'-glucoside, quercetin 4'-glucoside, quercetin 3,4'-diglucoside and isorhamnetin 3-glucoside (Omidiji 1993). Flavonoids in edible part of onion were isolated, and their structures were determined as quercetin 3-*O*- β -glucoside, quercetin 4'-*O*- β -glucoside, quercetin 7-*O*- β -glucoside, quercetin 3,4'-di*O*- β -glucoside and quercetin 3,7-di*O*- β -glucoside with the small amounts of quercetin 7,4'-di*O*- β -glucoside (Tsushida and Suzuki 1995). Kaempferol 3- β -glucoside, kaempferol 7-*O*- β -glucoside and kaempferol 3,7-di*O*- β -glucoside were obtained. The major flavonoid found in onion was quercetin 4'-*O*- β -glucoside, closely followed by quercetin 3,4'-di*O*- β -glucoside; these two flavonols accounted for more than 85 % of the total amount of flavonoids in onion. The flavonoid comprising more than 1 % of total flavonoid in onion were quercetin 3-*O*- β -glucoside, quercetin 7-*O*- β -glucoside, quercetin 7,4'-di*O*- β -glucoside and isorhamnetin 4'-*O*- β -glucoside. The minor flavonoids, isorhamnetin 3,4'-di*O*- β -glucoside, kaempferol 3,4'-di*O*- β -glucoside and kaempferol 4'-*O*- β -glucoside, were also detected in onion.

Total quercetin content in 75 yellow, pink and red onion cultivars varied from 54 to 286 mg/kg (Patil et al. 1995). White onions contained trace amounts of total quercetin. Free quercetin content in all the onions was low (<0.4 mg/kg) except in cultivar '20,272-G' (12.5 mg/kg fresh weight). Onion bulbs stored at 5, 24 and 30 °C, and controlled atmosphere (CA) for 0,1,2,3,4 and 5 months showed a most marked change in total quercetin content at 24 °C compared to other treatments, with a rise in mid-storage followed by a drop. Storage at 5 and 30 °C also demonstrated a similar change. Two major components, quercetin monoglucoside and quercetin diglucoside, account for 80 % of the total flavonoids

in onions (Rhodes and Price 1996). Anthocyanins are only minor components of the flavonoid spectrum in the edible portion of red varieties. Seven major flavonoid compounds in onions were isolated and identified as quercetin, quercetin monoglucoside, quercetin diglucoside, isorhamnetin, isorhamnetin glycoside, rutin and kaempferol (Park and Lee 1996). Two flavonol-glucosides, quercetin 3,4'-*O*-diglucoside (Qdg) and quercetin 4'-*O*-monoglucoside (Qmg), accounted for over 85 % of the total flavonoids in three varieties of onion with Qdg as the main component (Price and Rhodes 1997). Quercetin was detected in these long stored onions but only at low levels of less than 2 % of the total. The remaining flavonoid fraction (approx. 15 %) comprised up to 17 different components of which quercetin 3-*O*-glucoside and isorhamnetin glucoside were prominent members although each contributes less than 1 % of the total flavonoid fraction. There were significant differences in the levels of Qdg and Qmg between the four different onion varieties analysed, Qdg varying from 50 to 1,300 mg kg⁻¹ fresh onion tissue and Qmg from 36 to 394 mg/kg. Maceration of the tissue for the three varieties tested led to a loss of Qdg and the appearance of Qmg and free quercetin. Hirota et al. (1998) reported that the two major onion flavonol glycosides, quercetin 3,4'-*O*-diglucoside and quercetin 4'-*O*-monoglucoside, and a flavonol aglycone quercetin were mainly localised in the abaxial epidermis of scales. Their contents increased on aging. Peroxidase in scales oxidised flavonols in the order quercetin >> quercetin 4'-*O*-monoglucoside > isoquercetin >> quercetin 3,4'-*O*-diglucoside 1, and the activity was higher in the outer than in the inner scales. Contents of quercetin 3,4'-*O*-diglucoside and quercetin 4'-*O*-monoglucoside in scales were decreased by cooking by boiling. Quercetin 3,7,4'-*O*- β -*triglucopyranoside* together with quercetin, quercetin 4'-*O*- β -glucopyranoside and quercetin 3,4'-*O*- β -diglucopyranoside was isolated from the pigmented scales of *Allium cepa* var. 'Red Baron' (Fossen et al. 1998). Minor amount of taxifolin 4'-*O*- β -gluopyranoiside, a rare dihydroflavonol, was also detected. A new compound named quercetin 3'-methoxy-4'-*O*- β -D-GLUCOPYRANOSIDE, together with three known compounds kaempferol, quercetin 4'-*O*- β -D-GLUCOPYRANOSIDE and

quercetin 3,4'-di-*O*- β -D-glucopyranoside(IV), were isolated from *A. cepa* var. *aggregatum* bulbs (Yang et al. 2000).

Three major flavonoids, kaempferol, myricetin and quercetin, were identified and quantified in Georgia-grown *Vidalia* onions (Sellapan and Akoh 2002). Quercetin was the major flavonoid (7.70–46.32 mg/100 g fresh weight, FW) present in all varieties, followed by myricetin (2.77–4.13 mg/100 g FW). Minor quantities of kaempferol (1.10–1.98 mg/100 g FW) were also detected. The flavonols extracted from 12 onion varieties (red, yellow, white) consisted mainly of quercetin and isorhamnetin in the form of aglycones and glycosides (Marotti and Piccaglia 2002). The highest amount of free quercetin was detected in the fresh bulbs of 'Tropea rossa tonda' (557.8 mg/kg), whereas that of total flavonoids was found in 'Dorata Density' (979.1 mg/kg). The golden cultivar 'Castillo' resulted in the highest bulb and flavonoid yields (6.7 kg/m and 5.2 g/m, respectively). The main flavonol in two Portuguese onion regional varieties, Póvoa white and Póvoa red onions, was quercetin 4'-glucoside, representing 55.3 % in the red variety (35.43 mg/100 g FW) and 54.35 % in the white (3.94 mg/100 g FW) (Rodrigues et al. 2003). Total anthocyanin content in red variety (5.37/100 g FW) was higher than for white variety (3.94/100 g FW). Consequently, antioxidant activity was higher for the red variety. Concerning pungency, red variety was classified as sweet (4.69 μ mol pyruvic acid/g FW) and white as very sweet (3.12 μ mol pyruvic acid/g FW).

Furusawa et al. (2003) isolated four flavonoid compounds from brown onion scales: different quercetin dimers (1 and 2), quercetin and quercetin 4'-glucoside. Seven flavonols were identified in southern Italian red onion, quercetin 4'-glucoside and quercetin 3,4'-diglucoside being the most abundant components (Bonaccorsi et al. 2005). Five minor flavonols, quercetin 3-glucoside, quercetin 7,4'-diglucoside, quercetin 3,7,4'-triglucoside, isorhamnetin 4'-glucoside and isorhamnetin 3,4'-diglucoside, were also found. Traces of isorhamnetin 3-glucoside and free quercetin were also detected. Fisetin (3,7,3',4'-tetrahydroxyflavone), a flavonol, was reported in onions (Adhami et al. 2012; Syed et al. 2013).

Kaempferol 3-*O*- β -D-glucopyranoside (astragalin) was isolated from onion husk (Muminov et al. 2006). Furusawa et al. (2002) isolated quercetin and quercetin 4'-*O*- β -D-glucoside together with novel isomeric quercetin dimmers, 1,3,11 α -trihydroxy-9-(3,5,7-trihydroxy-4H-1-benzopyran-7-on-2-yl)-5 α -(3,4-dihydroxyphenyl)-5,6,11-hexahydro-5,611-trioxanaphthacene-12-one (quercetin dimer) and [1,3,11 α -trihydroxy-9-(3,5,7-trihydroxy-4H-1-benzopyran-7-on-2-yl)-5 α -(3,4-dihydroxyphenyl)-5,6,11-hexahydro-5,6,11-trioxanaphthacene-12-one]-4'-*O*- β -D-GLUCOPYRANOSIDE (4'-*O*- β -D-glucopyranoside of quercetin dimer) from onion. Ly et al. (2005) isolated the following flavonoid compounds from the methanol extract of dry outer scales of onion: protocatechuic acid (3,4-dihydroxybenzoic acid) [1]; 2-(3,4-dihydroxybenzoyl)-2,4,6-trihydroxy-3(2*H*)-benzofuranone [2]; quercetin 4'-*O*- β -D-GLUCOPYRANOSIDE [3]; quercetin [5]; 4'-*O*- β -D-glucopyranoside of quercetin dimer, i.e. 1,3,11 α -trihydroxy-9-(3,5,7-trihydroxy-4H-1-benzopyran-4-on-2yl)-5 α -[4-(β -D-glucopyranosyloxy)-3-hydroxyphenyl]-5,6,11-hexahydro-5,611-trioxanaphthacene-12-one [7]; 1,3,11 α -trihydroxy-9-(3,5,7-trihydroxy-4H-1-benzopyran-4-on-2yl)-5 α -(3,4-dihydroxyphenyl)-5,6,11-hexahydro-5,611-trioxanaphthacene-12-one [8] and a stereoisomer of 1,3,11 α -trihydroxy-9-(3,5,7-trihydroxy-4H-1-benzopyran-4-on-2yl)-5 α -[4-(β -D-glucopyranosyloxy)-3-hydroxyphenyl]-5,6,11-hexahydro-5,611-trioxanaphthacene-12-one [9]. Compounds [4a] and [4b] were found to be isomers of quercetin and protocatechuic acid moieties, but their precise structures could not be determined. Compound [6] was assumed to be stereoisomers of 2-[4-(β -D-glucopyransoyloxy)-3-hydroxyphenyl]-3,5,7-trihydroxy-9-[2-(3,4-dihydroxyphenyl)-2,3-dihydro-2,3-epoxy-5,7-dihydroxy-4H-1-benzopyrane-4-on-8-yl]-4-H-1-benzopyrane-4-one. Mohamad (2008) isolated a new flavonoid named alliuocide G, with the structure 1,3,9,11 α -tetrahydroxy-5 α -(3,4-dihydroxyphenyl)-5,11-dihydro-5,6,11-trioxanaphthacene-12-one, together with four known compounds: 2-(3,4-dihydroxybenzoyl)-2,4,6-trihydroxy-3 (2*H*)-benzofuranone; 1,3,11 α -trihydroxy-9-(3,5,7-trihydroxy-4H-1-benzopyran-7-on-2-yl)-5 α -(3,4-dihydroxyphenyl)-5,6,11-hexahydro-5,611-trioxanaphthacene-12-one (quercetin dimer); luteolin-7-*O*- β -D-

glucopyranoside and [1,3,11 α -trihydroxy-9-(3,5,7-trihydroxy-4H-1-benzopyran-7-on-2-yl)-5 α -(3,4-dihydroxyphenyl)-5,6,11-hexahydro-5,6,11-trioxanaphthacene-12-one]-4'-O- β -D-GLUCOPYRANOSIDE (4'-O- β -D-glucopyranoside of quercetin dimer) from the ethyl acetate fraction of the dried outer onion scales.

High concentrations of quercetin, quercetin 4(I)-glucoside, taxifolin, taxifolin 7-glucoside and phenylalanine were isolated from Tropea red onion bulb (Correa et al. 2005). Five quercetin compounds (isoquercetin, quercetin diglucoside, quercetin monoglucoside 1, quercetin monoglucoside 2 and free quercetin) and kaempferol were identified and quantified from five traditional onion cultivars from Tenerife (Rodríguez Galdón et al. 2008a). Quercetin monoglucoside 1 and quercetin diglucoside were the major flavonoids accounting for 80 % of the total quercetin content. Microwave extraction of antioxidant flavonoids from onion offered important advantages like shorter extraction time (23 minutes), cleaner feature (no solvent or water used) and extraction of valuable onion crude juice retaining fresh organoleptic properties with higher phenolic content (58.29 mgGAE/gDW) at optimised power (500 W) (Zill-E-Huma et al. 2009). Microwave extraction afforded significant yield (81.5 %) with 41.9 % of flavonol contents, with better retention of remaining flavonoids (55.9 %) in residues of onions. Quercetin 3,4'-diglucoside (239.7 mg/100 gDW) and quercetin 4'-monoglucoside (82.55 mg/100 gDW) were found as the main flavonols. Minor quantities of quercetin aglycone (traces), quercetin 3-monoglucoside (4.22 mg/100 gDW) and kaempferol (3.99 mg/100 gDW) were also detected in microwave onion extracts.

Quercetin (Q), quercetin 3,4'-di-O- β -glucoside (Q3, 4'G), quercetin 3-O- β -glucoside (Q3G) and quercetin 4'-O- β -glucoside (Q4'G) were determined in onion bulbs by electrochemical methods (Zielińska et al. 2008a). Total quercetin ranged from 83 to 330 μ g/g F.W. in six selected cultivars of long-day or short-day onions (Yoo et al. 2010). Quercetin 3,4'-diglycoside and quercetin 4'glycoside were the two major compounds and comprised approximately between

94 and 97 % of total quercetin in onions. Also present were quercetin 4,7'-diglycoside, quercetin 3-glycoside, isorhamnetin 4'glycoside and quercetin.

Four new quercetin-derived oxidation products, namely, 2-(3,4-dihydroxyphenyl)-4,6-dihydroxy-2-methoxybenzofuran-3-one; 3-phloroglucinoyl-2,3-epoxyflavanone; 3-[3-(1-methylglyoxylate-2,4,6-trihydroxyphenyl)]-2,3-epoxyflavanone and 3-(quercetin-8-yl)-2,3-epoxyflavanone and 2,5,7,3',4'-pentahydroxy-3,4-flavandione; and lunularin-4-*O*- β -D-glucoside, were isolated from a water extract of onion skin, together with other known compounds: 2,5,7,3',4'-pentahydroxy-3,4-flavandione; β -sitosterol-3-*O*- β -D-glucopyranoside; syringaresinol; quercetin and quercetin 4'-*O*- β -glucopyranoside; 4'-methylquercetin-3-*O*- β -glucopyranoside, 4'-*O*-methylquercetin and trihydroxyphenylglyxolate; methyl 2,4,6-trihydroxyphenylglyxolate; 4,2'3'-trihydroxybibenzyl; phloroglucinoyl-3,4-dihydroxybenzoate; methyl 3,4-dihydroxybenzoate; 3,4-dihydroxybenzoic acid; *p*-hydroxybenzoic acid and phloroglucinol (Ramos et al. 2006). Two known compounds, quercetin and quercetin 3'-*O*- β -D-glucopyranoside (Q3'G), and one novel compound, quercetin 3-*O*- β -D-glucopyranoside-(4 $\rightarrow$ 1)- β -D-glucopyranoside (Q3M), was identified in onion (Xue et al. 2011). These flavonoids were found to be more abundant in the onion peel than in the flesh or core. The major polyphenols detected in onion solid wastes were quercetin and quercetin 4'-*O*-glucoside, accompanied by protocathechuic acid and a benzofuranone derivative (Khiari and Makris 2012). It was found that quercetin 4'-*O*-glucoside content increased by 13.3 %, while quercetin, benzofuranone derivative and protocathechuic acid contents increased by 68.6, 37.5 and 58.4 %, respectively. β -Glycosidase activity exhibited fluctuations and increased by 38.2 %, whereas the peroxidase showed a constant increasing trend, leading in 21.7 % higher activity.

Lindahl et al. (2013) used a continuous flow hot water extraction and thermostable β -glucosidase enzymatic hydrolysis (84 °C, 5 % ethanol, pH 5.5, 3 mL/minute) to extract quercetin from quercetin 3,4'-diglucoside in yellow, red

and shallot onions and resulted in higher or similar yield (e.g. 8.4 $\mu\text{mol g}^{-1}$ fresh weight yellow onion) compared to a conventional batch extraction method using methanol as extraction solvent. Onion treated by high-pressure processing (HPP) and combined with freeze-drying and pulverisation (HPP-FD-P) increased quercetin 3,4'-diglucoside, quercetin 4'-glucoside, quercetin 3-glucoside and isorhamnetin 3,4'-diglucoside extractability (González-Peña et al. 2013). Eighteen compounds were identified in the volatile fraction of onion, belonging mainly to di- and trisulfides and aldehydes (Colina-coca et al. 2013). Freeze-dried and pulverised onion samples presented an increase in 2-methyl 2-pentenal, dimethyl trisulfide and methyl propyl trisulfide compared with diced samples regardless of the high-pressure treatment (Colina-coca et al. 2013). However, freeze-drying and pulverisation processes affected the stability of propionaldehyde, 1-propanethiol, hexanal, dipropyl disulfide and dipropyl trisulfide, diminishing their content regardless of high-pressure treatment. HP at 200 and 400 MPa/25 °C/5 minutes were the least detrimental treatments to the total fraction of volatile compounds, not affecting or even increasing the levels of some volatile compounds.

Main flavonoids (mg/kg FW) in the dry skin, outer fleshy layer, edible portion of Tropea red onions were, respectively, as follows: delphinidin 3-glucosylglucoside (3,524 mg, 47 mg, 65 mg), cyanidin 3-(6"-malonylglucoside) (330 mg, 100 mg, 15 mg), cyanidin 3-(6"-malonyl-3"-glucosylglucoside) (2,054 mg, 50 mg, 10 mg) and quercetin 4'-glucoside (1,887 mg, 656 mg, 598 mg) (Gennaro et al. 2002). Flavonols quercetin and quercetin derivatives were the major flavonols in Tropea red onion with quercetin 4-glucoside as the major compound. The anthocyanins were heavily concentrated in the skin and outer fleshy layer. The dry skin was found to be rich in anthocyanins and flavonols with a high percentage of aglycone forms. Anthocyanins comprised about 63 % of the dry skin. The outer fleshy layer was found to be rich in cyanidin derivatives. Major anthocyanins in Tropea red onions were delphinidin 3-(glucosylglucoside) and cyanidin 3-(malonylglucoside); other anthocyanins found included cyanidin glucoside, cyanidin (glucosylglucoside), delphinidin glucosylglucoside, petunidin

(glucosylglucoside), cyanidin (malonylglucoside), cyanidin (malonyl glucosylglucoside), delphinidin 3-glucoside, petunidin glucoside, delphinidin and cyanidin aglycones. Storage of onions for 6 weeks in different conditions, all of them mimicking home storage habits, resulted in a decrease to 64–73 % of total anthocyanins. The same trend was verified for the total antioxidant activity, which was reduced to 29–36 %. A decrease in glucose and fructose content correlated with anthocyanin degradation was also observed. Storage at low temperature appeared to better preserve the onion anthocyanins.

Altogether at least 25 different anthocyanins had been reported from red onions, including two novel 5-carboxypyranocyanidin derivatives (Slimestead et al. 2007). The quantitative content of anthocyanins in some red onion cultivars had been reported to be approximately 10 % of the total flavonoid content or 39–240 mg/kg FW. The anthocyanins of red onions were mainly cyanidin glucosides acylated with malonic acid or nonacylated. Seven cyanidin and one peonidin glycosides were found in the bulbs of the Ruby and Southport Red Globe varieties of red onion; the major ones were cyanidin 3-glucoside and cyanidin 3-diglucoside (Fuleki 1971). The peonidin monoside present only in minor quantity was identified as peonidin 3-glucoside. Cyanidin 3-laminariobioside was identified in Spanish red onion by Du et al. (1974). Four cyanidin-based anthocyanins were isolated from the red onion and identified as cyanidin 3-glucoside, cyanidin 3-malonylglucoside, cyanidin 3-laminaribioside and cyanidin 3-malonyllaminaribioside (Teraha et al. 1994). Anthocyanins cyanidin 3-glucoside, cyanidin 3-arabinoside, cyanidin 3-malonylglucoside and cyanidin 3-malonylarabinoside and the flavonoids quercetin 3,4'-diglucoside, quercetin 7,4'-diglucoside, quercetin 3-glucoside, dihydroquercetin 3-glucoside and isorhamnetin 4'-glucoside were identified in the edible parts of the Spanish red onion (cultivar 'Morada de Amposta') (Ferrerres et al. 1996). The amount of anthocyanins reached 233 mg/kg and that of the flavonoids 943 mg/kg fresh weight of onions. The stability of the individual anthocyanins in onions after 7 days of storage at

8 °C was very different, the malonated anthocyanins being much more stable than the corresponding nonacylated pigments. Additionally, the arabinosides were shown to be less stable than the corresponding glucosides. Fossen et al. (1996) found that in five different red onion cultivars, cyanidin 3-(6'-malonyl-3'-glucosylglucoside), cyanidin 3-(6'-malonylglucoside) and cyanidin 3-glucoside constituted >95 % of the total anthocyanins. The colour of red onions was found to be due primarily to anthocyanins present in the epidermal cells of the scale leaves of the bulb (Donner et al. 1997). The occurrence of the four major anthocyanins, cyanidin 3-glucoside, cyanidin 3-laminaribioside, cyanidin 3-malonylglucoside and cyanidin 3-malonyllaminaribioside, was confirmed in four red onion cultivars, namely, 'Mambo', 'Red Jumbo', 'Red Bone' and 'Red Granex'. In addition, four new minor anthocyanin pigments including peonidin 3-glucoside and peonidin 3-malonylglucoside were isolated and characterised from red onions. Four anthocyanins with the same 4-substituted aglycone, carboxypyranocyanidin, were isolated from acidified, methanolic extracts of the edible scales and from the dry outer scales of red onion (Fossen and Andersen 2003). The structures of the two of them were identified as the 3-*O*- β -glucopyranoside (1) and 3-*O*-(6''-*O*-malonyl- β -glucopyranoside) of 5-carboxypyranocyanidin (2). The aglycone, 5-carboxy-2-(3,4-dihydroxyphenyl)-3,8-dihydroxy-pyrano[4,3,2-de]-1-benzopyrylium, was similar to carboxypyranomalvidin (vitisidin A) recently isolated from red wines with exception of the substitution pattern on the phenyl ring. Two analogues of compound 2 methylated at the terminal carboxyl group of the acyl moiety (compound 3) or at the aglycone carboxyl (compound 4), respectively, were also identified. The anthocyanins, cyanidin 3-*O*-(3''-*O*- β -glucopyranosyl-6''-*O*-malonyl- β -glucopyranoside)-4'-*O*- β -glucopyranoside, cyanidin 7-*O*-(3''-*O*- β -glucopyranosyl-6''-*O*-malonyl- β -glucopyranoside)-4'-*O*- β -glucopyranoside, cyanidin 3,4'-di-*O*- β -glucopyranoside, cyanidin 4'-*O*- β -glucoside, peonidin 3-*O*-(6''-*O*-malonyl- β -glucopyranoside)-5-*O*- β -glucopyranoside and peonidin 3-*O*-(6''-*O*-malonyl- β -glucopyranoside) were isolated in minor amounts from pigmented scales of red onion (Fossen et al. 2003).

Inheritance studies indicated that a single gene determined the colour difference between yellow and red onions and that anthocyanin was a primary determinant of red colour in onions (Kim et al. 2004b). Of five structural genes, chalcone synthase (CHS), flavanone 3-hydroxylase (F3H), dihydroflavonol 4-reductase (DFR) and anthocyanidin synthase (ANS) genes, it was found that inactivation of DFR gene transcription resulted in blockage of anthocyanin production in yellow onions. Four anthocyanins were identified in red onion predominated by peonidin 3-glucoside and cyanidin 3-(6"-malonoyl-laminaribioside), while cyanidin 3-glucoside and cyanidin 3-(6"-malonoylglucoside) were found in lower amounts (Duangjit et al. 2014).

Microwave cooking without water better retained onion flavonoids quercetin 4'-*O*- β -glucoside (Q4'G) and quercetin 3,4'-*O*- β -diglucosides (Q3,4'G) and ascorbic acid (Ioku et al. 2001). Frying with oil or butter did not affect flavonoid intake. The boiling of onion led to about 30 % loss of quercetin glycosides, which were transferred to the boiling water. The hydrolysis of quercetin glycosides for daily cooking might occur with the addition of seasonings such as glutamic acid. Additional ferrous ions accelerated the loss of flavonoids. Commercial, dehydrated onion products contained low amounts or no flavonoids (Lee et al. 2008). Losses of onion flavonoids subjected to 'cooking' (in per cent) ranged as follows: frying, 33; sauteing, 21; boiling, 14–20; steaming, 14; microwaving, 4 and baking, 0. Small onions had higher flavonoid content per kilogram than large ones. There was a graduated decrease in the distribution of the flavonoids across an onion bulb from the first (outside) to the seventh (innermost) scale. Exposure to fluorescent light for 24 and 48 hours induced time-dependent increases in the flavonoid content. Olsson et al. (2010) found that neither storage nor heat treatment caused any major differences in total flavonol content in sweet onion 'Recorra' and red onions 'Hyred' and 'Red Baron' cultivars. Quercetin 4'-glucoside did not show any consistent changes during storage in the two red cultivars, independent of treatment, whereas quercetin 3,4'-diglucoside increased significantly by 30 or 51 %, respectively, during storage in 'Hyred' and 'Red Baron' in the 24 hour heat treated

onions. Isorhamnetin 4'-glucoside was present at two to three times higher amount in the sweet onion cultivar than in the two red cultivars. Some of the quercetin glucosides present at lower concentrations, isorhamnetin 3,4'-diglucoside, quercetin 3,7,4'-triglucoside and quercetin 7,4'-diglucoside, increased during storage in all treatments in both 'Hyred' and 'Red Baron', though sometimes a decrease was found at the end of the 8-month storage. Onion coproduct material from onion processing comprising the outer dried protective layer (outer paper layer) and first two fleshy leaf layers and onion press cake (material generated after juice extraction) was found to be potential commercial sources of flavonoids especially quercetin (Lee and Mitchell 2011). The first layer had significantly higher levels of flavonoids than the outer paper, second and inner flesh layers on a DW basis. The predominant forms of quercetin were the quercetin 3,4'-*O*-diglucoside and quercetin 4'-*O*-glucoside. Onion press cake had significantly higher levels of total quercetin as compared with fresh onions. The levels of quercetin 4'-*O*-glucoside significantly decreased during the first month of storage and remained stable for 12 months of storage at either 4 or 22 °C.

Quercetin 3,4'-*O*-diglucoside (3,4'-Qdg) and quercetin 4'-*O*-glucoside (4'-Qmg) comprised >80 % of the total flavonol content detected in the studied varieties using infrared spectroscopy (Lu et al. 2011). The method was found to have advantages over the traditional HPLC method in providing a valid, efficient and cost-effective method requiring less sample preparation for the quantification of quercetins in onion.

Volatiles and Sulfur Compounds

According to Block (1992), most of the nonprotein sulfur in *Alliums* could be found in the form of four principal ACSOs: methyl (MeCSO), 2-propenyl (2-PeCSO), 1-propenyl (1-PeCSO) and propenyl (PCSO). 1-PeCSO was found in the highest concentration in onions, and 2-PeCSO was found in the highest concentrations in garlic with only trace amounts in onions. Among three common *Allium* crops, the total ACSO concentration was generally highest in garlic, intermediate in onion and lowest in leek (Block 1992; Coley-Smith 1986). Of

eight *Allium* species, garlic and giant garlic contained greatest amounts of total S-alk(en)yl-L-cysteine sulfoxides (ACSO) (5.0–11.7 mg/g); Chinese chive, dehydrator onion, leek, shallot had moderate amounts (2.0–5.0 mg/g), and Japanese bunching onion, onion (TG 1015Y) and chive leaves contained least amounts of total CSO (<2 mg/g) (Yoo and Pike 1998). AlCSO (S-allyl-L-cystine sulfoxide, alliin) was the major precursor in garlic and giant garlic (3.2–9.8 mg/g) and was also contained in chive and Chinese chive. PeCSO (S-propenyl-L-CYSTEINE sulfoxide) was the main flavour precursor in onion, green onion, leek and shallot (0.3–2.2 mg/g) but also found in chive, Chinese chive, garlic and giant garlic. MeCSO (S-methyl-L-cysteine sulfoxide) was a major precursor in chive and Chinese chive (0.68–1.85 mg/g fresh wt.) and found in all eight species examined with less amounts. S-propyl CSO, however, was not found in any of these species. In onion, *S*-2-propenyl-L-cysteine sulfoxide (alliin; 2-PRENCOSO) was found as the major sulfoxide (Fritsch and Keusgen 2006) which afforded propanethial *S*-oxide (lachrymatory factor [LF]), 1-propenyl methane thiosulfinate and dipropyl disulfide (Block et al. 1992; Rose et al. 2005).

Major volatile components detected in onion were 2-methyl-2-pentenal, (*E*)-methyl 1-propenyl disulfide, methyl propyl trisulfide and propanethiol, whereas dipropyl trisulfide, dipropyl disulfide and (*E*)-propenyl propyl disulfide predominated in leek oils (Schulz et al. 1998). According to the higher amount of leek chromosomes in the cell nucleus, the percentages of the measured sulfur volatiles in the hybrid material corresponded more to the leek than to the onion flavour profile.

Niegisch and Stahl identified hydrogen sulfide, sulfur dioxide, acetaldehyde, propionaldehyde, methyl alcohol, *n*-propyl alcohol, *n*-propyl mercaptan and traces of *n*-propyl disulfide from onion (Niegisch and Stahl 1956). S-methylcysteine sulfoxide and S-*n*-propyl cysteine sulfoxide or dihydroalliin, from which the corresponding thiosulfates were formed enzymatically, were isolated from Finnish onions (Virtanen and Matikkala 1959a). Methyl sulfide, methyl trisulfide, methyl-*n*-propyl disulfide, methyl-*n*-propyl

trisulfide, *n*-propyl disulfide and *n*-propyl trisulfide were isolated and identified as important flavour components in onion (Carson and Wong 1961b). (+) S-methyl-L-cysteine sulfoxide and of (+) Sn-propyl-L-cysteine sulfoxide were isolated from onions as their N-2, 4-dinitrophenyl derivatives (Carson and Wong 1961a). Presence of thiothiamine was demonstrated in onion extract after adsorption on acid clay, fractional separation from filter paper pulp and paper chromatography (Suhara 1962). Existence of thiothiamine had been demonstrated in onion extract after adsorption on acid clay, fractional separation from filter paper pulp and paper chromatography (Suhara 1962). Existence of thiothiamine had been demonstrated in onion extract after adsorption on acid clay, fractional separation from filter paper pulp and paper chromatography (Suhara 1962). The precursor of the lachrymatory factor in onion was characterised as (+)-S-(prop-1-enyl) – L-cysteine sulfoxide which was cleaved by onion enzyme preparation to the lachrymatory factor (propenylsulfenic acid) – pyric acid and ammonia (Spare et al. 1963). Propenylsulfenic acid was very unstable and was spontaneously degraded to propionaldehyde from which some 2-methyl-2-pentenal was formed. In mild alkaline solution, the precursor of the lachrymatory factor, S-(propen-1-yl)-L-cysteine sulfoxide, was cyclised to the amino acid cycloalliin (3-methyl-1,4-thiazane-5-carboxylic acid-1-oxide) (Virtanen and Matikkala 1959b). The highest content of cycloalliin was found from onion imported from Hungary (3.2 g hydrochloride per kg), and from a batch of Finnish onions, 1.4 g/kg. was isolated. The amino acid S-(2-carboxypropyl)-cysteine and its sulfoxides were found to be precursors in the biosynthesis of cycloalliin (3-methyl-1,4-thiazane-5-carboxylic acid-1-oxide) in onion (Granroth and Virtanen 1967). A lachrymatory factor in onion was identified as thiopropanal S-oxide (Brodnitz and Pascale 1971). Lukes (1971) used thin-layer chromatography to determine the relative concentration of the lachrymator and other cysteine derivatives of the action of alliinase on the flavour precursor, S-propenyl-L-cysteine sulfoxide. The lachrymator factor (thiopropanal S-oxide) was extracted from onion juice by rapid spectrophotometric method and other flavour compounds

identified from the action of alliinase (Freeman and Whenham 1975). Methyl propyl disulfide, methyl propyl trisulfide and dipropyl trisulfide with three unidentified compounds were mainly responsible for the characteristic flavour of onion (Galletto and Bednarczyk 1975). 2,5-Dimethylthiophenes, 2,4-dimethyl thiophene and 3,4-dimethyl thiophene were identified as onion volatile flavour components (Galletto and Hoffman 1976).

The principal disulfide present among the volatiles fresh 'Sunspice' onions was di-St-propyl, followed in descending order of concentration by n-propyl allyl, methyl-n-propyl, methyl allyl, dimethyl and diallyl disulfides (Bernhard 1968). In dehydrated onions, this order was markedly altered. Methyl-n-propyl is the principal disulfide, followed by dimethyl, methyl allyl, di-n-propyl, n-propyl allyl and diallyl disulfides. Loss of measured volatiles averaged 98 %, while loss of disulfides was greater than 89 %. The following aliphatic sulfur compounds were identified in the headspace volatiles of onions: di-n-propyl, n-propyl allyl, methyl-n-propyl, methyl allyl, dimethyl and diallyl sulfides (Bernhard 1969). These aliphatic disulfides appeared to be one of the principal groups of compounds responsible for the aroma and flavour of onions. 3,5-Dimethylthiophene, methyl *cis*-propenyl disulfide, methyl *trans*-propenyl disulfide, *cis*-propenyl disulfide, *trans*-propenyl propyl disulfide, two new methyl trisulfides and two propenyl trisulfides were found to be important components in onion oil (Brodnitz 1969). The identification of 45 flavour constituents were identified in steam-distilled onion oil (Boelens et al. 1971). These several oxygen compounds are thiols, thiopenes, monosulfide, disulfides, trisulfide and tetrasulfide. Propyl thiosulfates were found to be important in fresh onion flavour, propyl and propenyl disulfides and trisulfides in boiled onions and dimethylthiophenes, namely, 2,5-dimethylthiophenes, 2,4-dimethylthiophene and 3,4-dimethylthiophene in fried onions. The flavour precursor contents of short-day onion bulbs ranged from 0.03 to 0.16 mg/g fresh weight (FW) for S-methyl-L-cysteine-sulfoxide (MCSO), 0.07–0.65 mg for S-1-propenyl-L-cysteine sulfoxide (1-PeCSO) and 0.12–0.77 mg in total, and the precursor contents increased with the pungency

levels (Lee et al. 2009). Onions of different pungency levels did not differ in the contents of individual or total free amino acids, and the most abundant amino acids were glutamine and arginine. The total sugar contents ranged from 50 to 75 mg/g FW, and total S contents (3.5–5.1 mg/g dry weight) were not correlated with the pungency levels. The study indicated onion pungency to be primarily determined by the content of flavour precursor compounds and not by total S, total sugars or individual/total free amino acids in short-day bulbs. Storage in controlled atmosphere maintained the quality of short-day onions best, as evidenced by the smallest changes in flavour precursors, pungency and sugar concentrations, while storage at 5 °C resulted in increased pungency (Yoo et al. 2012). Onion pungency levels significantly increased at 5 °C and decreased at 30 °C. For storage at 24 and 30 °C, fructose and glucose concentrations continuously decreased, accompanied by a continuous increase in sucrose concentrations.

A new volatile compound, 3, 4-dimethyl-2, 5-dioxo-2, 5-dihydrothiophene, was identified in onion together with methyldithiomethane; 2-methylbut-2-enal; 2-methylpent-2-enal; 1-(methyldithio)propane; 2,5-dimethylthiophene; 2,4-dimethylthiophene, 3,4-dimethylthiophene and 1-(propyldithio)propane; *cis*-1-(1-propenyldithio)propane, *trans*-1-(1-propenyldithio)propane; 1-(methyltrithio)propane and 1-(propyltrithio) propane (Albrand et al. 1980). In the case of onion, the processes of flavour development from n-propyl-L-cysteine sulfoxide (PCSO) and 1-propenyl-L-cysteine sulfoxide (PeCSO) were proposed (Yagami et al. 1980). The presence of propyl propanethiosulfinate, propanal and thiopropanal S-oxide was confirmed by isolation and identification of their sulfide derivatives. Propyl disulfide and 1-propenyl propyl disulfide (2 isomers 4) were detected as the main components of the characteristic onion flavour headspace. Other compounds identified included 2-methyl-2-pentenal, dimethylthiophenes (3 isomers) and propyl trisulfide. Cysteine derivatives of onion flavour intermediates found included cystine, lachrymatory factor derivative, cysteine, propanal derivative to 2-ethyl-thiazolidine-4-carboxylic acid and S-propyl-L-cysteine.

Sulfur metabolism of onions, garlic and chives differed in some but not all respects from that in other plants (Granroth 1970). The cysteine formed was not stored but reacted further to give various S-substituted derivatives of which *trans*-(+)-S-(propen-1-yl)-L-cysteine sulfoxide (CSO) was the most efficiently accumulated, and this compound appeared to be the most important precursor of the flavour substances in onion, garlic and chive. 1-propenyl-L-cysteine sulfoxide (PeCSO) was the main flavour precursor in onion, green onion, leek and shallot (0.3–2.2 mg g⁻¹), but also found in chive, Chinese chive, garlic and giant garlic (Yoo and Pike 1998). *Trans*-(+)-S-(propen-1-yl)-L-cysteine sulfoxide (CSO) was also found to be important precursor of the flavour substances in onion, garlic and chive. S-methyl cysteine sulfoxide (MeCSO) was a major precursor in chive and Chinese chive (0.68–1.85 mg g⁻¹ fresh wt.) and found in garlic, onion and leek in lesser amounts. Four non-volatile, odourless S-alk(en)yl cysteine sulfoxide (CSOs) were reported as the precursors of the flavour and odours of the *Allium* (Jones et al. 2004). These were S-methyl cysteine sulfoxide (MCSO, methiin; present in garlic, onion and other *Allium*), S-allylcysteine sulfoxide (ACSO, alliin; characteristic of garlic), S-*trans*-prop-1-enyl cysteine sulfoxide (PeCSO, isoalliin; characteristic of onion) and S-propyl cysteine sulfoxide (PCSO, propiin; in onion, garlic and related species). The enzyme alliinase had been reported to cleave these precursors to give pyruvate, ammonia and a thiosulfinate. The lachrymatory effect, that is, characteristic of onions, was caused by the volatile product propanethial S-oxide (Brodnitz and Pascale 1971). The lachrymatory factor was reported to be generated by the activity of a second enzyme, lachrymatory factor synthase, following alliinase action on PeCSO, the major flavour precursor of onion (Imai et al. 2002). As well as CSOs, several γ -glutamyl peptide (γ GP) derivatives of these flavour compounds had been detected within the *Allium* (Whitaker 1976). Over 17 types had been isolated (Granroth 1970) and including γ -glutamyl-S-alk(en)yl glutathiones, γ -glutamyl-S-alk(en)yl cysteines and γ -glutamyl-S-alk(en)yl cysteine sulfoxides, all proposed to derive from glutathione (γ -glutamyl cysteinyl glycine). However, they did not appear to contribute

directly to flavour. Granroth (1970) confirmed that onion could hydrolyse *S*-2-carboxypropyl glutathione and that, in onion leaf tissue, *S*-2-carboxypropyl cysteine was rapidly converted to PeCSO. *S*-methyl cysteine, *S*-ethyl cysteine, *S*-propyl cysteine and *S*-propenyl cysteine could all be oxidised to the corresponding sulfoxide by onion leaf tissue (Granroth 1970). Methacrylate was proposed as the precursor of the allyl, propyl and propenyl groups (Granroth 1970). Glutathione and γ -glutamyl peptides were reported to be intermediates in the biosynthetic pathway to *S*-alk(en)yl-L-cysteine sulfoxides (flavour precursors) in *Allium sativum*, *A. cepa* and *A. siculum* (Lancaster and Shaw 1989). In all onion cultivars, the top and bottom onion sections contained the highest levels of both pyruvate and flavour precursors (alk(en)yl cysteine sulfoxides) with levels in the dry, brown skin being low or absent (Bacon et al. 1999). Significant increases in levels of both pyruvate and flavour precursors were observed in inner tissues and top/bottom sections after storage under commercial conditions.

S-alk(en)yl-L-cysteine sulfoxide (ACSO) flavour precursors concentration and composition of three onion cultivars changed with five sulfur fertility levels, and the response was cultivar dependent (Randle et al. 1995). At sulfur treatments that induced sulfur deficiency symptoms during active bulbing, (+)*S*-methyl-L-cysteine sulfoxide was the dominant flavour precursor, and the flavour pathway was a strong sink for available sulfur. As sulfur fertility increased to luxuriant levels, *trans*(+)-*S*-(1-propenyl)-L-CYSTEINE sulfoxide (PRENCISO) became the dominant ACSO. (+)*S*-propyl-L-cysteine sulfoxide was found in low concentration relative to total ACSO at all sulfur fertility levels. With low sulfur fertility, sulfur rapidly was metabolised, and low γ -glutamyl peptide (γ -GP) intermediates concentrations were detected. As sulfur fertility increased, γ -GP increased, especially γ -L-glutamyl-*S*-(1-propenyl)-L-cysteine sulfoxide, the penultimate compound leading to ACSO synthesis. Intermediates eluted were in the following sequence: (1) γ -L-GLUTAMYL-L-glutamic acid, (2) aspartic acid, (3) 2-carboxypropyl glutathione, (4) γ -glutamyl-1-propenyl-L-cysteine sulfoxide, (5) (+)-*S*-methyl-L-cysteine sulfoxide (MCSO), (6) *S*-methyl glutathione, (7) γ -L-glutamyl-L-

methionine, (8) *trans*(+)-S-(L-propenyl)-L-cysteine sulfoxide (PRENCSO), (9) γ - glutamyl-L-phenylalanine, (10) (+)-S-propyl-L-cysteine sulfoxide (PCSO), (11) butyl-L-cysteine sulfoxide and (12) butyl-L-cysteine sulfoxide. Nearly 95 % of the total bulb sulfur could be accounted for in the measured sulfur compounds at low sulfur fertility. However, at the highest sulfur treatment, only 40 % of the total bulb sulfur could be attributed to the ACSO and gamma-GP, indicating that other sulfur compounds were significant sulfur reservoirs in onions. Concentrations of enzymatically produced pyruvic acid were most closely related to PRENCSO concentrations. Onion bulbs accumulated significant levels of SO_4^{-2} and S (Randle et al. 1999). The amount of bulb- SO_4^{-2} and bulb-S increased linearly as S-fertility increased. The three varieties differed in total bulb-S, bulb- SO_4^{-2} , the per cent of total bulb-S accumulated as SO_4^{-2} and pyruvic acid. Bulb- SO_4^{-2} ranged from 0.047 to 0.318 % dry mass in response to S-fertility level and variety, while total bulb-S ranged from 0.154 to 0.535 % dry mass.

From the chloroform extract of onion juice, five partially new thiosulfinates and six hitherto unknown α -sulphinyldisulfides ('cepaenes') were isolated and their structures elucidated as *trans*- and *cis*-methylsulphinothioic acid *S*-1-propenyl ester; *cis*- and *trans*-*n*-propylsulphinothioic acid *S*-1-propenyl ester; *n*-propylsulphinothioic acid *S*-*n*-propyl ester and *trans*-5-ethyl-4,6,7-trithia-2-decene 4-*S*-oxide, *trans*, *trans* and *trans*, *cis* 5-ethyl-4,6,7-trithia-2,8-decadiene 4-*S*-oxide and the diastereoisomers of the latter three compounds (Bayer et al. 1989). Studies by Ferary et al (1996) found that *A. cepa* odours contained only thiopropanal *S*-oxide and thiosulfinates as sulfur volatiles. 3-Mercapto-2-methylpentan-1-ol, a powerful aroma compound, was isolated from raw onions (Widder et al. 2000). At low concentration (0.5 ppb), a pleasant meat broth, sweaty, onion and leek-like odour could be perceived. As one intermediate 3-mercapto-2-methylpentanal, another new strong flavour compound, was suggested. The amount of the potent onion odourant 3-mercapto-2-methylpentan-1-ol detected in raw onions ranged

between 8 and 32 µg/kg, whereas 34 + 246 µg was found in sliced, stored (50 minutes) and then cooked onions (Granvogl et al. 2004). Highest concentration amounting to >1,200 µg/kg was obtained by simultaneous steam distillation.

Volatiles found in onion headspace were thiopropanal S-oxide, 2-methyl-2-pentenal, dimethyl thiophene, methyl propenyl disulfide, propenyl propyl disulfide, propenyl propenyl disulfide, dipropyl disulfide, 1-propenyl propyl disulfide, di-1-propenyl disulfide, methyl propyl trisulfide and traces of propenyl propenyl disulfide, dipropyl trisulfide and propenyl propyl trisulfide (Järvenpää et al. 1998). Among 49 identified components, in the steam distillate of onion, 1-(methylthio)l-propanethiol; 1-(propylthio)l-propanethiol; 5,6-dihydro-2-methyl-4,6-diethyl-4H-1,3,5-dithiazine; 5,6-dihydro-6-methyl-2,4-diethyl-4H-1,3,5-dithiazine; 5,6-dihydro-2,4,6-triethyl-4H-1,3,5-dithiazine and 2,4,6-triethyl-L,3,5-trithiane were reported in the oil of onion for the first time (Farkas et al. 1992). The other compounds included hydrogen sulfide; methane thiol; propanal; 1-propanethiol; *cis*-1-propenethiol; *trans*-1-propenethiol; 2-cyclopenten-1-one; 2-methyl-2-pentenal; 2,4-dimethylthiophene; 3,4-dimethylthiophene; *cis*-methyl 1-propenyl disulfide; *trans*-methyl 1-propenyl disulfide; methyl propyl disulfide; dimethyl trisulfide; dipropyl disulfide; *cis*-propyl 1-propenyl disulfide; *trans*-propyl 1-propenyl disulfide; methyl propyl trisulfide; *cis*-methyl 1-propenyl trisulfide; *trans*-methyl 1-propenyl trisulfide; isomer of 3,5-methylethyl-L,2,4-trithionale; isomer of 3,5-methylethyl-L,2,4-trithionale; 4-ethyl-2,3,5-trithiahexane; 3,5-diethyl-1,2,4-trithiolane; dipropyl trisulfide; isomer of 3,5-diethyl-1,2,4-trithionale; isomer of 3,5-diethyl-1,2,4-trithionale; *cis*-propyl 1-propenyl trisulfide; *trans*-propyl 1-propenyl trisulfide; 5,6-dihydro-2-methyl-4,6-diethyl-4H-1,3,5-dithiazine; 5,6-dihydro-6-methyl-2,4-diethyl-4H-1,3,5-dithiazine; isomer of 5,6-dihydro-6-methyl-2,4-diethyl-4H-1,3,5-dithiazine; 4-ethyl-2,3,5-trithiaoctane; 6-ethyl-4,5,7-trithiaoctane; 4-ethyl-2,3,5-trithia-6-octane; isomer of 5,6-dihydro-2-methyl-4,6-diethyl-4H-1,3,5-dithiazine; isomer of 5,6-dihydro-2-methyl-4,6-diethyl-4H-1,3,5-dithiazine; dipropyl tetrasulfide; 6-ethyl-4,5,7-trithiadecane; 6-ethyl-4,5,7-trithia-2,8-decadiene; 4-ethyl-2,3,5,6-tetrathianonane; 6-

ethyl-4,5,7,8-tetrathiaundecane; 6-ethyl-4,5,7,8-tetrathia-trans-2-undecene; 6-ethyl-4,5,7,8-tetrathia-*cis*-2-undecene; 4-Pentyl-6-ethyl-L,2,3,5-tetrathiane and 5,7-diethyl-1,2,3,4,6-pentathiepane.

Forty-five compounds were identified in roasted onion volatiles from five different cultivars (Tokitomo 1995). Methyl propenyl trisulfide, diallyl trisulfide, methyl (*Z*)- and (*E*)-propenyl disulfides and furan compounds were the major aroma components of roasted onion, compared with those of boiled onion. Many aliphatic aldehydes existed in roasted onion volatiles. These volatile aldehydes were thermal generation and oxidation products from corn oil. Those aldehydes seemed to contribute to the characteristic oily and heavy roasted onion flavour. Twenty-four volatile compounds were identified in boiled onions; the major compounds were dipropyl trisulfide, diallyl disulfide, (*Z*)-propenyl propyl trisulfide, (*Z*)-propenyl propyl disulfide; dipropyl disulfide and dimethyl trisulfide in decreasing amount (Tokitomo 1995). Other minor compounds included 2-methyl-2-pentenal, methyl propyl trisulfide, methyl (*Z*)-propenyl disulfide, methyl (*E*)-propenyl disulfide, (*E*)-propenyl propyl trisulfide, methanethiol, propanethiol, 2,4-dimethylthiophene, 3,4-dimethylthiophene, dibenzothiophene, 3-ethyl-5-vinyl-1,2,4-trithiolane (isomer), 3-ethyl-5-vinyl-1,2,4-trithiolane (isomer), 3,4-dimethyl-2,5-dihydrothiophen-2-one, 6-ethyl-4,5,7-trithia-2,8-decadiene, *n*-hexanal, 2-pentylfuran, furfural and ethyl furyl ketone. Volatiles obtained from combined GC-MS analysis of garlic juice by solid-phase microextraction (SPME) are the following: lachrymatory factor E and Z isomers, dimethyl thiosulfinate, dipropyl disulfide, propyl 1-propenyl disulfide, dipropenyl disulfide and dipropyl trisulfide, and obtained from solvent extraction are dimethyl thiosulfinate, methyl propyl thiosulfinate, methyl 1-propenyl thiosulfinate, propyl methyl thiosulfinate, 1-propenyl methyl thiosulfinate, dipropyl thiosulfinate, zwiebelane 1, zwiebelane 2, zwiebelane 3 and 1-propenyl propyl thiosulfinate (Mondy et al. 2001). In onion, 1-propenyl sulfenic acids rearrange to give mostly (*Z*, *E*) thiopropanal S-oxide, the lachrymatory factor and zwiebelanes isomers of di(1-propenyl)thiosulfinate.

Onionin A, a new, stable, sulfur-containing compound, was isolated from acetone extracts of onion bulbs, and its structure was characterised as 3,4-dimethyl-5-(1*E*-propenyl)-tetrahydrothiophen-2-sulfoxide-*S*-oxide (El-Aasr et al. 2010). The occurrence of the *S*-(+)-alk(en)ylthio-L-cysteine derivatives (*R*)-2-amino-3-(methyldisulfanyl)propanoic acid (*S*-methylthio-L-cysteine); (*R*)-2-amino-3-(propyldisulfanyl)propanoic acid (*S*-propylthio-L-cysteine); (*R*)-2-amino-3-(1-propenyldisulfanyl)propanoic acid (*S*-(1-propenylthio)-L-cysteine) and (*R*)-2-amino-3-(2-propenyldisulfanyl)propanoic acid (*S*-allylthio-L-cysteine) in onion was confirmed by Starkenmann et al. 2011. Their concentrations in fresh onion were estimated to be 0.19 mg/kg *S*-methylthio-L-cysteine, 0.01 mg/kg *S*-propylthio-L-cysteine and 0.56 mg/kg (*S*-(1-propenylthio)-L-cysteine), concentrations that were about 3,000 times lower than that of isoalliin *S*-(1-propenyl-*S*-oxo-L-cysteine). These compounds were treated with *Fusobacterium nucleatum*, a microorganism responsible for the formation of mouth malodour. These L-cysteine disulfides were demonstrated to predominantly produce trisulfides and tetrasulfides. Isoalliin was almost entirely consumed by the plant enzyme alliin lyase (*S*-alk(en)yl-*S*-oxo-L-cysteine lyase) in a few seconds, but it was not transformed by *F. nucleatum*. Yoshinari et al. (2012) identified cycloalliin, *S*-methyl-L-cysteine, *S*-propyl-L-CYSTEINE sulfoxide and dimethyl trisulfide in onions.

The total phenolic content determined in the crude onion extract was 11.3 mg phenols/g extract, the quercetin concentration was 27.5 µg/mL and propyl disulfide concentration was 0.23 µg/mL (Votto et al. 2010). Some of the sulfur compounds in crude onion extract were 1,3-dithiane, 2,2-dimethyl; 2-vinyl-1,3-dithiane; diallyl disulfide; 2,4-dimethylthiophene; 2-ethylidene[1,3]dithiane; [1,2,3,4]tetrathiine; 1-propene, 1-(methylthio)-, (*E*)-; 1-propene, 1-(methylthio)-, (*Z*)-; 5-methylthiophen-3-ylamine; thiophene; 2-ethyl-5-[(2-ethylbutyl)thio] and dimethyl tetrasulfide. Compounds belonging to other classes, such as phenols (phenol, 2,6-*bis*(1,1-dimethylethyl)-4-methyl) and carboxylic acids (1,2-benzenedicarboxylic acid, *bis*(2-methyl propyl) ester), were also identified. Seventeen organosulfides,

including disulfides, trisulfides and cyclic polysulfides, were identified in shallot (*Allium cepa* Aggregatum group) (Tocmo et al. 2014). Significant differences in the quantitative and qualitative profiles of organosulfides in the hydrodistilled and solvent extracted oils were observed. Freeze-drying retained the majority of the organosulfides, but the whole-autoclaved and whole-boiled shallots lost more than 95 % of their organic polysulfides. Crushed-boiled and crushed-autoclaved shallot lost 76–80 % of their organosulfides, likely due to the thermal sensitivity of these compounds. In general, disulfides increased at basic pH (pH 9.0), while trisulfides and cyclic organosulfides were much higher at the acidic to neutral pH values (pH 3.0–5.0).

In normal onion (*Allium cepa*), *trans*-*S*-1-propenyl-L-cysteine sulfoxide was transformed via 1-propenesulfenic acid into propanethial *S*-oxide, a lachrymatory factor, through successive reactions catalysed by alliinase and lachrymatory factor synthase (LFS) (Aoyagi et al. 2011). Suppression of the LFS activity caused a dramatic increase in thiosulfinates previously reported as ‘zwibelane isomers’. After purification, they established the planar structure of the putative ‘zwibelane isomers’ as *S*-3,4-dimethyl-5-hydroxythiolane-2-yl 1-propenethiosulfinate. Of at least three stereoisomers observed, one in the (2'*R*, 3'*R*, 4'*R*, 5'*R*)-configuration was collected as an isolated fraction, and the other isomers were collected as a combined fraction. Both fractions showed inhibitory activities against cyclooxygenase-1 and α -glucosidase in-vitro. After cutting onion, the headspace composition changed rapidly due to the very reactive volatile sulfurous compounds emitted from onion tissue after cell disruption (Løkke et al. 2012). It was found that propanethial *S*-oxide (the lachrymatory factor) and breakdown products of this compound dominated 0–10 minutes after cutting. Subsequently, propanethiol and dipropyl disulfide predominantly appeared, together with traces of thiosulfinates. The concentrations of these compounds reached a maximum at 60 minutes after cutting. Propanethiol was present in highest concentrations and had an odour activity value 20 times higher than dipropyl disulfide. Thus, propanethiol was suggested to be the main source of the

characteristic onion odour. Minor amounts of hydrogen sulfide and methanethiol were also detected.

Twenty one compounds were identified in onion essential oil (Kocić-Tanackov et al. 2012). The major components were dimethyl trisulfide (16.64 %), methyl propyl-trisulfide (14.21 %), diethyl-1,2,4-trithiolan (3*R*, 5*S*, 3*S*, 5*S* and 3*R*, 5*R* isomers) (13.71 %), methyl-(1-propenyl)-disulfide (13.14 %) and methyl-(1-propenyl)-trisulfide (13.02 %).

Garlic and onion, wild leek, had been reported to accumulate the selenium (Se) from soil, endowing the plants greater protection against carcinogenesis (Arnault and Auger 2006). Selenium level was found to be 0.024 µg/g for onion (Izgi et al. 2006). Selenomethionine, selenocysteine and Se-methyl-selenocysteine had been identified in garlic and onion (Yang 2002; Auger et al. 2004). Gamma-glutamyl-Se-methyl-L-selenocysteine had been identified in extracts of garlic cultivated in Se-rich soil (Auger et al. 2004). However, several Se compounds from Se-enriched garlic or onion remain unidentified (Arnault and Auger 2006). Se-methyl-selenocysteine was unstable in water extract of Se-enriched garlic when the extract was prepared and stored at room temperature (Yang 2002). Specific alliinase inhibitor hydroxylamine (NHOH.HCl) effectively prevented the loss of Se-methyl-selenocysteine, which suggested that the decomposition of Se-methyl-selenocysteine may be catalysed by alliinase. Se-enriched onion also contained alliinase and Se-methyl-selenocysteine, but its Se-methyl-selenocysteine was proved to be stable in the same water extract as that of Se-enriched garlic. The existence of Se-alk(en)yl-L-cysteine selenoxides (Se-‘alliins’) in garlic and onion had been demonstrated (Auger et al. 2004). An additional experiment showed that *Allium* species cultivated in Se-rich soil might contain two different Se-‘alliins’.

Saponins and Other Phytochemicals

The saponins sitosterol, oleanolic acid and amyirin were found in onion (Smockiewicz et al. 1982). Steroid sapogenins isolated from onion included diosgenin (25*R*)-spirost-5-en-3β-

ol; ruscogenin (25R)-spirost-5-ene-1 β , 3 β -diol and cepagenin (24S, 25R)-spirost-5-ene-1 β ,3 β -24-triol and steroid glycosides ceposide A, ceposide B, alliospiroside A, alliospiroside B, alliospiroside C, alliospiroside D, alliofuroside A and ceposide D (Kravets et al. 1990). Four furostanol saponins, named tropeoside A1/A2 and tropeoside B1/B2, along with the respective 22-*O*-methyl derivatives (extraction artefacts), were isolated from Tropea red onion bulbs (Correa et al. 2005). High concentrations of ascalonicoside A1/A2 and ascalonicoside B were also found. Three saponins, named ceposide A, ceposide B and ceposide C, were isolated from the bulbs of white onion, and their structures elucidated as (25R)-furost-5(6)-en-1 β ,3 β ,22 α ,26-tetraol 1-*O*- β -D-xylopyranosyl 26-*O*- α -D-rhamnopyranosyl-(1 $\rightarrow$ 2)-*O*- β -D-GALACTOPYRANOSIDE (ceposide A), (25R)-furost-5(6)-en-1 β ,3 β ,22 α ,26-tetraol 1-*O*- β -D-xylopyranosyl 26-*O*- α -D-rhamnopyranosyl-(1 $\rightarrow$ 2)-*O*- β -D-glucopyranoside (ceposide B) and (25R)-furost-5(6)-en-1 β ,3 β ,22 α ,26-tetraol 1-*O*- β -D-galactopyranosyl 26-*O*- α -D-rhamnopyranosyl-(1 $\rightarrow$ 2)-*O*- β -D-galactopyranoside (ceposide C) (Lanzotti et al. 2011).

Pyruvic acid was detected in onion juice (Morgan 1946). Besides acetaldehyde and propionaldehyde, one unknown flavour compound of onion was identified as 2-methyl-2-pentenal which was formed enzymatically in crushed onions; the only alcohols detected were methanol and ethanol (Spare and Virtanen 1961). 2,3-dihydro-3,5-dihydroxy-6-methyl-4H-pyranone (DDMP) was isolated from onions (Ban et al. 2007).

The following compounds with active quinone reductase inducing activity were isolated from *A. cepa*: *p*-hydroxyphenethyl *trans*-ferulate; 5,6-dimethyl-2-pyridinecarboxylic acid; ferulic acid; 1-(6-hydroxy-[3]pyridyl)-propan-1-one and *N-trans*-feruloyl 3-*O*-methyldopamine (Xiao and Parkin 2006); 5-hydroxy-3-methyl-4-propylsulfanyl-5H-furan-2-one; 5-(hydroxymethyl) furfural; acetovanillone; methyl 4-hydroxyl cinnamate and ferulic acid methyl ester (Xiao and Parkin 2006). Zwiebelane A (*cis*-2,3-dimethyl-5,6-dithiabicyclo[2.1.1]hexane 5-oxide) was reported from onion bulbs (Borjihan et al. 2010).

Onion bulbs were found to contain two volatile organic aliphatic methyl ketones 2-undecanone and 2-tridecanone (Antoniou 2013). Soil amended with chicken manure enhanced 2-undecanone and 2-tridecanone production by 28 and 43 %, respectively. The increased concentrations of 2-undecanone and 2-tridecanone in onion bulbs may provide a protective character against insect and spider mite attack in field-grown onions.

A fatty acid fraction separated from yellow onion corresponded for prostaglandin A1 (15-hydroxy-9-ketoprostanoic acid or PGA_1) or a prostaglandin-like compound (Attrep et al. 1973). The following prostaglandins F1 α , E1, B1 and A2 were identified in onions (Al-Nagfy et al. 1986). Two isomeric trihydroxy octadecenoic acids, 9,10,13-trihydroxy-11-octadecenoic and 9,12,13-trihydroxy-10-octadecenoic acid, lipoxygenase metabolites of linoleic acid, with prostaglandin E-like activity were isolated from onion (Ustünes et al. 1985).

Seed Phytochemicals

Free radicals in onion seeds were found to be attributable to the melanins present in the black seed coats (Edwards et al. 1961). A new cysteine sulfoxide, (S(S)R(C))-S-(3-pentenyl)-L-cysteine sulfoxide, was identified from onion seeds, together with the known cysteine sulfoxides methiin, etiin, alliin, isoalliin, propiin and butiin (Dini et al. 2008). Four furostanol saponins, two of which were new compounds, named ceparoside A and ceparoside B, were isolated from onion seeds (Yuan et al. 2008b). Seven compounds tianshichic acid, *N-trans*-feruloyl tyramine, β -sitosterol-3 β -glucopyranoside-6'-palmitate, sitosterol, daucosterol, tryptophan and adenine riboside were isolated from the ethanol extract of onion seeds (Yuan et al. 2008a). Two new steroidal saponins, ceparosides C and D, were isolated from onion seeds, and their structures established as 26-*O*-(β -D-glucopyranosyl)-(25R)-furost-5,20(22)-dien-3 β ,26-diol-3-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 4)-[α -L-rhamnopyranosyl (1 $\rightarrow$ 2)]- β -D-galactopyranoside (1) and 26-*O*-(β -D-glucopyranosyl)-(25S)-furost-5,20(22)-dien-3 β , 26-

diol-3-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 4)-[α -l-rhamnopyranosyl(1 $\rightarrow$ 2)]- β -D-galactopyranoside (Yuan et al. 2009).

A sucrose–sucrose 1^F- β -D-fructosyltransferase was purified from onion seeds (Shiomi et al. 1985). The purified enzyme catalysed fructosyltransferase from sucrose to another sucrose to form 1-kestose and glucose and also in some degree transferred a fructosyl residue from sucrose to raffinose and stachyose but not to 1-kestose and nystose.

Root/Meristem/Cell Culture

Phytochemicals

Changes in the activity of arginine decarboxylase and in polyamine content corresponded in time with growth activities of sprout meristems of onions (Matejko and Dalhem 1991). Alterations in the ratio of individual polyamines appeared to be an indicator of changes in the physiological state of onions during dormancy. Myosin was found to be localised to plasmodesmata in onion root tissues and may also play a role in the regulation of transport at the neck region of plasmodesmata (Radford and White 1998). Studies demonstrated that actin occurred not only in intact nuclei and chromosomes but also in DNA- and histone-depleted nuclei and chromosomes of *A. cepa* (Wan and Xing 1998). In addition, tropomyosin was found to be present in the nuclei and chromosomes of *A. cepa*. Sc II-like protein was found as a novel component in the nuclei, chromosomes and chromosome scaffolds of onion root meristematic cells (Wang et al. 2000). Spliceosomal proteins Sm and U2B were found in two nuclear domains: (1) a diffuse nucleoplasmic network similar to that formed by interchromatin granules and (2) numerous Cajal bodies in onion meristematic cells (Cui et al. 2003). Cruz et al. (2009) showed that actin isoforms with distinct solubilities were present in onion cell nuclei with a consistent subnuclear compartmentalisation. Actin and protein nuclear myosin 1 (NMI) were highly enriched in foci that were similar to transcription foci, although actin was also distributed diffusely in the nucleus and nucleolus as well as

accumulating in a subset of the Cajal bodies. A water-soluble pectic polysaccharide (PS) was isolated from immature onion stick (Patra et al. 2013). It contained D-galactose, 6-O-Me-D-galactose, 3-O-acetyl-D-methyl galacturonate and D-methyl galacturonate in a molar ratio of nearly 1:1:1:1.

Lamins were detected in the nuclear matrix of *Allium cepa* meristematic root cells (Mínguez and de La Espina 1993). A nuclear coiled-coil structural protein NIF (nuclear intermediate filament) with molecular mass of 65kDA was found in the nuclear matrix of onion interacting directly with structural nuclear spectrin-like proteins (Pérez-Munive et al. 2012). Its similarities with some of the proteins described as onion lamin-like proteins suggested that they could be highly related or perhaps of the same proteins. Lamin-like protein analogues termed nuclear matrix constituent proteins (NMCP) which exhibited the typical tripartite structure of lamins were found in onion roots (Ciska et al. 2013). These proteins exhibited many similarities to lamins (structural organisation, conserved regions, subnuclear distribution and solubility) and that they may fulfil the functions of lamins in plants.

Exogenic application of O^{2-} and H_2O_2 generators resulted in formation of antimicrobial phytoalexins Tcibulins 1D and 2 in cultured onion cells (Kravchuk et al. 2003). Three major nucleolar proteins, nucleophosmin, nucleolin and fibrillarin, were found in onion root tip cells (Qin et al. 2013). A novel alliinase with two isoforms were purified from onion roots (Lancaster et al. 2000). Isoform I had an isoelectric point of 9.3, while isoform II had isoelectric points of 7.6, 7.9, 8.1 and 8.3. The isoforms differed in their glycosylation. Both contained xylose/fucose containing complex-type N-linked glycans, and isoform II also contained terminal mannose structures. Both isoforms had activity with S-alk(en)yl-L-cysteine sulfoxides. Unlike other *Allium* alliinases, onion root isoforms had cystine lyase activity.

Two major antifungal compounds purified from the n-butanol extract of shallot (*Allium cepa* Aggregatum group) basal plates and roots and were determined to be alliospiroside A and alliospiroside B (Teshima et al. 2013). Results of

studies indicated that *A. cepa* plants were able to biotransform inorganic selenium compounds into their organic derivatives, e.g. Se-methyl-selenocysteine (SeMetSeCys) from the Se(IV) inorganic precursor (Michalska-Kacymirow et al. 2014). The content of selenium in onion roots (mg/kg dry mass) when plants were grown in the presence of selected Se compounds were 670 mg Se when plants grown in sodium selenite (Na_2SeO_3); 979 mg Se when grown in sodium hydrogen selenite (NaHSeO_3); 2,700 mg Se when grown in sodium selenate ($\text{Na}_2\text{SeO}_4 \cdot 10\text{H}_2\text{O}$) and 2,100 mg Se when in grown in sodium ammonium selenate ($\text{NaNH}_4\text{SeO}_4$). Organic derivatives found in onion roots of plant grown in sodium selenite and in sodium hydrogen selenite were selenomethionine-Se-oxide, SeMetSeCys, selenomethionine, Se(IV), L- γ -glutamyl-Se-methylseleno-l-cysteine (γ -glutamyl-SeMetSeCys) and Se(VI). In contrast, roots of plants grown in sodium selenate and sodium ammonium selenate afforded Se (VI).

Leaf/Flower Phytochemicals

In the green leaves of onion, the flavonol synthesis was reported to be light dependent, and also kaempferol glucosides were formed beside quercetin glucosides, but not spiraeoside (quercetin 4'-glucoside) (quercetin 4'-glucoside) and the known diglucosides of the scales (Starke and Herrmann 1975). During drying on the field, an accumulation of flavonols takes place in the drying leaves. Fresh leaves of Romanian *Allium* spp. (*Allium cepa* var. 'Diamant', *Allium cepa* var. 'Rubiniu' and *Allium ursinum*) were found to be low pungent cultivars based on the enzymatically produced pyruvate level (between 42 and 222 $\mu\text{mol/g}$ fresh weight) (Gîtin et al. 2014). Disulfides were detected as the major sulfur compounds, an allicin was found as an important sulfur compound.

Gołaszewska and Bednarska (1999) found that the cell walls of all mature anther tissues of onion mainly contained esterified pectins; only small amounts of unesterified pectins were present in the cell wall junctions and adjacent middle lamellae and in the cell walls of the connective tissue.

Endogenous polyamines (PA) were reported to be involved in gametic embryogenesis in onions (Geoffriau et al. 2006). Spermidine in both free and conjugated forms was the most abundant PA quantitatively present in onion flower buds, accounting for 71–81 % of the total free PAs and 86–98 % of the total conjugated PAs. Free and conjugated putrescine put was detected in all varieties but was lower in concentration (maximum 0.36 $\mu\text{mol/g}$ FW). Hydroxyputrescine was detected in some varieties but not the conjugated form. Spermin was found in lower concentration in one variety than in the other varieties, the conjugated form was not detected. Among the aromatic PAs, only tyramine and 3-hydroxy,4-methoxyphenylethylamine were detected. Free tyramine was found only in one ascension and also conjugated tyramine.

Antioxidant Activity

In-Vitro Studies

Garlic showed a higher DPPH free radical scavenging activity than red onion but had lower total phenolic content (37.60 mg GAE/100 g) than red onion (53.43 mg GAE/100 g) (Othman et al. 2011). However, the primary antioxidant activities of both were lower than the standard antioxidant, BHA. Red onion had higher ferrous ion-chelating effect (i.e. 45.00 %) as compared to garlic (43.29 %) but both showed slightly higher ion-chelating effect than BHA (tert-butyl-4-hydroxyanisole) (43.14 %) but lower than EDTA (ethylenediamine tetraacetic acid) (97.9 %). Among the 18 Korean onion cultivars, Sunpower was the most promising cultivar in terms of total phenolics, total flavonoids and antioxidant activity (Sharma et al. 2014). The antioxidant activity for cultivar Sunpower was highest in ethanol extracts 24.12 and 16.13 $\mu\text{M TE/g DW}$ with FRAP and DPPH, respectively. Methanol extracts of cv Sunpower showed highest level of total phenolics (5,016 $\mu\text{g GAE/g DW}$) and flavonoids (2873.95 $\mu\text{g quercetin/g DW}$) among the 18 cultivars. Major phenolics in both methanol and ethanol extracts were quercetin, quercetin 3,4'-O-diglucoside (QDG), quercetin 4'-O-monoglucoside (QMG) and isorhamnetin 3-glucoside. The total polyphenols and Trolox

equivalent antioxidant capacity (TEAC) ranged from 73.33 to 180.84 mg/100 g FW and 0.92–1.56 μ M TEAC/g FW, respectively, in Georgia-grown *Vidalia* onions (Sellapan and Akoh 2002). The data indicated *t* *Vidalia* onions were a rich source of quercetin, and they also contained myricetin and kaempferol. A positive but weaker correlation was obtained for total polyphenols versus antioxidant capacity. Nevertheless, a stronger correlation ($R^2 = 0.34$) was obtained between flavonoid content versus antioxidant capacity. The scavenging activity of DPPH radical and H_2O_2 of red, yellow and white onion ethyl acetate extracts increased with increasing concentration (Shon et al. 2004). The antioxidant activities using β -carotene-linoleate system and reducing power also increased, but the effect was lower than that of BHT and ascorbic acid. The methanol extracts of onion and garlic extract gave similar antioxidant activity as determined by inhibition of lipid peroxidation induced by tert-butyl hydroperoxide in isolated rat hepatocytes and scavenging activity against DPPH radical (Nuutila et al. 2003). The radical scavenging activities also correlated positively with the total phenolics of the extracts. Onions had clearly higher radical scavenging activities than garlic, red onion being more active than yellow onion. The skin extracts of onion possessed the highest activities. The lowest levels of phenolics were detected for garlic (75–700 GAE mg/kg), whereas the highest amounts of phenolics were detected for the dry skin of onions: 80,000 GAE mg/kg in red and 26,000 GAE mg/kg in yellow onion. Intermediate levels were found in onion bulbs and stems (800–3,200 GAE mg/kg). Quercetin and kaempferol were found to be the most abundant flavonoids in the hydrolysed onion and garlic samples. The onion leaves contained mainly kaempferol, but quercetin was the major flavonoid in the other parts. The quercetin contents in the red onions were about twofold higher than those of the yellow onions, and, in the spring varieties, the differences were even bigger. Garlic did not contain quercetin or kaempferol in detectable amounts. The extracts of yellow onion were effective inhibitors of lipid peroxidation in rat hepatocytes, the dry skin again being the most effective. Concentrations of 10–80 mg/mL (based on the dry weight of the original extracted sample) resulted in 20–80

% lipid peroxidation inhibition. The edible part of onion was clearly less effective than the skin and a concentration of 1,000 mg/mL (dry weight of the original extracted sample) resulted in only 40 % lipid peroxidation inhibition. Garlic was a much less effective inhibitor of lipid peroxidation than yellow onion. However, according to Miller et al. (2000), garlic was found to be very high in antioxidants, its activity (1,300 Trolox equivalents/100 g) being about sixfold that of yellow onion (200 Trolox equivalents/100 g).

The total phenolic content (gallic acid, ferulic acid, protocatechuic acid, quercetin and kaempferol) of four (red, violet, white and green) onion varieties varied from 4.6 to 74.1 mg/g GAE, antioxidant activity varied from 13.6 to 84.1 % and free radical scavenging activity showed wide range in terms of IC₅₀ (inhibitory concentration) from 0.1 to 15.2 mg/mL, EC₅₀ (efficient concentration) from 4.3 to 660.8 mg/mg and antiradical power from 0.15 to 23.2 (Prakash et al. 2007). The outer dry layers of red and violet varieties showed better inhibition of lipid peroxidation assayed by ammonium thiocyanate than α -tocopherol. The non-site-specific inhibition of hydroxyl radical-induced deoxyribose degradation was also higher in the outer dry layers of red and violet varieties than in their middle and inner layers. The outer layers were also potential inhibitors of nitroblue tetrazolium chloride (NBT) reduction caused by superoxide anions. In contrast, the ferrous ion-chelating capacity of the red and violet varieties was highest in the inner layers. The unutilised outer layers of the red variety were a rich source of quercetin (5,110 μ g/g) with high antioxidant (AOA) and free radical scavenging activities and also showed significant protection of DNA damage caused by free radicals.

The onion peel extracts by ethanol extraction showed greater DPPH radical scavenging activities and greater antioxidant activities as determined by ferric thiocyanate assay and lipid peroxidation inhibition than those by hot water extraction and subcritical water (SW) extraction at 165 °C. Antioxidant activity of onion peel extract by SW extraction at 110 °C was similar to that of ethanol extraction. Extraction yields of subcritical water (SW) extraction of antioxidant from

onion peels were fourfold higher than ethanol extraction (Lee et al. 2014). However, the ethanol extraction increased total phenolic contents (327.5 mg GAE/g extract) and flavonoid contents (183.95 mg QE/g extract) in the onion peel extract. In contrast, SW extract at 110 °C afforded 218.73 mg GAE/g extract of total phenolics and 119.50 mg quercetin/g extract; SW at 165 °C afforded 56.68 mg GAE/g extract GAE/g extract and 27.10 mg quercetin/g extract, and hot water (HW) extraction yielded 120.60 mg GAE/g extract total phenolic and 25.78 mg quercetin/g extract.

Nemeth and Piskula (2007) reported that the antioxidant quercetin (usually present in onions mainly as glycosides), even after being metabolised, may still affect the redox balance by inducing antioxidative and detoxifying enzymes or compounds which may be involved in sustaining homeostasis and confer beneficial effects to the human body. The flavonoid compounds especially quercetin and its dimerised compound isolated from onion skin having *o*-dihydroxy substituent in the B-ring were shown to be effective antioxidants against nonenzymatic lipid peroxidation (Ly et al. 2005). Compounds 5 and 8 had higher antioxidative activity compared to the corresponding glucoside (3 and 7). Four new quercetin-derived oxidation products isolated from onion skin, namely, 2-(3,4-dihydroxyphenyl)-4,6-dihydroxy-2-methoxybenzofuran-3-one; 3-phloroglucinoyl-2,3-epoxyflavanone; 3-[3-(1-methylglyoxylate-2,4,6-trihydroxyphenyl)]-2,3-epoxyflavanone and 3-(quercetin-8-yl)-2,3-epoxyflavanone; and 2,5,7,3',4'-pentahydroxy-3,4-flavandione, were more active in scavenging DPPH free radical than quercetin (Ramos et al. 2006). Aqueous and hydroalcoholic extracts of raw were found to possess interesting antioxidant properties (DPPH scavenging, H₂O₂ scavenging and reducing power) which were significantly influenced by their chemical composition (Tătăringă et al. 2008). Studies in a human digestion model showed that after digestion by the small intestine, the antioxidant activity values were dramatically increased, whereas the antioxidant activity was less influenced by digestion in the stomach for both onion extract and quercetin standard (Hur et al. 2013). The inhibitory

effect of lipid oxidation of onion extract in mouse brain lipids increased after digestion in the stomach. The inhibitory effect of lipid oxidation of onion extract was higher in the high-fat-fed mouse brain lipids than that in the low-fat-fed mouse brain lipids. Thus, dietary onion may have important applications as a natural antioxidant agent in a high-fat diet.

The antioxidant and reducing activity of the dominant onion flavonoids quercetin (Q), quercetin 3-*O*- β -glucoside (Q3G), quercetin 4'-*O*- β -glucoside (Q4'G) and quercetin 3,4'-di-*O*- β -glucoside (Q3,4'G) in onion varieties Sochaczewska and Szalotka were determined by spectrophotometric (Trolox equivalent antioxidant capacity (TEAC), peroxy radical trapping capacity (PRTC)) and cyclic voltammetry methods, respectively (Zielinska et al. 2008b). The dominant forms of quercetin in the onion var. Sochaczewska and Szalotka included Q4'G (61 and 54 %), Q3,4'G (37 and 44 %), Q3G (1.4 and 1.1 %) and free quercetin (1.1 and 0.7 %), respectively. The highest antioxidant capacity of onion was found under cumulative consideration of photochemiluminescence (water-soluble compounds + lipid-soluble compounds) and TEAC assays. The relative contribution of Q and its glucosides to the antioxidant capacity of onions showed a low contribution of Q, Q3G and Q3,4'G derived from CV, TEAC and PRTC assays, while the highest contribution to the antioxidant capacity of onions was provided by Q4'G.

Flavonoids were mainly present in ethyl acetate subfraction of three varieties of Spanish onions 34.92, 7.95, 0.38 $\mu\text{mol/g}$ of rutin equivalent, and its antioxidant capacity was 74.86, 34.59 and 4.55 $\mu\text{mol/g}$ Trolox (Santas et al. 2010). Red onion cultivars had the highest antioxidant activity as activity determined by both 'Ferric-reducing ability of plasma' (FRAP) and 'Trolox equivalent antioxidant capacity' (TEAC); 15.4 $\mu\text{mol TE/g DW}$ for TEAC and 9.3 $\mu\text{mol TE/g DW}$ for FRAP (Gokce et al. 2010). Yellow onions had higher TEAC (14.7 $\mu\text{mol TE/g DW}$) and FRAP value (9.8 $\mu\text{mol TE/g DW}$) than white onions (8.7 $\mu\text{mol TE/g DW}$) for TEAC and (5.6 $\mu\text{mol TE/g DW}$) for FRAP. Yellow onion group was found to have the highest total phenolic (TP) content (3.7 mg GAE/g

DW), followed by red onion (2.2 mg GAE/g DW) and then white onion (1.1 mg GAE/g DW) group. The values of TEAC and FRAP were significantly correlated by TP with similar Rs (0.74 and 0.73, respectively). TP, TEAC and FRAP were significantly and positively correlated to soluble solids (0.41, 0.43 and 0.40, respectively).

The ethyl acetate fraction of red onion peel was found to have high total phenolic content (384.7 mg GAE/g), total flavonoid content (165.2 mg QE/g), antioxidant activity (97.4 %), antiradical power (75.3) and reducing power (1.6 ASE/mL) (Singh et al. 2009). The ethyl acetate fraction had markedly higher antioxidant capacity than butylated hydroxytoluene (BHT) in preventive or scavenging capacities against FeCl₃-induced lipid peroxidation, protein fragmentation, hydroxyl (site-specific and non-site-specific), superoxide anion and nitric oxide radicals. The large amount of polyphenols (ferulic, gallic, protocatechuic acids, quercetin and kaempferol) contained in ethyl acetate fraction may cause its strong antioxidant and antimutagenic properties indicating that the ethyl acetate fraction of red onion peel may be used as natural antioxidant in nutraceutical preparations. Shim et al. (2011) found that the antioxidant activity (DPPH and Folin–Ciocalteu methods) of yellow and red onions was stronger in the outer layer than in the inner layer, and strong correlation was found between antioxidant activity and total phenolic content ($R^2 = 0.927$). Myricetin was the most bioaccessible among flavonoids in both red and yellow onions after digestion. The anthocyanin extract of outer and inner layers of white onion showed high free radical scavenging activities with $IC_{50} = 2.69 \times 10^{-5}$ and 5.89×10^{-5} mg/mL, respectively, exhibiting a tenfold higher antioxidant scavenging activity as compared with ascorbic acid (Benamalek et al. 2013). The outer layer of onion was rich in flavonols with contents of 103 µg/g DW (red variety) and 17.3 µg/gDW (white variety). The anthocyanin contents in the inner and outer layers of white onion were 0.045 mg/g and 0.077 mg/g, respectively.

The volatile sample of freeze-dried onion sprout (extracted with dichloromethane) inhibited hexanal oxidation for 40 days by >99 % at levels >100 µg/mL (Takahashi and Shibamoto

2008). Among the total of 71 components identified in the volatile sample, 24 were sulfur-containing compounds, which comprised 36.87 % of the total volatile chemicals identified. The volatile sample and water sample II exhibited moderate antioxidant activity in a malonaldehyde/gas chromatography assay and thiobarbituric acid assay, whereas water sample I did not show appreciable activity. It was found that blanching and frying and then microwaving of garlic and onions did not decrease significantly the amounts of their bioactive compounds (polyphenols, flavonoids, flavonols, anthocyanins, tannins and ascorbic acid) and the level of antioxidant activities (Gorinstein et al. 2008). The HPLC profiles of free and soluble ester- and glycoside-bound phenolic acids showed that *trans*-hydroxycinnamic acids (caffeic, *p*-coumaric, ferulic and sinapic) were as much as twice higher in garlic than in onions. Quercetin quantity was the highest in red onion among the studied vegetables. The electrophoretic separation of non-reduced garlic and onion proteins after boiling demonstrated their degradation in the range from 50 to 112 kDa.

High hydrostatic pressure (HHP) of 300 or 600 MPa/1–3 minutes/25 °C treatment of onions increased extracted phenolic content and antioxidant activity (Vázquez-Gutiérrez et al. 2013). HHP produced changes in membrane permeability and disruption of onion cell walls favouring the release of phenolic compounds from tissue and, in consequence, improving their extractability. Onion treated by high-pressure processing (HPP) and combined with freeze-drying and pulverisation (HPP-FD-P) increased quercetin 3,4'-diglucoside, quercetin 4'-glucoside, quercetin 3-glucoside and isorhamnetin 3,4'-diglucoside extractability (González-Peña et al. 2013). The results suggested that HPP (especially treatment at 400 MPa) and HPP-FD-P may be of benefit for obtaining functional ingredients from onion, as suggested by increased NO(•) scavenging capacity and maintenance of the antioxidant activity mainly in hydrolysed extracts.

The methanolic onion peel extract exhibited the highest oxygen radical absorbance capacity (ORAC) values, which were 1.7- and 1.1-fold greater than those of acetonitrile and ethanolic extracts, respectively (Kim et al. 2013). The total

phenolic contents, expressed as mg GAE/g of onion peel, ranged from 53.7 to 123.8 mg; they were highest in methanolic onion peel extract: 2.3- and 1.2-fold higher than those in acetone and ethanol extracts. ORAC was strongly correlated with total phenolic content ($R^2 = 0.980$). In the DPPH assay, all onion peel extracts (5–100 $\mu\text{g/mL}$) exhibited a dose–response effect. The half-maximal inhibitory concentrations on DPPH free radicals (IC_{50}) were as follows: methanolic extract (44.7) > ethanolic extract (41.7) > acetonetic extract (39.3). In contrast to the total phenolic content, ORAC and DPPH assay results, total radical trapping antioxidant potential (TRAP) was highest in ethanol extract ($\text{EC}_{50} = 86.9$), which was 1.7- and 1.2-fold higher than those of methanolic and acetonetic extracts, respectively. In HepG2 cells, onion peel extract at concentrations from 1 to 100 $\mu\text{g/mL}$ reduced oxidative stress; 5 $\mu\text{g/mL}$ extracts restored them to levels similar to that of the control group. In HepG2 cells, onion peel extract at concentrations from 1 to 100 $\mu\text{g/mL}$ reduced oxidative stress; 5 $\mu\text{g/mL}$ extracts restored them to levels similar to that of the control group.

The 60 °C water (mild heat) treatment of fresh-cut onion slices resulted in a significant increase in total phenolics from 44.92 to 52.32 mg GAE/100 g (Siddiq et al. 2013). Except for 50 and 70 °C treatments, total phenolics in control and 60 °C treated fresh-cut onions decreased during storage. The antioxidant properties of fresh-cut onions were 1.31, 0.99 and 62.49 $\mu\text{M TE/g}$ using ABTS, DPPH and ORAC assays, respectively. The mild-heat treatments did not affect ABTS and DPPH antioxidant activities and the colour of fresh-cut onions. The storage time had mixed effect on the antioxidant properties (ABTS decreased; DPPH and ORAC remained fairly stable). The 50 °C samples exhibited the lowest weight loss during the 21-day storage.

The antioxidant activity of an onion seed extract containing cysteine sulfoxides was found to have reducing activity (FRAP) rather than DPPH radical scavenging effects (Dini et al. 2008). The new cysteine sulfoxide, (S(S)R(C))-S-(3-pentenyl)-L-cysteine sulfoxide, showed a low antioxidant activity, when compared with the standards used. Yellow

onion extract showed enhanced antioxidative effects in 2,2-diphenyl-1-picrylhydrazyl (DPPH), Trolox equivalent antioxidant capacity (TEAC) and 5-(and-6)-chloromethyl-2',7'-dichlorodihydrofluorescein diacetate and acetyl ester (CM-H(2)DCFDA) assay after being treated with a crude enzyme extract from soybean paste fungi, *Aspergillus kawachii* (Yang et al. 2012a). After enzyme treatment, contents of quercetin 3,4'-di-*O*- β -D-glucoside and quercetin 4'-*O*- β -D-glucoside decreased while that of quercetin 3-*O*- β -D-glucoside and quercetin increased. Among the increased compounds, only quercetin showed strong antioxidative activity in the DPPH assay.

All 31 shallot (*Allium cepa* var. *aggregatum*) strains derived from different regions of Vietnam and six other countries showed potent antioxidant activities in a DPPH assay (Vu et al. 2013). The highest antioxidant capacity was in the strains possessing relatively high contents of polyphenol, quercetin and saponin. Significant correlations were found between antioxidant capacity and four groups of chemical compounds (polyphenols, quercetins, saponins and S-alk(en)yl-L-cysteine sulfoxide (ACSO)). The phenolic content of skins from different coloured onions (pearl, red, yellow and white) was approximately six times higher than that of their fleshy edible parts (Albishi et al. 2013). Among onion varieties, pearl onion skin showed the highest phenolic content (26.4 mg quercetin eq./g freeze-dried sample). Quercetin 3,4'-diglucoside, quercetin and kaempferol were the predominant phenolics in all onion extracts tested. A similar trend was observed for free radical scavenging activity of the tested samples. Extracts from edible part of onion showed lower activity in all antioxidant tests carried out. Onion essential oil showed moderate antioxidant activities in ABTS assay (0.67 mg/mL as IC₅₀ value), DPPH test (IC₅₀ value = 0.63 mg/mL) and metal-chelating assay (IC₅₀ value of 0.51 mg/mL) (Ye et al. 2013). Furthermore, the reducing power of the oil was dose dependent, but was inferior to butylated hydroxytoluene, a better known reducing agent.

Animal Studies

Both the garlic oil and onion oil supplementation to nicotine-treated rats increased resistance to lipid peroxidation (Helen et al. 1999). The supplementation increased activities of antioxidant enzymes, catalase, superoxide dismutase and glutathione peroxidase and increased concentrations of glutathione. The results indicated that oils of garlic and onion were effective antioxidants against the oxidative stress.

Onion oil supplemented to nicotine-treated rats showed increased resistance to lipid peroxidation, and the effect was near to that of vitamin E-fed rats (Helen et al. 2000). On onion oil or vitamin E supplementation, the concentration of antioxidants was significantly raised in all the tissues studied; however, a significantly increased concentration of glutathione, vitamin E and retinol was noticed in vitamin E + nicotine-treated rats. Thus, the results indicated that onion oil was an effective antioxidant against the oxidative damage caused by nicotine as compared to vitamin E.

Studies showed that rats fed with diets of garlic or onions could reduce the exercise-induced oxidative stress but does not alter plasma cholesterol profile (Choi and Cho 2006). In garlic- or onion-fed animals, the ratio of reduced glutathione/oxidised glutathione was significantly higher than those of the control animals before and after exercise. The level of liver malondialdehyde (MDA) was lower than that of control animals after exercise. Compared to control animals, catalase activity of garlic-fed animals was higher before exercise but was lower after exercise, while superoxide dismutase (SOD) activity of garlic-fed animals was lower in before and after exercise. Catalase activity of onion-fed animals was higher before and during exercise, while SOD activity was higher during exercise. Plasma cholesterol profiles were not significantly different in rats fed with different *Allium* vegetable diets. The results suggested that *Allium* vegetable diets had antioxidative activities and could reduce the oxidative stress from exercise in rats but did not alter the plasma cholesterol profile.

Rats fed with onion flesh powder or onion peel powder had a higher plasma total antioxidant status than rats fed the onion-free control diet (Park et al. 2007). Onion peel powder

reduced liver thiobarbituric reactive substances relative to those of the control diet in aged rats. Brain 8-isoprostane levels were markedly decreased by all four onion diets, and the decrease was significant for the onion flesh powder and onion peel powder diets. There was no significant decrease in cellular DNA damage in the kidney or brain tissue among rats fed with the four onion diets. Total antioxidant status (TAS) and levels of total polyphenols and quercetin were greatest in onion peel ethanol extract, followed by onion peel powder, onion flesh ethanol extract and onion flesh powder. Plasma quercetin and isorhamnetin levels were markedly increased by onion peel powder and onion peel ethanol extract. Onion flesh or onion peel enhanced antioxidant status in aged rats and may be beneficial for the elderly as a means of lowering the lipid peroxide levels. Feeding rats with dietary red onion peel and/or flesh was found to enhance antioxidant defence mechanism through the induction of plasma SOD and glutathione peroxidase (GPx) activities and inhibition of liver lipid peroxidation indicating that red onion may exert important protective effects against oxidative stress-related diseases (Lee et al. 2012a).

Clinical Studies

In a study on five healthy volunteers, following the onion meal, quercetin was found to be absorbed to high enough concentrations to increase the overall antioxidant activity of the plasma (McAnlis et al. 1999). Quercetin, however, had a strong affinity for protein and provided no direct protective effect during low-density lipoproteins (LDL) oxidation. In a separate human volunteer study, Moon et al. (2000b) found that after the short-term ingestion of onion rich in quercetin glucosides, conjugated metabolites of quercetin accumulated exclusively in human blood plasma in the concentration range of 10^{-7} to approximately 10^{-6} M, although these metabolites were hardly incorporated into plasma LDL. Human LDL isolated from the plasma after the trial showed little improvement of its resistance to copper ion-induced oxidation. Overall, quercetin was the most effective inhibitor of oxidative damage to LDL in-vitro (O'Reilly et al. 2000). However, no

significant difference was found in the Cu^{2+} ion-stimulated lag time of LDL oxidation in humans given a diet enriched with onions and black tea (high flavonoids) (48 minutes) and low-flavonoid dietary treatments (49 minutes). In a randomised crossover design of 32 healthy humans consumption of flavonoid-rich onion and black tea, predominantly the flavonoid quercetin, had no significant effect on plasma F2-isoprostane concentrations and MDA-LDL (malondialdehyde-modified low-density lipoprotein) autoantibody titre in the study and thus did not appear to inhibit lipid peroxidation in humans (O'Reilly et al. 2001).

Anticancer Activity

In-Vitro Studies

Organosulfur compounds (OSCs) in garlic and onion such as oil-soluble OSCs methyl propyl disulfide and propylene sulfide demonstrated inhibitory effects on the development of liver glutathione S-transferase placental (GST-P)-positive foci (Fukushima et al. 1997). Similarly water-soluble OSCs S-methylcysteine and cysteine decreased GST-P focus formation. In contrast, OSCs such as diallyl sulfide, diallyl trisulfide and allyl methyl trisulfide enhanced formation of such altered hepatocellular foci. Inhibitory potential for colon and renal carcinogenesis was observed in rats treated with diallyl disulfide. Thus, the results indicated that some OSCs exert chemopreventive effects on chemical carcinogenesis.

Incubation of human promyelocytic leukaemia cells HL-60 with garlic or onion oil (20 $\mu\text{g}/\text{mL}$) caused a marked suppression of HL-60 proliferation; the suppression was almost identical with those obtained by all-*trans*-retinoic acid (ATRA) or dimethyl sulfoxide (DMSO) used as positive controls (Seki et al. 2000). These oils induced the generation of nitroblue tetrazolium (NBT)-reducing activity, and about 20 % of the HL-60 cells became NBT positive. CD11b, another marker of the differentiation of these cells, was also significantly induced by garlic oil or onion oil. The data suggested that garlic and onion oils had the ability to induce differentiation of HL-60 cells into those of the granulocytic

lineage. Quercetin inhibited the proliferation of HT-29 human colon cancer cells with an IC_{50} value of 81.2 μ M (Wenzel et al. 2004). It was found that quercetin altered the levels of a variety of proteins involved in growth, differentiation and apoptosis of colon cancer cells.

The proliferation of HepG(2) and Caco-2 cells was significantly inhibited in a dose-dependent fashion after exposure to the Western Yellow, New York Bold and Northern Red onion and shallot extracts, with Western Yellow, shallots and New York Bold exhibiting the highest antiproliferative activity against HepG(2) cells and New York Bold and Western Yellow exhibiting the highest antiproliferative activity against Caco-2 cells (Yang et al. 2004). However, the varieties of Western White, Peruvian Sweet, Empire Sweet, Mexico, Texas 1015, Imperial Valley Sweet and Vidalia demonstrated weak antiproliferative activity against both HepG(2) and Caco-2 cells. Shallots contained the highest total phenolic content (114.7 mg/100 g of sample) among the varieties tested and exhibited the highest total antioxidant activity (45.5 μ mol of vitamin C equiv./g of onion). For all varieties, both total phenolic and flavonoid contents were strongly correlated with total antioxidant activity ($R^2 = 0.9668$ and $R^2 = 0.7033$, respectively).

Quercetin aglycone was found to be the most effective inducer of the anticarcinogenic phase II marker enzyme, quinone reductase (QR), in mouse Hepalcl7 cells (Williamson et al. 1996). Of the onion purified glycosides (quercetin 3,4'-diglucoside and quercetin 4'-glucoside), only quercetin 4'-glucoside was able to induce QR activity in the assay. Inhibition of NADPH-/iron- and ascorbate-/iron-induced lipid peroxidation of human liver microsomes, and the Trolox C-equivalent antioxidant capacity (TEAC), assay showed that the 4'-glycosylation dramatically decreased activity in the 'antioxidant' assays, whereas 3-substitutions produced much smaller changes. The nonpolar extracts of freeze-dried onion was found to contain potential cancer-preventive constituents based on the ability to induce quinone reductase (QR, a representative phase II enzyme) in murine hepatoma cells (Hepa 1cl7) (Xiao and Parkin 2006). Five

pure compounds were isolated from active fractions and identified as *p*-hydroxyphenethyl *trans*-ferulate; 5,6-dimethyl-2-pyridinecarboxylic acid; ferulic acid; 1-(6-hydroxy-[3]pyridyl)-propan-1-one and N-*trans*-feruloyl 3-*O*-methyldopamine. *p*-Hydroxyphenethyl *trans*-ferulate (1) doubled QR-specific activity in Hepa 1c1c7 cells at a level of 2.1 µg/mL (6.6 µM). One newly identified compound, 5-hydroxy-3-methyl-4-propylsulfanyl-5H-furan-2-one, and four known compounds, 5-(hydroxymethyl) furfural, acetovanillone, methyl 4-hydroxyl cinnamate and ferulic acid methyl ester, were also isolated from onion and identified as active quinone reductase inducing agents (Xiao and Parkin 2007). Results of in-vitro studies suggested that onion oil may exert chemopreventive action by inducing cell cycle arrest at the G2/M phase and apoptosis in A540 lung carcinoma cells (Wu et al. 2006). Hung (2007) found that quercetin-inhibited A549 lung carcinoma cell proliferation was associated with activation of the extracellular signal-regulated kinase (ERK). Inhibition of MEK1/2 but not PI3 kinase, p38 kinase or JNK abolished quercetin-induced apoptosis suggesting that MEK-ERK activation was required to trigger apoptosis. Treatment with different concentrations (0.5–1.5 mg/mL) of 2,3-dihydro-3,5-dihydroxy-6-methyl-4H-pyranone (DDMP), isolated from onions, for various periods (0–48 hours) inhibited the growth of colon cancer cells (SW620 and HCT-116) followed by the induction of apoptosis in a dose-dependent manner (Ban et al. 2007). It was also found that DDMP modulated tumour necrosis factor-alpha (TNF-alpha) and tetradecanoylphorbol acetate (TPA)-induced NF-kappaB transcriptional and DNA binding activity. In addition, DDMP suppressed the NF-kappaB target antiapoptotic genes (Bcl-2), whereas it induced the expression of the apoptotic genes (Bax, cleaved caspase-3 and cleaved PARP).

Quercetin, flavonoid of onion, had been reported to inhibit the growth of certain malignant cells in-vitro and histamine and most cyclin-dependent kinases and also displayed unique anticancer properties (Shaik et al. 2006). It was found that MSTO-211H human malignant pleural mesothelioma cell viability was reduced, and apoptotic cell death was increased

by quercetin (20–80 μM), with an IC_{50} value of 58 μM (Chae et al. 2012). In addition, quercetin increased the sub- G_1 cell population and was found to interact with specificity protein 1 (Sp1) and significantly suppressed its expression at the protein and mRNA levels. Furthermore, quercetin modulated the levels of Sp1 regulatory genes, such as cyclin D1, myeloid cell leukaemia (Mcl)-1 and survivin in MSTO-211H cells. Quercetin, a principal flavonoid compound in onion, inhibited migration and invasion of SAS human oral cancer cells (Lai et al. 2013). This was associated with the downregulation of PKC and RhoA by suppressing MAPK and PI3K/AKT signalling pathways and NF- κB and uPA, resulting in inhibition of matrix metalloproteinase MMP-2 and MMP-9 expression and activation.

Fisetin, a flavonol found in onion, acted as a dual inhibitor of the PI3K/Akt and the mTOR pathways in prostate cancer and lung adenocarcinoma cells (Adhami et al. 2012; Syed et al. 2013). The Akt/mTOR pathway is known to play a central role in various cellular processes that contribute to the malignant phenotype. Dihydroquercetin (taxifolin), a potent flavonoid found in onions, had been reported to show therapeutic promise in major disease states such as cancer, cardiovascular disease and liver disease (Weidmann 2012). The proposed mechanism(s) of action reported included the activation of the antioxidant response element (ARE) and detoxifying phase II enzymes, inhibition of cytochrome P(450) and fatty acid synthase in carcinogenesis. Among the nine dihydroquercetin derivatives, the maximum antiproliferative activity on the model of rat fibroblast culture was exhibited by KN-2, KN-4, KN-7 and KN-8 compounds, while KN-7 and KN-8 compounds also showed maximum activity on the model of MCF-7 tumour (human breast cancer) cell culture (Rogovskii et al. 2010). The maximum general antioxidant activity was observed for the native dihydroquercetin and KN-8 compound. There was a strong correlation ($R^2 = 0.93$) between the antiproliferative effects of dihydroquercetin derivatives on murine skin fibroblasts and MCF-7 cells (human breast cancer). The dose of S-allylmercaptocysteine (CySSA) from garlic or S-1-propenylmercaptocysteine

(CySSPe) (the major onion analogue) alone required to reduce viable breast cancer MCF-7 cells by 50 % was >400 μM , (Zhang et al. 2014). This was synergistically reduced to 62 and 91 μM for CySSA + Se and CySSPe + Se in the presence of Na_2SeO_3 (Se), respectively, at molar ratios of 39:1. Apoptosis was confirmed and cell cycle arrest occurred at the G2/M and sub-G1 interphases.

Onionin A isolated from onion bulb showed the potential to suppress tumour cell proliferation by inhibiting the polarisation of M2 alternatively activated macrophages (El-Aasr et al. 2010). Crude onion extract was cytotoxic to Lucena multidrug resistance (MDR) human erythroleukaemic and its K562 parental cell line (Votto et al. 2010). Similar sensitivities were obtained for both tumoral cells. In K562 cells, a significant increase of apoptosis was verified while the Lucena cells experienced a significant increase of necrosis. The onion extract also exhibited antioxidant effect and induced significant DNA damage in both tumoural cell lines. No significant cytotoxic effects were observed in either cell line treated with its components quercetin or propyl disulfide.

The fermented aqueous onion extract, lacking the usual onion flavonoid profile, was found to be the most active in antibacterial, antigenotoxic, and antiproliferative activity of these extracts was assessed by means of agar disc diffusion, bacterial growth kinetics, a comet assay, cell cycle distribution analysis and cell viability assays (Millet et al. 2012). The finding indicated that metabolites of onion compounds, generated by lactic acid fermentation, may be more active than their precursor substances.

Animal Studies

The tumour yield and incidence of phorbol-myristate-acetate promotion were inhibited in a dose-dependent manner over the range of 10–10,000 μg onion oil, applied three times per week (Belman 1983). Garlic oil was also inhibitory but was less effective. Eight organosulfur compounds from garlic and onions allyl methyl trisulfide (AMT), allyl methyl disulfide (AMD), diallyl trisulfide (DAT) and diallyl sulfide (DAS) and

also four corresponding saturated compounds in which propyl groups were substituted for the allyl groups were tested for their inhibitory effects on benzo[a]pyrene (BP)-induced neoplasia of forestomach and lung of female A/J mice (Sparnins et al. 1988). DAS and AMD, but not DAT or AMT, inhibited pulmonary adenoma formation. All four allylic compounds induced increased glutathione S-transferase (GST) activity in the forestomach, but varied in their capacity to induce GST in lung, liver and small bowel. Their saturated analogues produced little or no induction. Studies on diethylnitrosamine-induced neoplasia of the liver in male F344 rats using the medium-term bioassay system based on the two-step model of hepatocarcinogenesis found that four organosulfur compounds from garlic and onions, isothiocyanic acid isobutyl ester, dipropyl trisulfide, allyl mercaptan and dimethyl trisulfide appeared to promote rat hepatocarcinogenesis (Takada et al. 1994a, b). Their promoting effect might be caused by increased cell proliferation with increased ornithine decarboxylase biosynthesis. Spermidine/spermine N1-acetyltransferase activity was not significantly changed.

Application of onion oil inhibited skin tumorigenesis in Sencar mouse initiated by 7,12-dimethylbenz[a]-anthracene (DMBA) and promoted in two tumour stages by 12-O-tetradecanoylphorbol-13-acetate (TPA) (Perchellet et al. 1990). The number of papillomas per mouse was significantly reduced by onion oil but not by propenyl sulfide. Onion oil inhibited the TPA-stimulated DNA synthesis when given as single doses of 5 mg one hour before TPA. Jung et al. (2008) reported that mouse skin tumorigenesis data clearly showed that pretreatment with myricetin significantly suppressed UVB-induced skin tumour incidence in a dose-dependent manner. Their results indicated that myricetin exerted potent chemopreventive activity mainly by inhibiting Fyn kinase activity directly and subsequently attenuated UVB-induced COX-2 expression in skin carcinogenesis. Also myricetin was found to inhibit UVB-induced angiogenesis by targeting PI3-K in an SKH-1 hairless mouse skin tumorigenesis model (Kang et al. 2011). Raf kinase was found to be a critical target for myricetin in inhibiting the UVB-induced formation of

wrinkles and suppression of type I procollagen and collagen levels in mouse skin.

Administration of quercetin (active onion flavonoid) to BALB/c mice injected with leukaemia WEHI-3 cells inhibited proliferation of WEHI-3 and promoted an immune response (Yu et al. 2010). Quercetin decreased the percentage of Mac-3 and CD11b markers, suggesting that the differentiation of the precursors of macrophages and T cells was inhibited. There was no effect on CD3 levels, but quercetin increased CD19 levels. Quercetin decreased the weight of the spleen and liver compared with the olive oil-treated animals. Quercetin stimulated macrophage phagocytosis of cells isolated from peritoneum and also promoted natural killer cell activity.

Atypical prostatic hyperplasia-induced prostatic rats developed hyperplasia and inflammation with cellular proliferation and reduced apoptosis, accompanied by increased tissue expressions of proinflammatory cytokines IL-6, IL-8, TNF- α , IGF-1 and clusterin and decreased TGF- β 1 which were all ameliorated by treatment with saw palmetto and red onion scale methanol extract (Elberry et al. 2014). These ameliorative effects were more evident in onion-treated groups and were dose dependent. Assay of total phenolic content of methanolic extract was determined to be 12.9 mg GAE/g DE. Quercetin and quercetin 4'- β -O-D-glucoside were identified as the major flavonoids, also sterols and/or terpenoids, and tannins were detected. The onion extract exhibited DPPH scavenging activity in a dose-related manner with IC₅₀ value of 368 μ g/mL. The protective effect against atypical prostatic hyperplasia I rats was ascribed to potential anti-inflammatory and immunomodulatory effects.

Epidemiological/Meta-analytical Studies

In the Zutphen Elderly Study of 738 men aged 65–84 years from 1985 to 1990, a high intake of flavonoids from vegetables and fruits (mainly onions, kale, endive and apples) was inversely associated with the risk of cancer of the alimentary and respiratory tract (relative risk of highest vs. lowest tertile = 0.51) (Hertog et al. (1994)). The Netherlands

Cohort Study which started in 1986 with 120,852 men and women ranging in age from 55 to 69 years provided evidence for a strong inverse association between onion consumption and stomach carcinoma incidence (Dorant et al. 1996b). The rate ratio for stomach carcinoma in the highest onion consumption category (≥ 0.5 onions/day) was 0.50 compared with the lowest category (0 onions/day) after adjustment for other risk factors. The reduction in risk was restricted to carcinoma in the noncardia part of the stomach. The consumption of leeks and the use of garlic supplements were not associated with stomach carcinoma risk. The Netherlands Cohort Study did not support an inverse association between the consumption of onions and leeks or the use of garlic supplements and the incidence of male and female colon and rectum carcinoma (Dorant et al. 1996a). In a case-control study of 345 patients diagnosed with primary breast carcinoma between 1986 and 1989 conducted in France, Challier et al. (1998) found that accounting for total caloric intake and established risk factors, breast cancer risk was shown to decrease as consumption of fibre, garlic and onions increased. This study also supported the epidemiologic evidence that saturated fat intake and breast cancer risk are associated in postmenopausal women and conversely that unsaturated fat intake could lower the risk in the same subgroup. In an interview study of 582 patients with incident lung cancer and 582 age-, sex- and ethnicity-matched control subjects, Le Marchand et al. (2000) found that after adjusting for smoking and intakes of saturated fat and β -carotene, there was a statistically significant inverse associations between lung cancer risk and the main food sources of the flavonoids quercetin (onions and apples) and naringin (white grapefruit). The lung cancer odds ratio (OR) for the highest compared with the lowest quartile of intake was 0.5 for onions and 0.6 for apples. The OR for the highest compared with the lowest tertile of intake for white grapefruit was 0.5. No association was found for important food sources of other flavonoids.

In a case-referent study conducted in Jiangsu province, China, on histopathologically confirmed cases for oesophageal cancer ($n = 81$) and stomach cancer ($n = 153$) and population-based referents ($n = 234$), frequent intake of *Allium* vegetables

(garlic, onion, Welsh onion and Chinese chives) was found to be inversely associated with the risk for both cancers (Gao et al. 1999). In the highest consumption category (≥ 1 time/week) of garlic, onion, Welsh onion and Chinese chives, the adjusted odd ratios compared with the lowest category (<1 time/month) were 0.30 (CI = 0.19–0.47), 0.25 (CI = 0.11–0.54), 0.15 (CI = 0.08–0.26) and 0.57 (CI = 0.23–1.42) for oesophageal cancer and 0.31 (CI = 0.22–0.44), 0.17 (CI = 0.08–0.36), 0.22 (CI = 0.15–0.31) and 0.40 (CI = 0.17–0.94) for stomach cancer, respectively. In an interview study, six of four patients with stomach cancer and 1,131 controls in an area of China with high rates of gastric cancer showed a significant reduction in gastric cancer risk with increasing consumption of garlic, onions and other *Allium* vegetables (You et al. 1989). Persons in the highest quartile of intake experienced only 40 % of the risk of those in the lowest. Protective effects were seen for *Allium* foods. In a large population-based case–control study in Shanghai (750 cases and 750 age- and gender-matched controls) and Qingdao (201 cases and 201 age- and gender-matched controls), Setiawan et al. (2005) found an inverse relationships with dose–response pattern that were observed between frequency of onion intake and stomach cancer in Qingdao and Shanghai after adjusting for matching variables, education, body mass index, pack-years of smoking, alcohol drinking, salt intake and fruit and vegetable intake. In Shanghai, negative dose–response relationships were observed between monthly intake of onions or garlic stalks and distal, but not cardia cancer. A negative association was also noted between intake of garlic stalks (often vs. never) and risk of stomach cancer in Qingdao (OR = 0.30). Our results confirmed protective effects of *Allium* vegetables (especially garlic and onions) against stomach cancer.

Using a large data set from an integrated network of Italian and Swiss case–control studies, Galeone et al. (2006) found an inverse association between the frequency of use of *Allium* vegetables and the risk of several common cancers. The multivariate odds ratios (ORs) for the highest category of onion and garlic intake were, respectively, 0.16 and 0.61 for cancer of the oral cavity and pharynx, 0.12 and 0.43 for

oesophageal cancer, 0.44 and 0.74 for colorectal cancer, 0.17 and 0.56 for laryngeal cancer, 0.75 and 0.90 for breast cancer, 0.27 and 0.78 for ovarian cancer, 0.29 and 0.81 for prostate cancer and 0.62 and 0.69 for renal cell cancer. A large multi-centre case–control study of 1,369 patients with benign prostatic hyperplasia and 1,451 controls in Italy showed an inverse association between onion and garlic consumption and benign prostatic hyperplasia (Galeone et al. 2007); the inverse relationships were consistent across age strata. In a multi-centre case–control study of 454 endometrial cancer cases and 908 controls, Galeone et al. (2009) found a moderate protective role of onion and garlic on the risk of endometrial cancer. Compared with nonusers, the odd ratio of endometrial cancer for successive categories of onion intake were 0.94 for < two portions/week and 0.40 for ≥ two portions/week, with a significant inverse trend in risk. The odd ratio for an increment of one portion (i.e. 80 g) of onions per week was 0.81. For garlic, the odd ratio for successive categories of intake was 0.89 for intermediate use and 0.62 for high use, with a significant inverse trend in risk. In humans, the total average intake of quercetin and kaempferol was estimated at 20 mg/day, and the consumption of quercetin from onions and apples was inversely correlated with lung cancer risk (Hung 2007). In a meta-analysis, consumption of high levels of *Allium* vegetables (onion, garlic, leek, Chinese chive, scallion, garlic stalk and Welsh onion) reduced the risk for gastric cancer risk (Odds ratio, 0.54) (Zhou et al. 2011). Specific analyses for onion, garlic, leek, Chinese chive, scallion, garlic stalk and Welsh onion yielded similar results, except for onion leaf.

Antibacterial Activity

Fresh homogenised onion exhibited strong antimicrobial effect, 50–100 mg, completely inhibited the in-vitro growth of *Staphylococcus aureus* strain (Virtanen and Matikkala 1959a). It was found to contain S-methylcysteine sulfoxide (MCSO) and S-n-propyl cysteine sulfoxide (PCSO) or dihydroalliin, from which the corresponding thiosulfinates were formed enzymatically. These compounds also exhibited strong

antimicrobial activity. All extracts of onion bulb were inhibitory in-vitro to *Escherichia coli*, *Pseudomonas pyocyaneus*, *Salmonella typhi* and *Bacillus subtilis* (Abdou et al. 1972). The ether extract gave the strongest inhibition followed by ethyl acetate, ethanol and petroleum ether extract.

All test organisms: five Gram-negative and three Gram-positive bacterial species and two yeast species were inhibited by garlic juice, while onion and shallot juice showed no effect upon Gram-negative bacteria (Dankert et al. 1979). Garlic extract showed greater activity against Gram-positive organisms, Gram-negative organisms as compared to the extract of onion (Elnima et al. 1983). Onion oil was highly active against all Gram-positive bacteria tested and only one isolate (*Klebsiella pneumoniae*) of Gram-negative bacteria (Zohri et al. 1995). Onion extract exhibited antibacterial activity in-vitro against *Streptococcus mutans* and *Streptococcus sobrinus*, the main causal bacteria for dental caries, and *Porphyromonas gingivalis* and *Prevotella intermedia*, the main causal bacteria of adult periodontitis (Kim 1997). Grated onion left to stand at 37 °C for 48 hour and steam treated (100 °C for 10 minutes) onion did not show antibacterial activity. The essential oil extracts of these *Allium* plants (garlic and green, yellow, red onions) exhibited marked antibacterial activity against *Staphylococcus aureus* and *Salmonella enteritidis*, with garlic showing the highest inhibition and green onion the lowest (Benkeblia 2004). Comparatively, 50 and 100 mL/L concentrations of onions extracts were less inhibitory than 200, 300 and 500 mL/L concentrations. However, with garlic extract, high inhibitory activity was observed for all tested concentrations. *S. aureus* showed less sensitivity towards essential oil inhibition; however, *S. enteritidis* was strongly inhibited by red onion and garlic extracts.

Quercetin derivatives from onion skin, 2-(3,4-dihydroxyphenyl)-4,6-dihydroxy-2-methoxybenzofuran-3-one, exerted selective activity against *Helicobacter pylori* strains and 3-(quercetin-8-yl)-2,3-epoxyflavanone showed antibacterial activity against methicillin-resistant *Staphylococcus aureus* (MRSA) and *H. pylori* strains at the

same time that it increased susceptibility of MRSA to β -lactams (Ramos et al. 2006). Quercetin inhibited growth of periodontal pathogens *Actinobacillus actinomycetemcomitans* and *Porphyromonas gingivalis* in-vitro (Geoghegan et al. 2008, 2010). No significant difference was found between the chlorhexidine group and the quercetin solution after 24 hours of incubation.

Quercetin and kaempferol isolated from Spanish onions were inhibitory against Gram-positive bacteria such as *Bacillus cereus*, *Staphylococcus aureus*, *Micrococcus luteus* and *Listeria monocytogenes* (Santas et al. 2010). Gram-negative bacteria *Escherichia coli* and *Pseudomonas aeruginosa* were less sensitive, while *Candida albicans* was totally resistant. Among the onion extracts tested, only ethyl acetate subfraction showed antimicrobial inhibition. Thirty-three clinical isolates of *Vibrio cholera* were sensitive to onion extracts of two types (purple and yellow) (Hannan et al. 2010). Purple onion extract had MIC range of 19.2–21.6 mg/mL. The extract of yellow type onion had an MIC range of 66–68.4 mg/mL. The outer and inner layers of red onion showed antibacterial activity in-vitro against *Escherichia coli*, *Pseudomonas aeruginosa* and *Staphylococcus aureus* (two strains) (Benamalek et al. 2013). The largest inhibition zone was observed with flavonols of the inner layer of red onion (40 mm), inhibiting the Gram-negative *Escherichia coli*. Ethyl acetate fractions of onion showed inhibitory activities against all tested eight microbes including bacteria and a fungus, while chloroform fractions inhibited all the microbes except *Pseudomonas aeruginosa* (Bakht et al. 2014). Butanol fractions showed second highest activity at both lower and higher concentrations. Ethanol and water fractions were found least effective or ineffective. Among Gram-positive microbes, *Staphylococcus aureus* was the most susceptible bacteria and the most resistant Gram-negative bacteria were *Pseudomonas aeruginosa* and *Salmonella typhi*.

Antifungal Activity

The fungus *Fusarium oxysporum* showed the lowest sensitivity towards the onion essential oil extract, whereas

Aspergillus niger and *Penicillium cyclopium* were significantly inhibited particularly at low concentrations (Benkeblia 2004). Growth of two important dermatophytes, *Trichophyton rubrum* and *Trichophyton mentagrophytes*, was found to be strongly inhibited by aqueous onion extract as a dose-dependent manner (Ghahfarokhi et al. 2004). Onion extract showed fungicidal effect for both fungi at concentrations >3.12 % (v/v). The fungus *T. mentagrophytes* was more affected by the onion as compared to *T. rubrum* at all concentrations used. Onion oil (200 ppm) completely inhibited the growth of *Microsporum canis*, *M. gypseum* and *Trichophyton simii*, while the growth of both *Chrysosporium queenslandicum* and *Trichophyton mentagrophytes* was completely inhibited by 500 ppm of onion oil (Zohri et al. 1995). The growth of four other species of dermatophytic fungi was gradually reduced by increasing the concentrations of onion oil. Onion oil at different concentrations (100, 200 and 500 ppm) tested gradually reduced fungal growth and aflatoxin production by *Aspergillus flavus* and *A. parasiticus* var. *globosus*. Fungal growth and production of toxins sterigmatocystin and rubratoxin A by *A. versicolor* and *Penicillium rubrum* were completely inhibited by the addition of 200 ppm onion oil. Garlic and onion essential oils and their constituent diallyl trisulfide, diallyl tetrasulfide and dimethyl trisulfide were potent inhibitors of yeast growth with minimum inhibitory concentrations between 2 and 45 ppm (Kim et al. 2004a). Film formation on soy sauce by *Zygosaccharomyces rouxii* SS1 was completely prevented for 30 days by the addition of 30 and 40 ppm of garlic oil and onion oil, respectively. The oils and their constituent sulfides, however, were only very weakly antibacterial, showing minimum inhibitory concentrations of greater than 300 ppm for most of the bacteria tested.

Allium ampeloprasum and two *A. cepa* cultivars Junski srebrnjak and Kupusinski jabučar essential oils showed the strongest inhibitory effect against *Saccharomyces cerevisiae* at 1 % concentration (Kocić-Tanackov et al. 2009). Among onion cultivars, Kupusinski jabučar essential oil had stronger inhibition against *Candida tropicalis*, while *A. ampeloprasum* essential oil exerted no inhibition on this yeast. *Rhodotorula* sp. was inhibited only by *Allium ampeloprasum* essential oil.

The strongest inhibitory effect on *Aspergillus tamarii* was shown by Kupusinski jabučar (57 % inhibition at 10 % concentration), and against *Penicillium griseofulvum*, the strongest inhibition was shown by *A. ampeloprasmus* essential oil (78.3 % of inhibition at 10 % concentration). Junski srebrnjak and Kupusinski jabučar essential oils, at 7 and 10 % concentrations, respectively, completely inhibited the growth of *Eurotium amstelodami*.

Onion essential oil exhibited antimicrobial effect against food spoilage and food-borne pathogenic microorganisms with the MIC and MBC values in the ranges of 0.18–1.80 mg/mL and 0.54–3.6 mg/mL, respectively (Ye et al. 2013). Aqueous extracts prepared from onion garlic and the antifungal drug, ketoconazole, inhibited the growth of fungi *Malassezia furfur* (25 strains), *Candida albicans* (18 strains), other *Candida* sp. (12 strains) as well as 35 strains of various dermatophyte species tested in a dose-dependent manner with maximum of 100 % at defined concentrations (Shams-Ghahfarokhi et al. 2006). Compared to the garlic essential oil, the onion essential oil showed a stronger inhibitory effect on the *Aspergillus versicolor* mycelial growth and sterigmatocystin production (Kocić-Tanackov et al. 2012). After a 21-day incubation of the fungus 0.05 and 0.11 µg/mL of onion essential oil and 0.11 µg/mL of garlic essential oil completely inhibited *Aspergillus versicolor* mycelial growth and mycotoxin sterigmatocystin biosynthesis. The combination of essential oils of onion (75 %) and garlic (25 %) had a synergistic effect on growth inhibition of *A. versicolor* and sterigmatocystin production.

Zwiebelane A (*cis*-2,3-dimethyl-5,6-dithiabicyclo[2.1.1]hexane 5-oxide), a natural product of onion bulbs, was found to enhance the potential fungicidal activity of polymyxin B (PMB) (Borjihan et al. 2010). Zwiebelane A amplified the disruptive effect of PMB on the vacuole of *Saccharomyces cerevisiae*.

Antiplatelet/Fibrinolytic Activity

After ingestion of fed-enriched breakfast without onions, fibrinolytic activity decreased in convalescent patients, but

addition of dried (fried) or lyophilised (boiled) onions not only prevented the decrease but also caused a marked increase in fibrinolytic activity (Menon et al. 1968, 1969, 1970). Dried and lyophilised onions were found to increase blood fibrinolytic activity but had no effect on serum cholesterol levels, recalcified clotting times, thrombo tests and fibrinogen levels. Further, it was found that the property that caused an increase in fibrinolytic activity was inherent in fresh onions and not brought about by heating and that it was established to be heat stable and not water soluble. The least polar fraction of an oily chloroform extract of onion was found to contain most of the inhibitory activity towards platelet aggregation induced by either ADP or arachidonic acid (Makheja et al. 1979). The observed antiplatelet activity of onion was ascribed to the presence of a nonpolar, heat stable inhibitor of thromboxane synthesis. Nagda et al. (1983) found that only onion aqueous extract exhibited anticoagulant and fibrinolytic activity, while garlic extract and garlic oil were inactive. Alliin, (+)-*S*-allyl-L-cysteine sulfoxide, an active compound from *Allium cepa*, inhibited platelet aggregation in-vitro (Liakopoulou-Kyriakides et al. 1985). Onion oils exhibited antiasthmatic effect; it inhibited bronchial obstruction induced by platelet-activating factor (PAF) inhalation (Dorsch et al. 1987). Inhibition of platelet aggregation by onion was found to be mediated largely by a reduction on platelet thromboxane and lipoxygenase production from exogenous arachidonic acid (Srivastava 1986). *Allium cepa* var. *aggregatum* Don was shown to interfere with arachidonic acid metabolism of platelets (Gu et al. 1988). Cyclooxygenase products, thromboxane (TXA₂) and 12(S)-hydroxy-heptadecatrienoic acid (HHT) were decreased, while PGE₂ did not change. However, the product of lipoxygenase hydroxy-eicosatetraenoic acid (HETE) was increased. One of onion's thiosulfinates, diphenylthiosulfinate, inhibited PAF-induced bronchial hyperreactivity to histamine in guinea pigs (Dorsch et al. 1989). Quercetin the most prominent flavonoid in onions had shown great promise as an in-vivo antioxidant and platelet inhibitor but less promising results when studied in-vivo (Janssen et al. 1998). Results of in-vitro studies by Hubbard et al. (2003) showed that quercetin inhibited collagen-stimulated

platelet aggregation via inhibition of multiple events in signalling generated by the collagen receptor GPVI.

Administration of aqueous extracts of garlic and onion, orally or intraperitoneally, daily for a period of 4 weeks exerted an antithrombotic on rats (Bordia et al. 1996). Thromboxane B₂ (TXB₂) level in the serum was inhibited, but boiled garlic and onion at high concentration (500 mg/kg) had very little effect on TXB₂ synthesis. Infusion of a single dose 100 mg/kg onion extract did not elicit any inhibitory effect on TXB₂ synthesis in the serum of rabbit during the treatment period (Thomson et al. 2000). Goldman et al. (1996) found that onions with mild flavour and low sulfur content exhibited significantly lower antiplatelet activity than those containing high levels of sulfur. Antiplatelet activity was significantly positively correlated with genotypically determined bulb sulfur content and dissolved solids, indicating these latter factors to be good predictors of antiplatelet capacity. Onion showed dose-dependent inhibitory effects on the collagen-induced platelet aggregation, but this inhibition was of a lesser magnitude compared to garlic when related to dose (Ali et al. 1999). The concentration required for 50 % inhibition of the platelet aggregation for garlic was calculated to be approximately 6.6 mg/mL plasma, whereas the concentration for onion was 90 mg/mL plasma. Boiled garlic and onion extracts showed a reduced inhibitory effect on platelet aggregation. Antiplatelet actions of aqueous extract of onion were investigated in rat and human platelet; IC₅₀ values of onion extract for collagen-, thrombin- and arachidonic acid-induced aggregations and collagen-induced thromboxane A₂ formation were 0.17, 0.23, 0.34 and 0.12 g/mL, respectively (Moon et al. 2000a). In fura-2-loaded platelets, the elevation of intracellular Ca²⁺ concentration stimulated by collagen was inhibited by onion. They found that the mechanism for antiplatelet effect of onion may, at least partly, involve arachidonic release reduction, thromboxane A₂ synthase inhibition and thromboxane A₂/prostaglandin H₂ receptor blockade.

Studies by Briggs et al. (2001) suggested that the consumption of raw onion may help prevent platelet-mediated cardiovascular disorders. However, in-vitro incubations of onion juice demonstrated that the platelet inhibitory response was significantly greater in dog blood than in human blood. Onion showed a significant inhibitory effect on collagen- or arachidonic acid-induced thromboxane B(2) formation with greater potency in diabetic rat platelets than in normal rats (Jung et al. 2002). Similarly, more potent inhibitory effects of onion in diabetes were observed in collagen- or arachidonic acid-induced platelet aggregation and collagen-induced arachidonic acid release response. The results suggested that onion could produce more beneficial antithrombotic effect in diabetes.

A crude MeOH extract of brown onion scales (0.5–1.0 mg/mL) showed inhibitory effects on human platelet aggregation induced by collagen, adenosine 5'-diphosphate (ADP), thrombin and epinephrine (Furusawa et al. 2003). The antiplatelet extract (1.0 µg/mL) rigidified liposomal membranes by acting on the hydrocarbon core more intensively than the surface of membrane lipid bilayers. The flavonoidal components quercetin dimer 1, quercetin, quercetin dimer and quercetin 4'-glucoside (0.5–2 mM) inhibited collagen-induced platelet aggregation in increasing order of intensity. The antiplatelet flavonoids (0.25–10 µM) acted on liposomes of the lipid composition resembling human platelets to cause membrane rigidification which was greatest in the order of quercetin dimers (1 and 2), quercetin and quercetin 4'-glucoside. All freshly juiced onion extracts (ca. 5 minutes post-juicing) appeared to exhibit both an agonist-free aggregation peak (AFP) and a platelet inhibitory peak (PIP) characteristic of inhibition of platelet aggregation (Osmont et al. 2003). The AFP was minimal by 30 minutes and dissipated in all treatments by 120 minutes, while the PIP increased as onion extracts aged and did not change after 30 minutes at 25 °C. This finding confirmed the observation that the in-vitro platelet inhibitory activity of onion organosulfur compounds was time dependent. AFPs were abolished in apyrase-treated extracts, suggesting that this response may have been due to free ADP in onion extracts. Furthermore, platelet aggregates

were not observed in the AFP, suggesting this response may be associated with changes in light transmission through platelet-rich plasma that were not associated with platelet aggregation. An onion variety, Toyohira, showed significant antithrombotic activity both in-vitro and in-vivo (Yamada et al. 2004). Toyohira showed thrombolytic activity in addition to the antiplatelet effect. Superkitamomiji, 2935A, and K83211 showed only thrombolytic activity.

In-vitro, multiwall carbon nano-onions (MWCNOs) exhibited the potent inhibitory effects on rat platelet aggregation caused by ADP in a concentration-dependent manner; platelet aggregation in the highest dosage of 20.0 µg/mL group was 50.0 % (Yang et al. 2011). In-vivo, the highest inhibitory was up to 20.4 %, but there was no significant difference, as compared with control group. The MWCNOs might inhibit platelet aggregation but did not affect hemostatic function. Multiwalled carbon nano-onions exerted inhibitory effect on platelet adhesion in-vitro, but in-vivo their injection via the caudal vein had no effects on the blood flow and wet weight of thrombus per millimetre in experimental thrombosis in rats (Yang et al. 2012b). Lee et al. (2013) found that oral supplementation of quercetin-rich onion peel extract (2 and 10 mg) influenced blood coagulation and arterial thrombosis in male Sprague-Dawley rats. The results indicated that onion peel extract may have antithrombotic effects through restricting thrombin-induced expression of tissue factor in human umbilical vein endothelial cells (HUVECs) via downregulating mitogen-activated protein kinase (MAPK) activation upon coagulation stimulus, leading to the prolongation of time for arterial thrombosis. Collagen-induced in-vitro platelet aggregation was significantly reduced by tearless onion extract (with repressed lachrymatory factor synthase activity) over normal onion extract (Thomson et al. 2013).

An onion extract possessed anticoagulative activity apparently by inhibiting thrombin, and it was dependent upon the concentration of onion extract added (Kim et al. 2002). Boiling the onion extract at 100 °C for 30 minutes did not alter its anticoagulative activity compared to that of fresh onion.

The anticoagulative activity of the onion extract was also retained after an acid treatment by incubating at pH 2.0 for 4 hours. However, dialysis of the extract substantially eliminated the anticoagulative activity. Hansen et al. (2012) found that steam cooking rapidly destroyed onion-induced antiplatelet activity. Extracts from cooked onion had the potential to reverse the inhibitory effect on blood platelets by 25 % without affecting the polyphenolic concentration. Although heating was, in general, detrimental for onion in-vitro antiplatelet activity (IVAA), the extent of this effect varied greatly, from unaffected antiplatelet activity (AA) (i.e. similar to raw onion) to a complete loss of activity, depending upon the manner in which onions were prepared prior to heating, the cooking method used and the intensity of the heat treatment (Cavagnaro and Galmarini 2012). 'Whole', 'quarters' and 'crushed' onions lost their IVAA after 30, 20 and 10 minutes of oven heating, respectively. The longer retainment of AA in intact bulbs was attributed to a later alliinase inactivation. Proaggregatory effects observed in samples subjected to the most intense oven and microwave heat treatments suggested that extensively cooked onions may stimulate rather than inhibit platelet aggregation.

Platelet aggregation in human subjects was inhibited 30 and 120 minutes after ingestion of 150 mg and 300 mg doses of quercetin 4'-O- β -D-glucoside (Hubbard et al. 2004). Correspondingly, collagen-stimulated tyrosine phosphorylation of total platelet proteins was inhibited. This was accompanied by reduced tyrosine phosphorylation of the tyrosine kinase Syk and phospholipase Cgamma2, components of the platelet glycoprotein VI collagen receptor signalling pathway. In a double-blind randomised crossover pilot study, ingestion of onion soup high in quercetin by subjects inhibited collagen-stimulated platelet aggregation and collagen-signalling pathway via glycoprotein VI, Syk (Hubbard et al. 2006). The inhibition of Syk tyrosine phosphorylation was correlated with the area under the curve for the high-quercetin plasma profile. The study further substantiated the epidemiological data suggesting that those who preferentially consume high amounts of quercetin-containing foods have a reduced risk of thrombosis and potential CVD risk.

Cardiovascular Protective/Antiatherosclerotic Activity

Oral administration of petroleum ether extract of *Allium cepa* in albino rats significantly prevented the rise in serum cholesterol and serum triglyceride level, caused by atherogenic diet (Lata et al. 1991). It also conferred significant protection against atherogenic diet-induced atherosclerosis. *Allium* intake has been associated with significant reductions in blood pressure, cholesterol and platelet aggregation (Block 1992). When eaten raw on a regular basis, onion will promote the general health of the body. When used regularly in the diet, onion counteracts tendencies towards angina, arteriosclerosis and heart attack. Studies found that the preventative effect of quercetin on angiotensin II-induced smooth muscle cell (VSMC) hypertrophy was attributable, in part, to its inhibitory effect on Src homology and collagen (Shc)-activation and PI3-K-dependent c-Jun N-terminal kinase (JNK) activation in VSMC (Yoshizumi et al. 2001). Thus, inhibition of JNK by quercetin may imply its usefulness for the treatment of cardiovascular diseases relevant to VSMC growth.

On incorporation of 5 % garlic, amla or onion separately in the animal fat (butter fat, beef) diets to albino rats for 3 months, each of them ameliorated the deleterious effects of the animal fats (Augusti et al. 2001). Butter fat was found to be more atherogenic than beef. The order of ameliorative effects of the vegetables were garlic > amla > onion. The better hypolipidaemic effects and correction of elevated levels of certain enzymes shown by garlic and amla may be due to the facts that they contain comparatively better active principles than that found in onions.

Terao et al. (2008) found that quercetin metabolites glucuronides and/or sulfate conjugates circulating in the human blood stream were mostly localised in plasma albumin fraction, but not LDL fraction. Onion consumption failed to enhance the antioxidant activity of plasma fraction against LDL oxidation, indicating that the level of quercetin metabolites bound to albumin was insufficient to exert the antioxidative effect in-vivo. In contrast, they discovered that

quercetin metabolites accumulated in the aorta tissue and exerted their antioxidant activity, when rabbits were fed with quercetin glucoside and high-cholesterol diet. Further, quercetin metabolites were detected in human atherosclerotic aorta exclusively. These implied that quercetin metabolites were incorporated into the atherosclerotic region and acted as complementary antioxidants, when oxidative stress was loaded in the vascular system.

The methanolic extract of onion attenuated ischaemia-/hypoxia-induced apoptotic death in murine heart H9c2 cells in-vitro and in rat heart in-vivo through, at least in part, an antioxidant effect (Park et al. 2009). The onion extract (0.05 g/mL) inhibited the elevation of the ROS, mitochondrial membrane depolarisation, cytochrome c release and caspase-3 activation during hypoxia in H9c2 cells. In the in-vivo rat myocardial infarction model, onion extract (10 g/kg) significantly reduced the infarct size, the apoptotic cell death of the heart and the plasma MDA (malondialdehyde) level. Administration of onion extract to atherosclerotic rats decreased atherosclerotic lesions and increased endogenous aortic H₂S production, but decreased plasma ADM content, aortic ADM content and aortic CRLR, RAMP2 and RAMP3 mRNAs (Li et al. 2011). In addition, it increased plasma GSH-PX level and SOD activities but reduced MDA; it decreased inflammatory response but increased plasma eNOS activity and NO content.

Oral administration of onion extract restored the liver and kidney toxicities and blood dysproteinaemia and lipid dyslipidaemia (increased total cholesterol, triglycerides, LDL cholesterol and serum albumin and reduced HDL cholesterol, total plasma protein and plasma testosterone) induced by cadmium in rats (Ige and Akhighe 2013). Further, the onion extract improved Cd-induced decrease in urinary volume and renal clearance and also protected against Cd-induced oxidative stress by normalising redox status. The results provided the evidence of the therapeutic efficacy of onion extract against atherosclerotic conditions and organ toxicity in Cd-intoxicated rats. Administration of onion extract in rats exhibited antiapoptotic potential on doxorubicin (DOX)-

induced apoptosis in aortic endothelial cells (Alpsoy et al. [2013b](#)). DOX-treated with onion extract groups also showed a significant decrease in malondialdehyde levels and increased levels of glutathione in comparison with the DOX-treated group. Data showed that prevention of endothelial cell apoptosis by onion extract may contribute to the restoration of aortic endothelial dysfunction induced by DOX. Further, they found that the DOX-treated with onion extract rats showed a significant decrease in malondialdehyde levels and increased activities of superoxide dismutase, glutathione and glutathione peroxidase in comparison with the DOX-treated group (Alpsoy et al. [2013a](#)). Creatine kinase, creatine kinase MB, lactate dehydrogenase activities and cardiac troponin I levels were significantly decreased in the DOX + onion group in comparison with the DOX group. These biochemical and histological disturbances were effectively attenuated on pretreatment with onion extract. Intragastric intubation of onion extract to cadmium-induced cardiotoxic rats for 30 days attenuated the adverse toxic effects of cadmium possibly through its antioxidant and antiapoptotic activity (Alpsoy et al. [2014](#)). Onion extract reversed the increased tissue malondialdehyde (MDA) levels and decreased levels of the enzymatic antioxidants superoxide dismutase (SOD), glutathione peroxidase (GSH-Px) and catalase (CAT) caused by cadmium intoxication in cardiac tissue. Histological abnormalities caused by cadmium such as myofibrillar loss, vacuolisation of cytoplasm and irregularity of myofibrils were effectively attenuated by the treatment by onion extract. Also, onion extract significantly reduced apoptosis in the cardiomyocytes of the cadmium group.

Studies suggested that chronic onion extract intake for 30 days ameliorated postprandial endothelial dysfunction by an oral maltose load in healthy men and may be beneficial for improving cardiovascular health (Nakayama et al. [2013](#)).

Hypotensive Activity

Dietary onion decreased the thiobarbituric acid-reactive substances (TBARS) in plasma in L-NAME-induced-hypertensive rats and stroke-prone spontaneously hypertensive

rats (SHRSP) (Sakai et al. 2003). Also, onion increased the nitrate/nitrite (products of nitric oxide (NO)) excreted in urine and the NO synthase (NOS) activity in the kidneys in SHRSP. The results suggested that the increased NO caused by the greater NOS activity, and additionally by the increased saving of NO by the antioxidative activity of onion, was one of the causes of the antihypertensive effects of onion in SHRSP. In the L-NAME-induced-hypertensive rats, onion did not significantly block the inhibition of NOS activity by L-NAME, and decreased nitrate/nitrite excretion in urine was not restored. Raw onion significantly reduced the increase in systolic blood pressure in both L-NAME-induced-hypertensive rats and spontaneously hypertensive rats (SHR) and inhibited the increase in thiobarbituric acid-reactive substances (TBARS) and conjugated dienes in the plasma and tissues of SHR (Kawamoto et al. 2004). Boiling negated the antihypertensive effect as a result of a decrease in antioxidative activity. Quercetin-supplemented diets lowered blood pressure, attenuated cardiac hypertrophy in rats with aortic constriction and normalised cardiac protein kinase C betaII translocation (Jalili et al. 2006). The results supported an antihypertensive and antihypertrophic effect of quercetin in-vivo in the absence of changes concerning vascular and myocardial function. Intravenous administration of garlic, onion, ginkgo extracts produced dose-dependent and reversible hypotensive and bradycardic effects in anaesthetised normotensive rats (Brankovic et al. 2011). The most effective in reducing arterial blood pressure and heart rate was garlic extract.

Studies by Naseri et al. (2008) showed that onion peel hydroalcoholic extract dose dependently reduced murine aorta contractions induced by KCl or phenylephrine possibly via inhibition of calcium influx but without involving NO, cGMP, endothelium and prostaglandins. The onion peel hypotensive effect could be due to extract quercetin content, antioxidant activity and inhibiting vascular smooth muscle cells Ca^{2+} influx.

In an open and a randomised, placebo-controlled, double-blind, crossover phase-I study, a spontaneous pharmacological

effect 5 hours after administration of an onion–olive oil maceration capsule formulation on arterial blood pressure could be demonstrated in apparently healthy subjects (Kalus et al. 2000). In addition to a decrease in arterial blood pressure, a significant reduction in plasma viscosity and haematocrit was observed. In a subsequent study of 24 patients with arterial hypertension (WHO class I), administration of onion–olive oil maceration product (capsule) after a week led to a significant decrease in systolic blood pressure (Mayer et al. 2001). There was also a trend towards a decrease in diastolic blood pressure. The improved blood fluidity observed resulted from a decrease in haematocrit. In a separate randomised, double-blind, placebo-controlled, crossover study of men and women with prehypertension ($n = 19$) and stage 1 hypertension ($n = 22$), quercetin supplementation was found to reduce blood pressure in hypertensive subjects, but did not later reduce blood pressure in prehypertensive patients (Edwards et al. 2007). After quercetin supplementation, reductions in systolic (-7 mmHg), diastolic (-5 mmHg) and mean arterial pressures (-5 mmHg) were observed in stage 1 hypertensive patients. Contrary to animal-based studies, there was no quercetin-evoked reduction in systemic markers of oxidative stress.

Antiobesity/Antihypercholesterolemic Activity

Administration of onion extract to sucrose-fed rabbits significantly reduced serum, liver and aorta triglycerides and serum and liver proteins (Sebastian et al. 1979). In contrast, liver-free amino acids were significantly increased in the onion-treated group as compared to the sucrose-fed control. The effects of onion were ascribed to its sulfur-containing principles which oxidised thiol compounds either present free or combined in a protein and NADPH which were necessary for lipid synthesis. Streptozotocin-induced diabetic rats fed with onion diet exhibited lowered lipid peroxides in circulation and in urine when compared to diabetic control group (Babu and Srinivasan 1997). Plasma cholesterol from LDL-VLDL fraction phospholipids and triglycerides was lowered significantly by dietary onion in diabetic animals.

Hepatic cholesterol, triglycerides and phospholipids which were elevated under diabetic condition were lowered significantly by dietary onion. Thus, the study revealed that onion feeding improved the metabolic status in diabetic condition, probably because of its hypoglycaemic as well as hypocholesterolaemic effect.

In HepG2 cells, S-propyl cysteine decreased the secretion of apolipoprotein B100 (Han et al. 2002). The compound reduced the secretion of newly synthesised triacylglycerol and cholesterol from radiolabeled acetate. Administration of onion *S*-methyl cysteine sulfoxide (SMCS) and two standard drugs, glibenclamide and insulin, to alloxan-induced diabetic rats for 2 months ameliorated the diabetic condition significantly, viz., maintenance of body weight and control of blood sugar in rats (Kumari and Augusti 2002). Further, they lowered the levels of malondialdehyde, hydroperoxide and conjugated dienes in tissues exhibiting antioxidant effect on lipid peroxidation in experimental diabetes. This was achieved by their stimulating effects on glucose utilisation and the antioxidant enzymes, viz., superoxide dismutase and catalase. In a subsequent study, administration of onion *S*-methyl cysteine sulfoxide (SMCS) at a dose of 200 mg/kg body weight for 45 days ameliorated the hyperlipidaemic condition in high-cholesterol diet-fed rats (Kumari and Augusti 2007). The lipid profile in serum and tissues showed that concentrations of cholesterol, triglyceride and phospholipids were significantly reduced when compared to their untreated counterparts. The total lipoprotein lipase activity in the adipose tissue was decreased with also a decrease in the free fatty acid levels in serum and tissues. The activities of the lipogenic enzymes glucose 6-phosphate dehydrogenase and malic enzyme as also of HMG CoA reductase in the tissues remained low on treatment indicating that both the drugs did not favour lipogenesis and cholesterologenesis in the hyperlipidaemic animals. The faecal excretion of bile acids and sterols was further increased upon treatment with onion SMCS.

Supplementation of cycloalliin, a sulfur-containing imino acid in onions, at 0.1 % and 0.3 % levels to the atherogenic

diet of Sprague-Dawley rats, reduced serum triacylglycerol (TAG) concentration by approximately 40 % compared to the control and also serum cholesterol ester level (Yanagita et al. 2003). Dietary cycloalliin had no significant effect on hepatic enzyme activities responsible for TAG synthesis. The study showed that dietary cycloalliin had serum TG-lowering effect without affecting hepatic TAG synthesis and content in rats, suggesting an alteration of lipoprotein assembly and secretion processes in the liver. Feeding hamsters for 8 weeks with onion powder dose dependently decreased plasma total cholesterol (TC) level (Guan et al. 2010). The change in plasma lipoprotein profile was accompanied by a greater excretion of both faecal neutral and acidic sterols. It was found that the hypocholesterolaemic activity of onion powder was mediated by enhancement of faecal sterol excretion and upregulation of liver X receptor alpha (LXR α) and cholesterol-7 α -hydroxylase (CYP7A1). Both raw red onion and white onion subjected to blanching for 90 seconds hindered elevation in plasma lipids more than the other vegetables studied in the supplemented diets (Gorinstein et al. 2010). Blanching for 90 seconds most fully preserved the bioactive compounds and antioxidant potentials and hindered the rise in plasma lipid levels and the decrease in plasma antioxidant activity of rats fed with cholesterol.

Ethyl acetate extract of onion (EEO) had potent inhibitory effects on animal fatty acid synthase (FAS) and could induce apoptosis in FAS overexpressing human breast cancer MDA-MB-231 cells (Wang et al. 2012). It was also found that EEO could suppress lipid accumulation during the differentiation of 3T3-L1 adipocytes, which was also related to its inhibition of intracellular FAS activity. Since obesity is closely related to breast cancer and obese patients are at elevated risk of developing various cancers, these findings suggested that onion might be useful for preventing obesity-related malignancy.

Quercetin-rich onion peel extract supplementation to diet-induced obese rats for 8 weeks reduced mesenteric fat weights and increased adiponectin mRNA expressions (Kim et al. 2012). Interleukin 6 mRNA levels (perirenal and mesenteric

fats) in the onion-treated group were slightly lower than those in the high-fat group. Quercetin-rich onion peel extract (OPE) markedly suppressed lipid accumulations and triglyceride contents in 3T3-L1 preadipocytes and inhibiting adipogenesis in high-fat-fed rats (Moon et al. 2013). Body weight, retroperitoneal and mesenteric fat weights of rats were significantly lower in the 8-week high-fat (HF) diet + 0.72 % OPE group than in the HF group. The mRNA levels of activating protein (AP2) were downregulated, and those of carnitine palmitoyltransferase-1 α (CPT-1 α) and fatty acid binding protein 4 (FABP4) were upregulated by 75 and 100 μ g/mL OPE. Peroxisome proliferator-activated receptor (PPAR) γ mRNA and CCAAT/enhancer binding protein (C/EBP) α mRNA levels were downregulated in the epididymal fat of OPE than those of control and HF groups. The mRNA levels of CPT-1 α and uncoupling protein-1 (UCP-1) were upregulated by the OPE, while those of fatty acid synthase (FAS) and acetyl-CoA carboxylase (ACC) were downregulated in HF and OPE groups compared to control group. A preliminary rat feeding trial indicated that the tearless onions (with repressed lachrymatory factor synthase activity) may also play a key role in reducing weight gain (Thomson et al. 2013).

In a randomised controlled clinical trial, raw red onion consumption appeared to be effective as a cholesterol-lowering food agent in obese and overweight women with polycystic ovary syndrome (Ebrahimi-Mamaghani et al. 2014). Onion significantly decreased the levels of total cholesterol and low-density lipoprotein cholesterol within each group; however, these changes were stronger in the high-onion group than in the low-onion group. The levels of fasting blood sugar, triglycerides, high-density lipoprotein cholesterol and lipoprotein (a) did not differ significantly after 8-week onion treatment.

Antihyperglycaemic/Antidiabetic Activity

Oral administration of the hypoglycaemic fraction of onion juice to alloxan-diabetic rabbits improved their glucose tolerance; the juice was about half as active as phenformin in

lowering the fasting blood sugar (Mathew and Augusti 1975). Juice-expressed residue of onion, when fed to diabetic patients along with their food, controlled the hyperglycaemia effectively. Kumari et al. (1995) found that oral administration of S-methyl cysteine sulfoxide (SMCS), a sulfur-containing amino acid isolated from onion daily at a dose of 200 mg/kg body weight for a period of 45 days to alloxan-diabetic rats controlled significantly their blood glucose and lipids in serum and tissues and altered the activities of liver hexokinase, glucose 6-phosphatase and HMG CoA reductase towards normal. The above effects of SMCS were comparable to those of glibenclamide and insulin. Sheela et al. (1995) showed that oral administration of onion and garlic sulfoxide amino acids, viz., S-methylcysteine sulfoxide (SMCS) and S-allylcysteine sulfoxide (SACS) to alloxan-diabetic rats for a month, ameliorated their diabetic condition, being characterised by glucose intolerance, weight loss, depletion of liver glycogen, etc., was ameliorated as comparable to rats treated with glibenclamide and insulin. Administration of onion solution increased the fasting serum high-density lipoprotein levels and demonstrated alleviation of hyperglycaemia in streptozotocin-diabetic rats (Campos et al. 2003). The hypoglycaemic and hypolipidaemic actions of *A. cepa* were associated with antioxidant activity, since onion decreased superoxide dismutase activities, while no increased lipid hydroperoxide and lipoperoxide concentrations were observed in diabetic rats treated with onion.

Oral administration of garlic or onion juice daily for 4 weeks to alloxan-induced diabetic rats reverted the adverse biochemical changes induced by alloxan such as significant elevation of plasma levels of glucose, urea, creatinine and bilirubin; significant increase of aspartate aminotransferase (AST), alanine aminotransferase (ALT), lactate dehydrogenase (LDH) and alkaline and acid phosphatases (ALP, ACP) activities in plasma and testes and their reduction in the liver; significant increase in brain LDH; increase in concentration of thiobarbituric acid-reactive substances and the activity of glutathione S-transferase in the plasma, liver, testes, brain and kidney (El-Demerdash et al. 2005). Compared to consumption of fenugreek and onion, only consumption of garlic by

alloxan-induced diabetic rats was able to reduce blood glucose significantly compared with the control group (Jelodar et al. 2005). In the control positive group, all the mentioned morphometric factors volume density of B cells, volume density of islets, per cent of B cells, number of islets per square millimetre, average area of islets and average volume density of B cell in whole pancreas were significantly changed in comparison with the control negative (normal health) group, but the same did not show significant change between treated and untreated diabetics.

Islam et al. (2008) found that high-fat onion diet may increase insulin secretion and consequently insulin resistance in a dose-dependent manner, resulting in a worsened hyperglycaemic and hyperlipidaemic streptozotocin-diabetic rat and that higher dietary fat may impair the antidiabetic effects of dietary onion intake. Supplementation of onion powder decreased blood glucose, total serum lipid, triglyceride and atherogenic index and increased HDL cholesterol/total cholesterol ratio in streptozotocin-induced diabetic rats (Bang et al. 2009). Also, onion reduced renal oxidative stress in streptozotocin-induced diabetic rats.

Ethyl alcohol extract of onion skin had the highest α -glucosidase inhibitory activity, ORAC (oxygen radical absorbance capacity) antioxidant value and total phenolic content, followed by water extract of skin, ethyl alcohol extract of pulp and water extract of pulp (Kim et al. 2010). Ethyl alcohol extract of onion skin had highest quercetin content 209.22 mg/100 g FW followed by water extract of onion skin 15.94 mg, water extract of onion pulp 0.64 mg and ethyl alcohol extract of onion pulp 0.33 mg. Quercetin, a major phenolic compound in onion extract, had high α -glucosidase inhibitory activity. The α -glucosidase inhibitory activity of the onion extracts correlated to the phenolic content and antioxidant activity of the extracts. The results suggested that onion with high-quercetin content had the potential to contribute as a dietary supplement for controlling hyperglycaemia and oxidative stress-linked diabetes complications. Onion peel extract (OPE) containing high-quercetin ameliorated hyperglycaemia and insulin resistance in

high-fat diet/streptozotocin-induced diabetic rats (Jung et al. 2011). The data suggested that OPE might improve glucose response and insulin resistance associated with type 2 diabetes by alleviating metabolic dysregulation of free fatty acids, suppressing oxidative stress, upregulating glucose uptake at peripheral tissues and/or downregulating inflammatory gene expression in the liver. Moreover, in most cases, OPE showed greater potency than pure quercetin equivalent. Body and adipose tissue weights in 5 % of onion extract-fed diabetes-prone Zucker diabetic fatty rats were found to be significantly lower than the control group without onion extract (Yoshinari et al 2012). Fasting blood glucose and HOMA-IR (homeostasis model of insulin resistance) levels were also improved, although the serum insulin and leptin levels did not show any remarkable difference. Serum triglyceride and free fatty acid levels in both the 3 % and 5 % onion-fed group were found to be reduced compared to the control group. Additionally the feeding of the onion extract increased the glucose tolerance. Cycloalliin, S-methyl-L-cysteine, S-propyl-L-CYSTEINE sulfoxide and dimethyl trisulfide especially S-methyl-L-cysteine sulfoxide were reported to be effective in inhibiting formation of oil drop in the cells, suggesting that these compounds may be involved in the antiobesity effect of the onion extract.

Ethyl alcohol extract of onion skin (EOS) and its major flavonoid quercetin inhibited in-vitro rat intestinal sucrose with IC_{50} values of 0.40 and 0.11 mg/mL, respectively (Kim et al. 2011). The content of quercetin in ethyl alcohol extract of onion skin (EOS) was 6.04 g/100 g dried weight of onion skin. In rats fed on sucrose, EOS significantly reduced the blood glucose spike after sucrose loading. The results indicated that although quercetin does have blood glucose-lowering potential via α -glucosidase inhibition, other bioactive compounds were also present in onion skin. In-vivo, in Sprague-Dawley (SD) rat model, the activities of sucrase in the lower parts of intestine remained significantly higher after 2 weeks of EOS treatment. The results indicated that EOS may improve exaggerated postprandial spikes in blood glucose and glucose homeostasis since it inhibited intestinal sucrase and thus

delayed carbohydrate absorption. Onion peel extract supplementation to rats fed a high-fat diet reverted high-fat-induced reduction in mRNA levels of sterol regulatory element-binding protein-2, low-density lipoprotein receptor and hydroxyl-3-methylglutaryl coenzyme reductase genes in the liver comparable with the levels of the control group (Lee et al. 2012b). Onion peel extract slightly increased stearoyl-coA desaturase 1 (SCD-1) expression and enhanced expression of ATP-binding cassette transporter A1, peroxisome proliferator-activated receptor γ 2 and scavenger receptor class B type I genes compared with high-fat feeding. Their results suggested that onion peel altered the expression of genes associated with cholesterol metabolism in favour of lowering blood low-density lipoprotein cholesterol and enhancing high-density lipoprotein cholesterol through increasing mRNA abundance of low-density lipoprotein receptor and ATP-binding cassette transporter A1 genes.

Ingestion of crude onion (100 g) caused a considerable reduction in fasting blood glucose levels by about 89 mg/dL in relation to insulin (145 mg/dL) in type 1 diabetic patients, and it reduced fasting blood glucose levels by 40 mg/dL, compared to glibenclamide (81 mg/dL) in type 2 diabetic patients, 4 hours later (Taj Eldin et al. 2010). The same dose of crude onion produced a significant reduction in the induced hyperglycaemia (glucose tolerance test (GTT)) by about 120 mg/dL compared to water (77 mg/dL) and insulin (153 mg/dL) in type 1 diabetic patients and considerably reduced GTT by 159 mg/dL in relation to water (55 mg/dL) and glibenclamide (114 mg/dL) in type 2 diabetic patients, after 4 hours. The results suggested that crude onion could be used as a dietary supplement in management of type 1 and/or type 2 diabetes mellitus.

The results of the meta-analysis conducted by Kook et al. (2009) suggested that onion extract intake and single component (including S-allylcysteine sulfoxide, S-methylcysteine sulfoxide and diallyl trisulfide) intake may be effective for lowering plasma glucose concentrations and body weight. In the meta-analysis, the antidiabetic effects of onion extract and single components were significant for glucose

concentration and body weight, but the effects of garlic extract were not significant.

Alliuocide G and four other known flavonoids isolated from the dried outer onion scales exhibited potent α -amylase inhibitory activity (Mohamad 2008). Alliuocide G also exhibited antioxidant activity. Quercetin was identified as a major flavonoid α -glucosidase inhibitor in *Allium* species including *A. cepa* (Schmidt et al. 2014). *N-p-coumaroyloctopamine* and *N-p-coumaroyltyramine* were also identified as major α -glucosidase inhibitors.

Anti-inflammatory/Antiasthmatic Activity

Oral pretreatment of guinea pigs with onion extract markedly reduced the asthmatic response induced by ovalbumin (Dorsch and Weber 1984). After onion pretreatment, near normal values were obtained after 30 seconds challenge (0.04 mL compared to 0.24 mL in the control) and only slightly increased values after 60 seconds challenge (0.16 mL compared to 0.33 mL in the control). Five alk(en)ylsulfinothioic acid alk(en)yl-esters isolated from onions and four synthetic thiosulfinates inhibited 5-lipoxygenase of porcine leucocytes, histamine release and leukotriene B₄ and C₄ biosynthesis of human polymorphonuclear leucocytes, thromboxane B₂ biosynthesis by human platelets and allergen-induced and PAF-induced bronchial obstruction of guinea pigs (Dorsch et al. 1988). The results suggested that the antiasthmatic and anti-inflammatory effects of onions depended in part on the thiosulfinate moiety. Nine thiosulfinates (TS) and four 'cepaenes' isolated from onions and/or synthesised showed dose-dependent (0.25–100 μ M) marked inhibitory effects on both cyclooxygenase from sheep seminal vesicle microsomes and 5-lipoxygenase activity from porcine leucocytes (Wagner et al. 1990). The following rank order of activity was observed: saturated aliphatic TS < aromatic TS $\approx$ α,β -unsaturated TS < cepaenes. Cepaenes inhibited both cyclooxygenase and 5-lipoxygenase by more than 75 % at 10 and 1 μ M concentrations, respectively.

Seven different synthetic thiosulfinates and cepaene- and/or thiosulfinate-rich onion extracts were found to inhibit in-vitro the chemotaxis of human granulocytes induced by formyl-methionine-leucine-phenylalanine in a dose-dependent manner and at a concentration range of 0.1–100 μ M (Dorsch et al. 1990). Diphenylthiosulfinate showed the highest activity and was found to be more active than prednisolone. The results indicated that anti-inflammatory properties of onion extracts were related, at least in part, to the inhibition of inflammatory cell influx by thiosulfinates and cepaenes. Quercetin had been reported to block substances involved in allergies and to be able to act as an inhibitor of mast cell secretion, causing a decrease in the release of tryptase, MCP-1 and IL-6 and the downregulation of histidine decarboxylase (HDC) mRNA from few mast cell lines (Shaik et al. 2006). In a 3-way, single-blind, randomised crossover study of eight subjects, quercetin conjugates were detected in plasma (up to a maximum concentration of 4 μ mol/L at approximately 1 hour) (de Pascaul-Teresa et al. 2004). However, the expression of COX-2 mRNA in lymphocytes was unchanged by the consumption of high-quercetin onions compared with the low-quercetin group though this change occurred in-vitro and ex-vivo.

The volatile sample of freeze-dried onion sprout (extracted with dichloromethane), water sample I and water sample II exhibited anti-inflammatory activity with a dose-related response in the lipooxygenase inhibitor screening assay (Takahashi and Shibamoto 2008). However, the methanol sample did not show appreciable activity in either antioxidant or anti-inflammatory tests. An herbal fraction (ALC-02) from onion bulb inhibited histamine release and attenuated intracellular calcium levels in compound 48/80-induced rat peritoneal mast cells (Kaiser et al. 2009). It also prevented compound 48/80-mediated systemic anaphylaxis while lowering histamine levels in plasma. ALC-02 suppressed carrageenan-induced rat paw oedema. It inhibited eosinophil peroxidase activity and protein content in bronchoalveolar lavage fluid (BALF) of ovalbumin-challenged mice and also caused a substantial reduction in lipid peroxidation in BALF/lung tissue and augmented superoxide dismutase

activity in lung tissue. ALC-02 suppressed erythrocytic lysis caused by Triton X-100. A significant quenching of 1,1-diphenyl-2-picrylhydrazyl radical by ALC-02 was observed.

Antilithogenic Activity

Dietary onion and garlic exerted antilithogenic influence by decreasing the cholesterol hypersecretion into bile and increasing the bile acid output thus decreasing the formation of lithogenic bile in experimental mice (Vidyashankar et al. 2009, 2010b). Dietary garlic and onion, either raw or heat processed, regressed preformed cholesterol gallstone in mice up to 53–59 %, whereas the regression in the basal control diet group was only 10 %. The antilithogenic potency of garlic was decreased by its heat processing, but not in the case of onion. Biliary cholesterol was significantly decreased in garlic- and onion-fed animals. Biliary cholesterol saturation index and hydrophobicity index were significantly lowered by dietary garlic and onion. Serum and liver cholesterol levels were decreased by feeding onion and garlic during post-cholesterol gallstone induction period. Hepatic hydroxymethylglutaryl-coenzyme A reductase activity was increased after feeding garlic and onion, whereas activities of the cholesterol-degrading enzymes cholesterol-7 α -hydroxylase and sterol-27-hydroxylase were increased in garlic- and onion-fed groups. These results indicated that feeding garlic and onion effectively accelerated the regression of preformed cholesterol gallstone by promoting cholesterol desaturation in bile. They also found that apart from the beneficial modulation of biliary cholesterol saturation index, onion and garlic influenced cholesterol nucleating and antinucleating protein factors that contributed to their antilithogenic potential (Vidyashankar et al. 2010a). Similar antilithogenic effects were found with fenugreek seed, onion and their combination administered as supplement to mice fed with a high-cholesterol diet (HCD) (0.5 %) for 10 weeks (Reddy and Srinivasan 2011). Fenugreek, onion and their combination reduced the incidence of cholesterol gallstones by 75 %, 27 % and 76 %, respectively, with attendant reduction in total cholesterol content by 38–42 %, 50–72 % and 61–80 % in the serum, liver

and bile, respectively, in high-cholesterol lithogenic diet-fed mice. Increased accumulation of fat in the liver and inflammation of the gallbladder membrane produced by high-cholesterol diet were reduced by fenugreek, onion and their combination. The antilithogenic influence was highest with fenugreek alone, and the presence of onion along with it did not further increase this effect. There was also no additive effect of the two spices in the recovery of antioxidant molecules or in the antioxidant enzyme activities.

Neuroprotective Activity

In-vitro studies showed that the flavonoids extracted from onion could effectively penetrate the blood–brain barrier model established by co-culturing of brain microvascular endothelial cells and astrocytes (Dan et al. 2011). The onion flavonoids also showed marked inhibition on the H₂O₂-induced neuron cell apoptosis and DNA injury. Yang et al. (2012a) found that the protective effect against glutamate-induced neurotoxicity in HT22 cells was increased when treated with 25 µg/mL of fermented onion. The enhanced neuroprotective effect was also originated from the increased quercetin content caused by fermentation.

Pretreatment of animals with a methanolic extract of outer scales and edible onion portions markedly reduced cerebral infarct size and attenuated impairment in short-term memory and motor coordination (Shri and Singh Bora 2008). The protective effect of onion on ischaemia and reperfusion-induced cerebral injury was accompanied by a marked decrease in mitochondrial TBARS. Treatment with methanol extracts of outer scales of onion significantly prevented loss in body weight, decreased plasma glucose level and significantly ameliorated thermal hyperalgesia, TBARS, serum nitrite and GSH levels in neuropathic diabetic mice. This was postulated to be due to the higher content of phenolic compounds in outer scales (Bhanot and Shri 2010). Onion extract (OE) and its major component, quercetin, exerted neuroprotective effects on ischaemic neuronal damage from transient cerebral ischaemia in the gerbil hippocampus (Hwang et al. 2009). In

the OE-treated ischaemic group, gliosis (activation of astrocytes and microglia) was attenuated in the hippocampal CA1 region 4 days after ischaemia/reperfusion. In addition, treatment with OE and quercetin decreased protein levels of 4-hydroxy-2-nonenal (a marker for lipid peroxidation) in the ischaemic CA1 region.

Hyun et al. (2013) demonstrated that onion extract attenuated brain ischaemia-induced oedema and blood–brain barrier (BBB) dysfunction in mouse middle cerebral artery occlusion model. Onion extract prevented brain oedema, BBB hyperpermeability and tight junction proteins disruption, possibly through its antioxidant effects. Their study suggested that onion extract may be a beneficial nutrient for the prevention of BBB function during brain ischaemia.

Hepatoprotective Activity

Studies showed that cadmium-induced oxidative damage in rat liver was amenable to attenuation by pretreatment of high dose of onion and moderate dose of garlic extracts possibly via reduced lipid peroxidation and enhanced antioxidant defence system (Obioha et al. 2009). Intraperitoneal injection of 15 mg/kg quercetin from onions exhibited significant protective effect on hepatocytes apoptosis in streptozotocin-induced diabetic rat (Bakhshaeshi et al. 2012). Quercetin also reduced malonaldehyde and aldehyde oxidase levels compared to untreated diabetic rats. Pretreatment of rats with onion extract protected against doxorubicin (DOX)-induced hepatotoxicity due to the antioxidant properties of onion extract (Mete et al. 2013). Further, onion treatment markedly reduced liver parenchymal necrosis and proliferation of biliary duct.

Renoprotective Activity

The study of Suru (2008) suggested that onion and garlic extracts may exert their protective effects against cadmium-induced nephrotoxicity in rats via reduction in renal lipid peroxidation and enhanced antioxidant defence. While treatment with high dose of onion extract exerted a significant dose-dependent restoration of the cadmium-induced decrease

in antioxidant activities, treatment with high dose of garlic elicited a pro-oxidant effect, relative to their respective low dose. Oral pre-administration of onion extract prevented cadmium-induced renal dysfunction in rats by improving the antioxidant status in plasma and tissues and reducing the elevated MDA level in plasma (Ige et al. 2009).

Gavage administration of fresh onion juice to rats with renal failure as a result of infection by the protozoan parasite, *Toxoplasma gondii*, ameliorated the parasite-induced harmful effects by reducing the apoptosis of renal cells and increase in antioxidant activity (Gharadaghiet al. 2012).

Antispasmodic Activity

The furostanol saponins, tropeoside A1/A2 and tropeoside B1/B2, isolated from Tropea red onion bulb were found to possess antispasmodic activity in the guinea pig-isolated ileum; such an effect might support the traditional use of onion in the treatment of disturbances of the gastrointestinal tract (Correa et al. 2005).

Studies by Grman et al. (2011) found that aqueous garlic, onion and leek extracts released nitric oxide from S-nitrosoglutathione (GSNO) in the following order: garlic > onion > leek. Garlic extract (0.045 mg/mL) prolonged relaxation time of aortic rings induced by GSNO (50 nmol/L) and inhibited intracellular chloride channels. It was suggested that NO-releasing properties of the garlic, onion and leek extracts and their interaction with Cys and GSH were involved in NO-signalling pathway which contributed to some of its numerous beneficial biological effects.

CNS Antidepressant Activity

The results of an animal study suggested that onion exerted antidepressant-like activity in a behavioural model that acted independently of the hypothalamic–pituitary–adrenal axis (Sakakibara et al. 2008). Daily administration of onion powder at a dosage of 50 mg/kg of body weight/day for 14 days significantly reduced the immobility time in the forced

swimming test without changing the motor dysfunction, indicating that the daily consumption of onion exerted antidepressant-like activity. Onion powder (50 mg/kg) suppressed the increase in the turnover of dopaminergic activity.

Antimutagenic Activity

Water extracts of garlic, deodorised garlic powder and onions, but not leeks, were found to reduced the in-vitro formation of N-nitrosomorpholine (NMOR), a known liver carcinogen (Dion et al. 1997). Addition of increasing quantities (20, 40 and 80 mM) of S-allylcysteine (SAC), a water-soluble compound in processed garlic, depressed NMOR formation by 16 %, 27 % and 43 %, respectively. SAC and S-propyl cysteine were less effective than isomolar cysteine in reducing NMOR formation. The oil-soluble sulfur compounds diallyl disulfide (DADS), dipropyl disulfide and diallyl sulfide were ineffective inhibitors of NMOR generation. SAC and DADS reduced the mutagenicity of NMOR in *Salmonella typhimurium* TA100. SAC at 70 $\mu\text{mol/plate}$ reduced the number of histidine revertants per plate by 51 %, whereas DADS at 0.12 $\mu\text{mol/plate}$ reduced mutant colony number by 76 %. SAC and DADS were more effective than isomolar cysteine in reducing NMOR mutagenicity. The ability of sulfur compounds in garlic and onions to depress nitrosamine formation and bioactivation accorded with epidemiologic evidence that higher intake of *Allium* plants was associated with a reduction in the risks of some cancers.

After digestion, ethyl acetate extracts from white, yellow and red onions extracts showed antimutagenic activity (Shon et al. 2004). The ethyl acetate fraction of red onion peel showed dose-dependent antimutagenic activity by following the inhibition of tobacco-induced mutagenicity in *Salmonella typhimurium* strains (TA102) and hydroxyl radical-induced nicking in plasmid pUC18 DNA (Singh et al. 2009). Kim et al. (2013) found that pretreatment with onion peel extract significantly reduced human leucocyte DNA damage induced

by H₂O₂ or 4-hydroxynonenal, indicating that it possessed antigenotoxic activity.

Antisteoporotic Activity

One gram of onion added to the food of rats inhibited significantly bone resorption as assessed by the urinary excretion of tritium released from bone of 9-week-old rats prelabelled with tritiated tetracycline from weeks 1 to 6 (Wetli et al. 2005). The bone resorption-inhibiting compound was identified as γ -L-glutamyl-*trans*-S-1-propenyl-L-cysteine sulfoxide (GPCS). It has a molecular mass of 306 Da and inhibited dose dependently the resorption activity of osteoclasts, the minimal effective dose being approximately 2 mM. The water solution of onion crude powder decreased the osteoclastogenesis from co-cultures of bone marrow stromal cells and macrophage cells by inhibiting the receptor activator of nuclear factor kappa B ligand (RANKL)-induced ERK, p38 and NF-kappaB activation (Tang et al. 2009). However, it did not affect cell proliferation and differentiation of human-cultured osteoblasts. The data showed that onion powder may benefit bone through an anti-resorption effect on the osteoclasts. Young adult female Wistar rats fed with onion-enriched diet showed a lesser ovariectomy-induced bone loss in a dose-dependent manner and counteracted deterioration of biochemical properties (Huang et al. 2008). Onion-fed rats showed lower levels of serum calcium and osteocalcin, suggesting a downregulation of bone turnover. Onion group had significantly more trabecular number, less separated trabeculae and fewer osteoclasts and reduced the ovariectomy-induced decrease in bending load and bending energy.

Studies showed that quercetin in a collagen matrix had the effect of increasing new bone formation locally in rabbits and could be used as a bone graft material (Wong and Rabie 2008). A total of 556 % more new bone was present in defects grafted with quercetin in a collagen matrix than those grafted with a collagen matrix alone. No bone was formed in the passive control group. The results of studies by Tsuji et al. (2009) suggested that dietary quercetin inhibited bone loss without

effect on the uterus in ovariectomised mice and did not act as a potent inhibitor of osteoclastogenesis or as a selective oestrogen receptor modulator in-vivo. In-vitro in mouse monocyte/macrophage cell line RAW264.7 cells, quercetin and its conjugate, quercetin 3-*O*- β -D-glucuronide, dose dependently inhibited the receptor activator of nuclear factor kappa β ligand (RANKL)-induced osteoclast differentiation, and the RANKL-stimulated expression of osteoclast related genes was also inhibited by quercetin.

Wound/Scar Healing Activity

The C1 extract of onion was found to be rich in flavonoids, triterpenic acids, amino acids and compounds recognised for their beneficial effects in wound and scar healing and also had good antimicrobial activity (Tătăringă et al. 2005). For onion (30 %w/w)-based gel ointments for wound healing, formula F1 was found to be most efficient in the membrane diffusion process, while formula F2 displayed good wound contracting ability (Gafițanu et al. 2006).

Whiting and Guinea (1998) reported that the pain and inflammation of a man wounded at in the instep of the right foot by a blue-spotted stingray in the Northern Territory, Australia, was subdued when half an onion was bandaged onto the wound. After an hour, he was able to walk on it with joint stiffness. In a side-by-side, randomised, double-blinded, split-scar study of 24 patients with new surgical wounds, no statistically significant difference was found between the onion extract gel and a petrolatum-based emollient in improving the appearance and symptoms of new surgical scars (Chun et al. 2006). In a comparative prospective study involving 60 patients, topical onion extract in gel form improved hypertrophic and keloid scars via multiple mechanisms (Hosnuter et al. 2007). However, it was statistically ineffective in improving scar elevation and itching. The most effective therapeutic results were obtained when the silicone gel sheet treatment was combined with onion extract. Data from studies by Cho et al. (2010) indicated that onion extract and quercetin played a role in the anti-scar effect in skin by inhibition of fibroblast activities and

upregulation of matrix metalloproteinase-1 expression, implying quercetin to be a promising material for reducing scar formation. In another study involving 60 subjects with symmetrical seborrheic keratoses at least 8 mm in diameter on the right and left upper chest, the application of the onion extract gel after surgical excision of lesions significantly improved scar softness, redness, texture and global appearance at the excision site at study weeks 4, 6 and 10 as assessed by the blinded investigator (Draelos 2008). In an open, randomised, controlled, comparative study of 27 patients, treatment with intralesional triamcinolone acetonide (TAC) alone and with onion extract were effective in the therapy of keloidal and hypertrophic scars (Koc et al. 2008). Combined with onion extract gel, intralesional TAC appears to be superior to TAC alone.

In an open-label, controlled, nonrandomised clinical trial of 15 patients, topical applications of a gel containing *Allium cepa*, pentaglycan and allantoin twice a day for 24 weeks appeared to be useful in reducing neoangiogenesis in hypertrophic scars and keloids, resulting in clinical improvement of skin lesions (Campanati et al. 2010). In a randomised, double-blinded, placebo-controlled study of 60 patients with hypertrophic scars after median sternotomy, the use of silicone derivative and onion extract gel was found to be safe and effective for the preventing the hypertrophic scarring (Jenwitheesuk et al. 2012). No adverse events were reported by any of the patients. Results of a 6-month prospective placebo-controlled study showed that application of onion extract in silicone derivative gel could significantly decrease the incidence of hypertrophic scar from median sternotomy wound from an open heart surgery in paediatric patients (4.3 years) (Wananukul et al. 2013). Keloid did not show statistically significant differences in both groups.

Ointments containing heparin, e.g. enoxaparin and onion extract, are popularly used in prevention and treatment of keloids and hypertrophic scars which result in abnormal wound healing (Pikuła et al. 2014). The therapeutic mechanism was found to be associated with the inhibition of proliferation, apoptosis and downregulation of $\beta 1$ integrin

expression in human fibroblasts. Almost complete inhibition of cell proliferation was achieved by enoxaparin in 500 µg/mL concentration (91.5 % reduction). The onion extract at a concentration of 250 µg/mL also strongly inhibited the proliferation of cells (50.8 % reduction). Depending on concentration, enoxaparin and onion extract induced apoptosis (500 and 1,000 µg/mL, respectively) and, depending on concentration, downregulated the expression of β 1 integrin on human fibroblasts.

Anti-ageing/Anti-photoageing Activity

Myricetin treatment reduced UVB-induced epidermal thickening of mouse skin and also suppressed UVB-induced matrix metalloproteinase-9 (MMP-9) protein expression and enzyme activity (Jung et al. 2010b). Overall, the results indicated that myricetin exerted potent anti-photoageing activity by suppressing UVB-induced Raf kinase activity and subsequent attenuation of UVB-induced phosphorylation of MEK and ERK in mouse skin. Topical treatment with myricetin inhibited repetitive UVB-induced neovascularisation in SKH-1 hairless mouse skin (Jung et al. 2010a). The induction of vascular endothelial growth factor, matrix metalloproteinase (MMP)-9 and MMP-13 expression by chronic UVB irradiation was significantly suppressed by myricetin treatment. Also, myricetin inhibited UVB-induced hypoxia-inducible factor-1alpha expression in mouse skin. The results indicated that myricetin suppressed UVB-induced angiogenesis by downregulating PI-3 kinase activity and subsequently attenuated the UVB-induced phosphorylation of Akt/p70(S6K) in mouse skin lysates.

Studies on antioxidant (DPPH assay) and anti-ageing (*Caenorhabditis elegans* lifespan assay) activities of onion flavonoids, quercetin, quercetin 3'-*O*- β -D-glucopyranoside (Q3'G) and quercetin 3-*O*- β -D-glucopyranoside-(4 $\rightarrow$ 1)- β -D-glucopyranoside (Q3M) found no direct correlation was found between antioxidative activity and anti-ageing activity (Xue et al. 2011). Quercetin showed the highest antioxidative activity, whereas Q3M showed the strongest anti-ageing activity among

these flavonoids, which might be related to its high hydrophilicity.

Skin Whitening Activity

Dried onion skin showed potent melanin biosynthesis inhibitory activity in B16 melanoma cells (Arung et al. 2011a, b). Bioassay-guided fractionation led to the isolation of quercetin 3'-*O*- β -D-glucoside which inhibited melanin formation in B16 melanoma cells with an IC₅₀ value of 38.8 μ M and mushroom tyrosinase with an IC₅₀ value of 6.5 μ M. It also exhibited tyrosinase inhibitory activity using L-tyrosine or L-DOPA as a substrate, with IC₅₀ values of 4.3 and 52.7 μ M, respectively. In addition, it showed antioxidant activity of 3.04 μ mol Trolox equivalents/mmol in the oxygen radical absorbance capacity assay. Dried onion skin and its flavonol could be useful for treating hyperpigmentation and for protecting against oxidative stress with potential for skin whitening cosmetics with antityrosinase activity.

Hair Growth Stimulating Activity

In a study of 23 patients, 16 males and 7 females with alopecia areata, topical treatment with crude onion juice applied twice daily for 2 months gave significantly higher results with regard to hair regrowth than did tap water (Sharquie and Al-Obaidi 2002).

Aphrodisiac/Fertility Enhancement Activity

Administration of fresh onion juice equivalent to 1 g/rat/day of fresh onion by gavage to Wistar male rats for 20 consecutive days significantly increased levels of luteinising hormone, but the levels of follicle-stimulating hormone did not differ between experimental and control groups (Khaki et al. 2009). The percentage of sperm viability and motility in both test groups (0.5 and 1 g) significantly increased, but the sperm concentration significantly increased only in the group that received the high dose of freshly extracted onion juice. The study showed that freshly prepared onion juice significantly

affected the sperm number, percentage of viability and motility. Oral administration of ethyl acetate fraction of onion to paroxetine-induced sexually impaired male rats for 7 days restored normal sexual dysfunction behaviour as evident from increased mount frequency, intromission frequency and ejaculatory frequency and reduced mount latency, intromission latency, ejaculatory latency and post-ejaculatory interval (Malviya et al. 2013). Allouh et al. (2014) demonstrated that fresh onion juice significantly reduced mount frequency and latency and increased the copulatory efficacy of sexually potent male rats and in those with paroxetine-induced sexual dysfunction by increasing serum testosterone levels.

Oral administration of onion and garlic extracts to rats successfully attenuated the adverse effects of cadmium-induced testicular damage and spermiotoxicity possibly reducing lipid peroxidation and increasing the antioxidant defence mechanism in rats (Ola-Mudathir et al. 2008). Cd caused a marked rise in testicular lipid peroxidation (LPO) and glutathione S-transferase (GST) levels and a decline in levels of glutathione (GSH), superoxide dismutase (SOD), catalase (CAT) and alkaline phosphatase (ALP). Cd intoxication significantly decreased epididymal sperm concentration and sperm progress motility and increased per cent total sperm abnormalities and live/dead count. Onion extract provided a dose-dependent protection. In a separate study, pretreatment of rats with crude onion extract ameliorated CdSO₄-induced alteration in testicular weight, sperm count, sperm motility and sperm morphology (Ige et al. 2012). Also, onion attenuated the derangement of lipid peroxidation profile in testicular tissues caused by CdSO₄ exposure.

Daily sperm production and total incidence of sperm abnormalities were significantly affected in mice injected with diesel exhaust particles (DEP) as compared with the vehicle group, but the total incidence of sperm abnormalities in the quercetin + DEP-treated mice was significantly reduced as compared with the DEP-treated mice (Izawa et al. 2008). The numbers of Sertoli cells were significantly decreased in DEP-treated mice as compared with the vehicle-treated mice, but the numbers of Sertoli cells were significantly increased in the

quercetin and the onion + DEP-treated mice as compared with the DEP-treated mice. The results clearly indicated alleviative effects of quercetin and onion against male reproductive toxicity induced by DEP. Diesel exhaust particles (DEPs) are particulate matter from diesel exhaust that contain many toxic compounds, such as polyaromatic hydrocarbons (PAHs).

Hormonal Activity

Onion juice fed to rats produced (1) a testosterone-like effect as it increased the seminal vesicles and testicle weight in castrated and non-castrated animals, (2) an insulin-like action as it reduced blood sugar level in experimentally induced hyperglycaemic animals and (3) a growth hormonelike activity as it increased the growth rate in young rats (Sharaf 1967). Additionally, onion juice possessed an oxytocic action when tested, in-vitro, on the rat uterus at various stages of the sex cycle.

Antiparasitic Activity

Feeding *Biomphalaria alexandrina* with onion and garlic powder separately exerted some biological and biochemical changes that reduced the snails' fecundity that in turn disturbed the life cycle of *Schistosoma mansoni* parasite (Mantawy 2001; Mantawy and Mahmoud 2002). Glucose and glycogen were decreased significantly after feeding on onion and garlic. Also, phenol oxidase activity was highly significantly decreased after 2 and 7 days of feeding on garlic, while feeding on onion decreased the activity of the enzyme at all periods. Alkaline phosphatase was highly significantly reduced in haemolymph of snails that fed on either onion or garlic. Also, alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were highly significantly reduced in haemolymph of snails that were fed on onion, while those fed on garlic showed no change in ALT activity and a high significant increase in AST activity. Total proteins were significantly decreased in haemolymph of all treated snails whereas variations in free amino acids contents were also observed. Administration of onion and garlic extract

individually and mixed either with or without the currently used drug, praziquantel, to *Schistosoma mansoni*-infected mice significantly reduced parasite burden, hepatic and intestinal eggs and oogram count (Mantawy et al. 2011). The extracts ameliorated the increase in IgM, IgG, interleukins 2 and 6 (IL-2 and 6) and tumour necrosis factor (TNF- α) and catalase enzyme, accompanied with a decrease in GPX and SOD antioxidant enzyme activities caused by the parasite. Results of in-vitro studies indicated their strong biocidal effects against all stages of *Schistosoma mansoni* miracidia, schistosomula, cercaria and adult worms and also showed scavenging inhibitory effect on 2,2-diphenyl-1-picrylhydrazyl (DPPH) and nitric oxide (NO) (Mantawy et al. 2012).

Aqueous onion extract inhibited growth of five leishmanial strains in the promastigote stage in-vitro with IC₁₀₀ and IC₅₀ values of 1.25 mg/mL and 0.376 mg/mL, respectively (Saleehan et al. 2004). Aqueous onion extract was found to have inhibitory activity against *Leishmania major* promastigotes, parasite isolated from cutaneous leishmaniasis (Sadeghi-Nejad and Saki 2014).

Nigella sativa and *Allium cepa* oils exhibited anthelmintic effect in the rats infected with *Trichinella spiralis* infection and increased the production of antibodies generated during life cycle of the parasite (Abu El Ezz 2005). *A. cepa* oil showed more effectiveness than *N. sativa* on decline number of adult worms and muscle larvae when used as therapeutic treatment postinfection.

Feeding sheep for 8 days with onion extract and coconut combined with milk powder and/or polyethylene glycol (PEG) propylene carbonate stopped gastrointestinal nematodes and cestodes (Melhorn et al. 2011). In more recent studies, addition of micronised coconut and onion reduced worm (trematodes, cestodes and nematodes) load in horses and sheep and increased sheep body weight (Jatzlau et al. 2014). In the case of the horse treatment, the worm load decreased so enormously that mostly only single eggs or larvae were found in those horses that had accepted the onion–coconut food addition.

Antihyperuricaemic Activity

Oral administration of onion at 3.5 and 7.0 mg/kg/day for 7 days was able to reduce serum uric acid levels in potassium oxonate-induced hyperuricaemic rats with no significant effects on the level of this compound in the normal animals (Haidari et al. 2008b). Further, onion when tested in-vivo on rat liver homogeneities elicited significant inhibitory actions on the xanthine dehydrogenase (XDH) and xanthine oxidase (XO) activities. In another study, *Allium cepa* and quercetin treatments for 14 days significantly reduced serum uric acid levels of potassium oxonate-induced hyperuricaemic rats in a time-dependent manner (Haidari et al. 2008a). All treatments significantly inhibited hepatic xanthine oxidase/xanthine dehydrogenase activity. *Allium cepa* and quercetin treatments led also to a significant improvement in biomarkers of oxidative stress in hyperuricaemic rats.

Immunostimulating Activity

The consumption of onions resulted in significant reductions in plasma triacylglycerol; however, the reductions were most pronounced in pigs fed with destiny onions (−26 %) (Ostrowska et al. 2004). Total plasma cholesterol and LDL–HDL ratios were not significantly different. Onion supplementation, regardless of the variety, resulted in dose-dependent reductions in erythrocyte counts and Hb levels, while the white blood cell concentrations, particularly lymphocytes, were increased in pigs that consumed onions. It was concluded that dietary supplementation with raw brown onions has moderate lipid-modulating and immunostimulatory properties. Studies revealed that CD4 and total white blood cell (WBC) counts were significantly increased in a dose-dependent manner in both onion- and garlic-treated rats when compared to the zero control (Mirabeau and Samson 2012). However, no significant effect was observed on these parameters when extracts were combined. The results from this study revealed the immune-boosting capabilities of onion and garlic, but underscored their synergistic activities. The pectic polysaccharide from immature onion stick showed in-

vitro splenocyte, thymocyte as well as macrophage activations (Patra et al. 2013).

Suppression of Onion Lachrymatory Factor Synthase

The lachrymatory factor synthase gene in onion was suppressed by a single genetic transformation using RNA interference silencing (Eady et al. 2008). This reduced lachrymatory synthase activity by up to 1,544-fold, so that when wounded, the onions produced significantly reduced levels of tear-inducing lachrymatory factor. The researchers confirmed that silencing had shifted the *trans*-S-1-propenyl-L-cysteine sulfoxide breakdown pathway so that more 1-propenyl sulfenic acid was converted into di-1-propenyl thiosulfinate. A consequence of this raised thiosulfinate level was a marked increase in the downstream production of a nonenzymatically produced zwiebelane isomer and other volatile sulfur compounds, di-1-propenyl disulfide and 2-mercapto-3,4-dimethyl-2,3-dihydrothiophene, which had previously been reported in trace amounts or had not been detected in onion.

Drug Metabolising Activities

Consumption of onion induced cytochrome P450 (CYP)s enzymes CYP 1A and CYP 2B activities, while it decreased CYP 2E1 activity in rats (Teyssier et al. 2001). The same dietary treatment caused a slight increase of the total glutathione S-transferase (GST) phase II enzyme activity. The relative proportions of GST subunits were modified; GST A1/A2 subunits were increased, while GST A3/A5 and GST M2 subunits were decreased and GST M1 and P1 were not modified. Onion consumption also increased *p*-nitrophenol UDP-glucuronosyltransferase (UGT) phase II enzyme activity. Taken together, the results suggested that the decrease of CYP 2E1 and the increase of phase II enzymes by onion could afford protection against some carcinogens, while the decrease of some GST subunits could increase the genotoxic effects of other chemicals. The modulating effect of onion could be

ascribed to alk(en)yl polysulfides and/or glycosides of flavonols, which were identified in the onion powder.

Anticataract Activity

Instillation of onion juice into the rat eyes was found to effectively prevent selenite-induced cataract formation (Javadzadeh et al. 2009). This effect was associated with increased total antioxidative level, glutathione peroxidase (GPX) and superoxide dismutase (SOD) activities in the lens.

Urease Inhibitory Activity

Quercetin 4'-*O*- β -D-glucopyranoside isolated from onion exhibited urease inhibition activity with an IC₅₀ value of 190 μ M (Shabana et al. 2010).

Protease Inhibitory Activity

Three protease inhibitors (OTI-1-3) with molecular masses of 7,370.2, 7,472.2 and 7,642.6 Da were purified from onion bulbs (Deshimaru et al. 2003). Based on amino acid composition and N-terminal sequence, OTI-1 and OTI-2 are the N-terminal truncated proteins of OTI-3. All the inhibitors were stable to heat and extreme pH. OTI-3 inhibited trypsin, chymotrypsin and plasmin.

Haematological Studies

The degree of haemolysis of albino Wistar rat erythrocyte was greater in the treatment group compared to control, and the percentage haemolysis was greater in blood samples with onion and garlic compared to the onion alone group (Salami et al. 2012). The same observation was made in the in-vitro study, but the degree of haemolysis was significantly higher in in-vitro than the in-vivo experiments. It was concluded that onion and garlic increase the osmotic fragility of red blood cells in albino rats.

Pharmacokinetic Studies

In a study of nine healthy ileostomy volunteers, supplementation of fried onions at breakfast (rich in quercetin glucosides) equivalent to 89 mg aglycone, pure quercetin rutinose (the major quercetin compound in tea) equivalent to 100 mg aglycone or 100 mg pure quercetin aglycone, in random order, showed that humans absorbed appreciable amounts of quercetin and that absorption was enhanced by conjugation with glucose (Hollman et al. 1995). Mean excretion of quercetin or its conjugates in urine was 0.5 % of the amount absorbed; quercetin excretion in urine was negatively correlated with excretion in ileostomy effluent. The following metabolites of quercetin flavonols, 3,4-dihydroxyphenylacetic acid (homoprotocatechuic acid), metahydroxyphenylacetic acid and 4-hydroxy-3-methoxyphenylacetic acid (homovanillic acid), were detected in human urine after intake of food rich in quercetin like onion, apples and tea (Gross et al. 1996). The mean concentrations of 3,4-dihydroxyphenylacetic acid, metahydroxyphenylacetic acid and homovanillic acid in human urine samples were approximately 0.7, 4.8 and 2.8 µg/mL, respectively.

After consumption of lightly fried onion containing conjugates of quercetin and isorhamnetin, including quercetin 3,4'-di-*O*-β-glucoside, isorhamnetin 4'-*O*-β-glucoside and quercetin 4'-*O*-β-glucoside by human volunteers, it was found that onion flavonols were absorbed into the bloodstream as glucosides and minor structural differences affected markedly both the level of accumulation and the extent to which the conjugates were excreted (Aziz et al. 1998). In a randomised two-phase crossover supplementation trial of six healthy nonobese normocholesterolaemic female volunteers in the age range 20–44 years, a meal of fried onions and fried onions together with tomatoes led to transient decreases in biomarkers of oxidative stress, although the particular biomarkers affected differed (Boyle et al. 2000). Flavonoid glucosides (quercetin 3-glucoside and isorhamnetin 4-glucoside) were significantly elevated in plasma following ingestion of the onion meal, and the increases were associated with an increased resistance of lymphocyte DNA to DNA strand breakage. A significant

decrease in the level of urinary 8-hydroxy-2'-deoxyguanosine was evident at 4 hours following ingestion of the onion meal. After the combined tomato and onion meal, only quercetin was detected in plasma. Endogenous base oxidation was decreased, but resistance to strand breakage was unchanged. There was no significant change in the excretion of urinary malondialdehyde following either meal. Following consumption of fried onions, five different glucuronides of quercetin could be identified in human plasma samples (Wittig et al. 2001). In contrast, neither the free flavonol nor the genuine glycoside could be detected in plasma. The major circulating compounds found in the plasma of four individuals after 1.5 hours after consumption of onions were identified as quercetin 3-glucuronide, quercetin 3'-methylquercetin 3-glucuronide and quercetin 3'-sulfate (Day et al. 2001).

Consumption of the dietary flavonoid quercetin had been reported to form conjugates with glucuronic acid, sulfate or methyl groups in human plasma (Janisch et al. 2004). The ability of these quercetin conjugates to inhibit Cu(II)-induced oxidation of human low-density lipoprotein was determined to be in the following order: quercetin 7-glucuronide > quercetin > quercetin 3-glucuronide = quercetin 3-glucoside > catechin > quercetin 4'-glucuronide > isorhamnetin 3-glucuronide > quercetin 3'-sulfate. Thus, the proposed products of small intestine metabolism (quercetin 7-glucuronide, quercetin 3-glucuronide) were more efficient antioxidants than subsequent liver metabolites (isorhamnetin 3-glucuronide, quercetin 3'-sulfate). Albumin-bound conjugates retained their property of protecting LDL from oxidation, although the order of efficacy was altered (quercetin 3'-sulfate > quercetin 7-glucuronide > quercetin 3-glucuronide > quercetin 4'-glucuronide = isorhamnetin 3-glucuronide). K_q values (concentration required to achieve 50 % quenching) for albumin binding, as assessed by fluorescence quenching of Trp214, were as follows: quercetin 3'-sulfate (approximately 4 μM) = quercetin > or = quercetin 7-glucuronide > quercetin 3-glucuronide = quercetin 3-glucoside > isorhamnetin 3-glucuronide > quercetin 4'-glucuronide (approximately 20 μM).

Twenty-three flavonols as a range of mixed sulfate, methyl, glucuronide and glucoside derivatives of quercetin were detected in the urine and blood plasma of six human volunteers 0–4 hours after ingestion of lightly fried red onions, rich in anthocyanins and flavonols (Mullen et al. 2004). The flavonoids quercetin 3-glucuronide, quercetin 3'-glucuronide, quercetin 4'-glucuronide, quercetin 3'-sulfate and isorhamnetin 3-glucuronide were detected in samples from all volunteers. Samples from one volunteer also contained trace amounts of quercetin 3,4'-diglucoside, quercetin 3-glucoside, isorhamnetin 3-glucoside and the aglycone quercetin. Despite a high dosage, neither anthocyanins nor anthocyanin metabolites accumulated in either plasma or urine in detectable quantities. After consumption of cooked onion, more than 80 % of quercetin metabolites were localised in the human plasma fraction containing concentrated serum albumin (Murota et al. 2007). Other lipoprotein fractions contained only small amounts of quercetin metabolites. Addition of quercetin 3-O- β -glucuronide to the lipoprotein-eliminated plasma fraction generated antioxidant activity against LDL oxidation in a dose-dependent manner. However, onion consumption failed to enhance the antioxidant activity of the lipoprotein-eliminated plasma fraction against LDL oxidation, probably because the amount of quercetin metabolites bound to albumin was less than the effective level in an ex-vivo study.

Wiczowski et al. (2008) found that when provided along with dietary sources, quercetin aglycone was more bioavailable than its glucosides in humans. The maximum plasma quercetin concentration of 1.02 $\mu\text{mol/L}$ was reached at 2.33 hours after shallot flesh consumption compared with 3.95 $\mu\text{mol/L}$ at 2.78 hours after dry skin consumption. The area under the concentration-time curve after dry skin consumption was 47.23 $\mu\text{mol/hour/L}$ and was significantly higher than that after shallot flesh intake (22.23 $\mu\text{mol/hour/L}$). In a study of eight healthy female and eight male volunteers, consumption of the onion powder led to faster absorption, higher concentration and greater bioavailability of quercetin glycosides as compared to consumption of apple peel powder (Lee and Michael 2012). No significant gender-related differences were observed in the absorption of quercetin,

whereas significant gender-related differences in the elimination half-time ($t(1/2)$) were observed. In the onion powder, quercetin occurred as the quercetin 3,4'-*O*-glucoside and quercetin 4'-*O*-glucoside. The predominant forms of quercetin in apple peel included quercetin *O*-arabinoside, quercetin 3-*O*-galactoside, quercetin 3-*O*-glucoside and quercetin 3-*O*-rhamnoside.

Studies with radiolabeled quercetin 4'-glucoside in rats showed that more than 95 % of the absorbed radioactivity was in the form of >20 different methylated glucuronated and/or sulfated quercetin conjugates (Graf et al. 2005). Five hours after ingestion, the main radiolabeled metabolites were quercetin diglucuronides in the gut, liver and kidneys and glucuronyl sulfates of methylated quercetin in plasma. The main site of quercetin metabolism seemed to be the gastrointestinal tract. Quercetin metabolites may have a major influence on the gut mucosal epithelium and on colonic disease.

Pure quercetin aglycone was absorbed by the Caco-2 cells in higher concentrations than quercetin 3-glucoside (Boyer et al. 2004). Caco-2 cells treated with quercetin 3-glucoside accumulated both quercetin 3-glucoside and quercetin. Caco-2 cells absorbed more onion quercetin aglycone than onion quercetin 3-glucoside, and the percentage of onion quercetin absorbed was greater than that of pure quercetin, most likely due to enzymatic hydrolysis of quercetin 3-glucoside and other quercetin glucosides found in the onion by the Caco-2 cells. An in-vitro anaerobic fermentation in rat caecal inoculums of onion-supplemented diet (10 % fructans) showed an increase in the production of total and individual (propionate, acetate and butyrate) short-chain fatty acids (SCFA) and a decrease in the pH of the caecal content compared to the control group (Pascoal et al. 2013). Additionally, onion-supplemented rats presented increases in the weight and moisture of the faeces, the moisture of the caecal content, the total weight of the cecum and the weight of the caecal wall. All parameters evaluated of rat diets showed that onion had a higher in-vitro fermentation than the CD control group as a consequence of the presence of fructans. The in-vitro results (increase in the

production of SCFA and in the molar proportion of propionate and butyrate and decrease in the molar proportion of acetate and in pH) were in accord with the in-vivo caecum fermentation results, suggesting the feasibility of using in-vitro fermentation to predict possible effects of the fermentation of onion products.

Cycloalliin, an organosulfur compound found in garlic and onion, when administered intravenously at 50 mg/kg to rats, was rapidly eliminated from blood and excreted into urine, and its total recovery in urine was 97.8 % in 48 hours (Ichikawa et al. 2006). After oral administration, cycloalliin appeared rapidly in plasma. Orally administered cycloalliin was distributed in the heart, lung, liver, spleen and especially kidney. When administered orally at 50 mg/kg, cycloalliin was excreted into urine but not faeces. However, the total faecal excretion of (3*R*,5*S*)-5-methyl-1,4-thiazane-3-carboxylic acid was 67.3 % (value corrected for cycloalliin equivalents). In addition, no (3*R*,5*S*)-5-methyl-1,4-thiazane-3-carboxylic acid was detected in plasma (<0.1 µg/mL), and negligible amounts (1.0 %) were excreted into urine. In in-vitro experiments, cycloalliin was reduced to (3*R*,5*S*)-5-methyl-1,4-thiazane-3-carboxylic acid during anaerobic incubation with caecal contents of rats. The data indicated that the low bioavailability (3.73 % and 9.65 % at 25 and 50 mg/kg, respectively) of cycloalliin was due mainly to reduction to (3*R*,5*S*)-5-methyl-1,4-thiazane-3-carboxylic acid by the intestinal flora and also poor absorption in the upper gastrointestinal tract.

Toxicity Studies

Oral or intraperitoneal administration of low doses of onion (50 mg/kg) to rats had little effect on lung and liver tissues when compared to control animals (Thomson et al. 1998). In contrast, administration of high doses of onion (500 mg/kg) resulted in apparent histological changes in lung and liver tissues of rats. Intraperitoneal administration of the high dose of onion was more damaging to lung and liver tissue than oral administration and resulted in a 25 % rate of mortality in this treatment group.

Allergy Issues

A case of a 44-year-old woman with severe systemic reactions (intense itching, urticaria, confusion, blurred vision, transient loss of consciousness, sweating, tachycardia) after ingestion of raw or lightly cooked onion was reported by Arena et al. (2000). Unheated onion extract resulted positive in class 2, heated extract negative, demonstrating that this patient was different from similar clinical cases described in literature and had IgE antibodies recognising just thermolabile onion fraction. A case of a 45-year-old man with at least five episodes of severe, systemic urticaria/angioedema some minutes after eating raw onions during the previous few years was reported by Asero et al. (2001). The patient showed IgE reactivity to onion proteins at different molecular weights.

Roussos and Hirsch (2014) reported a rare case of a 32-year-old woman migraineur with osmophobia and trigger to garlic and onion aroma. Upon exposure to onions and garlic aroma, she experienced a fortification spectra and visual entopia, followed by a biparietal, crushing level 10/10 headache, burning eyes and nose, lacrimation, perioral paresthesias, generalised pruritus, nausea, fatigue, sore throat, dysarthria, confusion, dyspnea, palpitations, presyncopal sensations, hand spasms, tongue soreness, neck pain, phonophobia and photophobia. The patient also experienced chemosensory complaints: dysosmias every few months, phantosmias of food or cleaning products every month for a minute of level 5/10 intensity, palinostmia of onion or garlic odour for 30 minutes after exposure and metallic parageusia after eating with metal utensils. Allergy skin test was positive for garlic and onion. Nose plug and counter stimulation with peppermint prevented the onset of headaches and associated symptoms.

Traditional Medicinal Uses

Onion bulb is anthelmintic, anti-inflammatory, antiseptic, antispasmodic, carminative, diuretic, expectorant, febrifuge, hypoglycaemic, hypotensive, lithontriptic, stomachic and tonic (Grieve 1971; Lust 1974; Chiej 1984). Onion and garlic rich in

several phytonutrients are recognised as important elements of the Mediterranean diet but are also used in the treatment and prevention of a number of diseases, including cancer, coronary heart disease, obesity, hypercholesterolaemia, diabetes type 2, hypertension, cataract, microbial infections and disturbances of the gastrointestinal tract (e.g. colic pain, flatulent colic and dyspepsia) because of their hypocholesterolaemic, hypolipidaemic, antihypertensive, antidiabetic, antibiotic, antithrombotic, antiasthmatic and anti-hyperhomocysteinaemia effects, and to possess many other biological activities including antimicrobial, antioxidant, anticarcinogenic, antimutagenic, antiasthmatic, immunomodulatory and prebiotic activities (Kendler 1987; Augusti 1996; Bianchini and Vaino 2001; Griffiths et al. 2002; Lanzotti 2006; Corzo-Martínez et al. 2007). Garlic and onion have been used as medicinal agents for thousands of years (Ali et al. 2000). Both garlic and onion had been shown to have applications as antimicrobial, antithrombotic, antitumour, hypolipidaemic, antiarthritic and hypoglycaemic agents. Historically, *Allium* crops have been used to treat a wide range of ailments, but the most prominent has been cardiovascular disease (Block 1992). In the Errachidia province in southeastern Morocco, *A. cepa* is one of several plants used to treat diabetes and hypertension (Tahraoui et al. 2007). *Allium cepa* is used for chilblains and to remove thorns and splinters in traditional phytotherapy in the Marche, Abruzzo and Latium regions in Central Italy Guarrera (2005). Fenugreek, garlic and onion are recommended in Persian folklore medicine as beneficial in the treatment of diabetes (Jelodar et al. 2005).

When used regularly in the diet, onions offset tendencies towards angina, arteriosclerosis and heart attack and also useful in preventing oral infection and tooth decay (Chevallier 1996). Baked onions can be used as a poultice to remove pus from sores and warmed onion juice can be used as eardrop to treat earache (Chevallier 1996). Fresh onion juice is a very useful first aid treatment for bee and wasp stings, bites, grazes or fungal skin complaints (Chiej 1984; Allardice 1993). It also aids in the formation of scar tissue on wounds, thus speeding up the healing process, and has been used as a cosmetic to remove freckles (Chiej 1984). Onion juice rubbed into the skin

is said to promote the growth of hair and to be a remedy for baldness (Chiej 1984; Chevallier 1996). Bulbs of red onion cultivars are used to make a homeopathic remedy particularly in the treatment of people whose symptoms include running eyes and nose (Castro 1996). The German Commission E Monographs (1998), a therapeutic guide to herbal medicine, approve *Allium cepa* onion for appetite loss, arteriosclerosis, dyspeptic complaints, fevers and colds, cough/bronchitis, hypertension, tendency to infection, inflammation of mouth and pharynx and common cold.

Other Uses

Onion plant and bulb contain phytochemicals that exhibit pesticidal activities against plant and animal insect pest and phytopathogens. The growing plant is reported to repel insects and moles (Allradice 1993). The juice of the plant is used as a moth repellent and can also be rubbed onto the skin to repel insects (Chiej 1984). Onion water extract is said to the resistance of other plants to diseases and parasites (Allardice 1993).

Allicepin, an antifungal peptide isolated from onion bulb, exerted an inhibitory activity on mycelial growth in several fungal species including *Botrytis cinerea*, *Fusarium oxysporum*, *Mycosphaerella arachidicola* and *Physalospora piricola* (Wang and Ng 2004). Antifungal activity of three onion saponins increased with their concentration and varied with the following rank: ceposide B > ceposide A = ceposide C (Lanzotti et al. 2011). A significant synergism in the antifungal activity of the three ceposides in combination was observed against *Botrytis cinerea* and *Trichoderma atroviride*. In contrast, *Fusarium oxysporum* f. sp. *lycopersici*, *Sclerotium cepivorum* and *Rhizoctonia solani* were very little affected by saponins. Six *Fusarium*-inoculated shallot (*Allium cepa* var. *aggregatum*) strains seemed to be adequately resistant against disease, and the levels of resistance may be related to the saponin content in the bulb tissues (Vu et al. 2013). The n-butanol extract of shallot (*Allium cepa* Aggregatum group) basal plates and roots showed antifungal activity against plant pathogenic fungi (Teshima et al. 2013). Inoculation experiments showed that alliospiroside A isolated from shallots protected strawberry plants against *Colletotrichum gloeosporioides* indicating it had the potential to control anthracnose of the plant.

Onion oil exhibited acaricidal effect on all stages of *Boophilus annulatus* hard tick at concentrations higher than 5 % (Aboelhadid et al. 2013). The 10 and 20 % onion oil in ethanol and methanol alcohols killed 76–86 % of the adult ticks within 72 hours postapplication. While, all larvae died

within 24 hours post subjected to these two concentrations. These concentrations (10 and 20 %) of onion oil in water killed 56–80 % of the treated ticks. Moreover, 10 % aqueous solution of onion oil prevented hatching of embryonated eggs.

The plant juice can be used as a rust preventative on metals and as a polish for copper and glass (Chiej 1984). A yellow–brown dye is obtained from the outer skin of the bulbs (Gare 1974). Polyphenols could be recovered from onion solid wastes under optimal conditions (60 % ethanol, pH 2 and 4.2 hours) with a predicted theoretical yield of 9,342 mg gallic acid equivalents per 100 g dry weight (Kiassos et al. 2009). The principal phytochemicals recovered were quercetin 3,4'-diglucoside, quercetin 4'-glucoside and quercetin.

Comments

Hanelt (1990) broadly divided *Allium cepa* into the common onion and Aggregatum groups. Fritsch and Friesen (2002) divided *A. cepa* into three groups: common onion group, Aggregatum group and an ever-ready onion group. The last group can be distinguished from the other two groups by its prolific vegetative growth and lack of a dormant period. Bulbs or leaves are used mainly as a salad onion and can be harvested at all times of the year.

Allium chinense

T. K. Lim¹✉

(1) Canberra, Aust Capital Terr, Australia

Scientific Name

Allium chinense G. Don

Synonyms

Allium bakeri Regel, *Allium bodinieri* H. Léveillé and Vaniot, *Allium exsertum* (Lindl.) Baker (illeg.), *Allium exsertum* G. Don, *Allium martini* H. Léveillé and Vaniot, *Allium splendens* Miq. (illeg.), *Allium triquetrum* Lour., *Caloscordum exsertum* (G. Don) Herb

Family

Amaryllidaceae

Common/English Names

Baker's Garlic, Chinese Onion, Chinese Scallion, Chinese Shallots, Japanese Scallion, Kiangsi Scallion, Kiangsi Shallot, Oriental Onion, Rakkyo, Small Angled Chives

Vernacular Names

Arabic: Tum El-Khabazeen

Chinese: Cong Ying Xie, Hsieh, Xie-Tou, Hsieh-Tou, Jiao Tou, Ku Jiao, Qiao Tou Tsung Tao, Xie, Ying Xie

Czech: Česnek Rakijo

Danish: Rakkyo, Rakkyoløg

Estonian: Rakkiolauk

Finnish: Valkoruohosipuli

French: Échalote Chinoise, Rakkyo

Hebrew: Shum sini

Hungarian: Iyabasi

Indonesia: Longkio, Bawang Kucai (Java) Bawang Ganda (Malay)

Japanese: Rakkyō, Rakkyou, Esharetto, Hana Rakkyou, Shima Rakkyou, Tama Rakkyou, Rakky

Korean: Yeom Kyo

Malaysia: Lokyo

Polish: Szczypiorek chiński

Portuguese: Chalota Chinesa

Spanish: Chalote Chinesa, Cebollino De La China, Cebolinha para picles

Swedish: Rakkyolök

Thailand: Mee Yoi (Northern), Krathiam-Chin, Hom-Prang, Hom-Paenyuak

Vietnamese: Kieu, Củ Kiệu

Origin/Distribution

Rakkyo occurs spontaneously in Central and Eastern China (in Anhui, Fujian, Guangdong, Guangxi, Guizhou, Hainan, Henan, Hubei, Hunan, Jiangxi and Zhejiang provinces) and in Japan, Korea, Russia and Mongolia. It is widely cultivated in China and Japan. It is also cultivated in Southeast Asia (Cambodia, Laos, Vietnam, Thailand, Myanmar, Malaysia, Singapore and Indonesia) and introduced with oriental emigrants from this region into further areas, e.g. the United States (Hawaii, California) and Cuba.

Agroecology

Rakkyo is well adapted to the temperate and subtropical conditions in latitude 30–40° N and S, in the temperature range of 15–35 °C. The crop prefers well-drained, friable and moderately fertile soils such as sandy loams and thrives in full sun. Too fertile soil such as the volcanic ash results in large and soft bulbs and a decrease in market value.

Edible Plant Parts and Uses

The bulbs and leaves are edible raw or cooked (Read 1982; Kunkel 1984; Facciola 1990; Larkcom 1991).

Bulbs are used raw or fried mixed with other vegetables in Indonesia. The bulbs are widely used as sweet or sour pickles after steeping in salt for several days. In Japan, they are used mainly in pickles as side dishes, often eaten with Japanese curry. Rakkyo is used as a pickled meal during Vietnamese New Year – Tet celebrations. Flowers and young seedpods are also edible raw, used as a garnish on salads.

Botany

A biennial clustered, caespitose bulbous herb up to 63 cm tall with adventitious roots (Plates 1, 2, 3, and 4). Bulbs are narrowly ovoid to ellipsoid, 1–4 cm in diameter with a white, membranous coat which is often tinged with reddish purple and gradually merging into the leaf blades at the top (Plates 1, 2, 3, 4, and 5). Leaves are hollow but the scape is solid. Leaves are distichous, cylindrical, hollow, 20–50 cm by 1–5 mm and 3–5 angled (Plates 1, 2, 3, and 4). Scape is lateral, 20–40 cm, terete and solid covered with leaf sheaths only at the base. Inflorescence consists of a hemispheric umbel with 6–30 lax flowers with two-lobed persistent spathe. Flowers are campanulate, purplish with six tepals arranged in two whorls, six stamens and a pistil longer than the tepals. Filaments equal, $1.5 \times$ as long as tepals, connate at base and adnate to tepals; outer ones subulate; inner ones broadened at base, one-toothed on each side. The ovary is obovoid–globose, with concave nectaries covered by hoodlike projections at the base. Style exerted.

Nutritive/Medicinal Properties

Nutrients

Rakkyo bulb was reported to contain the following nutrient composition (Leung et al. 1972): energy 109 kcal, moisture 70.1 g, protein 0.8 g, fat 0.1 g, total carbohydrate 27.7 g, dietary fibre 0.4 g, ash 1.3 g, calcium 26 mg, phosphorus 9 mg, iron 0.6 mg, thiamine 0.5 mg, riboflavin 0.3 mg, niacin 0.7 mg and ascorbic acid 2 mg.

Phytochemicals

Infrared spectra and relative retention volumes were used to confirm the production of asymmetric disulfides, methyl-allyl, methyl-*n*-propyl and allyl-*n* propyl compounds by *Allium chinense* (Jacobsen et al. 1964). The compounds identified from the neutral fraction of *A. chinense* volatile oil included sulfides, thiolanes, alcohols, aldehydes, ketones, furanones and others (Kameoka et al. 1984). Among the sulfur compounds, dipropyl disulfide comprised *ca* 30 % of rakkyo oil. Rakkyo oil was characterised by a large amount of 2,3-dihydro-2-hexyl-5-methylfuran-3-one (*ca* 20 %) 2,3-dihydro-2-hexyl-5-methylfuran-3-one (*ca* 20 %).

N-(*p*-*trans*-coumaroyl)tyramine and *N*-(*p*-*cis*-coumaroyl)tyramine, lunularic acid and *p*-coumaric acid were isolated from the bulb of *Allium chinense* (Goda et al. 1987). Adenosine, guanosine and tryptophan, as well as β -sitosterol β -D-glucoside, were isolated from the n-butanol-soluble fraction of Xiebai (rakkyo bulbs) (Okuyama et al. 1989). From bulbs of *Allium chinense*, a new furostanol glycoside, named chinenoside I, and its structure were established to be 26-*O*- β -glucopyranosyl 3 β , 22, 26-trihydroxy-25(R)-5 α -furostan-6-one 3-*O*- β -xylopyranosyl(1 $\rightarrow$ 4)[α -arabinopyranosyl(1 $\rightarrow$ 6)] β -glucopyranoside (Matsuura et al. 1989). Two furostanol saponins, named chinenosides II and III, were isolated along with seven known compounds, from *Allium chinense* bulbs (Peng et al. 1996a). The structures of chinenosides II and III were determined to be 26-*O*- β -glucopyranosyl 3,26-

dihydroxy-(25*R*)-5 α -furost-20(22)-en-6-one 3-*O*- β -xylopyranosyl-(1 $\rightarrow$ 4)-[α -arabinopyranosyl(1 $\rightarrow$ 6)]- β -glucopyranoside and 26-*O*- β -glucopyranosyl 3 β ,26-dihydroxy-(25*R*)-5 α -furost-20(22)-en-6-one 3-*O*- α -arabinopyranosyl (1 $\rightarrow$ 6)- β -glucopyranoside, respectively. Two new furostanol saponins, chinenoside IV and V, were isolated from *A. chinense* bulbs, and their structures elucidated as 26-*O*- β -glucopyranosyl-3 β ,26-dihydroxy-23-hydroxymethyl-25(*R*)-5 α -furost-20(22)-en-6-one 3-*O*- β -xylopyranosyl(1 $\rightarrow$ 4)-[α -arabinopyranosyl(1 $\rightarrow$ 6)]- β -glucopyranoside and that of 2 to be 26-*O*- β -glucopyranosyl-3 β , 26-dihydroxy-23-hydroxymethyl-25-(*R*)-5 α -furost-20(22)-en-6-one 3-*O*- α -arabinopyranosyl (1 $\rightarrow$ 6)- β -glucopyranoside, respectively (Peng et al. 1996b; Peng and Yao 1996). Both chinenosides IV and V may be the hydroxymethylation of chinenosides II and III in the plant by hydroxymethylase.

Six compounds were isolated from the anticoagulation and anticancer fractions of *Allium chinense* bulbs (Jiang et al. 1998). Their structures were established as (25*R*, *S*)-5 α -spirostane-3 β -ol 3-*O*-(β -D-glucopyranosyl-(1 $\rightarrow$ 2)-[β -D-glucopyranosyl-(1 $\rightarrow$ 3)]- β -D-glucopyranosyl-(1 $\rightarrow$ 4)- β -D-galactopyranoside); (25*R*, *S*)-5 α -spirostane-3 β -ol 3-*O*-(β -D-glucopyranosyl (1 $\rightarrow$ 2)-[β -D-glucopyranosyl-(1 $\rightarrow$ 3)](6-acetyl- β -D-glucopyranosyl)-(1 $\rightarrow$ 4)- β -D-galactopyranoside); (25*R*, *S*)-5 α -spirostane-2 α , 3 β -diol 3-*O*-(β -D-glucopyranosyl-(1 $\rightarrow$ 2)-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 4)- β -D-galactopyranoside); (25*S*)-24-*O*- β -D-glucopyranosyl-3 β , 24 β -dihydroxy-5 α -spirost-3-*O*- α -arabinopyranosyl-(1 $\rightarrow$ 6)- β -D-glucopyranoside (chinenoside VI), chinenoside II and 2,3,4,9-tetrahydro-1-methyl-1*H*-pyrido [3,4-*b*] indole-3-carboxylic acid. Two saponins, xiebai-saponin I (laxogenin 3-*O*- β -xylopyranosyl (1 $\rightarrow$ 4)-[α -arabinopyranosyl (1 $\rightarrow$ 6)]- β -glucopyranoside) and laxogenin 3-*O*- α -arabinopyranosyl (1 $\rightarrow$ 6)- β -glucopyranoside, and the aglycone, laxogenin, together with two chalcones, isoliquiritigenin and isoliquiritigenin-4-*O*-glucoside, and β -sitosterol glucoside were isolated from the Chinese crude drug 'Xiebai', the bulbs of *Allium chinense* (Baba et al. 2000).

Antiplatelet Aggregating Activity

N-(*p*-*trans*-coumaroyl)tyramine and *N*-(*p*-*cis*-coumaroyl)tyramine, lunularic acid and *p*-coumaric acid, isolated from *Allium chinense* bulbs, were found to be inhibitors of prostaglandin(PG) and thromboxane synthetases (Goda et al. 1987). These compounds that inhibited prostaglandin biosynthesis also showed significant inhibitory effects on platelet aggregation induced by arachidonic acid and collagen. Of the compounds isolated from rakkyo bulbs, adenosine showed a significant inhibitory activity against both the primary and secondary wave aggregation of human platelet induced by 2 μ M ADP, whereas guanosine and tryptophan and β -sitosterol β -D-glucoside showed no or very low inhibitory effects (Okuyama et al. 1989). Of the derivatives of adenosine and guanosine, adenosine 2'-monophosphate, adenosine 5'-monophosphate, adenosine triphosphate and guanylyl(3'→5')adenosine also inhibited the primary and secondary wave aggregation with a dose-dependent response but not guanosine 3'-monophosphate and guanosine 5'-monophosphate. Steroidal saponins from *A. chinense* bulb, chinenoside II and II, exhibited fibrinolysis promoting activity with IC₅₀ of 14 and 13 mg/mL, respectively, while laxogenin 3-*O*- α -arabinopyranosyl(1→6)- β -glucopyranoside or laxoside had blood coagulation inhibitory effect with IC₅₀ of 3.4 mg/mL (Peng and Yao 1996). Adenosine exhibited both platelet aggregation inhibitory effect and blood coagulation effect with IC₅₀ of 1.87 and 25 mg/gmL, respectively.

Six compounds were isolated from the anticoagulation and anticancer fractions of *Allium chinense* bulbs (Jiang et al. 1998).

Cardiotonic/Cardioprotective Activity

The saponin fraction prepared from the methanolic extract of *Allium chinense* bulbs exhibited inhibitory activities on cyclic AMP phosphodiesterase (cAMP PDE) (43.5 %) and Na⁺/K⁺ ATPase (59.3 %) at a sample concentration of 100 μ g/mL, respectively (Kuroda et al. 1995). The compounds isolated from the extract, (25*R,S*)-5 α -spirostan-3 β -ol tetrasaccharide, showed inhibitory activities on both cAMP PDE and Na⁺/K⁺

ATPase, while (25*R*)-3 β -hydroxy-5 α -spirostan-6-one di- and trisaccharides inhibited only cAMP PDE.

Pretreatment of cultured rat cardiac H9C2 cells with *A. chinense* steroids 24 hours before exposure to 0.2 mM hydrogen peroxide markedly attenuated the cellular injury induced by H₂O₂ (Ren et al. 2010). H₂O₂-elevated lipid peroxidation and increase in intracellular free calcium concentration and the decreased cell viability were reverted by *A. chinense* steroids.

Anticancer Activity

Six compounds were isolated from the anticoagulation and anticancer fractions of *Allium chinense* bulbs (Jiang et al. 1998). Chalcones isolated from *A. chinense* bulbs, isoliquiritigenin and isoliquiritigenin 4-*O*-glucoside, exhibited potential inhibitory activity on 12-*O*-tetradecanoylphorbol-13-acetate (TPA)-stimulated ³²Pi-incorporation into phospholipids of HeLa cells (Baba et al. 2000). Laxogenin showed marked inhibitory activity (82.1 %) at high dose (100 μ g/mL), and isoliquiritigenin showed 100 % inhibition at 50 μ g/mL, while the two saponins xiebai-saponin I and laxogenin 3-*O*- α -arabinopyranosyl (1 $\rightarrow$ 6)- β -glucopyranoside showed strong cytotoxicity to HeLa cells at the same dose. Oral administration of laxogenin reduced the average number of tumours per mouse (75.6 % inhibition) in two-stage murine lung carcinogenesis.

Antifungal Activity

Allium plants including *A. chinense* possessed antifungal activity, with garlic showing the lowest MFC (minimal fungicidal concentration) (Yin and Tsao 1999). With the exception of scallion, the inhibitory effect of *Allium* plants against *Aspergillus niger*, *A. flavus* and *A. fumigatus* decreased with increasing incubation and heating temperature. Acetic acid treatments increased the inhibitory effect for all plants against the three fungi, and there was no significant difference in this effect among the three pH (2, 4, 6) treatments

investigated. The combination of acetic acid plus *Allium* plants was found to be an effective way to inhibit fungal growth.

Traditional Medicinal Uses

Rakkyo plant is astringent, carminative and expectorant and is used in the treatment of stuffiness sensation and pain in the chest, angina pectoris, pleurisy, bronchitis, diarrhoea and tenesmus in cases of dysentery (Yeung 1985).

Allium chinense is used as a folk medicine in tonics to help the intestines and as a stomachic (Duke 1992).

Other Uses

The juice of the plant is used as a moth repellent. The whole plant is said to repel insects and moles (Riotte 1978).

Comments

Several cultivars are being cultivated in China and Japan. In Japan, Tama rakkyo is a small bulb group with 1–25, and the bulbs are ellipsoidal, soft and firm necked; the Rakuda is a large bulb group with 6–9 bulbs per cluster, ellipsoidal with a long neck.

Origin/Distribution

Studies by Hong and Etoh (1996) and Etoh et al. (2001) proposed the Tian Shan mountains in Central Asia to be the primary centre of origin of garlic (*Allium sativum*) and the secondary centre in the Mediterranean and Caucasus zones (Etoh and Simon 2002). The Tian Shan mountain range straddles the border regions of Kazakhstan, Kyrgyzstan and the Xinjiang Uyghur Autonomous Region of western China. *A. sativum* has been postulated to be transported from Central Asia to the Mediterranean and other areas of cultivation (Maaß and Klaas 1995). *Allium longicuspis* Regel is believed to be the progenitor of domesticated garlic, and it occurs within the range of the species *A. sativum* (Maaß and Klaas 1995; Mathew 1996; Etoh and Simon 2002).

Garlic has been domesticated since antiquity and has been mentioned in ancient Egyptian, Babylonian, Greek, Indian and Chinese historical manuscripts. Garlic is also mentioned in the Bible and Qur'an. Today garlic is grown globally in both warm temperate and subtropical areas, and many cultivars have been developed to suit different climates. The main garlic producers based on 2012 production figures are China (20,000,000 tonnes), India (1,150,000 tonnes), Egypt (309,155 tonnes), Republic of Korea (339,113 tonnes), Russian Federation (239,312 tonnes), Bangladesh (233,609 tonnes), Ethiopia (225,548 tonnes), Myanmar (213,000 tonnes), United States (195,910 tonnes), Ukraine (171,400 tonnes), Spain (151,900 tonnes), Argentina (135,000 tonnes) and Brazil (107,009 tonnes) (FAO 2013).

Agroecology

In its native range, *Allium sativum* is found in the following habitats: rocky valleys, riverbeds, streambeds and gullies.

Garlic thrives in well-drained, rich and friable soils in the cooler climates from 9 to 28 °C, and in the tropics it is cultivated in the cooler higher elevations above 1,500 m. For bulb formation a 2-month duration of 10–15 °C is required.

Edible Plant Parts and Uses

Garlic bulbs are used as a spice or condiment in various dishes, raw or cooked. Minced garlic is used raw in salads. Raw garlic appears in quite a multitude of Mediterranean sauces. Notable examples are the Provençal specialty *aïoli*, a mayonnaise based on olive oil and enriched with raw garlic; the Greek *skordalia*, a paste made from cooked potatoes and raw garlic; the Turkish *çaçık*, a refreshing soup made from plain yogurt, shredded cucumber, garlic and peppermint leaves; and the Greek *tsarsiki*, a thick garlic sauce served with barbecued lamb souvlaki. Elsewhere examples include the Chinese salad *suan ni huang-gua* of crunchy cucumber cubes with a dressing of vinegar, sesame oil and garlic, topped with coriander leaves; the Nepal Newari *kochila* of lean buffalo mince mixed with mustard oil and served with loads of raw garlic cloves; grated garlic is used in Vietnamese spring rolls and soups. Fresh garlic is crushed and left in water with added Sichuan pepper to prepare the Tibetan garlic water *gog-chu*. Raw garlic may be pickled in vinegar or oil usually olive. Fried and cooked garlic is commonly used in almost every cuisine of the world in stir-fries with meat, seafood or eggs and in soups, stews, noodles, pastas, curries, pizzas, sauces, mixed spices and pastes. Oils are often flavoured with garlic cloves.

The leaves, immature scapes and inflorescence stalks are eaten as vegetables. Chopped leaves are used in salads, and inflorescence stalks are cut into piece and are used in stir-fries with eggs, meat or other vegetables. The scapes are similarly used or prepared like asparagus and have a milder taste than the cloves. The sprouted seeds are added to salads. In some cuisine, the young bulbs are pickled for 3–6 weeks in a mixture of sugar, salt and spices. In eastern Europe the shoots are pickled and eaten as an appetiser.

Botany

Low, erect annual herb 30–60 cm high with a depressed globose to broadly ovoid solitary bulb up to 6 cm diameter made up of several cloves or bulbils covered with a common membranous, entire whitish to purplish tunic. The cloves comprised a series of functional leaves. Roots are adventitious. Real stem is much reduced to a basal disc at the base of the bulb. Pseudostem is formed by the sheathing bases of the leaves. Leaves broadly linear to linear-lanceolate, shorter than scape, to 2.5 cm wide, apex acuminate, glabrous with smooth margin. The scape is 50–100 cm, erect, terete. Inflorescence is a hemispherical umbel, 2.5–5 cm diameter, comprising numerous bulbils and a few flowers and covered with a membranous spathe that split to one side on opening. Pedicels slender up to 4 cm long. Bracteoles ovate, large, membranous, apex acute. Flowers are sub-campanulate, tepals ovate-lanceolate in two whorls, and up to 4 mm long, greenish purple, stamens in two whorls and pistil globose, tricarpellate, style not exserted. Fruit abortive and without seeds (Plates 1, 2, 3, 4, 5, 6, and 7).

Nutritive/Medicinal Properties

The nutritional value per 100 g of peeled garlic cloves (i.e. 79 % of the dry bulb weight) was reported as: water 64.3 g, energy 411 kJ (98 kcal), protein 7.9 g, fat 0.6 g, carbohydrate 16.3 g, dietary fibre 4.1 g, Ca 19 mg, P 170 mg, Fe 1.9 mg, carotene trace, thiamine 0.13 mg, riboflavin 0.03 mg, folate 5 µg and ascorbic acid 17 mg (Holland et al. 1991). The nutritional composition of garlic bulb per 100 g edible portion was reported as: water 58.58 g; energy 623 kJ (149 kcal); protein 6.36 g; fat 0.5 g; carbohydrate 33.06 g; total dietary fibre 2.1 g; total sugars 1.00 g; ash 1.50 g; Ca 181 mg; Mg 25 mg; P 153 mg; K 401 mg; Na 17 mg; Fe 1.70 mg; Zn 1.16 mg; Cu 0.299 mg; Mn 0.1672 mg; Se 14.2 µg; vitamin C (total ascorbic acid) 31.2 mg; thiamine 0.200 mg; riboflavin 0.110 mg; niacin 0.700 mg; total folate 3 µg; total choline 32 mg; pantothenic acid 0.596 mg; vitamin A 9 IU; β-carotene 5 µg; lutein + zeaxanthin 16 µg; vitamin E (α-tocopherol) 0.08 mg; vitamin K (phylloquinone) 1.7 µg; total saturated fatty acids 0.089 g, 10:0 0.002 g; 16:0 (palmitic acid) 0.087 g; total monounsaturated fatty acids 0.011 g; 18:1 undifferentiated (oleic acid) 0.011 g; total polyunsaturated fatty acids 0.249 g, 18:2 undifferentiated (linoleic acid) 0.229 g, 18:3 undifferentiated (linolenic acid) 0.020 g; and amino acids, tryptophan 0.066 g, threonine 0.157 g, isoleucine 0.217 g, leucine 0.308 g, lysine 0.273 g, methionine 0.076 g, cystine 0.065 g, phenylalanine 0.183 g, tyrosine 0.081 g, valine 0.291 g, arginine 0.634 g, histidine 0.113 g, alanine 0.132 g, aspartic acid 0.489 g, glutamic acid 0.805 g, glycine 0.200 g, proline 0.100 g and serine 0.190 g (USDA, ARS 2014).

Selenium level was found to be 0.015 µg/g for garlic (Izgi et al. 2006). An essential fatty acid, ethyl linoleate, was isolated from the garlic cloves (Park et al. 2014). Garlic had been reported to contain 0.41 % phosphorus to constitute more than 10 % of its ash (Anantakrishnan and Venkataraman 1940). Garlic was also found to contain 30.5 % of total phosphorus as phytin which comprised the major fraction of barium-precipitable acid-soluble phosphorus. This fraction

largely composed of the resistant hexose monophosphate 65 %, and labile phosphorus compounds 35 %, whose nature was not identified. Crude protein, dimethyl sulfite and essential oil contents were determined as 17.2 %, 1,779 µg/kg and 0.14 %, respectively, in garlic bulb (Hacıseferoğulları et al. 2005). In addition, K (21,378.84 mg/kg), P (6,009.37 mg/kg), Mg (1,056.15 mg/kg), Na (532.78 ppm) and Ca (363.61 ppm) were reported as the major minerals in garlic bulbs. Six water-soluble vitamins including thiamine (B1), riboflavin (B2), niacin (B3), pantothenic acid (B5), pyridoxine (B6) and cobalamin (B12) were separated from different garlic extracts (Abd Al-Timimi et al. 2013). The highest concentration belongs to vitamin B3 (niacin) in all types of aqueous garlic extracts, Iraqi, Iranian, Lebanese, French and Chinese aqueous garlic extracts, but the highest level concentration was in Iraqi garlic extract (15.58) ppm.

Lipids

Total lipid ranged from 310 to 342 mg/100 g in fresh garlic (Yang and Shin 1982). These lipids were shown to consist of 36.4–43.5 % neutral lipids, 20.3–24.3 % glycolipids and 36.2–39.3 % phospholipids. Among the neutral lipids, triglycerides were predominant (80.5–83.6 %) and esterified steryl glycosides and steryl glycosides were major sugar-containing lipids. Of the phospholipids, phosphatidyl cholines and serines and phosphatidyl ethanolamines were the major components, comprising over 85 % of this class. The major fatty acids in the total and lipids classes were linoleic, palmitic, oleic and linolenic acid. Eighty percent of the total lipids of *Allium cepa*, *Allium sativum* and *Allium porrum* were found to consist of four fatty acids: linoleic (46–53 %), palmitic (20–23 %), oleic (4–13 %) and α -linolenic acid (3–7 %) (Tsiaganis et al. 2006). In garlic, 70 fatty acids are determined, 14 of that above 0.4 % and only 4 above 2.5 %. Phospholipids consisted of a limited number of specific fatty acids, while neutral lipids contained a wide range including some unusual fatty acids.

Garlic lipids comprised 62.6 % neutral lipids (NL), 14.0 % glycolipids and 23.4 % phospholipids (PL) (Kamanna and Chandrasekhara 1980). Garlic lipids contained a considerably

high percentage of polar lipids. The fatty acid composition of the total lipids (TL) and component fractions showed that palmitic, oleic, linoleic and linolenic acids constituted the major fatty acids; capric, lauric, myristic and stearic acids amounted to about 6 % in all the lipid fractions. The unsaturated fatty acids together amounted to 72–80 %, and among these, linoleate was predominant in total lipids as well as in the NL and PL fractions. The glycolipid fraction was richer in linolenate (37.5 %) compared to 4–9.5 % in TL, NL and PL. Neutral lipids of garlic contained considerable quantities of monoglycerides (18.5 %), diglycerides (14.2 %), sterols (16.3 %) and triglycerides (41.5 %), respectively (Kamanna and Chandrasekhara 2006). The phospholipid fraction was rich in phosphatidyl choline (23.5 %), phosphatidyl ethanolamine (17.9 %), lysophosphatidyl choline (11.8 %) and lysophosphatidyl ethanolamine (8.2 %). Digalactosyl diglyceride (10.1 %), sterol glycoside (15.6 %), cerebrosides (8.1 %), acylsterol glycoside (38.6 %) and monogalactosyl diglyceride (22.5 %) were the major components of the glycolipids of garlic. Lauric, myristic, palmitic and linoleic acids constituted the major fatty acids of monoglycerides, diglycerides and free fatty acid fractions, whereas palmitic, linoleic and linolenic acids were the major fatty acids of triglycerides. Palmitic and linoleic acids were the major fatty acids of garlic phospholipids. Except the acylsterol glycoside fraction glycolipids were rich in lauric, palmitic, linoleic and linolenic acids; palmitic acid was the only major fatty acid of acylsterol glycosides.

Fructans/Polysaccharides/Peptides/Protein

Hot water extraction of defatted garlic bulbs yielded a mixture of polysaccharides containing a D-galactan, a D-galacturonan, an L-arabinan, a D-glucan and a D-fructan (Das and Das 1977). A trace of L-rhamnose was also detected in the polysaccharide hydrolysate. The fructan component contained fructose (94.4 %) and glucose (4.3 %) (Das and Das 1978). Methanolysis and hydrolysis of the permethylated fructan gave (a) 1,3,4,6-tetra-O-methyl-D-fructose, (b) 2,3,4,6-tetra-O-methyl-D-glucose, (c) 2,4,6-tri-O-methyl-D-glucose and (d) 3,4,6-tri-O-methyl-d-

fructose. On periodate oxidation, the fructan reduced one molar equivalent of the oxidant per hexosyl residue and liberated one molar equivalent of formic acid per 51 hexosyl residues. In *Allium cepa* (cv. Creamgold), *A. cepa* (cv. Bunching Onion), *A. porrum* (leek) and *A. sativum* (garlic), fructans were the only nonstructural carbohydrates detected apart from glucose, fructose and sucrose (Darbyshire and Henry 1981). *A. sativum* was different from the rest in that larger polymers of fructans were present, reaching a (degree of polymerisation) DP of 50. The trisaccharides, 1^F-fructosylsucrose and 6^G-fructosylsucrose, were found in all species. *A. cepa* and *A. sativum* contained similar fructan: fructan fructosyltransferases. Enzymes from both plants transferred fructosyl residues from trisaccharide to form tetrasaccharide and sucrose as the major products. Xyloglucans were isolated from the cell walls of bulbs of onion (*Allium cepa*), garlic (*Allium sativum*) and their hybrid (Ohsumi and Hayashi 1994). The polysaccharides yielded single peaks upon gel filtration with average molecular weights of 65,000 for onion, 55,000 for garlic and 82,000 for the hybrid. The polysaccharides were constructed of four kinds of a repeating oligosaccharide unit, namely, a decasaccharide (glucose/xylose/galactose/fucose, 4:3:2:1), a nonasaccharide (glucose/xylose/galactose/fucose, 4:3:1:1), an octasaccharide (glucose/xylose/galactose, 4:3:1) and a heptasaccharide (glucose/xylose, 4:3). The xyloglucan from the hybrid contained highly fucosylated units that resembled those from onion rather than from garlic. Garlic cloves contained a high concentration of oligo- and polyfructosaccharides, ranging from 125 to 235 mg/g, on a wet weight basis (Losso and Nakai 1997). Fructose–glucose ratio in the fructooligo/fructopolysaccharides was about 15:1. Molecular masses of fructans ranged from less than 1,000 Da to around 4,500 Da, corresponding to DP as high as 38. A high molecular weight fructan belonging to the neo-ketose family was isolated from garlic (Baumgartner et al. 2000). Garlic fructan, an insulin-type fructan, possessed a (2→1)-linked β-D-Fruf backbone with (2→6)-linked β-D-Fruf side chains with a degree of polymerisation of about 58. Zhang et al. (2012b) isolated a low molecular weight fructooligosaccharide

(LMWF) from garlic. LMWF was a neo-ketose with a molecular weight of 1,770 Da and had a (2,1)-linked β -D-Fruf backbone with (2,6)-linked β -D-Fruf side chains, and it was mainly composed of fructose. Both high molecular weight (>3.5 kDa; HF) and low molecular weight (<3 kDa; LF) fructans were isolated from aged garlic extract (Chandrashekar et al. 2011). Both have (2 $\rightarrow$ 1) β -D-fructofuranosyl bonds linked to a terminal glucose at the non-reducing end and β -D-fructofuranosyl branching on its backbone.

The composition of fructooligosaccharides (FOS), together with glucose, fructose and sucrose, had been determined in commercial dehydrated samples of onion and garlic (Cardelle-Cobas et al. 2009). No qualitative differences were detected among the FOS identified in both onion and garlic. Results showed a lower FOS content in garlic than in onion in all samples analysed. In garlic samples, FOS with a degree of polymerisation from 3 to 7 were identified and quantified for the first time. Considering FOS fraction, trisaccharides: 1-kestose (1_F - β -D-fructofuranosylsucrose), neokestose (6^G - β -D-fructofuranosylsucrose); tetrasaccharides: nystose [1_F (1- β -D-fructofuranosyl) $_2$ sucrose], 6^G (1- β -D-fructofuranosyl) $_2$ sucrose and 1_F (1- β -D-fructofuranosyl)- 6^G (1- β -D-fructofuranosyl) sucrose; pentasaccharides: 1_F (1- β -D-fructofuranosyl) $_3$ sucrose, 6^G (1- β -D-fructofuranosyl) $_3$ sucrose, 1_F (1- β -D-fructofuranosyl) $_2$ - 6^G (1- β -D-fructofuranosyl) sucrose and 1_F (1- β -D-fructofuranosyl)- 6^G (1- β -D-fructofuranosyl) $_2$ sucrose; hexasaccharides: 1_F (1- β -D-fructofuranosyl) $_4$ sucrose, 6^G (1- β -D-fructofuranosyl) $_4$ sucrose, 1_F (1- β -D-fructofuranosyl) $_3$ - 6^G (1- β -D-fructofuranosyl) sucrose, 1_F (1- β -D-fructofuranosyl)- 6^G (1- β -D-fructofuranosyl) $_3$ sucrose and 1_F (1- β -D-fructofuranosyl) $_2$ - 6^G (1- β -D-fructofuranosyl) $_2$ sucrose; and heptasaccharides: 1_F (1- β -D-fructofuranosyl) $_5$ sucrose were found in onion and in garlic samples.

Alliin lyase was purified up to sevenfold from garlic bulb homogenates (Mazelis and Crews 1968). Alliin lyase purified from garlic was found to have a molecular mass of 108,000

and to consist of two equal subunits (Jansen et al. 1989). The enzyme was found to be thermolabile. The activities of γ -glutamyl transpeptidase/ γ -glutamyl peptidase enzymes were determined in sprouted garlic bulbs (Ceci et al. 1992). A novel amino acid glycoside (–)-*N*-(1'-deoxy-1'- β -d-fructopyranosyl)-*S*-allyl-L-cysteine sulfoxide was isolated from a hydrophilic extract of garlic leaves (Mütsch-Eckner et al. 1993). Fractions of garlic aqueous extract with high angiotensin I-converting enzyme (ACE) inhibitory activity yielded seven dipeptides with ACE inhibitory properties (Suetsuna 1998). These dipeptides were identified as Ser–Tyr, Gly–Tyr, Phe–Tyr, Asn–Tyr, Ser–Phe, Gly–Phe and Asn–Phe. (*R*)-3-(allylthio)-2-((*R*)-3-(allylthio)-2-aminopropanamido)propanoic acid, a dipeptide, was isolated from garlic bulb, together with four known amino acids (Zhou et al. 2014a). Garlic polysaccharide was modified by the HNO₃–Na₂SeO₃ method to obtain nine selenising garlic polysaccharides, sGPS1–sGPS9 (Qiu et al. 2014).

Two novel lectins were isolated from garlic roots and leaves (Smeets et al. 1997b). The leaf lectin ASAL was a dimer of two identical subunits of 12 kDa, which closely resembled the leaf lectins from onion, leek and shallot with respect to its molecular structure and agglutination activity. In contrast, the root lectin ASARI was a dimer of subunits of 15 kDa, strongly different from the leaf lectin with respect to its agglutination activity. cDNA cloning of the leaf and root lectins revealed that the deduced amino acid sequences of ASAL and ASARI were virtually identical. Garlic bulb contained both heterodimeric mannose-binding lectins ASAI (*Allium sativum* agglutinin I) and homodimeric lectin ASAIL (*Allium sativum* agglutinin II) (Smeets et al. 1997a). It was found that only the heterodimeric lectin ASAI was capable of binding to the glycan chains of the alliinase molecule in garlic bulb. It appeared that only a subpopulation of the alliinase molecules was involved in the formation of lectin–alliinase complexes and that the complexed alliinase contained more glycan chains than the free enzyme. Dam et al. (1998) also purified two mannose-binding lectins, *Allium sativum* agglutinin (ASA) I (25 kDa) and ASAIL (48 kDa), from garlic bulbs. Both ASAI and ASAIL comprised of 12.5- and 11.5-

kDa subunits. In addition, a complex (136 kDa) comprising a polypeptide chain of 54 kDa and the subunits of ASAI and ASAIII eluted earlier than these lectins on gel filtration. The 54-kDa subunit was confirmed to be alliinase, known to form a complex with garlic lectins. Constituent subunits of ASAI and ASAIII exhibited the same sequence at their amino termini. The potencies of the ligands for ASAs increased in the following order: mannobiose (Man α 1-3Man) < mannotriose (Man α 1-6Man α 1-3Man) approximately mannopentaose << Man₉-oligosaccharide. Interaction with glycoproteins suggested that these lectins recognised internal mannose as well as bind to the core pentasaccharide of N-linked glycans even when they were sialylated. Glycosylated dimeric alliinase was purified to homogeneity from garlic (Kuettner et al. 2002).

Agglutinins of 110 and 25 kDa (ASA110 and ASA25) were isolated from garlic (Gupta and Sandhu 1997). ASA25 was a dimeric protein comprising of subunits of 12.5 and 13.0 kDa and ASA110 a glycoprotein of two identical subunits of 47 kDa. ASA110 had a high content of aspartic acid, glycine, leucine and serine but low content of cysteine and methionine. It contained 14 residues of neutral sugars in addition to 43 residues of hexosamines per mole of lectin and requiring metal ions for its functional conformation. Serological cross-reactions with other species showed some common epitopes of ASA110 and ASA25 present in *A. porrum*, *A. ascalonicum*, *Narcissus alba*, PHA and Con A but not in *A. cepa*. ASA110 with CHO cells indicated it to be weakly cytotoxic with LD₅₀ of 160 μ g/mL. Results from in-vitro analysis indicated a higher homology of garlic LECASAI lectin with those of insecticidal lectins and the presence of mannose-binding region in LECASAI (Gogia et al. 2014).

The garlic plant alliinase, which catalyses the synthesis of allicin, was purified to homogeneity from garlic bulbs (Rabinkov et al. 1994). The enzyme was found to be a glycoprotein containing 6 % carbohydrate and a dimer of two subunits of MW 51.5 kDa each. 13-hydroperoxide-specific divinyl ether synthase activity was found in the microsomal fraction of garlic bulbs (Grechkin and Hamberg 1996). The

enzyme was found to utilise 13(*S*)-HPOD as its preferential substrate and possessed stereoselectivity, utilising preferentially the (*S*)-enantiomer. A protein-designated alliumin, with a molecular mass of 13 kDa and an N-terminal sequence similar to a partial sequence of glucanase, was isolated from garlic cloves (Xia and Ng 2005). Phospholipase D bulbs (PLD_{GB}) were identified and partially characterised from garlic (Khatoon et al. 2008). PLD_{GB} exhibited both hydrolytic and transphosphatidylolation activities, both of which appeared to be higher than those of PLD from cabbage leaves. Garlic extract and its protein fraction significantly and dose dependently augmented oxidative burst of T-lymphocyte (Lau et al. 1991). The protein fraction also enhanced the T-lymphocyte blastogenesis. The data suggested that garlic compounds may serve as biological response modifiers by augmenting macrophage and T-lymphocyte functions. Two major proteins (12–14 kDa) were detected in aged garlic extract; the purified protein components QA-1, QA-2 and QA-3 displayed immunomodulatory and mannose-binding activity (Chandrashekar and Venkatesh 2009). Three protein components of molecular weight ~13 kD (QR-1, QR-2 and QR-3 in the ratio 7:28:1) were separated from raw garlic extract (Clement et al. 2010). Studies indicated that characteristics of major proteins QR-2 and QR-1 present in a ratio of 4:1 in raw garlic were markedly similar to the abundant *Allium sativum* agglutinins (ASA) I and II, respectively (Clement et al. 2010; Clement and Venkatesh 2010). The two proteins actin and myosin were found to be co-localised and closely linked to each other in plasmodesmata- and ectodesmata-like structure in ageing parenchymatous cells of *Allium sativum* (Dong et al. 2011). A cellulase gene from garlic was cloned and characterised in gene and protein levels (Kim et al. 2010). The DNA sequence of the garlic cellulase gene showed 81 % identity with the sequence of the endo- β -1,4-glucanase of *Pisum sativum*. A superoxide dismutase was purified and characterised from garlic (Liu et al. 2011). The native enzyme was homodimeric and had a native molecular mass of 28 kDa. A 47-kDa protein was extracted from aged garlic (Ahmadabad et al. 2012).

Phenolic Compounds/Flavonoids/Anthocyanins

Cyanidin 3-*O*-glucoside was the main anthocyanin in the external layer of garlic clove (Du and Francis 1975). Acidified methanolic extract of inner scale leaves of garlic contained mostly anthocyanins with aliphatic acylation. These are the rare 3'',6''-dimalonylglucoside (13 %) and 3''-malonylglucoside (3 %) of cyanidin, in addition to cyanidin 3-(6''-malonylglucoside) (71 %) and cyanidin 3-glucoside (12 %) (Fossen and Andersen 1997).

Low-temperature (5 °C) conditioning of garlic 'seed' cloves accelerated the development of the crop cycle, decreased plant growth and increased the synthesis of phenolic compounds and anthocyanins in the outer scale leaves of the bulbs at harvest time, leading to 3-fold content increase compared with those conditioned at room temperature (Dufooo-Hurtado et al. 2013). Cold conditioning of 'seed' cloves also altered the anthocyanin profile during bulb development and at harvest. On both sampling dates (122 and 158 days after sowing(DAS)), total phenolic content was higher in cloves conditioned at 5 °C (3.25 and 1.87 mg GAE/g of freeze-dried cataphylls, respectively) than in cloves sampled at (122 and 200 DAS) stored at room temperature (2.61 and 0.61 mg GAE/g of freeze-dried cataphylls, respectively). Similarly total anthocyanin content was higher in cloves conditioned at 5 °C (1.156 and 0.380 mg C3G/g of freeze-dried cataphylls, respectively) than in cloves stored at room temperature (0.89 and 0.103 mg C3G/g of freeze-dried cataphylls, respectively). Five anthocyanins were identified in the outer scale leaves of garlic bulbs cv Coreano: cyanidin 3-*O*- glucoside (C3G), cyanidin 3-*O*-(3''-malonyl) glucoside, cyanidin 3-*O*-(3''-acetyl) glucoside, cyanidin 3-*O*-(6''-malonyl) glucoside and cyanidin 3-*O*-(6''-malonyl acetyl) glucoside. Putative genes involved in the biosynthesis of anthocyanins and phenolic compounds in garlic sprouts were identified as phenylalanine ammonia lyase, cinnamate 4-hydrolyase, 4-coumarate-CoA ligase, UDP-glucose–flavonoid 3-*O*-glycosyltransferase and sucrose–sucrose 1-fructosyltransferase. The high phenolics

and anthocyanin contents in bulbs of plants generated from 'seed' cloves conditioned at 5 °C for 5 weeks were preceded by the overexpression of some putative genes of the phenolic metabolism (6-fold for phenylalanine ammonia lyase) and anthocyanin synthesis (1-fold for UDP-glucose–flavonoid 3-*O*-glycosyltransferase) compared with those conditioned at room temperature.

The bulbs of garlic contained only few milligrams of glycosides of kaempferol and quercetin per kg fresh weight (Starke and Herrmann 1976). Four flavonols quercetin 3-*O*-β-d-glucopyranoside (isoquercitrin), quercetin 3-*O*-β-d-xylopyranoside (reynoutrin), kaempferol 3-*O*-β-D-glucopyranoside (astragalin) and isorhamnetin 3-*O*-β-D-glucopyranoside and their aglycones quercetin, kaempferol and isorhamnetin were isolated from garlic leaf and shoot (Kim et al. 2005). Garlic contained the flavonols kaempferol 0.3 mg, myricetin 1.6 mg and quercetin 1.7 mg (Kevers et al. 2007).

The total phenolic content in garlic varied from 3.4 mg to 10.8 mg gallic acid equivalents (GAE)/g with a mean value of 6.5 mg GAE/g dm (Beato et al. 2011). The myricetin, quercetin, kaempferol and apigenin flavonoids were not detected in any of the samples. Caffeic acid and ferulic acid were the major phenolic acids found with mean values of 2.9 mg/kg dm and 2.6 mg/kg dm, respectively. The mean contents of vanillic, *p*-hydroxybenzoic and *p*-coumaric acids were comparable (0.4–0.8 mg/kg of dm), and the level of sinapic acid was negligible (<0.1 mg/kg of dm). There was a significant effect of location but an insignificant effect of genotype on contents of caffeic, vanillic, *p*-hydroxybenzoic and *p*-coumaric acids. However, genotype but not location affected the contents of total phenolics and ferulic acid. On average, the white garlic cultivars and Chinese garlic cultivars contained higher contents of total phenolics and ferulic acid than the purple garlic cultivars. However, the differences in the total phenolic content between the purple and white garlic cultivars were not significant. The following major phenolic compounds were identified and quantified (mean values) in garlic: flavonol quercetin 13.9 mg/kg, phenolic acids caffeic

acid 7.2 mg/kg and ferulic acid 3.5 mg/kg and flavone apigenin 1.9 mg/kg DW (Alarcón-Flores et al. 2014).

Black garlic was produced in a ripening chamber by using a programmed stepwise heating schedule, and the total phenolic content (TPC) and total flavonoid content (TFC) of the garlic subjected to different thermal processing steps were higher than those of fresh garlic (Kim et al. 2013).

Hydroxycinnamic acid derivatives were found to be the major phenolic acids of garlic at different processing steps. Among the four major flavonoid subgroups in garlic, flavonols were found at the highest concentrations followed by flavanones and flavones, except in the fresh garlic sample.

Sulfur Compounds

Cavallito et al. (1944, 1945; Stoll and Seebeck 1949, 1951) showed that garlic contained S-allylcysteine sulfoxide (alliin) and an enzyme alliinase which acted on alliin, generating diallyl thiosulfinate (allicin) $\text{CH}_2=\text{CH}-\text{CH}_2\text{S}(=\text{O})-\text{SCH}_2-\text{CH}=\text{CH}_2$. Addition of S-allyl-L-cysteine markedly increased the level of alliin in both shoot-forming and root-forming callus tissues of *A. sativum* (Ohsumi et al. 1993). The content of alliin and other S-alk(en)ylcysteine sulfoxides was determined in nine different samples of garlic (*Allium sativum* L.) originating from the Czech Republic, France and China (Kubec et al. 1999). The total content of S-alk(en)ylcysteine sulfoxide pool ranged between 0.53 and 1.3 % fresh weight, with S-allylcysteine sulfoxide (alliin) being predominant. A novel S-alkylcysteine derivative, S-ethylcysteine sulfoxide (ethiin), not previously reported to occur in *Allium* species, was found in some of the garlic samples.

Allithiamine, a newly found derivative of vitamin B1 (thiamine), was first identified in heated garlic in 1950 (Fujiwara et al. 1954). It was later confirmed that similar compounds could be formed using other *Allium* vegetables from compounds similar to allicin, and a study in rabbits appeared to show that allithiamines were formed in situ in the intestine in the presence of garlic and thiamine (Fujiwara 1976). Methyl, ethyl and propyl derivatives of alliin, allicin

and allithiamine were identified in garlic and other *Allium* (Fujiwara et al. 1958). (–) *S*-Allyl-L-cysteine (Suzuki et al. 1962), (–) *S*-propenyl-L-cysteine (Sugii et al. 1963), γ -L-glutamyl-*S*-allylmercapto-L-cysteine and *S*-allylmercapto-L-cysteine (Sugii et al. 1964) were isolated from garlic bulb. A thioglycoside scordinin A₁ was isolated from boiled garlic, and its structure was elucidated as R-CH: CH-CH₂-S-C₆H₈O₆ · 1/2Ca, in which R was a peptide containing a new amino acid and the carbohydrate part was calcium fructuronate (Kominato 1969a). On acid hydrolysis of scordinin A₁, fructuronic acid was detected, and by garlic enzyme allyl mercaptan was confirmed (Kominato 1969b). On hydrolysis with barium hydroxide, one kind of peptide, scormin, was isolated. From the results, the author postulated that allyl thiofructuronic acid combined with scormin to form scordinin A₁. Diallyl thiosulfinate was found to be a major constituent of solvent extracted garlic (Brodnitz et al. 1971). On dehydration, it formed two isomeric disulfides. At room temperature it undergoes a rearrangement. After 24 hours, sulfur dioxide, diallyl mono-, di- and trisulfides were the major products.

Two γ -glutamyl-*S*-alkylcysteines, namely, γ -glutamyl-*S*-*trans*-1-propenyl cysteine and γ -glutamyl-*S*-allylcysteine, were found to be in homogenates of fresh picked garlic cloves; both were found to decrease markedly when fresh picked garlic was stored at 4 °C (Lawson et al. 1991a). Six *S*-alk(en)yl-L-cysteine sulfoxides and γ -L-glutamyl-*S*-alk(en)yl-L-cysteines including (+)-*S*-allyl-L-cysteine sulfoxide, γ -L-glutamyl-*S*-allyl-L-cysteine and γ -L-glutamyl-*S*-(*trans*-1-propenyl)-L-cysteine were found in garlic (Mütsch-Eckner et al. 1992b). Four γ -glutamyl peptides were isolated from a hydrophilic extract of garlic bulbs: γ -L-Glutamyl-*S*-(*trans*-1-propenyl)-L-cysteine; γ -L-glutamyl-*S*-allyl-L-cysteine; γ -L-glutamyl-*S*-(*trans*-1-propenyl)-L-cysteine; and γ -L-glutamyl-*S*-allylthio-L-cysteine (Mütsch-Eckner et al. 1992a). Among glutamyl peptides, γ -glutamyl-*S*-allyl-L-cysteine (GSAC) and γ -glutamyl-*S*-*trans*-1-propenyl-L-cysteine (GSPC), γ -glutamyl-*S*-*trans*-1-propenyl-L-cysteine (GSPC) was predominant, followed by γ -glutamyl phenylalanine (γ GPA) in garlic cloves (Yoo et al. 2010). The contents of GSAC, GSPC and γ GPA

were a range of 13.04–23.51, 17.40–27.00 and 5.51–9.62 mg/g garlic (dry weight), respectively. γ -Glutamyl-*S*-methyl-L-cysteine (GSMC) was present in a small amount (0.85–1.39 mg/g garlic). The content of alliin, the most abundant sulfur compound in whole garlic, was 25.65–30.03 mg/g garlic. The amount of allicin, a major bioactive compound of garlic and garlic preparations, was 3.25–4.60 mg/g garlic. The contents of *S*-allylcysteine (SAC) and *S-trans*-1-propenyl-L-cysteine sulfoxide (isoalliin) were 0.36–0.60 and 0.14–0.54 mg/g garlic, respectively. *S-trans*-1-propenyl-L-cysteine (SPC) was found only in trace amounts in raw garlic bulbs. There was a significant effect of the location, cultivar and garlic ecotype on the contents of the following organosulfur compounds studied, three γ -glutamyl peptides, namely, γ -L-glutamyl-*S*-(2-propenyl)-L-cysteine (GSAC), γ -L-glutamyl-*S*-(*trans*-1-propenyl)-L-cysteine (GSPC) and γ -L-glutamyl-*S*-methyl-L-cysteine (GSMC) and four cysteine sulfoxides (alliin, isoalliin, methiin and cycloalliin) (Montaño et al. 2011). Purple-type cultivars showed on average the highest contents of GSMC, GSAC, alliin and methiin but the lowest isoalliin content. The impact of genotype was relatively high for GSAC, whereas this factor hardly contributed to the total variability in alliin and isoalliin content. Planting date had a significant effect on the content of alliin and isoalliin.

According to Block (1992) most of the nonprotein sulfur in *Allium* could be found in the form of four principal ACSOs: methyl (MeCSO), 2-propenyl (2-PeCSO), 1-propenyl (1-PeCSO) and propenyl (PeCSO). 1-PeCSO was found in the highest concentration in onions, and 2-PeCSO was found in the highest concentrations in garlic with only trace amounts in onions. Among three common *Allium* crops, the total ACSO concentration was generally highest in garlic, intermediate in onion and lowest in leek (Block 1992; Coley-Smith 1986). Of eight *Allium* species, garlic and giant garlic contained the greatest amounts of total *S*-alk(en)yl-L-cysteine sulfoxides (ACSO) (5.0–11.7 mg/g); Chinese chive, dehydrator onion, leek and shallot had moderate amounts (2.0–5.0 mg/g), and Japanese bunching onion, onion (TG 1015Y) and chive leaves contained the least amounts of total CSO (<2 mg/g) (Yoo and Pike 1998). AlCSO (*S*-allyl-L-cystine sulfoxide, alliin) was the

major precursor in garlic and giant garlic (3.2–9.8 mg/g) and was also contained in chive and Chinese chive. PeCSO (*S*-propenyl-L-cysteine sulfoxide) was the main flavour precursor in onion, green onion, leek and shallot (0.3–2.2 mg/g), but also found in chive, Chinese chive, garlic and giant garlic. MeCSO (*S*-methyl-L-cysteine sulfoxide) was a major precursor in chive and Chinese chive (0.68–1.85 mg/g fresh wt.) and found in all eight species examined with less amounts. *S*-propyl CSO, however, was not found in any of these species. Allison et al. (2006a) reported aged garlic extract to be a complex mixture containing allin, cycloalliin, *S*-allyl-L-cysteine, *S*-methyl-L-cysteine, *S*-ethylcysteine, *S*-1-propenyl-L-cysteine, *S*-allylmercapto-L-cysteine, fructosyl-arginine, β -chlorogenin, L-arginine, L-cysteine and L-methionine.

Unsaturated acyclic sulfur-containing components may consist up to more than 70 % of the garlic oil (Kimbaris et al. 2006). Infrared spectra and relative retention volumes were used to confirm the production of asymmetric disulfides, methyl-allyl, methyl-*n*-propyl and allyl-*n* propyl compounds by *Allium sativum* (Jacobsen et al. 1964). Two new sulfur-containing amino acids γ -glutamyl-*S*-allylmercapto-L-cysteine and *S*-allylmercapto-L-cysteine were isolated from garlic bulbs (Sugii et al. 1964). A novel amino acid glycoside (–)-*N*-(1'-deoxy-1'- β -D-fructopyranosyl)-*S*-allyl-L-cysteine sulfoxide, together with three known compounds: (+)-*S*-allyl-L-cysteine sulfoxide, (+)-*S*-methyl-L-cysteine sulfoxide and (+)-*S*-(*trans*-1-propenyl)-L-cysteine sulfoxide, were isolated from a hydrophilic extract of garlic leaves (Mütsch-Eckner et al. 1993).

Potent antiplatelet compounds were isolated from garlic bulbs: diallyl trisulfide, 2-vinyl-1,3-dithiin and allyl 1,5-hexadienyltrisulfide (Apitz-Castro et al. 1983). Garlic extracts contained a compound termed ajoene, which was found to be a potent inhibitor of platelet aggregation (Block et al. 1984, 1986). The structure of ajoene was determined to be (*E* and *Z*)-4, 5, 9-trithiadodeca-1,6,11-triene 9-oxide. Ajoene was proposed to be formed by *S*-thioallylation of alliin, followed by Cope-type elimination and readdition of 2-propenesulfenic acid. Ajoene was reported to be produced most efficiently

from pure allicin and possessed the advantage of a greater chemical stability than allicin (Hassan 2004). Other ajoene-type organosulfur compounds *Z*-4,5,9-trithiadeca-1,6-diene-9-oxide (*Z*-10-devinylajoene; *Z*-10-DA) (Yoshida et al. 1998) and *E*-4,5,9-trithiadeca-1,7-diene-9-oxide, (iso-*E*-10-devinylajoene, iso-*E*-10-DA) were isolated from oil-macerated garlic extract (Yoshida et al. 1999a). The latter compound was different from *E*-4,5,9-trithiadeca-1,6-diene-9-oxide (*E*-10-devinylajoene, *E*-10-DA) only in the position of a double bond.

Three thiosulfinates were isolated from oil-macerated garlic extract, and their structures were identified as 2-propene-1-sulfinothioic acid *S*-(*Z,E*)-1-propenyl ester [AllS(O)SPn-(*Z,E*)], 2-propenesulfinothioic acid *S*-methyl ester [AllS(O)SMe] and methanesulfinothioic acid *S*-(*Z,E*)-1-propenyl ester [MeS(O)SPn-(*Z,E*)] (Yoshida et al. 1999b). A novel antifungal protein, designated allivin, with molecular weight of 13 kDa was isolated from garlic bulbs (Wang and Ng 2001). Three known compounds, *bis*-2-propenyl trisulfide, *bis*-2-propenyl tetrasulfide and *bis*-2-propenyl pentasulfide; two novel compounds, *bis*-2-propenyl thiosulfonate and *trans*-sulfuric acid allyl ester 3-allylsulfanyl-allyl ester (Hu et al. 2002); and *trans*-sulfurous acid allyl ester 3-allylsulfanyl-allyl-ester; 2-propene-1-sulfinothioic acid-*S*-methyl ester and 2-propene-1-sulfinothioic acid-*S*-(*E*)-1-propenyl ester were isolated from an aqueous ethanol garlic extract (Yang et al. 2003).

Sulfur metabolism of onions, garlic and chives differed in some but not all respects from that in other plants (Granroth 1970). The cysteine formed was not stored but reacted further to give various *S*-substituted derivatives of which *trans*-(+)-*S*-(propen-1-yl)-L-cysteine sulfoxide (CSO) was the most efficiently accumulated, and this compound appeared to be the most important precursor of the flavour substances in onion, garlic and chive. 1-Propenyl-L-cysteine sulfoxide (PeCSO) was the main flavour precursor in onion, green onion, leek and shallot (0.3–2.2 mg/g), but also found in chive, Chinese chive, garlic and giant garlic (Yoo and Pike 1998). *trans*-(+)-*S*-(propen-1-yl)-L-cysteine sulfoxide (CSO) was also found to be

an important precursor of the flavour substances in onion, garlic and chive. *S*-methylcysteine sulfoxide (MeCSO) was a major precursor in chive and Chinese chive (0.68–1.85 mg/g fresh wt.) and found in garlic, onion and leek in lesser amounts. Four nonvolatile, odourless *S*-alk(en)yl cysteine sulfoxides (CSOs) were reported as the precursors of the flavour and odours of the *Allium* (Jones et al. 2004). These were *S*-methylcysteine sulfoxide (MeCSO, methiin; present in garlic, onion and other *Allium*), *S*-allylcysteine sulfoxide (ACSO, alliin; characteristic of garlic), *S-trans*-prop-1-enyl cysteine sulfoxide (PeCSO, isoalliin; characteristic of onion) and *S*-propyl cysteine sulfoxide (PCSO, propiin; in onion, garlic and related species). The enzyme alliinase had been reported to cleave these precursors to give pyruvate, ammonia and a thiosulfinate. The lachrymatory effect, that is, characteristic of onions was caused by the volatile product propanethial *S*-oxide (Brodnitz et al. 1971). The lachrymatory factor was reported to be generated by the activity of a second enzyme, lachrymatory factor synthase, following alliinase action on PeCSO, the major flavour precursor of onion (Imai et al. 2002). As well as CSOs, several γ -glutamyl peptide (γ GP) derivatives of these flavour compounds had been detected within the *Allium* (Whitaker 1976). Over 17 types had been isolated (Granroth 1970), including γ -glutamyl-*S*-alk(en)yl glutathiones, γ -glutamyl-*S*-alk(en)yl cysteines and γ -glutamyl-*S*-alk(en)yl cysteine sulfoxides, all proposed to derive from glutathione (γ -glutamyl cysteinyl glycine). However they did not appear to contribute directly to flavour. Granroth (1970) confirmed that onion could hydrolyse *S*-2-carboxypropyl glutathione and that, in onion leaf tissue, *S*-2-carboxypropyl cysteine was rapidly converted to PeCSO. *S*-methylcysteine, *S*-ethylcysteine, *S*-propyl cysteine and *S*-propenyl cysteine could all be oxidised to the corresponding sulfoxide by onion leaf tissue (Granroth 1970). Methacrylate was proposed as the precursor of the allyl, propyl and propenyl groups (Granroth 1970). Whole garlic typically contains ~1 % alliin, together with (+)-*S*-methyl-L-cysteine sulfoxide (methiin) and (+)-*S*-(*trans*-1-propenyl)-L-cysteine sulfoxide. *S*-(2-Carboxypropyl)glutathione, γ -glutamyl-*S*-allyl-L-cysteine, γ -glutamyl-*S*-(*trans*-1-propenyl)-L-cysteine and γ -glutamyl-*S*-

allyl-mercapto-L-cysteine are also present in garlic cloves (Fenwick and Hanley 1985, Sugii et al. 1964). The primary sulfur-containing constituents in whole, intact garlic are the γ -glutamyl-S-alk(en)yl-L-cysteines and S-alk(en)yl-L-cysteine sulfoxides, including alliin. Glutathione and γ -glutamyl peptides were reported to be intermediates in the biosynthetic pathway to S-alk(en)yl-L-cysteine sulfoxides (flavour precursors) in *Allium sativum*, *A. cepa* and *A. siculum* (Lancaster and Shaw 1989).

All dipropenyl thiosulfinates (allicin, 1-propenyl allyl and allyl 1-propenyl) were formed at an optimum pH of 4.5–5.0 in garlic (Lawson and Hughes 1992). The methyl propenyl thiosulfinates (allyl methyl + methyl allyl and 1-propenyl methyl + methyl 1-propenyl) and dimethyl thiosulfinate were optimally formed at pH 6.5–7.0 and pH 5.5, respectively. Below pH 3.6 no thiosulfinates were formed. Neutralisation of the pH failed to restore thiosulfinate generation from garlic previously incubated at pH 3 or below. Thus, alliinase was completely and irreversibly inhibited by the acidic conditions found in the stomach. Allyl 1-propenyl thiosulfinate was the most rapidly formed, and the most unstable, thiosulfinate. The stability of the dipropenyl thiosulfinates was improved at pH 4.5 or lower. Drying garlic at 60 °C had no effect on alliin or the rate of formation of the dipropenyl thiosulfinates, but decreased *trans*-1-propenyl cysteine sulfoxide (isoalliin) and the rate of formation of the methyl thiosulfinates. The results demonstrated that there were two alliinase activities in garlic, that a stomach acid-resistant coating on garlic powder tablets was necessary for thiosulfinate release and that carefully prepared garlic powder could release similar amounts of total thiosulfinates to whole garlic cloves. Eight known dialk(en)yl thiosulfinates were found in crushed garlic: allyl-2-propenethiosulfinate (allicin) the most abundant (50–90 % mol), allylmethyl thiosulfinate (3–20 % mol), *trans*-1-propenyl-2-propene thiosulfinate (5–18 % mol), methyl-2-propene thiosulfinate (1.5–8 % mol), allyl-*trans*-1-propenyl thiosulfinate (1.5–2 % mol), methylmethane thiosulfinate (1–2 % mol), *trans*-1-propenylmethane thiosulfinate (1–2 % mol) and methyl-*trans*-1-propene thiosulfinate (0.5 % mol) (Block 1992; Kyung and Lee 2001; Lawson and Gardner 2005).

In blended fresh garlic, the sulfur compounds derived from alliin included allicin (diallyl thiosulfinate), allyl methyl thiosulfates, allyl-*trans*-1-propenyl thiosulfates and allyl sulfides; sulfur compounds not derived from alliin included γ -glutamyl-*S*-allylcysteine, γ -glutamyl-*S-trans*-1-propenylcysteine, γ -glutamyl-*S-cis*-1-propenyl cysteine and *S*-allylcysteine; non-sulfur compounds found included γ -glutamylphenylalanine and arginine (Lawson and Gardner 2005). The allyl thiosulfates of blended fresh garlic were stable for at least 2 years when stored at -80°C . The dissolution release of thiosulfates from the enteric-coated garlic tablets was found to be $>95\%$. The bioavailability of allyl thiosulfates from these tablets, measured as breath allyl methyl sulfide, was found to be complete and equivalent to that of crushed fresh garlic. *S*-Allylcysteine was stable for 12 months at ambient temperature.

Garlic was found to contain large amounts of alliin (16.63–29.10 mg/g dry weight (DW)), γ -glutamyl-*S*-allyl-L-cysteine (GSAC) (12.88–24.92 mg/g) and γ -glutamyl-*S-trans*-1-propenyl-L-cysteine (GSPC) (20.40–38.87 mg/g) (Yoo et al. 2014b). γ -Glutamyl phenylalanine (γ GPA) ranged from 4.13 to 9.56 mg/g. The main organosulfur compounds in garlic were glutamyl peptides, including GSAC, GSPC and γ GPA. Allicin was the major biological compound at 5.28–7.90 mg/g DW. Methiin, cycloalliin and γ -glutamyl-*S*-methyl-L-cysteine (GSMC) were also present in smaller amounts. Methiin and cycloalliin were present at 0.53–2.94 and 0.44–3.24 mg/g garlic (dry weight), respectively, while GSMC was found to be between 0.57 and 1.26 mg/g garlic and *S*-allyl-L-cysteine (SAC) 0.31–0.57 mg/g. Finally, *S-trans*-1-propenyl-L-cysteine sulfoxide (isoalliin) (0.02–0.05 mg/g) and *S-trans*-1-propenyl-L-cysteine (SPC) (0.04–0.10 mg/g) were found in trace amounts. The major chemical components of fresh garlic were diallyl sulfides and methyl allyl sulfides. Differences in the pattern of organosulfur composition and degradation components of thiosulfates from warm- and cool-type garlic were demonstrated by principal component analysis. A total of 21 chemical compounds were identified, including diallyl sulfides, methyl allyl sulfides and vinylidithiins. The dominant degradation compounds in cool-type garlic were diallyl

disulfides at 40.53–59.27 %, while diallyl disulfides in warm-type garlic were 60.62–70.26 %. The methyl allyl sulfide content in garlic was 2.5–14.35 %. Thiosulfinate degradation compounds from garlic were propene acetaldehyde, 2-propen-1-ol, allyl mercaptan(2-propen-1-thiol), 2-butenal, allyl methyl sulfide, acetoin, dimethyl sulfide, 2,4-dimethylfuran, hexanal, diallyl sulfide, methyl allyl disulfide, *cis*-propenyl methyl disulfide, *trans*-propenyl methyl disulfide, dimethyl trisulfide, diallyl sulfide, 3-(allylthio)-propionic acid, unknown, methyl allyl trisulfide, 3,4-dihydro-3-vinyl-1,2-dithiin, 2-vinyl-4H-1,3-dithiin and diallyl trisulfide.

Garlic and onion, wild leek, had been reported to accumulate the selenium (Se) from soil, endowing the plants greater protection against carcinogenesis (Arnault and Auger 2006). Selenomethionine, selenocysteine and Se-methyl-selenocysteine had been identified in garlic and onion (Yang 2002; Auger et al. 2004). Gamma-glutamyl-Se-methyl-L-selenocysteine had been identified in extracts of garlic cultivated in Se-rich soil (Auger et al. 2004). However, several Se compounds from Se-enriched garlic or onion remain unidentified (Arnault and Auger 2006). Se-methyl-selenocysteine was unstable in water extract of Se-enriched garlic when the extract was prepared and stored at room temperature (Yang 2002). Specific alliinase inhibitor hydroxylamine (NHOH.HCl) effectively prevented the loss of Se-methyl-selenocysteine, which suggested that the decomposition of Se-methyl-selenocysteine may be catalysed by alliinase. Se-enriched onion also contained alliinase and Se-methyl-selenocysteine, but its Se-methyl-selenocysteine was proved to be stable in the same water extract as that of Se-enriched garlic. The existence of Se-alk(en)yl-L-cysteine selenoxides (Se-‘alliins’) in garlic and onion had been demonstrated (Auger et al. 2004). An additional experiment showed that *Allium* species cultivated in Se-rich soil might contain two different Se-‘alliins’.

Thiacremonone (2, 4-dihydroxy-2, 5-dimethyl-thiophene-3-one), an antioxidant sulfur compound, was generated from high-temperature high-pressure-treated garlic (Jo et al. 2014).

Garlic Essential Oil/Volatiles

Garlic essential oil obtained from Likens–Nickerson distillation/solvent extraction contained more 2,4-dimethylfuran, 2-propen-1-ol, aniline and 3,5-diethyl-1,2,4-trithiolane than those from water and steam distillation (Yu et al. 1989). Water layer of garlic distillate contained more 3,5-diethyl-1,2,4-trithiolane and 2-propen-1-ol than its oil layer. A total of 28 volatile compounds were found including 3-vinyl-1,2-dithiocyclohex-4-ene and 3-vinyl-1,2-dithiocyclohex-5-ene. Typical volatiles in crushed garlic and garlic essential oil include diallyl sulfide (DAS), diallyl disulfide (DADS), diallyl trisulfide, methyl allyl disulfide, methyl allyl trisulfide, 2-vinyl-1,3-dithiin, 3-vinyl-1,2-dithiin (Fenwick and Hanley 1985) and *E,Z*-ajoene (Block et al. 1984). Variation in the content of thiosulfinates including allicin; diallyl, methyl allyl and dimethyl mono-, di-, tri-, tetra-, penta- and hexasulfides; the vinyl dithiins; and (*E*)- and (*Z*)-ajoene were determined in fresh garlic cloves and commercial products (Lawson et al. 1991c). The thiosulfinates were found to be released only from garlic cloves and garlic powder products. The vinyl dithiins 2-vinyl-3,4-dihydro-1,2-dithiin and 3-vinyl-3,4-dihydro-1,2-dithiin and (*E*)- and (*Z*)-ajoenes were found only in products containing garlic macerated in vegetable oil. The diallyl, methyl allyl and dimethyl sulfide series were the exclusive constituents found in products containing the oil of steam-distilled garlic. Typical steam-distilled garlic oil products contained about the same amount of total sulfur compounds as total thiosulfinates released from freshly homogenised garlic cloves; however, oil-macerated products contained only 20 % of that amount, while garlic powder products varied from 0 to 100 %. Products containing garlic powder suspended in a gel or garlic aged in aqueous alcohol did not contain detectable amounts of these nonionic sulfur compounds.

Eight main constituents and 26 minor ones were identified with two unknowns in Egyptian garlic oil (Jirovetz et al. 1992). The main constituents identified were diallyl trisulfide (29.7 %), linoleic acid (12.4 %), palmitic acid (4.8 %), diallyl tetrasulfide (4.4 %), diallyl disulfide (3.2 %), myristic acid (3.1 %), diallyl sulfide (2.5 %) and methyl allyl trisulfide (2.1

%). The other components were <1 % and included dipropyl sulfide; 2, 5-dimethyl thiophene; tetrahydro-2,5-dimethyl-thiophene; methylallyl sulfide; methyl-1-propenyl-disulfide; dimethyl trisulfide; propyl allyl disulfide; methyl-1-propenyl-trisulfide; methyl propyl trisulfide; 2-methyl benzaldehyde; 3,5-diethyl-1,2,4-trithiolane; 3-vinyl-4H-1,2-dithiin; allyl-1-propenyl trisulfide; di-L-propenyl trisulfide; propyl allyl trisulfide; 2-vinyl-4H- 1,3-dithiin; methyl allyl tetrasulfide; methyl-1-propenyl tetrasulfide; allyl-1-propenyl tetrasulfide; dipropyl tetrasulfide; pentadecanone; pentadecanol; hexadecanol; pentadecanoic acid; heptadecanone; and octadecanol.

Volatiles obtained from combined GC–MS analysis of garlic juice by solid phase microextraction (SPME): dimethyl disulfide, methyl allyl disulfide, methyl propyl disulfide, methyl 1-propenyl disulfide, diallyl disulfide, allyl propyl disulfide, allyl 1-propenyl disulfide, diallyl trisulfide, lachrymatory factor E isomer, methyl 1-propenyl thiosulfinate and 1-propenyl methyl thiosulfinate, and volatiles obtained from solvent extraction: allyl 1-propenyl disulfide, methyl 1-propenyl thiosulfinate, 1-propenyl methyl thiosulfinate, 3-vinyl-[4H]-1,3-dithiin, 2-vinyl-[4H]-1,3-dithiin and allicin (Mondy et al. 2001). In garlic allicin (18) 2-propenyl thiosulfinate was dominant; decomposition of allicin afforded two isomeric cyclic compounds, 3-vinyl-[4H]-1,2-dithiin and 2-vinyl-[4H]-1,3-dithiin.

A total of 47 compounds were identified in garlic essential oil: allyl mercaptan; methyl allyl sulfide; dimethyl sulfide; diallyl sulfide; methyl allyl disulfide; 1-propenyl methyl disulfide; methyl propyl disulfide; diallyl trisulfide; butylpropenyl sulfide; cyclopentyl hexyl sulfide; *N*-morpholinomethyl isopropyl sulfide; dimethyl trisulfide; methyl allyl trisulfide; dimethyl tetrasulfide; 2,4-dimethylthiophene; methyl allyl thioacetate; metoxymethyl isothiocyanate; cyclopentathiazole; thiazole; methylthiocyclopentane; 3-(methylthio)penta-2,4-dione; 5-(methylthio)-4-penten-2-ol; 2-thiophenecarboxaldehyde; methylthiocyclohexane; 3-vinyl-1,2-dithiocyclohex-4-ene; 3-vinyl-1,2-dithiocyclohex-5-ene; 2-(1-propenylthio)thiophene;

ethyl-2-thiopheneacetate; 4,5-dimethylisothiazole; 3-methyl-1,1-bis(methylthio)-1,3-butadiene; 1,3 benzenedithiol; benzothiophene; 3,5-diethyl-1,2,4-trithiolane; 2-ethyl-1,3-dithiane; 2-vinyl-1,3-dithiane; 2-ethylidene-1,3-dithiane; 1,3,5-trithiane; 3-methylpyridine; 2,5-dimethylpyridine; 2-butenal; 2-methyl-4-pentenal; 2-methyl-2-butenal; 2-methylene-4-pentanone; 2-pentenal; 2-methylfuran; and 2,4-hexadienal (Calvo-Gómez et al. 2004).

Garlic bulb extract obtained from supercritical CO₂ extraction was found to contain 3-vinyl-1,2-dithiocyclohex-4-ene (47.78 %), 3-vinyl-1,2-dithiocyclohex-5-ene (15.33 %), diallyl disulfide (10.88 %) and diallyl trisulfide (10.4 %) as the main volatile compounds and other compounds diallyl tetrasulfide (1.78 %), methyl 2-propanol disulfide (1.66 %) and methyl 2-propanol trisulfide (1.68 %), while petroleum ether soxhlet extraction afforded methyl 2-propanol trisulfide (16.75 %), diallyl trisulfide (16.39 %), 3-vinyl-1,2-dithiocyclohex-4-ene (8.195), dimethyl trisulfide (7.89 %), 2-ethylidene[1,3]dithiane (6.91 %), diallyl sulfide (5.06 %), benzene acetaldehyde (2.80 %), methyl 2-propanol disulfide (1.18 %) and diallyl tetrasulfide 0.87 %) (Hincapié et al. 2008). Three key intermediates 2-propenesulfenic and 2-propenesulfinic acids and diallyl trisulfane S-oxide, along with other reactive volatile sulfur compounds allicin and related thiosulfinates, allyl alcohol, sulfur dioxide, propene and pyruvate as coproducts, were detected in crushed garlic (Block et al. 2010). A commercial dietary supplement containing garlic powder, which was sampled after crushing, was found to contain alliin, methiin and S-allylcysteine and produced allicin upon addition of water.

Although the main compositions of the essential oils of garlic obtained by solvent extraction (SE) and supercritical fluid extraction (SFE) were basically similar, their minor compositions differed quantitatively (Li et al. 2010). The extraction yield (0.78 %) of garlic by employing SE method was slightly lower than that (0.81 %) obtained by SFE, but the extraction time (42 minutes) by SE method was shorter than that (130 minutes) obtained by SFE. The compounds of garlic essential oil extracted by SFE and SE were, respectively, as

follows: 3-vinyl-4H-1,2-dithiin (32.17, 31.89 %); propyl allyl disulfide (13.95, 13.89 %); diallyl trisulfide (12.94, 13.31 %); dimethyl disulfide (7.44, 7.05 %); diallyl disulfide (8.02, 6.87 %); methyl allyl trisulfide (4.67, 5.02 %); 3,5-diethyl-1,2,4-trithiolane (2.62, 2.56 %); diallyl sulfide (2.30, 2.22 %); 2-vinyl-4H-1,3-dithiin (1.78, 1.10 %); methyl propyl disulfide (1.2, 1.06 %); vinylfuran (0.98, 0.92 %); 1,2-epithiopropene (0.34, 0.04 %); 3-methylthio propanal (0.3, 0 %); 3-methyl-2-cyclopentene-1-thione (0.52, 0 %); methyl butyl trisulfide (0, 0.14 %); and methyl 2-propenyl disulfide (0.34, 0 %). The major components of garlic essential oil were diallyl trisulfide (33.55 %) and diallyl disulfide (28.05 %) (Kocić-Tanackov et al. 2012).

Sixteen compounds in the commercial garlic essential oil, accounting for 97.44 % of the total oil, were identified, and the main components of the essential oil of *A. sativum* were diallyl trisulfide (50.43 %), diallyl disulfide (25.30 %), diallyl sulfide (6.25 %), diallyl tetrasulfide (4.03 %), 1,2-dithiolane (3.12 %), allyl methyl disulfide (3.07 %), 1,3-dithiane (2.12 %) and allyl methyl trisulfide (2.08 %) (Zhao et al. 2013).

Over 40 constituents were detected from steam-distilled garlic essential oil, and more than 95 % were identified as sulfur-containing compounds (Shaath et al. 1995). Diallyl trisulfide, diallyl disulfide, methyl allyl trisulfide, methyl allyl disulfide and diallyl sulfide were identified as the main constituents. Studies by Ferary et al. (1996) found that *A. sativum* odours contained only thiopropanal *S*-oxide and thiosulfinates as sulfur volatiles. Volatile compounds released from microwave heating of garlic and 2,4-decadienals were identified as: sulfur dioxide; allyl mercaptan; isopropyl alcohol; hexanal; allyl alcohol; allyl sulfide; 2-pentylfuran; methyl allyl sulfide; dimethyl trisulfide; nonanal; (*E*)-2-octenal; dithio(1-propenyl)propionate; diallyl disulfide; 1,2-dithiacyclopent-3-ene; *n*-hexanethiol; methyl benzyl sulfide; dihydro-2(3*H*)-thiophenthione; 3-vinyl-4*H*-1,2-dithiin; (*E,Z*)-2,4-decadienal; 2-vinyl-1,3-dithiane; (*E,E*)-2,4-decadienal; hexanoic acid; and 2-vinyl-4*H*-1,3-dithiin (Chyau and Mau 1999). A total of 23 compounds were identified from these samples, among which 14 sulfide compounds, five

aldehydes, two alcohols, one acid and one furan were identified. Three compounds, dithio(1-propenyl)propionate, dihydro-2(3*H*)-thiophenthione and *n*-hexanethiol, were newly found in deep-fried garlic flavour. During microwave heating, levels of most volatiles decreased as the heating time continued. 2-Pentylfuran, isopropyl alcohol, hexanal and (*E*)-2-octenal were formed from the degradation of 2,4-decadienals. Sulfur dioxide was generated predominantly from the degradation and oxidation of sulfide compounds.

Sixteen compounds were identified in garlic steam distillate: α -pinene 1.5 %, *bis* (propen-1-yl) sulfoxide 1.8 %, 1,8-cineole 6 %, diallyl sulfide 10.8 %, linalool 2.1 %, methyl allyl sulfide 1.2 %, camphor 4.6 %, isomenthone (isomer 1) 8 %, isomenthone (isomer 2) 5 %, menthol 1.5 %, 4-terpineol 1.2 %, 5-methyl-1,2,3-thiadiazole 3.1 %, pulegone 5.7 %, diallyl trisulfide 3 %, carvacrol 2.7 % and sulfur (cyclooctasulfur) 10.1 % (Attia et al. 2012).

The major peaks observed in the chromatogram of *A. sativum* extract were attributed to diallyl disulfide (8.45 mg/L), diallyl trisulfide (4.54 mg/L), methylallyl trisulfide (7.17 mg/L) and vinylidithiins (23 mg/L).

Relative concentration (weight %) of volatiles from oils of fresh garlic; cabinet-dried and ground garlic powder; and microwave-dried and ground garlic powder were determined, respectively, as follows: methyl propyl sulfoxide (1.31, 0.49, 0.29 %), diallyl sulfide (4.38, 4.11, 3.91 %), methyl (δ)-prop-1-enyl disulfide (7.29, 6.31, 8.09 %), dimethyl trisulfide (1.83, 0.55, 0.22 %), sabinene (0.08, 0, 0 %), δ -2-carene (0.08, 0, 0.06 %), limonene (0.13, 0, 0.06 %), diallyl disulfide (20.99, 26.51, 36.72 %), allyl (*Z*)-prop-1-enyl-disulfide (0.14, 0.48, 0.18 %), allyl (*E*)-prop-1-enyl-disulfide (0.31, 0.98, 0.17 %), allyl methyl trisulfide (16.56, 9.43, 5.86 %), 2-vinyl-4H-1,3-dithiin (0.21, 2.19, 0.05 %), diallyl trisulfide (41.53, 32.89, 25.89 %), allyl methyl tetrasulfide (0.57, 1.14, 1.09 %) and diallyl tetrasulfide (3.27, 11.6, 12.55 %) (Rao et al. 2007). Methanethiol, methyl thiirane, allyl methyl sulfide, dimethyl disulfide, allyl sulfide, methyl 2-propenyl disulfide, diallyl disulfide and allyl trisulfide were identified in garlic using

head space solid phase microextraction/gas chromatography/mass spectroscopy (Clemente et al. 2011).

Volatile flavour compounds found in both fresh and stored Jin Xiang (JX) garlic and Tai'an (TA) garlic included 1,3-two thiophene; allyl disulfide; allyl trisulfide (allicin); diallyl tetrasulfide; 1,3-dithiane; and 3-(allylsulfanyl) propanoic acid (Shan et al. 2013). Allyl sulfide and 1,1'-thiobis 1-propene were found in stored JX and TA; methyl 1-propenyl disulfide, methyl 12-propenyl disulfide and N-N-dimethyl ethanamide were found in fresh TA only; dimethyl trisulfide in stored JX and TA; 2-vinyl-1,3-dithiane and 2-ethylidene[1,3] dithiane in stored TA; dioxane and 3-aminorhodanine in stored JX and TA; methyl (allylsulfanyl) acetate in stored JX and TA; 6-(methylthio)hexa-1,5-dien-3-ol and 1,3,5-trithiane in fresh TA only; 2-mercapto-3,4-dimethyl-2,3-dihydrothiophene in stored JX and TA; 3-vinyl-3,4-dihydro-1,2-dithiane in stored JX only; 1-ethyl-2-methyl-4-pentenyl methyl ether in stored TA and fresh JX; 5-methoxy-4-methyl-1-heptene in stored JX and TA and fresh JX; 2,5-dimethyl-1,3,4-thiadiazole in stored JX only; and benzothiofuran in fresh TA garlic only.

Steroidal Saponins/Sapogenins

The steroid saponin sitosterol was found in garlic (Smockiewicz et al. 1982). An azurogen C steroid glycoside $C_{57}H_{96}O_{30}$ was isolated from garlic (Kravets et al. 1990). A furostanol glycoside was isolated from garlic bulb and its structure elucidated as 26-*O*- β -glucopyranosyl 22-hydroxy-25(R)-5 α -furostane-3 β , 6 β , 26-triol 3-*O*- β -glucopyranosyl(1 $\rightarrow$ 2)-[β -glucopyranosyl(1 $\rightarrow$ 3)]- β -glucopyranosyl-(1 $\rightarrow$ 4)- β -galactopyranoside, i.e. proto-eruboside-B (Matsuura et al. 1988). On enzymatic hydrolysis it yielded eruboside-B. A new furostanol glycoside, named sativoside-B1, with the structure (25R)-26-*O*- β -D-glucopyranosyl-22-hydroxy-5 α -furostane-3 β , 6 β , 26-triol 3-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 3)-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 2)-*O*-[β -D-glucopyranosyl(1 $\rightarrow$ 3)]-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 4)-*O*- β -D-galactopyranoside along with proto-desgalactotigonin were isolated from garlic bulbs (Matsuura et al. 1989). From

the plant roots, two new steroidal glycosides, named sativoside-R1 and sativoside-R2, were isolated, and their structures were determined to be (25R)-26-O- β -D-glucopyranosyl-22-hydroxy-5 α -furostane-3 β , 26-diol 3-O- β -D-glucopyranosyl-(1 $\rightarrow$ 3)-O- β -D-glucopyranosyl-(1 $\rightarrow$ 2)-O-[β -D-xylopyranosyl-(1 $\rightarrow$ 3)]-O- β -D-glucopyranosyl-(1 $\rightarrow$ 4)-O- β -D-galactopyranoside and tigogenin 3-O- β -D-glucopyranosyl-(1 $\rightarrow$ 3)-O- β -D-glucopyranosyl-(1 $\rightarrow$ 2)-O-[β -D-xylopyranosyl-(1 $\rightarrow$ 3)]-O- β -D-glucopyranosyl-(1 $\rightarrow$ 4)-O- β -D-galactopyranoside, respectively. Besides these glycosides, three known glycosides, proto-desgalactotigonin, desgalactotigonin and F-gitonin were isolated and identified. Six compounds were isolated from the fresh garlic bulbs including two new steroidal saponins proto-iso-eruboside-B and iso-eruboside plus known sativoside-C and adenosine and tryptophan (Peng et al. 1996). Two new steroidal saponins, iso-eruboside B and sativoside-C, along with a known compound, eruboside-B2, and a new furostanol saponin, proto-iso-eruboside-B, were isolated from garlic bulb (Peng and Yao 1996).

The following steroidal furostanol saponins, proto-eruboside-B, sativoside-B1, chinenoside-I and a new compound β -chlorogenin (25R)-26-O- β -D-glucopyranosyl-22-hydroxy-5 α -furostane-3 β , 6 β , 22, 26-tetraol 3-O- β -D-glucopyranosyl(1 $\rightarrow$ 2)-O-[β -D-glucopyranosyl(1 $\rightarrow$ 3)]-O- β -D-GLUCOPYRANOSYL(1 $\rightarrow$ 4)-O-[α -L-rhamnopyranosyl(1 $\rightarrow$ 2)-O- β -D-GALACTOPYRANOSIDE; spirostanol saponins, eruboside-B, sativoside-B1-sp., ampeloside-Bs1, chinenoside-I-sp. and a new compound β -chlorogenin 3-O- β -D-glucopyranosyl(1 $\rightarrow$ 2)-O-[β -D-glucopyranosyl(1 $\rightarrow$ 3)]-O- β -D-GLUCOPYRANOSYL(1 $\rightarrow$ 4)-O-[α -L-rhamnopyranosyl (1 $\rightarrow$ 2)]-O- β -D-galactopyranoside; aglycones, β -chlorogenin, agigenin and laxogenin; and a pentacyclic terpenoid derivative glycyrrhetic acid were identified from garlic and aged garlic (Matsuura 2001). Four steroidal saponins were isolated from crude extracts of garlic and elucidated as (25S)-26-O- β -D-glucopyranosyl-22-hydroxy-5 α -furostane-3 β , 6 β , 26-triol-3-O- β -D-glucopyranosyl-(1 $\rightarrow$ 2)-O-[β -D-glucopyranosyl-(1 $\rightarrow$ 3)]-O- β -D-glucopyranosyl-(1 $\rightarrow$ 4)-O- β -D-GALACTOPYRANOSIDE; (25S)-26-O- β -D-glucopyranosyl-22-methoxy-5 α -furostane-3 β , 6 β , 26-triol-3-O-

β -D-glucopyranosyl-(1 $\rightarrow$ 2)-O-[β -D-glucopyranosyl-(1 $\rightarrow$ 3)]-O- β -D-glucopyranosyl-(1 $\rightarrow$ 4)-O- β -D-GALACTOPYRANOSIDE; (25R)-26-O- β -D-glucopyranosyl-22-methoxy-5 α -furostane-3 β ,6 β ,26-triol-3-O- β -D-glucopyranosyl-(1 $\rightarrow$ 3)-O- β -D-glucopyranosyl-(1 $\rightarrow$ 2)-O-[β -D-glucopyranosyl-(1 $\rightarrow$)]-O- β -D-glucopyranosyl-(1 $\rightarrow$ 4)-O- β -D-GALACTOPYRANOSIDE; and (25R)-26-O- β -D-glucopyranosyl-22-methoxy-5 α ,6 β -furostane-3 β , 26-diol-3-O- β -D-glucopyranosyl-(1 $\rightarrow$ 2)-O-[β -D-xylopyranosyl-(1 $\rightarrow$ 3)]-O- β -D-glucopyranosyl-(1 $\rightarrow$ 4)-O- β -D-GALACTOPYRANOSIDE (Ma et al. 2011).

Five cerebroside, AS-1-1 (1), AS-1-2 (2), AS-1-3 (3), AS-1-4 (4) and AS-1-5 (5), were isolated CHCl₃–MeOH extract of garlic bulbs (Inagakai et al. 1998). The structures of 1–5 were elucidated as: 1-O-(β -D-glucopyranosyl)-(2*S*,3*R*,4*E*,8*E*)-2-[(2*R*)-2-hydroxytetradecanoylamino]-4,8-octadecadiene-1,3-diol (1); 1-O-(β -D-glucopyranosyl) -(2*S*,3*R*,4*E*,8*E*)-2-[(2*R*)-2-hydroxypentadecanoylamino]-4,8-octadecadiene-1,3-diol (2); 1-O-(β -D- glucopyranosyl)-(2*S*,3*R*,4*E*,8*Z*)-2-[(2*R*)-2-hydroxyhexadecanoylamino]-4,8-octadecadiene-1,3-diol (3); 1-O-(β -D-glucopyranosyl)-(2*S*,3*R*,4*E*,8*E*)-2-[(2*R*)-2-hydroxyhexadecanoylamino]-4,8-octadecadiene-1,3-diol (4); and -O-(β -D-glucopyranosyl)-(2*S*,3*R*,4*E*,8*E*)-2-[(2*R*)-2-hydroxyhexadecanoylamino]-4-octadecadiene-1,3-diol (5), respectively. Compounds 3 and 4 were identified with the known glucocerebroside soya-cerebroside I and II, respectively, which had been previously obtained from soybean with ionophoretic activity.

Antifungal furostanol saponins were isolated from bulbs of garlic *Allium sativum* var. Voghiera, voghieroside A1/A2 and voghieroside B1/B2, based on the rare agapanthagenin aglycone, voghieroside C1/C2; based on agigenin aglycone and voghieroside D1/D2 and E1/E2; and based on gitogenin aglycone (Lanzotti et al. 2012). In addition, two known spirostanol saponins, agigenin 3-O-trisaccharide and gitogenin 3-O-tetrasaccharide, were found. High concentrations of two eugenol diglycosides were also found for the first time in *Allium* spp.

Miscellaneous Phytochemicals

Incubations of [1-¹⁴C]linoleic acid or [1-¹⁴C]-(9 Z ,11 E ,13 S)-13-hydroperoxy-9,11-octadecadienoic acid (13-HPOD) with juice of garlic bulbs led to the formation of divinyl ether (9 Z ,11 E ,1' E)-12-(1'-hexenyloxy)-9,11-dodecadienoic acid ('etheroleic acid') (Grechkin et al. 1995). With lesser efficiency [1-¹⁴C] α -linolenic acid or [1-¹⁴C] (9 Z ,11 E ,13 S ,15 Z)-13-hydroperoxy-9,11,15-octadecatrienoic acid (13-HPOT) was converted in this way into (9 Z ,11 E ,1' E ,3' Z)-12-(1',3'-hexadienyloxy)-9,11-dodecadienoic acid ('etherolenic acid'). Thus, garlic bulbs possessed the activity of a 13-hydroperoxide-specific divinyl ether synthase.

Antifungal *N*-feruloyl amides *N*-feruloyltyrosine and *N*-feruloyltyramine were isolated from *A. sativum* roots (Fattorusso et al. 1999). A new stress compound, named allixin, was isolated from garlic bulbs the structure as 3-hydroxy-5-methoxy-6-methyl-2-pentyl-4H-pyran-4-one (Kodera et al. 1989). Allixin was also induced by irradiating fresh garlic cloves with sunlight or UV light (Kodera et al. 2001). The accumulated amounts of induced allixin were 3.1–6.3 $\mu\text{g/g}$ under experimental conditions. Extremely high accumulation of allixin, a phytoalexin derived from garlic, was observed in necrotic tissue areas after long-term storage (Kodera et al. 2002a). The allixin produced recrystallised on the surface of garlic cloves. The amount of allixin produced in raw garlic with necrotic tissue areas was 1,400 ng/mg wet garlic. After approximately 2 years of storage, the amount of allixin accumulated reached slightly less than 1 % of the dry weight of garlic cloves. *N*-*trans*-coumaroyloctopamine, *N*-*trans*-feruloyloctopamine, guaiacylglycerol- β -ferulic acid ether and guaiacylglycerol- β -caffeic acid ether were identified in garlic skins as were *trans*-coumaric acid and *trans*-ferulic acid (Ichikawa et al. 2003).

Extensive in-vitro and in-vivo studies and reviews had been reported on the wide array of pharmacological properties of garlic extracts and their potential medicinal benefits in cardiovascular diseases, neurodegenerative diseases, cancers, diabetics, dermatological ailments, osteoporosis, cataract,

gastrointestinal ailments and in the control of microbes, parasites, molluscs, worms and insect (Kendler 1987; Augusti 1996; Block 1997; Bianchini and Vainio 2001; Corzo-Martínez et al. 2007; Harris et al. 2001; Amagase 2006; Lanzotti 2006; Bongiorno et al. 2008; Singh and Singh 2008). These biological properties include hypocholesterolaemic, hypolipidaemic, antihypertensive, antidiabetic, antithrombotic, antihyperhomocysteinaemia effects, antimicrobial, antioxidant, anticarcinogenic, antimutagenic, antiasthmatic, immunomodulatory, insecticidal, nematocidal, rodenticidal, anthelmintic, molluscicidal and prebiotic activities. Studies suggested that oral administration of garlic was effective on immunological properties, cutaneous microcirculation, protection against UVB and cancer treatment (Pazyar and Feily 2011). Additionally, topical application of garlic extract could potentially be effective on psoriasis, alopecia areata, keloid scar, wound healing, cutaneous corn, viral and fungal infection, leishmaniasis, skin ageing and rejuvenation.

Antioxidant Activity

In-Vitro Studies

The lipid peroxidation and chemiluminescence (CL) of mouse liver mitochondria induced by a Vc/FeSO₄ reaction system was greatly inhibited by garlic oil and allitridin (diallyl trisulfide) at 0.1 mg/mL (Fu 1993). HpD-induced photohaemolysis was moderately inhibited by garlic oil (25 µg/mL) and allitridin (20 µg/mL). Allitridin (200 µg/mL) effectively prevented inactivation of red cell membrane acetylcholinesterase (AChEs) caused by .OH, and at 250 µg/mL it markedly inhibited blood CL stimulated by croton oil. Garlic oil (5 µg/mL) and allitridin (100 µg/mL) significantly increased O²⁻ production. Allitridin at 0.25 mg/mL and 1 mg/mL enhanced lipid peroxidation of mitochondria and blood CL caused by H₂O₂. Garlic extract (5–100 µL/mL) produced an inhibition (30–100 %) of 2,3-dihydroxybenzoic acid (2,3-DHBA) and 2,5-dihydroxybenzoic acid (2,5-DHBA) generated by photolysis of H₂O₂ in a concentration-dependent manner (Prasad et al. 1996). Garlic

extract prevented the .OH-induced formation of malondialdehyde in the rabbit liver homogenate in a concentration-dependent manner. It alone did not affect the MDA levels in the absence of .OH. The results indicated garlic extract to be a powerful scavenger of .OH and that heating reduced its activity slightly. Allicin (active ingredient of garlic) contained in the commercial preparation Garlicin was found to have antioxidant activity (Prasad et al. 1995). Allicin prevented the lipid peroxidation of liver homogenate in a concentration-dependent manner. Allicin produced concentration-dependent decreases in the formation of 2,3-DHBA and 2,5-DHBA generated by H₂O₂.

Aqueous and methanol garlic extracts exhibited strong DPPH antioxidant activity (80–90 % of the standard) (Meriga et al. 2012). Garlic showed a higher DPPH free radical scavenging activity than red onion but had lower total phenolic content (37.60 mg GAE/100 g) than red onion (53.43 mg GAE/100 g) (Othman et al. 2011). However, the primary antioxidant activities of both were lower than the standard antioxidant, BHA. Red onion had higher ferrous ion-chelating effect (i.e. 45.00 %) as compared to garlic (43.29 %) but both showed slightly higher ion-chelating effect than BHA (tert-butyl-4-hydroxyanisole) (43.14 %) but lower than EDTA (ethylenediamine tetraacetic acid) (97.9 %). Aged black garlic exhibited significantly higher phenolic content and greater antioxidative activity than fresh garlic as assessed by DPPH scavenging, ferricyanide reducing power, ferrous ion-chelating ability and inhibitory effect on linoleic acid peroxidation (Kim et al. 2012). Both garlic extracts showed strong antioxidant capacity in a dose-dependent manner.

Fanelli et al. (1998) found that diallyl disulfide (DDS), diallyl sulfide (DAS) and allyl mercaptan (AMT) but not allyl methyl sulfide (AMS) were able to trap trichloromethyl and trichloromethylperoxyl free radicals. Further, DDS but not DAS or AMT also inhibited CCL₄-promoted liver microsomal lipid peroxidation. DAS, but not DDS, AMT or AMS, was able to react with free radicals that appeared during UVC activation of hydrogen peroxide or tert-butyl hydroperoxide but not with those produced during UVC activation of tert-

butyl peroxide. However, all garlic components tested absorbed energy from UVC and became partially destroyed in the process. AMT, but not DDS, AMS or DAS, was able to destroy 4-hydroxynonenal, a key reactive aldehyde produced during lipid peroxidation. AMT and DDS were also able to prevent UVC plus CCL₄-promoted oxidation of albumin in-vitro, but DAS and AMS failed to do so.

An in-vitro study in Vero cells suggested that diallyl tetrasulfide from garlic inhibited the reactive oxygen species (super oxide anion and hydrogen peroxide) generation induced by cadmium and exerted a novel protective effect on the cytolethality associated with cadmium-induced mitochondrial injury, which contributed to the antiapoptotic effect of diallyl tetrasulfide against cadmium (Murugavel et al. 2007). Average contents of alliin, vitamin C, total phenol and total flavonoid per 100 g dry weight of 19 garlic cultivars were, respectively, 1,938.4 mg, 9.3 mg, 97.0 mg gallic acid equivalent (GAE) and 16.1 mg catechin hydrate equivalent (CE), and antioxidant activity was 27.5 % (Bhandari et al. 2014). Among the three free sugars analysed, sucrose was present in the greatest quantity (3.48 %), followed by fructose (1.05 %) and glucose (0.54 %). Total flavonoid content showed the highest positive correlations with antioxidant activity ($R^2 = 0.908$), followed by total phenol and vitamin C contents. Aged garlic extract inhibited the emission of low level chemiluminescence and the early formation of thiobarbituric acid reactive substances (TBARS) in liver microsomal fraction initiated by t-butyl hydroperoxide (Imai et al. 1994). However, the water extracts of raw and heat-treated garlic enhanced the emission of low level chemiluminescence. S-allylcysteine (SAC) and S-allylmercaptocysteine (SAMC), the major organosulfur compounds found in aged garlic extract, showed radical scavenging activity in both chemiluminescence and 1,1-diphenyl-2-picrylhydrazyl (DPPH) assays, indicating that these compounds may play an important role in the antioxidative activity of aged garlic extract. Studies found the bioactive compounds, electrophoretic patterns and antioxidant potential of fresh Polish, Ukrainian and Israeli garlic samples to be comparable (Gorinstein et al. 2005). Garlic samples

subjected to 100 °C during 20 minutes preserved their bioactive compounds, antioxidant potential and protein profile and were comparable with fresh garlic, and (c) fresh garlic should be added to dishes cooked at 100 °C in the last 20 minutes of the cooking process.

Garlic bulb and immature plant extracts reduced the DPPH radical formation (IC_{50} ranging from 1.03 to 6.01 mg/mL) and neutralised H_2O_2 (IC_{50} ranging from 0.55 to 2.01 mg/mL) in a dose-dependent manner (Bozin et al. 2008). Strong inhibition of lipid peroxidation in Fe^{2+} /ascorbate and Fe^{2+}/H_2O_2 systems of induction was observed for all tested garlic extracts. Various levels of phenolics (0.05–0.98 mg gallic acid equivalents/g of dry extract) and flavonoid aglycones (4.16–6.99 μ g quercetin equivalents/g of dry extract) in the investigated extracts of garlic could explain the obtained differences in these results only partially. Garlic essential oil exhibited potential to be a powerful antioxidant (Lawrence and Lawrence 2011). IC_{50} values observed for DPPH and nitric oxide scavenging assays were 0.5 mg/mL and 50 μ g/mL, respectively. In reducing power assay, absorbance increased linearly with increasing concentration of the oil, and in β -carotene bleaching method also, there was 84 % bleaching in the first one hour and it decreased to 45 % by the completion of the second hour.

The methanol extracts of onion and garlic extract gave similar antioxidant activity as determined by inhibition of lipid peroxidation induced by tert-butyl hydroperoxide in isolated rat hepatocytes and scavenging activity against DPPH radical (Nuutila et al. 2003). The radical scavenging activities also correlated positively with the total phenolics of the extracts. Onions had clearly higher radical scavenging activities than garlic, red onion being more active than yellow onion. The skin extracts of onion possessed the highest activities. The lowest levels of phenolics were detected for garlic (75–700 GAE mg/kg), whereas the highest amounts of phenolics were detected for the dry skin of onions: 80,000 GAE mg/kg in red onion and 26,000 GAE mg/kg in yellow onion. Garlic did not contain quercetin or kaempferol in detectable amounts. Garlic was a much less effective inhibitor of lipid peroxidation than

yellow onion. However, according to Miller et al. (2000), garlic was found to be very high in antioxidants, its activity (1300 Trolox equivalents/100 g) being about sixfold that of yellow onion (200 Trolox equivalents/100 g). The extract of garlic skins (peels) showed strong antioxidant (DPPH radical scavenging) activity, and some responsible constituents were isolated and identified (Ichikawa et al. 2003).

In-vitro studies showed four main chemical classes in garlic, alliin, allyl cysteine, allyl disulfide and allicin to have antioxidant activity (Chung 2006). Alliin scavenged superoxide, while allyl cysteine and allyl disulfide did not react with superoxide. Allicin suppressed the formation of superoxide by the xanthine–xanthine oxidase system, probably via a thiol exchange mechanism. Alliin, allyl cysteine and allyl disulfide all scavenged hydroxyl radicals. Alliin, allicin and allyl cysteine did not prevent induced microsomal lipid peroxidation, but both alliin and allyl cysteine were hydroxyl scavengers, and allyl disulfide was a lipid peroxidation terminator. Garlic aqueous extract was found to be effective in protecting against the nonsteroidal oestrogenic mycotoxin, zearalenone-induced cytotoxicity, reactive oxygen species (ROS) generation and DNA fragmentation in cultured Vero cells (Abid-Essefi et al. 2012).

Chen et al. (2013) found that the bulbs of garlic cultivar ‘74-x’ had the highest phenolic content (total phenolic, flavonoids) and the strongest antioxidant capacity (DPPH [2, 2-diphenyl-1-picrylhydrazyl] radical scavenging activity (ferric ion reducing antioxidant power) CUPRAC), followed by bulbs of cultivar ‘Hanzhong purple’; the bulbs of cultivar ‘Gailiang’ had the lowest phenolic content and antioxidant capacity (FRAP, CUPRAC, MCA (metal chelating activity)). The bolts of ‘Hanzhong purple’ also had higher phenolic content. All 8 test garlic bulb extracts successfully prevented human vascular endothelial cell death and significantly prevented reactive oxygen species (ROS) formation in oxidative stress model, in which cultivar ‘74-x’ had the highest protection capability, following by cultivar ‘Hanzhong purple’, and the bulbs of cultivar ‘No. 105 from Korea’ had the lower protection capability against cell death and ROS

formation. Extracts from garlic that sprouted for 5 days had the highest antioxidant (DPPH scavenging) activity, whereas extracts from raw garlic had relatively low antioxidant activity (Zakarova et al. 2014). Furthermore, sprouting changed the metabolite profile of garlic: the metabolite profile of garlic that sprouted for 5–6 days was distinct from the metabolite profile of garlic sprouted for 0–4 days, which supported the finding that garlic sprouted for 5 days had the highest antioxidant activity.

It was found that blanching and frying and then microwaving of garlic and onions did not decrease significantly the amounts of their bioactive compounds (polyphenols, flavonoids, flavonols, anthocyanins, tannins and ascorbic acid) and the level of antioxidant activities (Gorinstein et al. 2008). The HPLC profiles of free and soluble ester- and glycoside-bound phenolic acids showed that *trans*-hydroxycinnamic acids (caffeic, *p*-coumaric, ferulic and sinapic) were as much as twice higher in garlic than in onions. Quercetin quantity was the highest in red onion among the studied vegetables. The electrophoretic separation of non-reduced garlic and onion proteins after boiling demonstrated their degradation in the range from 50 to 112 kDa. Fresh garlic and its products, i.e. chopped with salt, chopped without salt, fried and mixed garlic (fresh garlic with dehydrated garlic), exhibited different magnitude of antioxidant activity as evaluated by three different methods: DPPH (1,1-diphenyl-2-picrylhydrazyl) assay, β -carotene/linoleic acid assay and Rancimat[®] method (Queiroz et al. 2009). Among all the analysed products, fried garlic presented the highest antioxidant activity. The free radical scavenging activity decreased during the shelf life of all analysed products that correlated with the decrease in the total polyphenol content.

Four flavonols and their aglycones isolated from garlic leaf and shoot exhibited in-vitro antioxidant activity (Kim et al. 2005). In the DPPH (1,1-diphenyl- β -picryl hydrazyl) radical scavenging assay, quercetin showed the highest antioxidant activity among the compounds: quercetin 88.38 %, kaempferol 61.87 %, isorhamnetin 55.03 %, isoquercitrin 54.76 %, reynoutrin 39.58 %, isorhamnetin 3-*O*- β -D-glucopyranoside

17.9 % and astragalin 3.11 % in comparison to known antioxidants BHA 24.01 % and α -tocopherol 44.12 %. In hydroxyl radical scavenging activity, quercetin and its glycosides showed the highest activity over 90 %, while kaempferol, astragalin, isorhamnetin and isorhamnetin 3-*O*- β -D-glucopyranoside showed 80–82 % activity. In linoleic acid peroxidation inhibition assay, quercetin (89.93 %) exhibited the highest activity, reynoutrin 62.28 %, isorhamnetin 63 %, kaempferol 61.9 %, isorhamnetin 3-*O*- β -D-glucopyranoside 58.62 %, astragalin 42.49 % and isoquercetin 42.09 %. In the soybean lipoxygenase assay, the IC₅₀ values of quercetin, isoquercitrin and reynoutrin were 16.9, 40.1 and 32.9 μ M, respectively. Quercetin was the most effective among the flavonols. In the hyaluronidase (HYA) inhibition assay, the IC₅₀ values of quercetin, isoquercitrin and reynoutrin were 23.0, 20.9 and 22.1 mM, respectively. Isoquercitrin had the most potent inhibitory activity on HYA.

Animal Studies

Administration of water-soluble proteins of garlic (500 mg/kg body wt/day) to alcohol-fed rats showed significant increase in antiperoxide activity and decrease in the activity of glutathione peroxidase and glutathione S transferase as compared to a standard drug gugu-lipid (Rajasree et al. 1998). In contrast rats fed with ethanol exhibited high levels of tissue malondialdehyde, hydroperoxide and diene conjugates and decreased contents of tissue superoxide dismutase, catalase and glutathione. Both garlic oil and onion oil supplementation to nicotine-treated rats increased resistance to lipid peroxidation (Helen et al. 1999). The supplementation increased activities of antioxidant enzymes, catalase, superoxide dismutase and glutathione peroxidase and increased concentrations of glutathione. The results indicated that oils of garlic and onion were effective antioxidants against the oxidative stress. Administration of garlic extract significantly decreased lipid peroxidation in 7, 12-dimethylbenz[a]anthracene (DMBA)-induced hamster buccal pouch carcinogenesis in male Syrian hamsters and induced and restored the depletion of antioxidants ascorbic acid,

vitamin E, reduced glutathione (GSH), glutathione peroxidase (GPx), superoxide dismutase (SOD) and catalase (Balasenthil et al. 2000). Studies showed that garlic oil and that GO and three allyl compounds, diallyl sulfide (DAS), diallyl disulfide (DADS) and diallyl trisulfide (DATS), played a differential role in modulation of glutathione (GSH)-related antioxidant system in rat livers and red blood cells (Wu et al. 2001). DATS displayed a greater enhancement than GO and DADS in increasing GSH content. In rat livers, DADS and DATS significantly increased the activity of GSH reductase (46 and 54 %, respectively) and of GSH S-transferase (GST) (63 and 103 %, respectively), but decreased the GSH peroxidase activity (27 and 28 %, respectively). In contrast, GSH reductase and GST activities in the DAS group were similar to the control group. An increase in GST activity and a decrease in GSH peroxidase activities were also noted in garlic oil-treated rats. In red blood cells, three GSH-related antioxidant enzyme activities were not affected by garlic oil and its organosulfur components.

Supplementation of the beef tallow diet of mice with red pepper (*Capsicum annuum*) or garlic suppressed plasma triacylglyceride level (Kuda et al. 2004). Red pepper lowered caecal Bacteroidaceae, a predominant bacterial group (from 9.4 to 9.0 log CFU/g), *Bifidobacteria* (from 8.7 to 7.6 log CFU/g) and Staphylococci, but garlic did not evoke significant changes in caecal microflora. Gorinstein et al. (2006a, b) showed that raw and boiled garlic at 100 °C for 20 minutes improved the plasma lipid levels in rats fed with cholesterol-containing diets and increased the plasma antioxidant activity (evaluated by cupric-reducing antioxidant capacity and Trolox equivalent antioxidant capacity assays) in groups of rats fed with cholesterol-free diets. Garlic boiled for a short time can be used as an additive in cooking. Supplementation of garlic at the dose of 500 mg (25 mg of lyophilised garlic/kg body weight) to the basal diet of rats was chosen as the most effective in terms of in-vivo plasma antioxidant activity and decrease of plasma lipids and fibrinogen (Jastrzebski et al. 2007). In-vitro antioxidant capacity measured by the ferric ion reducing antioxidant power (FRAP) method and by the 1,1-diphenyl-2-picrylhydrazyl (DPPH) free radical assay was the

highest in raw and in a short time processed garlic samples by cooking. The contribution of total polyphenols to the antioxidant activities of raw and cooked garlic was high (R^2 from 0.997 for FRAP and to 0.975 for DPH).

Studies showed that rats fed with diets of garlic or onions could reduce the exercise-induced oxidative stress but does not alter plasma cholesterol profile (Choi and Cho 2006). In garlic- or onion-fed animals, the ratio of reduced glutathione/oxidised glutathione was significantly higher than those of the control animals before and after exercise. The level of liver malondialdehyde (MDA) was lower than that of control animals after exercise. Compared to control animals, catalase activity of garlic-fed animals was higher before exercise but was lower after exercise, while superoxide dismutase (SOD) activity of garlic-fed animals was lower in before and after exercise. Catalase activity of onion-fed animals was higher before and during exercise, while SOD activity was higher during exercise. Plasma cholesterol profiles were not significantly different in rats fed with different *Allium* vegetable diets. The results suggested that *Allium* vegetable diets had antioxidative activities and could reduce the oxidative stress from exercise in rats but did not alter the plasma cholesterol profile.

Clinical Studies

In a clinical study of 25 healthy volunteers, 2 months intake of garlic tablets reduced malondialdehyde (MDA) level by about 60 % of the initial value (Grune et al. 1996). The MDA reducing effect was found in all age groups. The reduced GSH concentration in circulating human erythrocytes showed a significant increase after the 2-month period of garlic application, while the oxidised glutathione (GSSG) concentration showed no significant changes. Thus a significantly decreasing trend of the GSSG–total glutathione ratio was determined.

Anticancer Activity

In-Vitro Studies

Garlic powder failed to inhibit the growth of human hepatoma HepG2 or human colorectal carcinoma Caco-2 cells at concentrations of up to 1,000 µg/mL (Siegers et al. 1999). Garlic extract, in which the alliin content was highly enriched, was also unable to inhibit the growth of these cells. However, when the garlic extract was supplemented with garlic powder (to 10 % final concentration), there was a concentration-dependent clear inhibition of tumour cell growth (IC₅₀ values of 330 µg/mL for HepG2 and 480 µg/mL for Caco-2 cells). The growth of the human lymphatic leukaemia cell line CCRF CEM was significantly inhibited in a dose-dependent manner by both garlic powder and garlic extract at concentrations as low as 30 µg/mL.

A single p.o. pretreatment of male rats with diallyl sulfide (DAS), a component of garlic oil, caused a significant decrease in the oxidative metabolism of N-nitrosodiethylamine (NDEA) and 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK) in rat nasal mucosa (Hong et al. 1991). Whereas the nasal metabolism of N-nitrosodimethylamine (NDMA) was reduced by DAS pretreatment, there was no change in the amount of the nasal microsomal proteins immunoreactive with the antibodies against hepatic cytochrome P450IIE1. The inhibitory effect of DAS on the nasal oxidative metabolism of NDMA, NDEA and NNK was also observed in experiments in-vitro. The results demonstrated the ability of nasal mucosa to metabolically activate these nitrosamine carcinogens and the inhibition of this process by DAS, suggesting that DAS may be effective in inhibiting the related nasal tumorigenesis. DAS pretreatment significantly decreased the incidence of NNK-induced lung tumours (37.9 vs. 100 %) and the tumour multiplicity (0.6 vs. 7.2 tumours/mouse) in comparison to the vehicle control group (Hong et al. 1992). It was found that the chemopreventive effect of DAS against NNK-induced lung tumorigenesis in A/J mouse was probably by inhibiting the metabolic activation of NNK. Addition of 10 µM diallyl trisulfide (DATS) reduced human neoplastic lung cell (A549) growth by 47 %, whereas 10 µM diallyl disulfide (DADS)

decreased growth by only 20 % (Sakamoto et al. 1997). DATS treatment (10 μ M) did not alter nonneoplastic (MRC-5) lung cell growth. DATS (10 μ M) caused a marked and progressive increase in intracellular Ca^{2+} in A549 cells during the first 4 hours after treatment. Exposure to 1 μ M DATS for 24 hours significantly induced apoptosis, as indicated by increased DNA fragmentation.

S-allylcysteine (SAC), from garlic extract, inhibited proliferation of nine human and a murine melanoma cell line in a dose-dependent manner (1.2–10 mM) (Takeyama et al. 1993). SAC inhibited cellular growth and proliferation and modulated major cell differentiation markers of melanoma. Garlic extract induced a significant in-vitro cytotoxic activity on Sk-mel3 melanoma cell line (Hakimzadeh et al. 2010). *S*-allylcysteine (SAC) inhibited the proliferation and differentiation of LA-N-5 human neuroblastoma cells in-vitro in a time- and dose-dependent manner (Welch et al. 1992). However, the apparent inability of this compound to induce differentiation in neuroblastoma cells may limit its therapeutic potential. *S*-allylcysteine (SAC) and *S*-allylmercaptocysteine (SAMC) exhibited antiproliferative effects in-vitro on human breast cancer cells, MCF-7 and an aggressive, oestrogen-independent form MCF-7(ras) (Li et al. 1995). They altered the glutathione level without significant concurrent changes in the glutathione-metabolising enzymes. *S*-Allylmercaptocysteine, a garlic derivative, was shown to inhibit vascular smooth muscle and umbilical endothelial cell proliferation (Lee et al. 1994). Inhibition was dose dependent and affected smooth muscle cells more than endothelial cells. *S*-Allylmercaptocysteine to inhibit malignant cells could also reduce the proliferation of normal cells. *S*-Allylmercaptocysteine (SAMC) inhibited growth, arrests cells in G(2)-M and induces apoptosis in two human colon cancer cell lines, SW-480 and HT-29 (Shirin et al. 2001). SAMC exerted antiproliferative effects by binding directly to tubulin and disrupting the microtubule assembly, thus arresting cells in mitosis and triggering JNK1 and caspase-3 signalling pathways that led to apoptosis (Xiao et al. 2003).

Malignant cancer cell lines gastric (AGS) and breast (MCF-7) cells were sensitive in-vitro to garlic extracts (Ghazanfari et al. 2011). Garlic extract inhibitory effects were found to be tumour specific and dose dependent. Black garlic extract (BGE) could have significant inhibitory action on the growth of lung cancer Lewis cells (Yang et al. 2013). The combination of BGE and radiotherapy (by ^{60}Co gamma) significantly induced Lewis cells' apoptosis in G2/M stage, decreased the expression of Bcl-2, and upregulated the expression of bax. Garlic could not only induce apoptosis but also autophagy in cancer cells (Chu et al. 2013). Autophagy, also called type-II programmed cell death, provides new strategy in cancer therapy.

Diallyl disulfide (DADS) was more effective in inhibiting the growth of human colon tumour cells (HCT-15) than isomolar concentrations of S-allylcysteine, dipropyl disulfide (DPDS), allyl chloride, allyl glycidyl ether and allyl alcohol (Sundaram and Milner 1996a). A positive correlation ($R^2 = 0.944$) was found between DADS-induced DNA fragmentation and its ability to increase intracellular free calcium levels. The widespread effectiveness of DADS was evident by its ability to inhibit the growth of human colon (HCT-15), skin (SK MEL-2) and lung (A549) tumour cell lines. Addition of DADS (100 μM) was cytostatic to all three cell lines (Sundaram and Milner 1996b). Treatment with DADS also resulted in a dose-dependent increase in intracellular free calcium in cells. Alterations in calcium haemostasis were likely involved in the growth inhibition/cytotoxicity caused by DADS. Diallyl disulfide (DADS), an oil-soluble allyl sulfur compound found in processed garlic, markedly suppressed p34(cdc2) kinase activity and induced a G(2)/M phase arrest in cultured human colon tumour (HCT-15) cells (Knowles and Milner 1998). The ability of DADS to inhibit p34(cdc2) kinase activation occurred because of decreased p34(cdc2)/cyclin B(1) complex formation and modest p34(cdc2) hyperphosphorylation (Knowles and Milner 2000). They found that alterations in cell cycle, DNA repair and cellular adhesion factors accompanied DADS exposure and may also be involved in mediating the

block in G(2)/M progression (Knowles and Milner 2003). Jo et al. (2008) found that with the dynamic expression of cyclin B1, DADS induced reversible cell cycle arrest in the G2/M phase of HCT-116 colon cancer cells through a p53-independent mechanism. In HCT-116 colon cancer cells, p53-independent cell cycle arrest at G2/M phase was observed with DADS treatment, along with time-dependent increase of cyclin B1 (Song et al. 2009). In addition, apoptosis was also observed upon 24 hours DADS treatment accompanied by activation of p53. In HCT-116 cells, DADS application induced a dose-dependent increase and time-dependent changes in ROS production. The results suggested that ROS triggered the DADS-induced cell cycle arrest and apoptosis and that ROS were involved in stress-induced signalling upstream of p53 activation. Allicin exerted a time- and dose-dependent cytostatic effect on colon cancer cell lines HCT-116, LS174T, HT-29 and Caco-2 colon cancer cell lines HCT-116, LS174T, HT-29 and Caco-2 at concentrations ranging from 6.2 to 310 μ M (Bat-Chen et al. 2010). Treatment with allicin resulted in HCT-116 apoptotic cell death. Allicin also induced translocation of NF-E2-related factor 2 (Nrf2) to the nuclei of HCT-116 cells. Aged black garlic extract inhibited the growth and induced apoptosis in HT29 colon cancer cells through the inhibition of the PI3K/Akt pathway, suggesting that it may be effective in the prevention and treatment of colon cancer in humans (Dong et al. 2014).

Hepatocellular carcinoma cell line HepG2 and colon cancer cell line SW620, treated with MAPK inhibitors and S-allylmercaptocysteine (SAMC) from garlic, an increased apoptosis rate, was observed (Tong et al. 2014). A significantly lower apoptosis rate was noted in the SW620 cell line (with an imperfect TGF- β signal) than the rate noted in the HepG2 cell line (with an intact TGF- β signal); it was concluded that SAMC induced the apoptosis of cancer cells by activating the TGF- β signalling pathway, after MAPK signalling was inhibited. Allicin induced cell cycle arrest of human gastric cancer cell lines, MGC-803 and SGC-7901, in the M phase by upregulating the expression of p21WAF1 and p16INK4 genes (Ha and Yuan 2004). Allicin dose dependently inhibited proliferation of human gastric cancer SGC7901 cells

by arresting the cell cycle at the G2/M phase and induction of apoptosis (Tao et al. 2013). In-vitro studies indicated that the inhibitory effects of diallyl disulfide (DADS) on human gastric adenocarcinoma AGS cell motility and invasiveness were associated with increased tightness of the tight junctions and inhibition of metalloproteinase (TIMP)-1 and metalloproteinase (TIMP)-2 mRNA levels and proteins (Park et al. 2012b). Additionally, DADS repressed the levels of claudin proteins (claudin-2, claudin-3 and claudin-4), major components of TJs, that play key roles in control and selectivity of paracellular transport.

Treatment with diallyl trisulfide (DATS) resulted in significantly inhibited U937 leukaemia cell growth in a concentration- and time-dependent manner by induction of apoptosis (Choi and Park 2012). Cytotoxicity caused by DATS was mediated by generation of ROS and subsequent activation of the ROS-dependent caspase pathway in U937 leukaemia cells. Garlic oil (2.5 and 10 μ M) inhibited the proliferation of three human pancreatic cancer cell lines AsPC-1, PANC-1 and Mia PaCa-2 cells in-vitro (Lan et al. 2013). Moreover, due to programmed cell death, cell cycle arrest or both, pro-apoptosis effects on AsPC-1 cells were induced by garlic oil in a dose- and time-dependent manner.

Nishino et al. (1990) demonstrated that allixin, phytoalexin of garlic, exerted an anti-promoting activity against skin tumours induced by 12-*O*-tetradecanoylphorbol-13-acetate. Organosulfur compounds (OSC) from garlic and onions, namely, diallyl sulfide, diallyl trisulfide, allyl methyl sulfide, allyl methyl trisulfide and dipropyl sulfide, had enhancing effects on glutathione S-transferase placental (GST-P) form-positive foci formation induced by diethylnitrosamine (Den) in the liver of male F344 rats (Takada et al. 1994a, b). In contrast, high doses of methyl propyl disulfide and propylene sulfide significantly decreased the number of GST-P form-positive foci. To investigate the mechanism of the modifying effect on hepatocarcinogenesis, ornithine decarboxylase activity was measured in diallyl sulfide-, allyl methyl sulfide- and dipropyl sulfide-treated liver tissue without prior initiation with diethylnitrosamine, and its activity was increased

compared to controls. The results suggested that the promoting effect could be caused by increased cell proliferation with increased polyamine biosynthesis. In subsequent studies, oil-soluble OSCs such as methyl propyl disulfide and propylene sulfide demonstrated inhibitory effects on the development of GST-P positive foci induced by DEN, N-methyl-N-nitrosourea, N-butyl-N-(4-hydroxybutyl) nitrosamine, N,N'-dimethylhydrazine and dihydroxy-dipropylnitrosamine (Fukushima et al. 1997). Moreover, water-soluble OSCs such as S-methylcysteine and cysteine similarly decreased GST-P focus formation. In contrast, OSCs such as diallyl sulfide, diallyl trisulfide and allyl methyl trisulfide enhanced the formation of such altered hepatocellular foci. Inhibitory potential for colon and renal carcinogenesis was observed in rats treated with diallyl disulfide. Thus, the results indicated that some OSCs exerted chemopreventive effects on chemical carcinogenesis but may also demonstrate promotion potential, depending on the organ examined.

Garlic oil inhibited cyclin E expression in routinely cultured human gastric adenocarcinoma SGC7901 cells and also in transforming growth factor alpha (TGF- α)-treated ones, suggesting that garlic oil inhibited the TGF- α autocrine and paracrine loops, thus suppressing cancer cell proliferation (Liang et al. 2007). Garlic oil administration for 21 weeks significantly inhibited the increase of the nodule incidence and average nodule number per nodule-bearing liver induced by N-nitrosodiethylamine (NDEA), improved hepatocellular architecture and dramatically inhibited NDEA-induced elevation of serum biochemical indices (alanine aminotransferase, aspartate aminotransferase, alkaline phosphatase and gamma-glutamyl transpeptidase) and hepatic 8-hydroxy-2'-deoxyguanosine (8-OHdG) levels in a dose-dependent manner (Zhang et al. 2012a). Garlic oil counteracted NDEA-induced oxidative stress in rats illustrated by the restoration of glutathione (GSH), superoxide dismutase (SOD), catalase (CAT), glutathione reductase (GR), glutathione peroxidase (GPx) and glutathione S-transferase (GST) levels and the reduction of the malondialdehyde (MDA) levels in liver. The data suggested that garlic oil exhibited significant protection against NDEA-induced

hepatocarcinogenesis, which might be related with the enhancement of the antioxidant activity and the induction of apoptosis. Further, they found that garlic oil attenuated nitrosodiethylamine-induced hepatocarcinogenesis by modulating the metabolic activation and detoxification phase I (including cytochrome P450 enzyme (CYP) 2E1, CYP1A2 and CYP1A1) and phase II enzymes (including glutathione S-transferases (GSTs) and UDP-glucuronosyltransferases (UGTs)) (Zhang et al. 2013a).

Ajoene was one of the main compounds formed from heating crushed garlic as a mixture of *E*- and *Z*-isomers (*E*- and *Z*-4,5,9-trithiadodeca-1,6,11-triene 9-oxide) (Kaschula et al. 2010). Structure–activity studies on ajoene and ajoene analogues revealed that the *Z*-isomer was moderately more active than the *E*-isomer at inhibiting the in-vitro tumour cell growth, suggesting that specific protein interactions may be important. Substitution of the terminal end allyl groups in ajoene for alkyl, aromatic or heteroaromatic groups produced some analogues with superior in-vitro anticancer activity to ajoene. *Z*-ajoene exhibited antitumour properties via pro-apoptotic and cell cycle blockage activities on various cell lines involving activation of the p53 family gene products, p53, p63 and p73, at indicated doses (Terrasson et al. 2007). According to its known anti-proteasome activity, *Z*-ajoene induced a downregulation of MHC class I expression at the surface of treated cells but did not impair their recognition by CD8⁺ T cells. A tumourigenic lymphoid cell line derived from a Burkitt lymphoma (BJA-B) was found to be more sensitive in-vitro to ajoene than human primary fibroblasts (FS4), a permanent, non-tumourigenic cell line derived from baby hamster kidney cells (BHK21) (Scharfenberg et al. 1990). Ajoene and diallyl sulfide (DAS), two garlic compounds, at 100 mg/ mL inhibited [3H] aflatoxin B1 binding to calf thymus DNA and adduct formation (Tadi et al. 1991a). They decreased the formation of both organosoluble and water-soluble metabolites of [3H]AFB1. Neither compound significantly affected glutathione S-transferase (GST) activity. The results indicated that ajoene and DAS affected AFB1 metabolism and DNA binding by inhibiting phase I enzymes

and may therefore be considered as potential cancer chemopreventive agents. Ajoene inhibited both primary tumour growth and metastasis of B16/BL6 melanoma cells in C57BL/6 mice (Taylor et al. 2006). Ajoene also inhibited tumour–endothelial cell adhesion, as well as the in-vivo TNF- α response to lipopolysaccharide.

Studies suggested that ajoene might induce apoptosis in human leukaemic cells via stimulation of peroxide production and activation of nuclear factor- κ B (Dirsch et al. 1998a, b). In promyelocytic leukaemia cell HL60, garlic and onion oils showed marked antineoplastic effects representing both growth suppression and differentiation activities (Ariga et al. 2000). Incubation of human promyelocytic leukaemia cells with garlic or onion oil (20 μ g/mL) caused a marked suppression of HL-60 proliferation; the suppression was almost identical with those obtained by all-*trans*-retinoic acid (ATRA) or dimethyl sulfoxide (DMSO) used as positive controls (Seki et al. 2000). These oils induced the generation of nitroblue tetrazolium (NBT)-reducing activity, and about 20 % of the HL-60 cells became NBT positive. CD11b, another marker of the differentiation of these cells, was also significantly induced by garlic oil or onion oil. The data suggested that garlic and onion oils had the ability to induce differentiation of HL-60 cells into those of the granulocytic lineage. Ajoene-induced cell death in human promyeloleukaemic cells was found not to require the activation of c-Jun NH(2)-terminal kinase (JNK) but was found to be enhanced by the inhibition of extracellular signal-regulated kinases (ERK) $\frac{1}{2}$ (Antlsperger et al. 2003).

Results of in-vitro studies indicated that apoptosis in leukaemia HL-60 cells triggered by ajoene was based on the activation of a mitochondria-dependent caspase cascade which included also the activation of the initiator caspase-8 (Dirsch et al. 2002).

Z-ajoene, a sulfur-rich compound purified from garlic, induced time- and dose-dependent apoptosis in human promyelocytic leukaemia HL-60 cells (Li et al. 2002b). The transmission of apoptotic signal induced by Z-ajoene involved a reactive oxygen species-dependent pathway leading to

caspase-dependent Bcl-2 cleavage. Antiproliferative activity of Z-ajoene was demonstrated against a panel of human tumour cell lines with IC₅₀ values varying from 5.2 to 26.1 mM and at a lower extent in normal marsupial kidney cells (PtK2) (Li et al. 2002a). Meanwhile, Z-ajoene arrested HL60 cells in G(2)/M phase of cell cycle in a dose- and time-dependent way. In PtK2 cells, exposure to 20 microM Z-ajoene for 6 hours induced a complete disassembly of the microtubule network that was associated with an increased number of cells blocked in early mitotic stages. In-vitro, a reversible inhibition of the microtubule protein assembly was observed with an IC₅₀ of 25 µM Z-ajoene. In-vivo, Z-ajoene inhibited tumour growth by 38 % and 42 % in mice grafted with sarcoma 180 and hepatocarcinoma 22, respectively. In-vitro activities of 20S proteasome purified from human erythrocytes on fluorogenic peptide substrates specific for trypsin-like, chymotrypsin-like and peptidylglutamyl peptide-hydrolysing activities revealed that ajoene inhibited the trypsin-like activity in a dose- and time-dependent manner (Xu et al. 2004). Further, the ability of 20S proteasome to degrade the OVA(51-71) peptide, a model proteasomal substrate, was partially but significantly inhibited by ajoene. In addition, when human leukaemia cell line HL60 was treated with ajoene, both trypsin- and chymotrypsin-like activities were affected, and cells arrested in G2/M phase and total amount of cytosolic proteasome increased.

The following steroidal saponins and sapogenins isolated from garlic and related *Allium* species inhibited TPA (tissue plasminogen activator)-enhanced ³²P incorporation into phospholipids of HeLa cells: eruboside-B (39.4 % inhibition), sativoside-B1 (4 %), sativoside-B1-sp. (19.2 %), agigenin (20.8 %), ampeloside-Bs1 (32 %), laxogenin (43 %), chinenoside-I (4.2 %), chinenoside-I-sp. (51 %) and the terpenoid glycyrrhetic acid (30.9 %) (Matsuura 2001). Eruboside-B exhibited in-vitro cytotoxic activity against several cancer cell lines with the following ED₅₀ values (µg/mL): BC1 human breast cancer (3.6 µg/mL) Lu1 human lung cancer (1 µg/mL), Col2 human colon cancer (1 µg/mL), KB human oral epidermoid cancer (12.7 µg/mL), KB-V

(+VLB) drug-resistant KB assessed in the presence of vinblastine (9 µg/mL) and KB-V (–VLB) and drug-resistant KB assessed in the absence of vinblastine (8.7 µg/mL). The results of in-vitro studies revealed that 95 % of HeLa cervical cancer cells were killed at a dose of 500 µL aqueous garlic extract, whereas about 92, 87, 60 and 24 % cancer cells were killed at doses of 400, 300, 200 or 100 µL of, respectively, Islam et al. (2011).

Oil-soluble organosulfur compounds (diallyl sulfide, diallyl disulfide and diallyl trisulfide) markedly inhibited growth of canine mammary tumour cells (CMT-13) in culture but not water-soluble organosulfur compounds (S-allylcysteine, S-ethylcysteine and S-propylcysteine) (Sundaram and Milner 1993). Increasing addition of diallyl disulfide (DADS) resulted in a progressive decrease in CMT-13 cell growth. The inhibitory effects of these compounds were modified by intracellular glutathione. Diallyl trisulfide (DATS) inhibited oestrogen receptor- α (ER- α) activity in human breast cancer cells (Hahm and Singh 2014). Exposure of MCF-7 and T47D cells to DATS resulted in downregulation of ER- α protein, which peaked between 12- and 24-hour posttreatment. DATS was relatively more effective in suppressing ER- α protein expression compared with its mono and disulfide analogues. DATS treatment caused a decrease in protein levels of peptidyl-prolyl *cis-trans* isomerase (Pin1) and overexpression of Pin1 partially attenuated ER- α downregulation by DATS. The dose of S-allylmercaptocysteine (CySSA) from garlic or S-1-propenylmercaptocysteine (CySSPe) (the major onion analogue) alone required to reduce viable breast cancer MCF-7 cells by 50 % was >400 µM, (Zhang et al. 2014). This was synergistically reduced to 62 µM and 91 µM for CySSA+Se and CySSPe+Se in the presence of Na₂SeO₃ (Se), respectively, at molar ratios of 39:1. Apoptosis was confirmed and cell cycle arrest occurred at the G2/M and sub-G1 interphases.

Allicin inhibited the growth of cancer cells of murine and human origin by inducing the formation of apoptotic bodies, nuclear condensation and a typical DNA ladder in cancer cells (Oommen et al. 2004). Also allicin induced the activation of

caspase-3, caspase-8 and caspase-9 and cleavage of poly(ADP-ribose) polymerase. The protein alliumin, isolated from garlic bulb, exerted antiproliferative activity towards leukaemia L1210 cells (Xia and Ng 2005). However, it was devoid of ribonuclease activity, protease activity, mitogenic activity towards mouse splenocytes and antiproliferative activity towards hepatoma Hep G2 cells.

Diallyl sulfide (DAS) and diallyl disulfide (DADS) treatment of both H460 and H1299 cells non small cell lung cancer cells (NSCLC) resulted in the highest numbers of cells in apoptotic state (Hong et al. 2000). DADS was found to be more effective in inducing apoptosis on NSCLC. The results demonstrated that DAS, DADS and garlic extract are effective in the reduction of antiproliferative gene in NSCLC and suggested that the modulation of apoptosis-associated cellular proteins by DAS, DADS and garlic extract may be the mechanism for apoptosis. Diallyl sulfide (DAS) and diallyl disulfide (DADS) dose dependently inhibited arylamine N-acetyltransferase (NAT) activity in a human colon tumour (adenocarcinoma) cell line (Chen et al. 1998). The viability, arylamine N-acetyltransferase activity and N-acetyl-2-aminofluorene (2-AAF)-DNA adduct formation in human bladder tumour cells, was inhibited by diallyl sulfide (DAS) and diallyl disulfide (DADS) in a dose-dependent manner (Chung 1999). The data also indicated that DAS and DADS decreased the apparent values of K_m and V_{max} from human bladder tumour cells in both systems examined. Diallyl disulfide (DADS), one of the major components of garlic, induced cell cycle arrest and apoptosis in T24 human bladder cancer cells in-vitro (Lu et al. 2004). DADS also promoted caspase-3 activity after exposure which led to induce apoptosis. DADS also increased the product of intracellular hydrogen peroxide. DADS also increased cyclin E and decreased CDK2 gene expression which may lead to the G2/M arrest of T24 cancer cells. Diallyl disulfide (DADS) exerted antineoplasm activity in-vitro (Yu et al. 2005). DADS inhibited N-acetyltransferase activity and gene expression in human oesophagus epidermoid carcinoma CE 81T/VGH cells in a dose-dependent manner. Diallyl disulfide (DADS) treatment of colonic adenocarcinoma cells (HT-29) initiated a

cascade of molecular events characteristic of apoptosis that included a decrease in cellular proliferation, translocation of phosphatidylserine to the plasma membrane outer layer, activation of caspase-3 and caspase-9, genomic DNA fragmentation and G2/M phase cell cycle arrest (Altonsy and Andrews 2011). Short-chain fatty acids (SCFAs), particularly butyrate (abundantly produced in the gut by bacterial fermentation of dietary polysaccharides), enhanced colonic cell integrity but, in contrast, inhibited colonic cancer cell growth. Combining DADS with butyrate augmented the apoptotic effect of butyrate on HT-29 cells. Administration of diallyl disulfide (DADS) to colonic adenocarcinoma cell line (Caco-2) significantly increased the number of dead cells, exhibited morphological changes characteristic to apoptosis and induced caspase-3 cleavage but not caspase-8 (Altonsy et al. 2013). DADS induced membrane FAS expression, at the transcriptional level. The results suggested that DADS induced apoptosis in colonic cancerous cells not only through the intrinsic pathways but also through enhancing the extrinsic pathway.

Studies showed that *S*-allylmercaptocysteine (50 mg/L) reduced human prostate carcinoma (LNCaP) cell growth, whereas the antiproliferative effect of *S*-allylcysteine was not as pronounced (Pinto et al. 1997). Both *S*-allylmercaptocysteine and *S*-allylcysteine caused an increase in LNCaP cell reduced glutathione concentrations. Putrescine and spermine concentrations decreased, and spermidine increased 3 days after *S*-allylmercaptocysteine treatment. Diminished cell growth and altered polyamine concentrations suggested that *S*-allylmercaptocysteine may impede the polyamine synthesising enzyme, ornithine decarboxylase. Separate studies showed that DADS inhibited the growth of prostate cancer cells in a dose-dependent manner, compared to the control (Arunkumar et al. 2006). At 25 and 40 μ M concentrations, DADS induced cell cycle arrest at G2/M transition in PC-3 cells by downregulating CDK1 expression.

S-allylmercaptocysteine (SAMC), a stable organosulfur compound of aged garlic extract, induced dose-dependent growth inhibition of two erythroleukaemia cell lines, with a 50

% lethal dose of 0.046 mM for OCIM-1 cells and 0.093 mM for HEL cells (Sigounas et al. 1997). DNA showed fragmentation compatible with apoptosis. Flow cytometric analyses of DNA revealed an abnormal cell cycle progression in both types of erythroleukaemia cells, with the major portion of the unsynchronised cells in the G2/M phase. Two main water-soluble constituents of the garlic, S-allylcysteine (SAC) and S-allylmercaptocysteine (SAMC), were able to suppress invasive androgen-independent prostate cancer (PCa) cell proliferation and invasive abilities (Chu et al. 2006). This inhibitory effect was associated with the induction of mesenchymal to epithelial transition. Most importantly, the SAC and SAMC treatment led to restoration of *E*-cadherin expression at transcription and protein levels. Furthermore, examination of cell lines from other types of cancer (ovarian, nasopharyngeal and oesophageal carcinomas) also confirmed that the effect of SAC and SAMC on activation of *E*-cadherin might be a general effect on human cancer cells. In other studies, inhibitory effects of diallyl disulfide (DADS) on LNCaP prostate cancer cell motility and invasiveness were found to be associated with increased tightness of the tight junctions, which was demonstrated by an increase in transepithelial electrical resistance (Shin et al. 2010). DADS repressed the levels of the claudin proteins, major components of tight junctions that played a key role in control and selectivity of paracellular transport. Furthermore, the activities of matrix metalloproteinase (MMP)-2 and -9 in LNCaP cells were dose dependently inhibited by treatment with DADS, and this was also correlated with a decrease in expression of their mRNA and proteins. The study indicated that tight junctions and MMPs were critical targets of DADS-induced anti-invasiveness in human prostate cancer LNCaP cells. S-allylcysteine (SAC) suppressed the proliferation of androgen-independent human prostate cancer (PC-3) and led to cell cycle arrest at the G0/G1 phases, as well as inducing cell apoptosis which was accompanied by the decreased expression of Bcl-2 and increased expression of Bax and caspase-8 (Liu et al. 2012b).

Diallyl sulfides, organosulfur compounds isolated from garlic, selectively inhibited the activities of mammalian family

X DNA polymerases (pols), such as pol β , pol λ and terminal deoxynucleotidyl transferase (TdT), in-vitro (Nishida et al. 2008). The purified fraction consisted of diallyl trisulfide, diallyl tetrasulfide and diallyl pentasulfide (molecular ratio: 5.3:3:1). The suppression of human cancer cell (promyelocytic leukaemia cell line, HL-60) growth had the same tendency as the inhibition of pol X family among the compounds. Diallyl sulfides were suggested to bind to the pol β -like region of family X pols. Treatment of T24 human bladder cancer cells with diallyl trisulfide (DATS), compound of garlic, resulted in potent antiproliferative activity in-vitro (Shin et al. 2014). Additionally, some typical apoptotic characteristics, such as chromatin condensation and an increase in the population of sub-G1 hypodiploid cells, were observed. The results suggested that the pro-apoptotic activity of DATS was probably regulated by a caspase-dependent cascade through the activation of both intrinsic and extrinsic signalling pathways, which was mediated through the blocking of PI3K/Akt and the activation of the JNK pathway. Diallyl trisulfide (DATS)-induced apoptosis of pancreatic cancer cells (Capan-2) and non-tumourigenic pancreatic ductal epithelial cells (H6C7) (Ma et al. 2014). DATS-induced apoptosis was markedly elevated in Capan-2 cells compared with H6C7 cells. DATS-induced apoptosis was correlated with downregulation of Bcl-2, Akt and cyclin D1 protein levels, and upregulation of Bax, Fas, p53 and cyclin B protein levels in Capan-2 cells. DATS inhibited the viability of primary colorectal cancer cells in a time- and dose-dependent manner (Yu et al. 2012). DATS induced apoptotic cell death in human primary colorectal cancer cells through a mitochondria-dependent signalling pathway. In basal carcinoma cancer cells, DATS exerted chemopreventive potential via ER stress and the mitochondrial pathway (Wang et al. 2012a).

S-allylcysteine (SAC), a water-soluble garlic derivative (1–100 mmol/L), inhibited the proliferation of human ovarian cancer cells A2780 cells in dose- and time-dependent manners (the IC₅₀ value was approximately 25 mmol/L at 48 hours and less than 6.25 mmol/L at 96 hours) (Xu et al. 2014b). Treatment of A2780 cells with SAC resulted in G1/S phase

arrest and induced apoptosis, accompanied by decreased expression of pro-caspase-3, Parp-1 and Bcl-2 and increased expression of active caspase-3 and Bax. S-benzyl-cysteine (SBC), a structural analogue of aged garlic S-allylcysteine (SAC), exerted cytotoxic activity involving activation of mitochondrial-dependent apoptosis through p53 and Bax/Bcl-2 pathways in human gastric cancer SGC-7901 cells (Sun et al. 2013). Studies showed that the proliferation rate and colony-forming abilities of hepatocellular carcinoma HCC metastatic MHCC97L cells were suppressed by S-allylcysteine (SAC), together with significant suppression of the expressions of proliferation markers, Ki-67 and proliferating cell nuclear antigen (PCNA) (Ng et al. 2012). Moreover, SAC hindered the migration and invasion of MHCC97L cells and significantly induced apoptosis and necrosis of MHCC97L cells. In-vivo xenograft liver tumour model demonstrated that SAC single or combined with cisplatin treatment inhibited the progression and metastasis of hepatocellular carcinoma tumour.

Animal Studies

Growth of Ehrlich ascites tumour-bearing mice was significantly inhibited by feeding garlic as well as some amino acids (Choy et al. 1983). These materials significantly reduced the total number of free tumour cells growing in the peritoneal cavity of mice and prolonged significantly the length of time for 50 % death of tumour-bearing mice. The tumour yield and incidence of phorbol-myristate-acetate promotion were inhibited in a dose-dependent manner over the range of 10–10,000 µg onion oil, applied three times per week (Belman 1983). Garlic oil was also inhibitory but was less effective. Gavage administration of diallyl sulfide, from garlic, to C57BL/6J mice inhibited by 74 % the incidence and reduced the frequency of colorectal adenocarcinoma induced by 20 weekly injections of 1,2-dimethylhydrazine (Wargovich 1987). Gavage administration of diallyl sulfide, from garlic, to C57BL/6J mice inhibited by 74 % the incidence and reduced the frequency of colorectal adenocarcinoma induced by 20 weekly injections of 1,2-dimethylhydrazine (Wargovich 1987). Gavage administration of diallyl sulfide, from garlic, to

C57BL/6J mice inhibited by 74 % the incidence and reduced the frequency of colorectal adenocarcinoma induced by 20 weekly injections of 1,2-dimethylhydrazine (Wargovich 1987).

Topical application of garlic oil during the initiation phase of benzo[*a*]pyrene (B(a)P)-induced skin carcinogenesis in adult female Swiss albino mice caused a decline in the number of tumour-bearing mice as well as in the mean number of tumours per effective mouse (Sadhana et al. 1988). Garlic extract inhibited 7,12-dimethylbenz[*a*]anthracene (DMBA)-induced skin carcinogenesis in Swiss albino mice (Rao et al. 1990). Topical application of garlic extract twice daily for 3 days every week prior to DMBA administration at 200 nmol during the first week followed by 100 nmol during subsequent weeks reduced tumour incidence from 73.9 to 31.8 %. Similar garlic application prior to DMBA administration at 400 nmol during the first week followed by 200 nmol during subsequent weeks reduced tumour incidence from 100 to 43.45 %. Studies demonstrated that garlic powder was effective in inhibiting 7,12-dimethylbenz[*a*]anthracene (DMBA)-induced mammary tumours in rats, possibly by reducing DMBA–DNA binding (Liu et al. 1992). Supplementation of garlic, selenium-enriched garlic and allyl group-containing sulfide constituents of garlic to the basal AIN-76A diet suppressed DMBA-induced mammary tumour in rats (Ip et al. 1992). Animals given the selenium-enriched garlic (final concentration 3 ppm Se in the diet) developed the fewest mammary tumours. They found a high intake of selenium-enriched garlic did not affect 5'-deiodinase activity in rats suggesting that its anticarcinogenic effect was unlikely to be mediated by an imbalance in the blood T4 to T3 ratio (Ip and Lisk 1993). Dietary fortification with S-allylcysteine (SAC), a water-soluble constituent of processed garlic, caused a progressive decrease in the binding of the carcinogen 7,12-dimethylbenz[*a*]anthracene (DMBA) to rat mammary cell DNA (Amagase and Milner 1993). The results suggested the primary effect of garlic and its constituents SAC was on the bioactivation and binding of the carcinogen rather than DNA repair.

Oral administration of garlic at the dose level of 400 mg/kg body wt./day for 2 weeks before and 4 weeks following 3-methylcholanthrene carcinogen thread insertion into the uterine cervix of virgin young adult Swiss albino mice significantly reduced the incidence of carcinoma to 23 % compared with 73 % in the positive control (Hussain et al. 1990). Co-administration of aged garlic extract (AGE) with naltrexone resulted in improvement of immune responses against experimentally implanted WEHI-164 fibrosarcoma tumours in BALB/c mice (Ebrahimpour et al. 2013). AGE showed synergistic effects with naltrexone on the inhibition of tumour growth and increment of survival times of mice.

Eight organosulfur compounds from garlic and onions allyl methyl trisulfide (AMT), allyl methyl disulfide (AMD), diallyl trisulfide (DAT) and diallyl sulfide (DAS) and also four corresponding saturated compounds in which propyl groups were substituted for the allyl groups were tested for their inhibitory effects on benzo[a]pyrene (BP)-induced neoplasia of the forestomach and lung of female A/J mice (Sparnins et al. 1988). DAS and AMD, but not DAT or AMT, inhibited pulmonary adenoma formation. All four allylic compounds induced increased glutathione S-transferase (GST) activity in the forestomach, but varied in their capacity to induce GST in the lung, liver and small bowel. Their saturated analogues produced little or no induction. Topical application of diallyl sulfide or diallyl disulfide significantly inhibited skin papilloma formation from the ninth week of promotion and significantly increased the rate of survival in mice (Dwivedi et al. 1992). Diallyl disulfide (DDS) exhibited inhibitory potential in the colon and renal carcinogenesis induced by the carcinogen N-diethylnitrosamine in rats (Takahashi et al. 1992). However, diallyl sulfide (DS) demonstrated clear enhancing effects on the development of glutathione S-transferase placental form-positive foci in rats and may promote hepatocarcinogenesis. Diallyl disulfide (DADS) treatment significantly inhibited the growth of H-ras oncogene-transformed tumours in nude mice (Singh et al. 1996b). The levels of membrane-associated p21H-ras were markedly lower in the tumour tissues of DADS-treated mice as compared to controls. An opposite trend, however, was

evident for cytosolic p21H-ras. Further, DADS treatment resulted in a significant inhibition of hepatic as well as tumoral 3-hydroxy-3-methylglutaryl coenzyme A reductase activity. Treatment of mice with diallyl sulfide (DAS), diallyl disulfide (DADS) and diallyl trisulfide (DATS) prevented benzo(a)pyrene (BP)-induced cancer (Srivastava et al. 1997). Results suggested that while reduction of ethoxyresorufin O-deethylase (EROD) activity may, at least in part, contribute to the DAS-mediated inhibition of BP-induced lung cancer, anticarcinogenic effects of organosulfides against BP-induced forestomach carcinogenesis appeared to be independent of this mechanism. Treatment of mice with DAS, DADS and DATS resulted in a significant increase, as in hepatic and glutathione transferase (GST) activity towards anti-7 β ,8 α -dihydroxy-9 α ,10 α -oxy-7,8,9,10-tetrahydrobenzo(a)pyrene (anti-BPDE), the ultimate carcinogen of BP. The antitumour activity of DAS was of a much higher magnitude in benzo[a]pyrene (B(a)P)-induced carcinogenesis in comparison to mice exposed to 7,12-dimethylbenzanthracene (DMBA) in terms of tumour incidence, cumulative number of tumours and average number of tumours per mouse (Singh and Shukla 1998). The results showed that DAS had a protective effect in the polycyclic aromatic hydrocarbon-induced mouse skin carcinogenesis. Oral gavage of DATS significantly retarded the growth of human prostate cancer PC-3 xenografts in athymic mice without causing weight loss (Xiao et al. 2006). The DATS-mediated suppression of PC-3 xenograft growth correlated with the induction of pro-apoptotic proteins Bax and Bak.

Oral administration of 5 μ mol/kg diallyl trisulfide (DATS) to female BALB/c mice inhibited the growth of human MCF-7 cell tumour xenografts (Na et al. 2012). Diallyl trisulfide (DATS) showed the most potent antiproliferative effects in human breast cancer MCF-7 cells. MCF-7 cells treated with DATS underwent apoptotic death as revealed by a progressive increase in the proportion of the sub-G0/G1 cell population. In-vitro experiments indicated that DATS promoted gene expression of multidrug resistant 1 (Mdr1) and diallyl sulfide (DAS), and diallyl disulfide (DADS) promoted MRP3 gene expression, and DATS alone stimulated gene expression of multidrug resistance-associated protein 1 (MRP1) in colo 205

human colon cancer cells (Lai et al. 2012). In-vivo studies demonstrated that DADS and DATS induced Mdr1 and MRP1 gene expression. DADS promoted MRP3 gene expression as well as DADS, and DATS increased MRP4 and MRP6 gene expression in the colo 205 xenograft mice.

Garlic powder, water-soluble S-allylcysteine (SAC) and oil-soluble diallyl disulfide (DADS), supplementation significantly delayed the onset of mammary tumours induced by N-methyl-N-nitrosourea (MNU) and reduced the tumour incidence and total tumour number compared to rats receiving the unsupplemented diet (Schaffer et al. 1996). In a separate study the quantity of mammary DNA alkylation occurring 3 hours after MNU treatment was reduced in rats fed with garlic, SAC or DADS. Specifically, *O*(6)-methylguanine adducts and *N*(7)-methylguanine adducts were reduced, compared to controls. They also found that garlic powder and allyl sulfur compounds SAC and DADS enhanced the ability of dietary selenite to inhibit 7,12-dimethylbenz[*a*]anthracene-induced mammary DNA adducts (Schaffer et al. 1997). S-allylcysteine (SAC) at doses of 666 and 2,000 ppm did not exert an inhibitory effect on any index of mammary tumour development induced by N-methylnitrosourea in rats, including incidence, latency, multiplicity or volume, compared with untreated controls contradicting results of previous animal model studies (Cohen et al. 1999).

Animals that received 5 weekly immunisations of garlic (cumulative dose = 13 mg) had significantly reduced tumour incidence, tumour growth of MBT2 murine bladder carcinoma and increased survival when compared with mice that received the saline control (Riggs et al. 1997). No treatment-related deaths were observed with this treatment schedule. Further, mice that received 50 mg garlic orally had significant reductions in tumour volume when compared with animals that received the saline control, and mice that received 500 mg garlic orally had significant reductions in both tumour volume and mortality.

Studies showed that tomato and garlic suspensions had a protective effect on colon carcinogenesis induced by azoxymethane in rats (Sengupta et al. 2003). It was observed

that aberrant crypt foci were reduced in all treated groups (by 32.11 % in garlic, by 76.14 % in tomato and by 55.96 % in the tomato–garlic combined group). Among treated groups, glutathione S-transferase (GST) activity was found to be induced in both the liver and colon, whereas considerable reduction in lipid peroxidation level was observed in the liver as well as in the colon with respect to the untreated azoxymethane control group. Significant reduction in Brdu labelling index and increase in apoptotic index in the colon were noted in the treated groups. The growth of transplanted human colon cancer cell line SW480 in the back of nude mice was inhibited markedly by DADS (diallyl disulfide); the relative tumour growth rate (T/C%) was 49.85 % (Liao et al. 2007). The protein level of proliferating cell nuclear antigen (PCNA) was significantly lower in DADS group than in the control group. SW480 cells in DADS group were arrested in G2/M phase; the G2/M phase proportion was significantly higher in DADS group than in the control group. They found that DADS induced G(2)/M arrest in human colon cancer SW480 cells, probably through the downregulation of PCNA, p53 and cyclin B1 and upregulation of p21(WAF1) (Liao et al. 2009). Dose-dependent apoptosis was detected in aged black garlic extracts (ABGE)-treated gastric cancer cells in in-vitro studies (Wang et al. 2012b). In foregastric cancer tumour-bearing Kunming mice, significant antitumour effects of ABGE were observed, such as growth inhibition of inoculated tumours. Further investigation of serum superoxide dismutases, glutathione peroxidase, interleukin 2 and the increased indices of spleen and thymus indicated that the anticancer action of ABGE may be partly due to its antioxidant and immunomodulative effects.

Garlic extract was proven to be effective in inhibiting initial events caused by 12-*O*-tetradecanoyl-phorbol-13-acetate (TPA), type tumour promoters in-vitro and in-vivo (Nishino et al. 1989). The first stage of tumour promotion in two-stage mouse skin carcinogenesis in-vivo was suppressed by the treatment with garlic extract. Garlic oil was also inhibitory but was less effective. Garlic and onion oil treatments inhibited dramatically the sharp decline in the intracellular ratio of reduced glutathione (GSH)/oxidised

(GSSG) glutathione caused by tumour promoter 12-0-tetradecanoylphorbol-13-acetate (TPA); thus, it was suggested that some of the inhibitory effects of garlic and onion oils on skin tumour promotion may result from their enhancement of the natural GSH-dependent antioxidant protective system of the epidermal cells (Perchellet et al. 1986). Garlic oil (5 µg/mL) inhibited by about 50 % TPA-induced ornithine decarboxylase (ODC, L-ornithine carboxy-lyase) activity in the same epidermal cell system. Application of garlic oil inhibited skin tumorigenesis in Sencar mouse initiated by 7,12-dimethylbenz[a]-anthracene (DMBA) and also inhibited two tumour promotion stages by TPA in DMBA initiated SENCAR mice (Perchellet et al. 1990). The number of papillomas per mouse was significantly reduced by garlic oil but not by propenyl sulfide. DAS treatment caused a significant increase in glutathione S-transferase (GST) activity, an enzyme system responsible for the detoxification of a variety of electrophilic xenobiotics including several harmful benzo[a]pyrene (B[a]P) metabolites of mouse stomach in a dose-dependent manner (Gudi and Singh 1991). DAS treatment also resulted in increased pulmonary GST activity, but not in a dose-dependent fashion. Treatment of animals with DAS increased stomach glutathione (GSH) peroxidase activity. In contrast, GSH peroxidase activity in the liver and kidney was unchanged by DAS treatment. The results suggested that DAS and perhaps other naturally occurring organosulfur compounds may exert an antineoplastic effect by modulating GSH-dependent detoxification enzymes. The inhibition by garlic oil was most effective when given one hour before TPA but was evident when given from two hours before to two hours after TPA. Ajoene, oil-macerated garlic products, inhibited in a two-stage carcinogenesis test on mouse skin (Nishikawa et al. 2002). Treatment with ajoene suppressed skin tumour formation. Mice treated with 250 µg of ajoene had only 4.9 % the number of tumours per mouse compared with the control group at 18 weeks. Tamoxifen (TAM) combination with allicin (5 or 10 µM) showed a significant cytotoxic effect compared with the TAM-treated group as manifested by a decrease in the percent survival of Ehrlich ascites carcinoma to 35 % and 29 %, respectively

(Suddek 2014). Allicin (10 mg/kg, orally) enhanced the efficacy of TAM (1 mg/kg, i.p.) in mice as manifested by a significant increase in solid tumour growth inhibition by 82 % compared with 70 % in the TAM group. In rats, TAM intoxication resulted in a significant decline in SOD, GSH and total protein with significant elevation in TBARS, ALT and AST, ALP, LDH, total bilirubin, γ GT and TNF- α levels. These changes were abrogated by allicin treatment. The results suggested the beneficial role of allicin as an adjuvant to TAM in cancer treatment by alleviating liver injury.

Thiocremonone (0–50 μ g/mL), generated from high-temperature high-pressure-treated garlic, inhibited human lung cancer cell, A549 and NCI-H460, growth in a concentration-dependent manner through induction of apoptotic cell death accompanied by induction of cleaved caspase-3, caspase-8, caspase-9, Bax, p21 and p53, but decrease of xIAP, cIAP and Bcl-2 expression (Jo et al. 2014). Thiocremonone further inhibited glutathione peroxidase activity in lung cancer cells. In an allograft in-vivo model, thiocremonone (30 mg/kg) also inhibited lung cancer cell, A549 and NCI-H460, tumour growth accompanied with the reduction of peroxiredoxin 6 (PRDX6) expression and glutathione peroxidase activity, but increased expression of cleaved caspase-3, caspase-8, caspase-9, Bax, p21 and p53. The data indicated that thiocremonone inhibited tumour growth via inhibition of glutathione peroxidase activity of PRDX6 through interaction.

Clinical Studies

Tilli et al. (2003) applied ajoene topically to the tumours of 21 patients with either nodular or superficial basal cell carcinoma (BCC). A reduction in tumour size was seen in 17 patients. The BCC cell line TE354T and a short-term primary culture of BCC were analysed for apoptosis induction after treatment with the drug. Apoptosis was detected by morphology of the cells and by flow cytometry. Ajoene induced apoptosis in a dose- and time-dependent manner in these cultures.

Epidemiological/Meta-analytical/Review Studies

Omar and Al-Wabel (2010) reported that research evidence supported the protective effects of garlic in stomach, colorectal and breast cancer in humans. The protective effects appeared to be related to the presence of organosulfur compounds, predominantly allyl derivatives, which also had been shown to inhibit carcinogenesis in the forestomach, oesophagus, colon, mammary gland and lung of experimental animals. Several mechanisms had been proposed for the cancer-preventive effects, modulation of several metabolising enzymes that activated (cytochrome P450s) or detoxified (glutathione *S*-transferases) carcinogens, and inhibited the formation of DNA adducts in several target tissues and antiproliferative activity possibly mediated by the induction of apoptosis and alterations of the cell cycle.

It was found that the inhabitants in Cangshan County, Shandong Province, usually take fresh garlic as daily food, and the mortality from gastric cancer for the inhabitants in Cangshan was found to be significantly lower than that in Qixia County where the inhabitants rarely take garlic (Xing et al. 1982). It was also found that the nitrite concentration in gastric juice of the inhabitants in Cangshan was significantly lower than that in Qixia. The reduction rate (%) of nitrite concentration in gastric juice after the introduction of 10 g of fresh garlic in the form of homogenate was significantly larger than that of the control test in tested persons at Shandong Medical Research Institute. It was proven that garlic promoted the inhibition of nitrate-reducing bacteria and reduction of nitrite formation and be considered as a protective factor against the carcinogenesis of gastric cancer.

The Netherlands Cohort Study which started in 1986 with 120,852 men and women ranging in age from 55 to 69 years provided evidence for a strong inverse association between onion consumption and stomach carcinoma incidence (Dorant et al. 1996b). The consumption of leeks and the use of garlic supplements were not associated with stomach carcinoma risk. Also, the Netherlands Cohort Study did not support an inverse

association between the consumption of onions and leeks or the use of garlic supplements and the incidence of male and female colon and rectum carcinoma (Dorant et al. 1996a). Also, the Netherlands Cohort Study found that garlic supplement use was not associated with breast carcinoma incidence (rate ratio = 0.87) (Dorant et al. 1995) and lung carcinoma (Dorant et al. 1994). In a case-control study of 345 patients diagnosed with primary breast carcinoma between 1986 and 1989 conducted in France, Challier et al. (1998) found that accounting for total caloric intake and established risk factors breast cancer risk was shown to decrease as consumption of fibre, garlic and onions increased. This study also supported the epidemiologic evidence that saturated fat intake and breast cancer risk are associated in postmenopausal women and conversely that unsaturated fat intake could lower the risk in the same subgroup. In a case-referent study conducted in Jiangsu province, China, on histopathologically confirmed cases for oesophageal cancer ($n = 81$) and stomach cancer ($n = 153$) and population-based referents ($n = 234$), frequent intake of *Allium* vegetables (garlic, onion, Welsh onion and Chinese chives) was found to be inversely associated with the risk for both cancers (Gao et al. 1999). In the highest consumption category (≥ 1 time/week) of garlic, onion, Welsh onion and Chinese chives, the adjusted odd ratios compared with the lowest category (< 1 time/month) were 0.30 (CI = 0.19–0.47), 0.25 (CI = 0.11–0.54), 0.15 (CI = 0.08–0.26) and 0.57 (CI = 0.23–1.42) for oesophageal cancer and 0.31 (CI = 0.22–0.44), 0.17 (CI = 0.08–0.36), 0.22 (CI = 0.15–0.31) and 0.40 (CI = 0.17–0.94) for stomach cancer, respectively. In an interview study of 564 patients with stomach cancer and 1,131 controls in an area of China with high rates of gastric cancer, a significant reduction in gastric cancer risk with increasing consumption of garlic, onions and other *Allium* vegetables (You et al. 1989). Persons in the highest quartile of intake experienced only 40 % of the risk of those in the lowest. Protective effects were seen for *Allium* foods. The meta-analysis conducted by Fleischauer et al. (2000) found that high intake of raw garlic or cooked garlic may be associated with a protective effect against stomach and colorectal cancers. Heterogeneity of effect estimates,

differences in dose estimation, publication bias and possible alternative hypotheses (e.g. confounding by total vegetable consumption) precluded sole reliance on summary effect estimates. Results of a double-blind intervention study carried out in China, involving 2,526 people (35–74 years old) in the intervention group and 2,507 in the control group, showed that large doses of allitridum and micro-dose of selenium for a year may effectively prevent gastric cancer in the male population (Li et al. 2004).

Analysis of large data from an integrated network of Italian and Swiss case-control studies showed an inverse association between the frequency of use of onion and garlic and the risk of several common cancers (Galeone et al. 2006). The multivariate odd ratios for the highest category of onion and garlic intake were, respectively, 0.16 and 0.61 for cancer of the oral cavity and pharynx, 0.12 and 0.43 for oesophageal cancer, 0.44 and 0.74 for colorectal cancer, 0.17 and 0.56 for laryngeal cancer, 0.75 and 0.90 for breast cancer, 0.27 and 0.78 for ovarian cancer, 0.29 and 0.81 for prostate cancer and 0.62 and 0.69 for renal cell cancer. A large multi-centre case-control study of 1,369 patients with benign prostatic hyperplasia and 1,451 controls in Italy showed an inverse association between onion and garlic consumption and benign prostatic hyperplasia (Galeone et al. 2007). The inverse relationships were consistent across age strata. In a multi-centre case-control study of 454 endometrial cancer cases and 908 controls, Galeone et al. (2009) found a moderate protective role of onion and garlic on the risk of endometrial cancer. Compared with nonusers, the odd ratios of endometrial cancer for successive categories of onion intake were 0.94 for <2 portions/week and 0.40 for ≥2 portions/week, with a significant inverse trend in risk. The odd ratio for an increment of one portion (i.e. 80 g) of onions per week was 0.81. For garlic, the odd ratios for successive categories of intake were 0.89 for intermediate use and 0.62 for high use, with a significant inverse trend in risk.

In a large population-based case-control study in Shanghai (750 cases and 750 age- and gender-matched controls) and Qingdao (201 cases and 201 age- and gender-matched

controls), Setiawan et al. (2005) found inverse relationships with dose-response pattern were observed between frequency of onion intake and stomach cancer in Qingdao and Shanghai after adjusting for matching variables, education, body mass index, pack-years of smoking, alcohol drinking, salt intake and fruit and vegetable intake. In Shanghai, negative dose-response relationships were observed between monthly intake of onions or garlic stalks and distal, but not cardiac cancer. A negative association was also noted between intake of garlic stalks (often vs. never) and risk of stomach cancer in Qingdao (odds ratio = 0.30). Their results confirmed protective effects of *Allium* vegetables (especially garlic and onions) against stomach cancer. In a meta-analysis, consumption of high levels of *Allium* vegetables (onion, garlic, leek, Chinese chive, scallion, garlic stalk and Welsh onion) reduced the risk for gastric cancer risk (odds ratio = 0.54) (Zhou et al. 2011). Specific analyses for onion, garlic, leek, Chinese chive, scallion, garlic stalk and Welsh onion yielded similar results, except for onion leaf. In a population-based case-control study conducted in a Chinese population from 2003 to 2010, after adjusting for potential confounding factors, raw garlic consumption of two times or more per week was found to be inversely associated with lung cancer (odds ratio (OR) = 0.56) with a monotonic dose-response relationship (Jin et al. 2013).

In the meta-analysis of 8 studies with 20 reports of the effects of *Allium* vegetables (5,458 patients with colorectal cancer including 7,125,067 person-years) and 5 studies with 11 reports of the effects of garlic supplements (2,685 patients with colorectal cancer including 2,304,439 person-years), Zhu et al. (2014) found no evidence that higher intake of *Allium* vegetables reduced the risk for colorectal cancer. They observed that garlic supplements increased the risk for colorectal cancer.

Antimutagenic/Anticlastogenic Activity

Aqueous garlic bulb extract markedly suppressed the mutagenesis in both *Escherichia coli* WP2 trp⁻ and *E. coli* WP2 trp⁻ uvrA⁻ induced by 4-nitroquinoline 1-oxide (4NQO), but not that induced by UV (Zhang et al. 1989). It was

suggested that the extract might act by inactivating the electrophilic group(s) of 4NQO or inhibiting its metabolic activation. Experiments with *Salmonella* tester strains indicated that aqueous garlic extract possessed antimutagenic properties towards ionising radiation, peroxides, adriamycin and N-methyl-N'-nitro-nitrosoguanidine (Knasmüller et al. 1989). Radical scavenging garlic constituents, i.e. molecules with sulfur moieties, were confirmed to be responsible for the inhibitory effect of aqueous extract towards mutagenesis induced by radiation and radiomimetic compounds. Garlic extract attenuated the lethal effects of gamma rays on repair-deficient *Escherichia coli* strains; the garlic constituent allicin (thio-2-propene-1-sulfinic acid S-allyl ester) was partly responsible for the reduced radiation-induced mutagenesis in *Salmonella typhimurium* TA 102. No such inhibitory effects were detected with alliin (S-allyl-L-cysteine sulfoxide) or cysteine; aqueous garlic extract inhibited hydrogen peroxide-induced lipid peroxidation. Results obtained in preliminary experiments with Chinese hamster ovary cells suggested that the antimutagenic properties of garlic extract were not restricted to procaryotic cells.

Oral or parenteral pretreatment with DAS significantly and dose dependently inhibited N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)-induced nuclear aberration and ornithine decarboxylase activity in Wistar rat glandular stomach mucosa (Hu and Wargovich 1989; Hu 1990). The suppressions were observed to be dose dependent. The data supported the epidemiologic evidence of the chemopreventive effect of garlic on gastric cancer.

Allixin, a phytoalexin isolated from garlic, dose dependently inhibited histidine+ revertants induced by aflatoxin B1 (AFB1) in *Salmonella typhimurium* TA100 (Yamasaki et al. 1991). Allixin at 75 µg/mL inhibited [3H]AFB1 binding to calf thymus DNA and reduced formation of AFB1-DNA adducts. In addition, allixin exhibited a concentration-dependent inhibition of the formation of organosoluble metabolites and the glutathione conjugates of [3H]AFB1. The data indicated that the effect of allixin on AFB1-induced mutagenesis and binding of

metabolites to DNA may be mediated through an inhibition of microsomal P450 enzymes. Crude garlic extract, ajoene and diallyl sulfide (DAS) inhibited rat liver 9,000 g supernatant (S-9) mutagenesis induced by aflatoxin B1 (AFB1) (Tadi et al. 1991b). They also inhibited AFB1 binding to DNA. Dietary administration of turmeric (0.05 %), garlic (0.25 %), curcumin and ellagic acid (0.005 % each) to rats significantly reduced the number of γ -glutamyl transpeptidase-positive foci induced by aflatoxin B1, the precursor of hepatocellular neoplasm (Soni et al. 1997). The results indicated the usefulness of antioxidant food additives in ameliorating aflatoxin-induced mutagenicity and carcinogenicity. Studies demonstrated that while dietary garlic could reduce DNA adduct formation in mammary tissue caused by 7,12-dimethylbenz(a)anthracene (DMBA) in rats, this protection was influenced by several dietary components (Amagase et al. 1996). Garlic supplementation prevented the increase in DNA adducts caused by increasing dietary corn oil. Combining dietary supplements of garlic, selenite (0.5 mg/kg diet) and retinyl acetate (328 mg/kg diet) inhibited the occurrence of DNA adducts to a greater degree than when each was supplied individually.

The clastogenicity of three mutagens, clastogens, mitomycin C (1.5 mg/kg) and cyclophosphamide (25 mg/kg) or sodium arsenite (2.5 mg/kg), were reduced significantly in mice which had been given garlic extract as a dietary supplement (Das et al. 1993). Addition of 2 % garlic powder to diets containing aminopyrine and sodium nitrite (each at 600 mg/kg) reduced the occurrence of both 7-N-methyldeoxyguanosine (7-N-mG) and 6-O-methyldeoxyguanosine (6-O-mG) adducts to rat liver DNA by approximately 55 % and over 80 % when 4 % garlic was provided (Lin et al. 1994). Dietary supplementation with garlic powder (2 and 4 %) also reduced the occurrence of 7-N-mG and 6-O-mG adducts by approximately 40 and 60 %, respectively, in rats intubated with N-nitrosodimethylamine (150 mg/kg body wt). The quantity of 7-N-mG and 6-O-mG adducts in mammary tissue of rats given intravenous N-methyl-N-nitrosourea (50 mg/kg body wt) was reduced over 50 % in rats fed with 2 % garlic compared to controls. Raw

garlic aqueous extract significantly inhibited benzo[a]pyrene (BaP)–DNA adduct formation at concentrations of 0.001, 0.01 and 0.1 mg/mL (Hageman et al. 1997). S-allylcysteine (SAC) also significantly decreased BaP–DNA adduct formation at concentrations of 0.01 and 0.1 mg/mL. For diallyl sulfide, no significant reduction in BaP–DNA adduct formation was found. In addition, reactive oxygen species-induced 8-oxodeoxyguanosine in DNA was reduced in the presence of SAC.

Feeding house mouse, *Mus musculus*, with aqueous garlic extract or mustard oil separately or simultaneously prior to several subcutaneous injection of the clastogen, sodium arsenite, attenuated the clastogenic activity of sodium arsenite (Choudhury et al. 1997a). The degree of modulation of sodium arsenite-induced chromosomal aberrations was more pronounced in mustard oil than in garlic extract, and simultaneous administration of both the dietary supplements reduced the clastogenic effects of sodium arsenite closer to the level of the negative control. The greater efficacy could be due to the interaction of the two dietary supplements and its radical scavenging property.

Water extracts of garlic, deodorised garlic powder and onions, but not leeks, were found to reduce the in-vitro formation of N-nitrosomorpholine (NMOR), a known liver carcinogen (Dion et al. 1997). Addition of increasing quantities (20, 40 and 80 mM) of S-allylcysteine (SAC), a water-soluble compound in processed garlic, depressed NMOR formation by 16 %, 27 % and 43 %, respectively. SAC and S-propyl cysteine were less effective than isomolar cysteine in reducing NMOR formation. The oil-soluble sulfur compounds diallyl disulfide (DADS), dipropyl disulfide and diallyl sulfide were ineffective inhibitors of NMOR generation. SAC and DADS reduced the mutagenicity of NMOR in *Salmonella typhimurium* TA100. SAC at 70 µmol/plate reduced the number of histidine revertants per plate by 51 %, whereas DADS at 0.12 µmol/plate reduced mutant colony number by 76 %. SAC and DADS were more effective than isomolar cysteine in reducing NMOR mutagenicity. Garlic extract exhibited antigenotoxic and protective effects

against vinblastine in human lymphocyte cultures in-vitro (Sinduja et al. 2012). Garlic caused a significant decrease in the frequency of chromosome aberration suggesting that the garlic extract modulated the vinblastine-induced cytotoxicity in a dose-dependent manner.

Feeding rats with dried garlic powder at 0.1, 0.5 and 1 % concentrations for 4 weeks prior to intraperitoneal challenge with the carcinogen benzo[*a*]pyrene (1 mg/rat) caused a significant reduction in the excretion of urinary mutagens (Polasa and Krishnaswamy 1997). Further, there was stimulation in the activities of liver cytosolic glutathione S-transferase and liver and lung quinone reductases. The results suggested that the antimutagenic potential of garlic may be mediated through the induction of detoxification enzymes in target tissues.

Daily gavage administration of three concentrations (25, 50 and 100 mg/kg body weight) of fresh garlic to Swiss albino mice for different durations up to 60 days was observed to protect significantly against effects of known clastogens (Das et al. 1996). Frequencies of chromosomal aberrations and damaged cells induced in bone marrow preparations were found to be directly dose dependent and after an initial enhancement at 7 days were reduced following prolonged exposure for 30 and 60 days to the low level observed at 24 hours. Thus, administration of a low concentration of garlic extract daily was suggested for at least 30 days to obtain the maximum benefit of the extract in protecting against the clastogenic effects of known genotoxicants. The clastogenic affects of prolonged exposure to sodium arsenite, a strong clastogen, was reduced by a highly significant amount when crude garlic extract (equivalent to 6 g for 60 kg human body) was given daily to the mice by intubation for the same period (Choudhury et al. 1997b). Feeding house mouse, *Mus musculus*, with aqueous garlic extract or mustard oil separately or simultaneously prior to several subcutaneous injection of the clastogen, sodium arsenite, attenuated the clastogenic activity of sodium arsenite (Choudhury et al. 1997a). The degree of modulation of sodium arsenite-induced chromosomal aberrations was more pronounced in mustard oil

than in garlic extract, and simultaneous administration of both the dietary supplements reduced the clastogenic effects of sodium arsenite closer to the level of the negative control. The greater efficacy could be due to the interaction of the two dietary supplements and its radical scavenging property.

In a study of human volunteers, consumption of whole strawberries, garlic juice or kale juice immediately after an amine-rich diet with a nitrate was found to reduce endogenous N-nitrosodimethylamine (NDMA, a carcinogen) formation (Chung et al. 2002). NDMA excretion was decreased by 70, 71 and 44 %, respectively, compared with NDMA excretion after ingestion of an amine-rich diet with a nitrate. Strawberry, garlic and kale extracts inhibited nitrosation in-vitro.

Antifungal Activity

The mycelial phase of *Histoplasma capsulatum* was inhibited by both the volatile and water-soluble components of garlic (Fliermans 1973). Garlic extract at a concentration of 254 ppb was inhibitory, while 8.1 ppm was lethal to pure cultures of *H. capsulatum*. Garlic fractions A, B, allicin and ajoene exhibited antifungal activity in-vitro (Yoshida et al. 1987). Ajoene inhibited the growth of *Paracoccidioides brasiliensis*, a fungal pathogen for humans, by affecting the integrity of the fungal cytoplasmic membrane (San-Blas et al. 1989). Ajoene inhibited the growth of the dimorphic pathogenic fungus *Paracoccidioides brasiliensis*, yeast cells being more sensitive to its action than mycelial cultures (San-Blas et al. 1993). Low concentrations of aqueous garlic extract were both inhibitory and lethal to numerous strains of *Cryptococcus neoformans* (Fromtling and Bulmer 1978). Intravenous administration of commercial garlic extract to two patients with cryptococcal meningitis and three patients with other types of meningitis-augmented plasma titres of anti-*Cryptococcus neoformans* activity rose twofold over preinfusion titres (Davis et al. 1990). Anti-*Cryptococcus neoformans* activity was detected in four of five cerebrospinal fluid samples but not in pooled normal cerebrospinal fluid. Ajoene exhibited the most potent inhibitory activity against the growth of both *Aspergillus niger* and *Candida albicans* at less than 20 µg/mL (Yoshida et al.

1987). Allicin was effective in-vitro against *Candida*, *Cryptococcus*, *Trichophyton mentagrophytes*, *Epidermophyton floccosum* and *Microsporium gypseum* (Yamada and Azuma 1977). The minimal inhibitory concentrations (MICs) of allicin against these organisms were 3.13–6.25 µg/mL by the agar dilution method and 1.57–6.25 µg/mL by the broth dilution method, using Sabouraud glucose (SG) medium. The MIC value against *Aspergillus fumigatus* was 12.5–25 µg/mL in both agar dilution and broth after 5 days and against *Cryptococcus neoformans* and *Candida albicans* on both media after 5 days were 3.23 and 6.25 µg/mL, respectively. Garlic extract administered orally appeared to reduce brain cryptococcal populations in mice, although the results obtained were generally inconsistent (Louria et al. 1989).

Aqueous garlic extract inhibited the growth of *Microsporium gypseum*, *Trichophyton verrucosum*, *Trichophyton violaceum*, *Trichophyton rubrum*, *Trichophyton schoenleini*, *Trichophyton mentagrophytes* and *Epidermophyton floccosum* in-vitro (Amer et al. 1980). Experimental dermatophyte infection was induced in guinea pigs and rabbits, and topical application or injection of garlic extract was very effective, producing complete healing in 14–17 days following twice daily application of the extract for 1 week (Amer et al. 1980). Among the *Allium* plants exhibiting antifungal activity, garlic extract showed the lowest minimal fungicidal concentration against *Aspergillus niger*, *A. flavus* and *A. fumigatus* (Yin and Tsao 1999). Acetic acid treatments of the extracts increased the inhibitory effect for all plants against three fungi.

Volatile components of crude aqueous extracts of garlic bulbs inhibited germination of microconidia and hyphal extension in *Fusarium oxysporum* f. sp. *lycopersici* in axenic culture (Tariq and Magee 1990). Garlic volatiles also inhibited the production of microconidia and chlamydospores. Extracts of turmeric (*Curcuma longa*), garlic (*Allium sativum*) and asafoetida (*Ferula asafoetida*) inhibited *Aspergillus parasiticus* aflatoxin production considerably (more than 90 %) at concentrations of 5–10 mg/mL (Soni et al. 1992). Allicin, one of the active principles of freshly crushed garlic

homogenates, was found to exhibit (1) antibacterial activity against a wide range of Gram-negative and Gram-positive bacteria, including multidrug-resistant enterotoxigenic strains of *Escherichia coli*; (2) antifungal activity, particularly against *Candida albicans*; (3) antiparasitic activity, including some major human intestinal protozoan parasites such as *Entamoeba histolytica* and *Giardia lamblia*; and (4) antiviral activity (Ankri and Mirelman 1999). The main antimicrobial effect of allicin was attributed to its chemical reaction with thiol groups of various enzymes, e.g. alcohol dehydrogenase, thioredoxin reductase and RNA polymerase, which could affect the essential metabolism of cysteine proteinase activity involved in the virulence of *E. histolytica*. The protein alliumin, isolated from garlic bulb, demonstrated antifungal activity against *Mycosphaerella arachidicola*, but not against *Fusarium oxysporum* (Xia and Ng 2005).

Yeast-like fungi representing the genera *Candida*, *Cryptococcus*, *Rhodotorula*, *Torulopsis* and *Trichosporon* were inhibited in-vitro in the presence of an aqueous extract of garlic (Moore and Atkins 1977). Fungi associated with vaginitis were inhibited and killed by an aqueous garlic extracted and diluted to 1:1,024 when incubated at 37 °C. Antimycotic activity was greater at 37 than at 30 °C. Twenty-two *C. albicans* isolates from active vaginitis cases were all inhibited by the garlic extract. Aqueous extracts of garlic bulbs were fungicidal for 39 of 41 clinical isolates of *Candida albicans* at 68 µg total dry weight of crude extract per ml of 2 % (w/v) malt extract broth in standing culture; the remaining two isolates gave variable or moderate growth at 68 µg/mL (Barone and Tansey 1977). In shake culture, the crude extract was fungistatic between 50 and 300 µg/mL and fungicidal above 400 µg/mL. Gradual loss of anticandidal activity occurred when crude extract was stored at 37 °C before being assayed; loss of activity was proportional to duration of heat treatment. Activity was stable in acid and unstable in base. Results suggested allicin to be the major anticandidal component and that other thiosulfinates in garlic extracts may have some anticandidal activity. Adetumbi et al. (1986) found that aqueous garlic extract completely inhibited lipid synthesis in *C. albicans*. Protein and nucleic acid syntheses were

inhibited to the same extent as growth. Ghannoum (1988) found that the growth of *C. albicans* in the presence of aqueous garlic extract affected the yeast lipid in a number of ways: the total lipid content was decreased; garlic-grown yeasts had a higher level of phosphatidylserines and a lower level of phosphatidylcholines; in addition to free sterols and sterol esters, *C. albicans* accumulated esterified sterol glycosides; the concentration of palmitic acid (16:0) and oleic acid (18:1) increased and that of linoleic acid (18:2) and linolenic acid (18:3) decreased. Oxygen consumption of garlic-treated *C. albicans* was also reduced. The anticandidal activity of garlic was antagonised by thiols such as L-cysteine, glutathione and 2-mercaptoethanol. The data suggested that garlic exerted its anticandidal effect by the oxidation of thiol groups present in the essential proteins, causing inactivation of enzymes and subsequent microbial growth inhibition. Adhesion of *Candida* spp. to buccal epithelial cells was significantly reduced after both short and long time exposure to aqueous garlic extract (Ghannoum 1988). There was a significant reduction in the adherence of *Candida* spp. to buccal epithelial cells collected immediately or 15 minutes after an oral rinse with garlic extract. Garlic aqueous extract inhibited the growth in-vitro of *Malassezia furfur* (25 strains), *Candida albicans* (18 strains), other *Candida* sp. (12 strains) as well as 35 strains of various dermatophyte species tested in a dose-dependent manner with maximum of 100 % at defined concentrations (Shams-Ghahfarokhi et al. 2006). In-vitro studies found that MIC₅₀ and MIC₉₀ values of allicin alone against six *Candida* spp. ranged from 0.05 to 25 µg/mL (Khodavandi et al. 2010). However, when allicin was used in combination with fluconazole or ketoconazole, the MICs were decreased in some isolates. The synergistic effect between allicin and azoles was demonstrated in some of the *Candida* spp. such as *C. albicans*, *C. glabrata* and *C. tropicalis* but not in *C. rugosa*, *C. parapsilosis* and *C. krusei*. Allicin was shown to enhance significantly the effect of amphotericin B against *Candida albicans* in-vitro and in-vivo, although allicin did not exert a fungicidal effect (An et al. 2009). Further study demonstrated that allicin-mediated oxidative damage, such as phospholipid peroxidation in the plasma membrane, via

influencing the defence of *C. albicans* against oxidative damage may underpin the synergistic interaction between allicin and amphotericin B. Allicin was found to enhance amphotericin B-induced structural damage to fungal vacuolar membrane even at a non-lethal dose of the antibiotic (Ogita et al. 2006b). Allicin could also enhance the antifungal activity of AmB against the pathogenic fungus *Candida albicans* and against *Aspergillus fumigatus*. Allicin was not lethal but could markedly amplify the fungicidal activity of polymyxin B which was weakly detected with the increase in the plasma membrane permeability in *Saccharomyces cerevisiae* (Ogita et al. 2007). Their combined actions caused a dynamic structural damage to the yeast vacuole as judged by the disappearance of its swollen spherical architecture. The vacuole-targeting activity of PMB was similarly amplified in medium with t-butyl hydroperoxide as a substitute for the action of allicin. In-vitro studies suggested that the synergistic fungicidal action of Cu^{2+} and allicin from garlic was dependent on the selective accumulation of the ion in the plasma membrane fraction by allicin-enhanced cellular permeability and allicin-mediated phospholipid peroxidation (Ogita et al. 2006a). *Candida albicans* and *Candida tropicalis* cells treated with sublethal concentrations of diallyl disulfide (DADS) sustained a decrease in the activity of all antioxidant enzymes except catalase, resulting in oxidative stress and damaged cells (Yousuf et al. 2010). Increased levels of lipid peroxidation and decreased levels of glutathione were observed in DADS treated cells. Activity of glucose-6-phosphate dehydrogenase decreased significantly following DADS treatment and could be correlated with a decrease in glutathione concentration in both *Candida* species. The results indicated that diallyl disulfide acted as a pro-oxidant to *Candida* species and hence may act as a potent antifungal in the management of candidiasis.

Six different mixtures of garlic distilled oils containing diallyl disulfide (DDS) and diallyl trisulfide (DTS), ranging from 1 to 51 % and 88 to 38 %, respectively, exhibited antimicrobial activity against a number of yeasts (*Candida albicans*, *Candida tropicalis* and *Blastoschizomyces*

capitatus), Gram-positive bacteria (*Staphylococcus aureus* and *Bacillus subtilis*) and Gram-negative bacteria (*Pseudomonas aeruginosa* and *Escherichia coli*) (Avato et al. 2000).

Incubation of garlic extracts made up of 1 % DDS and 88 % DTS resulted, in fact, in the absence of growth inhibition against all the tested microorganisms, whereas garlic oils with higher quantities of DDS showed significant inhibitory activity, increasing with the increase of DDS amount.

Fresh garlic extract had a greater efficacy than freeze-dried garlic powder extract as indicated both by its effects on morphology and inhibition of growth of *C. albicans* (Lemar et al. 2002). Both the growth and respiration of *Candida albicans* were sensitive to garlic extracts and to allyl alcohol, a metabolic trituration product of garlic (Lemar et al. 2005). Changes typical of oxidative stress, NADH oxidation and glutathione depletion and increased reactive oxygen species were observed in the treated yeast. Known targets for allyl alcohol were alcohol dehydrogenases Adh1 and Adh2 (in the cytosol) and Adh3 (mitochondrial), although the significant decrease in NAD(P)H after addition of allyl alcohol was indicative of another mechanism of action. Fresh garlic extract demonstrated inhibitory activity against *C. albicans* GDH 2,346, a strain isolated from a denture stomatitis patient, in its planktonic, adherent and sessile phases (Shuford et al. 2005). MICs for planktonic yeast were 0.0625–0.125 mg/mL. The in-vitro activity decreases as the biofilm phenotype developed, as noted previously with traditional antifungal drugs. The superior activity at 1 hour versus 48 hours of treatment is probably related to the half-life of garlic extract at 37 °C and would be an important consideration in the development of in-vivo uses. Garlic and its bioactive components displayed ability to suppress hyphae production and to affect the expression level of SIR2 gene in *C. albicans* (Low et al. 2008). Eruboside-B obtained by enzymatic hydrolysis of the furostanol glycoside proto-eruboside-B from garlic bulb inhibited the growth of *Candida albicans* in-vitro (25 µg/mL MIC) (Matsuura et al. 1988). The MICs of garlic extract for the yeasts were 1.4 mg/mL for *Candida albicans* and 1.9 mg/mL for *Saccharomyces cerevisiae* (Rees et al. 1993). Garlic also inhibited *Fusarium laceratum*, *Trichoderma*

hamatum, *Aspergillus fumigatus* and *Geotrichum candidum* at the lowest concentration of 2 mg/mL. At this concentration, *Aspergillus fumigatus* was the most sensitive and *Geotrichum candidum* the least sensitive, although still showing 25 % after 8 days incubation. Antifungal N-feruloyl amides N-feruloyltyrosine and N-feruloyltyramine were isolated from *A. sativum* roots (Fattorusso et al. 1999). Both compounds resulted to be active against the pathogen *Fusarium culmorum* with ED₅₀ of 20 and 22 µg/mL, respectively. The ethanolic garlic extract exhibited moderate inhibitory activity against the two isolates each of *Rhizopus stolonifer* (50 %), *Mucor* sp. (40 %), *Aspergillus luchuensis* (30 %), *Aspergillus flavus* (30 %) and *Scopulariopsis* sp. (20 %) but lacked in inhibitory activity against *Penicillium oxalicum* (Pundir et al. 2010).

A concentrated *A. sativum* extract containing 34 % allicin, 44 % total thiosulfinates and 20 % vinyl dithiols exhibited potent in-vitro fungistatic and fungicidal activity against 3 different isolates of *Cryptococcus neoformans* (Davis et al. 1994). The minimum inhibitory concentration (MIC) of the concentrated garlic extract against 1×10^5 organisms of *C. neoformans* ranged from 6 to 12 µg/mL. In addition, in-vitro synergistic fungistatic activity with amphotericin B was demonstrated against all isolates of *C. neoformans*. Of 21 plant extracts tested, only the aqueous extract of garlic exhibited potent in-vitro activity against *Trichophyton rubrum* human skin pathogen (Samuel et al. 2000). However, the antifungal activity was lost when the extract was heated above 60 °C. Garlic and onion essential oils and their constituent diallyl trisulfide, diallyl tetrasulfide and dimethyl trisulfide were potent inhibitors of yeast growth with minimum inhibitory concentrations between 2 and 45 ppm (Kim et al. 2004). Film formation on soy sauce by *Zygosaccharomyces rouxii* SS1 was completely prevented for 30 days by the addition of 30 and 40 ppm of garlic oil and onion oil, respectively. The oils and their constituent sulfides, however, were only very weakly antibacterial, showing minimum inhibitory concentrations of greater than 300 ppm for most of the bacteria tested.

Among the tested *Allium* oils, *A. sativum* f. *pekinense* oil exhibited the strongest inhibition of growth of *Trichophyton*

rubrum, *T. erinacei* and *T. soudanense* with MICs (minimum inhibiting concentrations) of 64 µg/mL (Pyun and Shin 2006). Additionally, garlic oils showed significant synergistic antifungal activity when combined with ketoconazole. Ethanol extracts of *Allium sativum*, *Aloe barbadensis* and *Solanum nigrum* were found to be inhibitory in-vitro to the following fungi: *Trichophyton rubrum*, *Trichophyton verrucosum*, *Trichophyton violaceum*, *Trichophyton tonsurans*, *Trichophyton mentagrophytes*, *Aspergillus glaucus*, *Aspergillus flavus*, *Aspergillus fumigatus*, *Aspergillus terreus*, *Candida albicans*, *Candida glabrata* and *Candida tropicalis* (Shamim et al. 2004). However, none of the plant extracts were found active against *Epidermophyton floccosum*.

The fungus *Fusarium oxysporum* showed the lowest sensitivity towards garlic essential oil extracts, whereas *Aspergillus niger* and *Penicillium cyclopium* were significantly inhibited particularly at low concentrations (Benkeblia 2004). A novel antifungal protein, designated allivin, from garlic bulbs, exhibited antifungal activity against *Botrytis cinerea*, *Mycosphaerella arachidicola* and *Physalospora piricola* (Wang and Ng 2001). It inhibited translation in a cell-free rabbit reticulocyte system with an IC₅₀ of 1.6 µM. Compared to the garlic essential oil, the onion essential oil showed a stronger inhibitory effect on the *Aspergillus versicolor* mycelial growth and sterigmatocystin production. After a 21-day incubation of the fungus, 0.05 and 0.11 µg/mL of onion essential oil and 0.11 µg/mL of garlic essential oil completely inhibited the *Aspergillus versicolor* mycelial growth and mycotoxin sterigmatocystin biosynthesis. The combination of essential oils of onion (75 %) and garlic (25 %) had a synergistic effect on the growth inhibition of *A. versicolor* and sterigmatocystin production. Garlic essential oil, containing diallyl sulfides, exhibited antifungal effect against standard and wild strains of *Ascosphaera apis*, the fungal pathogen of chalkbrood disease (Kloucek et al. 2012).

Animal Studies

Oral treatment of BALB/c mice with garlic extracts showed that alcoholic garlic extracts (5 mg/kg, 4 times daily) provided 100 % protection of mice against disseminated cryptococcosis (Khan and Katiyar 2000). A concomitant increase in MST (mean survival time) (>35 days) was observed, along with a significant reduction in cfu ($\log_{10}$) burden of cryptococci in visceral (the liver, spleen, kidney, lung and heart) tissues, especially the brain (>4.5 $\log_{10}$). Ajoene treatment of mice intratracheally infected with *Paracoccidioides brasiliensis* was found to be effective in suppressing infection (Thomaz et al. 2008). Ajoene-treated mice developed Th1-type cytokine responses producing higher levels of IFN- γ and IL-12. Ajoene in association with antifungal drugs (sulfamethoxazole/trimethoprim) showed a positive additive effect. The efficacy of extracts was also evident in the sera of mice.

Allicin from crushed garlic clove inhibited the in-vitro growth of 31 clinical isolates of *Aspergillus* spp. (Shadkchan et al. 2004). The in-vitro MICs and MFCs of allicin were between 8 and 32 mg/L. Allicin intravenous (i.v.) treatment led to a significant 10-fold reduction in fungal burden in *A. fumigatus*-infected mice as evaluated by quantitative fungal cultures of kidney tissue samples. Allicin treatment significantly prolonged survival of infected mice from mean survival time (MST) = 7.7 days in untreated mice to MST = 21.3 and 13.9 days for allicin i.v. and orally treated mice. In immunosuppressed mice infected intranasally with conidia of *Aspergillus fumigatus*, intratracheal (i.t.) instillation of antibody–alliinase conjugate and alliin (four treatments) resulted in 80–85 % animal survival (36 days), with almost complete fungal clearance (Appel et al. 2010). Repetitive intratracheal administration of the conjugate and alliin was also effective when treatments were initiated at a more advanced stage of infection (50 hours). The fungus was killed specifically without causing damage to the lung tissue or overt discomfort to the animals. Intratracheal instillation of the conjugate without alliin or of the unconjugated monoclonal antibody significantly delayed the death of the infected mice, but only 20 % of the animals survived. In-vitro studies showed

that the purified antibody–alliinase conjugate bound to conidia and hyphae of *A. fumigatus* at nanomolar concentrations. In the presence of alliin, the conjugate produced cytotoxic allicin molecules, which killed the fungus.

Clinical Studies

The use of ajoene as a 0.4 % (w/w) cream resulted in complete clinical and mycological cure of tinea pedis in 27 of 34 patients (79 %) after 7 days of treatment (Ledezma et al. 1996). The remaining seven patients (21 %) achieved complete cure after seven additional days of treatment. In a randomised comparative study of 60 soldiers with clinical and mycological diagnosis of either tinea cruris and tinea corporis, 30 days after topical treatment, the percent healing rate was 77 and 75 for the groups treated with ajoene and terbinafine, respectively (Ledezma et al. 1999). Sixty days after treatment, the healing rate was 73 % and 71 % for the groups treated with ajoene and terbinafine, respectively.

In a 2-week randomised placebo-controlled double-blind trial of women with vulvovaginal candidiasis, oral ingestion of garlic tablets yielded no difference between the proportion of cases in the garlic and placebo groups, in the mean colony counts in both groups, or difference in the number of women reporting abnormal vaginal symptoms during the 2 weeks before menstruation (Watson et al. 2014).

Antibacterial Activity

A freshly prepared infusion of ground garlic cloves was found to possess high antibacterial activity (Cavallito and Bailey 1944; Cavallito et al. 1944, 1945). The active principle was identified as allicin. Maximal death rates of *Salmonella typhimurium* with freshly reconstituted dehydrated onion and garlic powders occurred at concentrations of 5 and 10 % (Johnson and Vaughn 1969). At these concentrations, the decimal reduction times were 1.1 and 1.2 hour, respectively, for resting cell cultures and 1.8 and 2.1 hour, respectively, for growing cultures. At comparable concentrations, growing cultures of *Escherichia coli* were as susceptible to garlic, but

apparently more resistant to onion than were those of *S. typhimurium*. All extracts of garlic bulb were inhibitory in-vitro to *Escherichia coli*, *Pseudomonas pyocyaneus*, *Salmonella typhi* and *Bacillus subtilis* (Abdou et al. 1972). Garlic extract concentrations higher than 1 % were inhibitory for *Lactobacillus plantarum*, while concentrations between 2 and 5 % were definitely germicidal (Karaioannoglou et al. 1977). Under favourable conditions garlic extract had a less inhibitory or germicidal effect upon *L. plantarum*. Large inocula (>10⁶ cells/mL) were able to overcome the inhibitory effects of garlic extract in concentrations of 1 %. Garlic oil inhibited the in-vitro growth of *Lactobacillus plantarum*, *Saccharomyces cerevisiae*, *Aspergillus niger*, *Escherichia coli*, *Bacillus cereus* and *Pseudomonas aeruginosa* (Pátkai et al. 1998). The organoleptically optimal concentration of garlic oil made by extraction was high enough to ensure microbiological stability of ketchup.

All test organisms, five Gram-negative and three Gram-positive bacterial species (including *Staphylococcus aureus*, *Pseudomonas aeruginosa*) and two yeast species, were inhibited by garlic juice, while onion and shallot juice showed no effect upon Gram-negative bacteria (Dankert et al. 1979). Garlic extract showed greater activity against Gram-positive organisms and Gram-negative organisms as compared to the extract of onion (Elnima et al. 1983). Studies conducted on the comparative action of raw garlic extract and tetracycline hydrochloride on equal concentrations on caecal microflora of albino rats showed raw garlic extract to be a more potent antimicrobial agent than tetracycline (Shashikanth et al. 1984). A mouthwash containing 10 % garlic in quarter Ringer solution produced a drastic reduction in the number of oral bacteria. The ether extract gave the strongest inhibition followed by chloroform and petroleum ether extract. Garlic extract was found inhibitory to six strains of *Mycobacterium tuberculosis* with an MIC of 1.67 mg/mL (Delaha and Garagusi 1985). Diallyl thiosulfinate (allicin) was reported as the agent in garlic responsible for the antibacterial and antifungal activity of garlic extracts (Feldberg et al. 1988).

The water, ethanol and chloroform extracts of garlic exhibited antibacterial activity against the nosocomial *S. aureus*, *E. coli*, *S. pneumoniae* and *P. aeruginosa* (El-Mahmood 2009). The MBC values of the aqueous extract for *S. aureus* was 75 mg/mL; *S. pneumoniae*, 100 mg/mL; *E. coli*, 125 mg/mL; and *P. aeruginosa*, 150 mg/mL. The water extract was more potent than the organic extracts, and all were inferior in activity, when compared to the standard antibiotic, metronidazole. The Gram-positive *S. aureus* was more susceptible to the toxic effects of garlic than its Gram-negative counterparts. Gram-negative diarrhoeagenic pathogens *Escherichia coli*, *Shigella* sp., *Salmonella* sp. and *Proteus mirabilis* from stool samples were highly sensitive to garlic (Eja et al. 2007). No isolates were resistant to garlic, making it a promising antimicrobial agent. Aqueous garlic extract showed concentration-dependent inhibitory activity against *Staphylococcus aureus* in-vitro (Derese 2010). Garlic extract and streptomycin were found to have synergistic effect against streptomycin-resistant strains of *Staphylococcus aureus* and *Escherichia coli* (Palaksha et al. 2010). The garlic ethanolic extract demonstrated antibacterial activity in-vitro against all tested food-associated bacteria with maximum zone of growth inhibition ranging from 20 to 31 mm: *Bacillus subtilis* (31 mm), *Escherichia coli* (30 mm), *Staphylococcus aureus* (28 mm), *Bacillus polymyxa* (21 mm), *Bacillus megaterium* (20 mm) and *Bacillus sphaericus* (20 mm) (Pundir et al. 2010). Aqueous garlic extract exhibited antibacterial activity against Gram-positive (*Bacillus subtilis*, *Staphylococcus aureus*) and Gram-negative (*Escherichia coli* and *Klebsiella pneumoniae*) strains and antifungal activity against *Candida albicans* (Meriga et al. 2012). The methanol extract showed antimicrobial activity against all the tested microorganisms except two (*Staphylococcus aureus* and *Candida albicans*), and the extracts of hexane, chloroform and ethyl acetate did not show any antimicrobial activity. Minimum inhibitory concentration of aqueous and methanol extracts against tested bacterial and fungal strains was 100–150 µg/mL.

All food bacterial pathogenic strains tested, namely, *Staphylococcus aureus*, *Salmonella typhi*, *Escherichia coli* and *Listeria monocytogenes*, were inhibited by garlic; *E. coli* was

the most sensitive and *Listeria monocytogenes* was the least sensitive (Kumar and Berwal 1998). Garlic essential oil and nisin possessed considerable antimicrobial effects against *Listeria monocytogenes* (Rohani et al. 2011). The MICs for nisin and garlic oil were 12.5 IU/mL and 100 µg/mL, respectively. The combination of nisin with garlic oil at 30 °C, pH 5.6 and 0 g/100 mL NaCl showed significant anti-listerial activity.

The use of powder from fresh garlic was more effective for antibacterial activity against *Escherichia coli* than that from old garlic, the 1 % solution of fresh garlic powder eradicating the bacterium in 6 hours (Sasaki et al. 1999). The antibacterial activity was resistant to heat treatment of 100 °C for 20 minutes. The antibacterial activity of garlic powder was also shown against other types of pathogenic bacteria such as methicillin-resistant *Staphylococcus aureus* (MRSA), *Salmonella enteritidis* and *Candida albicans*. On the agar plate test, 1–5 % garlic powder inhibited the growth of *Bacillus anthracis* and *Escherichia coli* O157 (Sasaki and Kita 2003). A number of intestinal bacteria in a BALB/c mouse decreased after the oral administration of 1 mL of 1 % garlic powder solution once a day for 3 days.

Garlic extract was inhibitory to bacteria (Rees et al. 1993). The minimum inhibitory concentration (MIC) values for bacteria at 24 hours was 0.8–1 mg/mL for *Staphylococcus aureus* (two strains), 1–2.2 mg/mL for *Escherichia coli* (three strains), 1.8 mg/mL for *Bacillus cereus*, 1.8 mg/mL for *Bacillus subtilis*, 1.9 mg/mL for *Proteus mirabilis*, 2.3 mg/mL for *Listeria monocytogenes*, 2.4 mg/mL for *Salmonella enteritidis*, 2.3 mg/mL for *Salmonella dublinii*, 2.8 mg/mL for *Salmonella typhimurium* and 3.3 mg/mL for *Klebsiella aerogenes*. The following were less sensitive to garlic extract with MICs of 9.1 mg/mL for *Pseudomonas aeruginosa*, 12.5 mg/mL for *Lactobacillus plantarum*, 16.7 mg/mL for *Lactobacillus acidophilus*, 17.5 mg/mL for *Lactobacillus casei*, 18.5 mg/mL for *Enterococcus faecium* and 34.5–39.7 mg/mL *Pedicoccus pentosaceus* (two strains). In mixed cultures of *E. coli* and *L. acidophilus*, garlic prevented the establishment of *E. coli*, although the final outcome of

completion was not affected. In in-vitro pure culture studies, the beneficial gut bacterium *Lactobacillus casei* was found to be resistant to garlic powder, whereas rapid killing and reduction in cell numbers were observed with commensal bacteria *Bacteroides ovatus*, *Bifidobacterium longum* and *Clostridium nexile* (Filocamo et al. 2012). Lactic acid bacteria were found to be more resistant to garlic powder compared to the clostridial members of the gut microbiota. Studies showed that the efficacy of garlic juice was higher than chlorhexidine against target bacteria and could be used as an effective mouthwash (Amin et al. 2012). The lowest MIC of garlic juice was for *Streptococcus mutans* 0.25 µg/mL and the highest was for *Lactobacillus casei* 2.5 µg/mL. The MIC of chlorhexidine for these two bacteria was 0.62 µg/mL and 5 µg/mL, respectively. The MBC of chlorhexidine and garlic for *S. mutans* was 0.35 µg/mL and 0.3 µg/mL, respectively. The highest MBC of chlorhexidine was for *Streptococcus salivarius* 10 µg/mL. The MBC of garlic for *Streptococcus sanguis* was similar at 10.4 µg/mL.

Inhibition of RNA synthesis was found to be the primary target of allicin in *Salmonella typhimurium*. The growth of *Staphylococcus aureus* was inhibited by dehydrated garlic at levels of 1.5 % (w/v) and over (González-Fandos et al. 1994). Enterotoxins A, B and C1 were only detectable in broth containing <1 % of garlic, while enterotoxin D was produced at a level of 2 %. Garlic also inhibited thermonuclease (TNase) production, complete inhibition being observed at levels > or = 1.5 %. The fresh aqueous garlic extract, 57.1 % (w/v), containing 324 µg/mL allicin inhibited the growth and killed most of the tested *Salmonella* serovars, namely, *Salmonella cerro*, *Salmonella enteritidis*, *Salmonella lindenberg*, *Salmonella montevideo*, *Salmonella hadar* and *Salmonella nikolai* fleet isolated from Tunisian fast foods, coproculture and wastewater (Belguith et al. 2010). The minimal inhibitory concentration and minimum bactericidal concentrations were very close, garlic MIC range 10–12.5 mg/mL and MBC range 13–15 mg/mL. Garlic extract could be stored at 4 °C because no detectable loss of antibacterial activity at this temperature over several days was observed.

However, excessive warming or longer periods at higher temperatures should be avoided.

Garlic extracts exhibited antibacterial activity against food pathogens *Staphylococcus aureus*, *Escherichia coli*, *Salmonella typhi* and *Bacillus cereus* (Gomaa and Hashish 2002). Results showed that the higher the garlic concentration, the higher was the microbial reduction percent. Water extract of garlic exhibited a higher microbial reduction percentage than fresh garlic. In-vitro studies demonstrated that allicin could inhibit early bacterial adhesion, reduce extracellular polysaccharide substance secretion and downregulate quorum-sensing controlled virulence factor production of *Pseudomonas aeruginosa* (Lin et al. 2013). Collectively, these findings suggested the potential of allicin as a therapeutic agent for controlling *P. aeruginosa* biofilm. The ethanolic garlic extract was more effective than the aqueous garlic extract, inhibiting all the test organisms, *Escherichia coli*, *Pseudomonas aeruginosa*, *Staphylococcus aureus* and *Klebsiella pneumoniae* in-vitro, while the aqueous extract was not inhibitory to *Staphylococcus aureus* (Arekemase et al. 2013). *Allium sativum* essence oil (AEO) exhibited antimicrobial activity against beef-related bacteria, namely, *Listeria monocytogenes*, *Escherichia coli* and *Brochothrix thermosphacta* (Sung et al. 2014). Low-density polyethylene/ethylene vinyl acetate (LDPE/EVA) co-polymer film with 8 % AEO significantly reduced the concentration of bacteria with inhibition strength of *L. monocytogenes* > *B. thermosphacta* > *E. coli*. Except *Enterobacter faecalis* all the bacteria tested *Escherichia coli*, *Pseudomonas aeruginosa*, *Proteus mirabilis*, *Klebsiella* sp., *Staphylococcus aureus* and *Bacillus subtilis* were susceptible to crude garlic extract (Karuppiah and Rajaram 2012). The highest inhibition zone was observed with garlic (19.45 mm) against *Pseudomonas aeruginosa*, and the minimal inhibitory concentration was as low as 67.00 µg/mL.

Ajoene at <20 µg/mL inhibited the growth of Gram-positive bacteria, such as *Bacillus cereus*, *Bacillus subtilis*, *Mycobacterium smegmatis* and *Streptomyces griseus* (Naganawa et al. 1996). *Staphylococcus aureus* and

Lactobacillus plantarum were also inhibited at this concentration. For Gram-negative bacteria, such as *Escherichia coli*, *Klebsiella pneumoniae* and *Xanthomonas maltophilia*, MICs were between 100 and 160 µg/mL. Ajoene also inhibited yeast growth at concentrations below 20 µg/mL. *B. cereus* and *Saccharomyces cerevisiae* were killed at 30 µg/mL after 24 hours of cultivation. However, the minimal microbicidal concentrations for resting cells were at 10–100 times higher concentrations than the corresponding MICs.

E-4,5,9-trithiadeca-1,7-diene-9-oxide isolated from oil-macerated garlic extract exhibited antimicrobial activity against Gram-positive bacteria, such as *Bacillus cereus*, *B. subtilis* and *Staphylococcus aureus* and yeasts at the concentration lower than 100 µg/mL, but Gram-negative bacteria were not inhibited at the same concentration (Yoshida et al. 1999a). Its antimicrobial activity was inferior to those of similar oil-macerated garlic extract compounds such as *E*-ajoene, *Z*-ajoene and *Z*-10-DA. *Z*-10-DA exhibited a broad spectrum of antimicrobial activity against such microorganisms as Gram-positive and Gram-negative bacteria and yeasts (Yoshida et al. 1998). The antimicrobial activity of *Z*-10-DA was comparable to that of *Z*-ajoene, but was superior to that of *E*-ajoene. Antimicrobial activity of 2-propenesulfinothioic acid *S*-methyl ester [AllS(O)SMe] and 2-propene-1-sulfinothioic acid *S*-(*Z,E*)-1-propenyl ester [AllS(O)SPn-(*Z,E*)] isolated from oil-macerated garlic extract was comparable and inferior to that of allicin, respectively (Yoshida et al. 1999b). The result suggested that the antimicrobial activity of 2-propene sulfinothioic acid *S*-alk(en)yl esters was affected by alk(en)yl groups.

Although the antimicrobial effects of phytoalexin, allixin was weak (Kodera et al. 1989, 2002a), and the amount of allixin accumulated on the surface of the stored garlic clove was sufficient to protect against the invasion of microorganisms, i.e. almost ten times the antimicrobial activity level and higher than the MIC of allixin (MIC, 160 mg/mL; *Aspergillus niger*, 100 mg/mL; *Staphylococcus aureus*, *Pseudomonas aeruginosa* and *Escherichia coli*, 80 mg/mL; *Candida albicans*, no MIC data (Kodera et al.

2002a)). *Lactobacillus acidophilus*, a homofermentative organism, produced lactic acid that lowered the pH of the culture medium, resulting in a reduction in numbers of *Candida albicans* and *Escherichia coli* in mixed culture (Elsom et al. 2003). When the extract of garlic was added at a concentration of 2.56 µg, total thiosulfinate/mL for *C. albicans* in mixed culture and at a concentration of 5.12 µg total thiosulfinate/mL for *E. coli* in mixed culture, the reduction in cell numbers of both *C. albicans* and *E. coli* was accelerated. After 4 hours no *C. albicans* cells were countable, while *E. coli* cells were absent after 24 hours. Of several commercial preparations of garlic, which included oil macerates, pastes, tablets and powders, only the garlic tablet formulation exhibited good anticandidal and antiplatelet activity, whereas all the other preparations possessed virtually no anticandidal and antiplatelet properties.

The garlic constituents all showed substantial but widely differing anti-*Helicobacter pylori* effects against all strains and isolates tested (O’Gara et al. 2000). The MICs (range, 8–32 µg/mL) and minimum bactericidal concentrations (MBCs) (range, 16–32 µg/mL) of undiluted garlic oil (GO) were smaller than those of garlic powder (GP) (MIC range, 250–500 µg/mL; MBC range, 250–500 µg/mL) but greater than the MIC of allicin (4.0 µg/mL) present in GP. Allicin (MIC, 6 µg/mL; MBC, 6 µg/mL) was more potent than diallyl disulfide (MIC range, 100–200 µg/mL; MBC range, 100–200 µg/mL), its corresponding sulfide, but of a strength similar to that of diallyl tetrasulfide (MIC range, 3–6 µg/mL; MBC range, 3–6 µg/mL). Antimicrobial activity of the diallyl sulfides increased with the number of sulfur atoms. Garlic compounds diallyl sulfide and diallyl disulfide decreased arylamine N-acetyltransferase activity in strains of *Helicobacter pylori* from peptic ulcer patients (Chung et al. 1998). Viability studies on *H. pylori* demonstrated that DAS or DADS elicited dose-dependent bactericidal effects on *H. pylori* cultures. The concentration of aqueous garlic extract required to inhibit *Helicobacter pylori* growth was between 2 and 5 mg/mL, and the concentration to inhibit 90 % (MIC₉₀) of *H. pylori* isolates was 5 mg/mL (Cellini et al. 1996). The minimum bactericidal

concentration (MBC) was usually equal to or twofold higher than the minimum inhibitory concentration (MIC). Heat treatment of extracts reduced the inhibitory or bactericidal activity against *H. pylori*; the boiled garlic extract showed a loss of efficacy from two- to fourfold the values of MIC and the MBC obtained with fresh garlic. A synergistic effect was found with garlic in after combination with a proton pump inhibitor (omeprazole) in a ratio of 250:1 in 47 % of *H. pylori* strains. MIC values of raw garlic extract and three types of commercial garlic tablets on *Helicobacter pylori* ranged from 10,000 to 17,500 mg/L (Jonkers et al. 1999). The combination of garlic and omeprazole, studied with killing curves, showed a synergic effect which was concentration dependent. Some oil-macerated garlic constituents (OMGE) inhibited the in-vitro growth of *Helicobacter pylori* isolates (Ohta et al. 1999). The vinylthiols and 2-propene-1-sulfinothioic acid *S*-(*E,Z*)-1-propenyl ester [AllS(O)SPn-(*E,Z*)] were not inhibitory. The MIC values determined were ajoenes, *Z* ajoene (15-20 µg/mL), *E*-ajoene (25 µg/mL), *Z*-10-DA (15-20 µg/mL) and Iso-*E*-10-DA (10-15 µg/mL); vinylthiols, 2-Vinyl-4*H*-1,3-dithiol and 3-Vinyl-4*H*-1,2-dithiol (>100 µg/mL); and thiosulfinates, AllS(O)SPn-(*Z,E*) AllS(O)SPn-(*Z,E*) (>100 µg/mL), 2-propene-1-sulfinothioic acid *S*-methyl ester [AllS(O)SMe] (20–25 µg/mL) and allicin (not a constituent of OMGE) (20–30 µg/mL). Allicin and allyl-methyl plus methyl-allyl thiosulfinate from acetic garlic extract inhibited the in-vitro growth of *Helicobacter pylori*, the bacterium responsible for serious gastric diseases such as ulcers and even gastric cancer (Cañizares et al. 2004). Additionally, these compounds showed a synergistic effect on the inhibition of the in-vitro growth of the bacterium. Allitridin exhibited dose-dependent inhibitory activity against *Helicobacter pylori*, and its bacteriostatic mechanism could be attributed to its multitarget inhibitory effects in energy metabolism and biosynthesis including amino acid biosynthesis, protein synthesis, mRNA synthesis and fatty acid biosynthesis (Liu et al. 2010). Allitridin could also disrupt the expression of antioxidant proteins and decrease the production of virulence factors.

The essential oil extracts of these *Allium* plants (garlic and green, yellow, red onions) exhibited marked antibacterial

activity against *Staphylococcus aureus* and *Salmonella enteritidis*, with garlic showing the highest inhibition and green onion the lowest (Benkeblia 2004). Comparatively, 50 and 100 mL/L concentrations of onions extracts were less inhibitory than 200, 300 and 500 mL/L concentrations. However, with garlic extract, high inhibitory activity was observed for all tested concentrations. *S. aureus* showed less sensitivity towards essential oil extract inhibition; however, *S. enteritidis* was strongly inhibited by red onion and garlic extracts. The protein alliumin, isolated from garlic bulb, was inhibitory in-vitro to the bacterium *Pseudomonas fluorescens* (Xia and Ng 2005). Garlic extract (57.1 % (w/v), containing 220 µg/mL allicin), inhibited the growth and killed most of the oral bacterial species tested (Bakri and Douglas 2005). In general, the minimal inhibitory and minimum bactericidal concentrations for the Gram-negative strains (garlic MIC range 35.7–1.1 mg/mL, allicin mean MIC 4.1 µg/mL, mean MBC 7.9 µg/mL) were lower than those for the Gram-positive strains tested (garlic MIC range 142.7–35.7 mg/mL, allicin mean MIC 27.5 µg/mL, mean MBC 91.9 µg/mL). Also, of the organisms tested, the putative periodontal pathogens had among the lowest MICs (17.8–1.1 mg/mL garlic) and MBCs (35.7–1.1 mg/mL garlic). Time-kill curves for *Streptococcus mutans* and *Porphyromonas gingivalis* showed that killing of the latter started almost immediately, whereas there was a delay before *S. mutans* was killed. The garlic extract also inhibited the trypsin-like and total protease activity of *P. gingivalis* by 92.7 % and 94.88 %, respectively. Ethanolic garlic extract (EGE) and aqueous garlic extract (AGE) exhibited inhibitory effects against two periodontal pathogens *Porphyromonas gingivalis* and *Aggregatibacter actinomycetemcomitans* (Shetty et al. 2013). AGE showed greater bacteriostatic activity against the *P. gingivalis* with minimum inhibitory concentration determined at 16.6 µL/mL. AGE showed better antiproteolytic activity on total protease of *P. gingivalis* compared to the EGE. All cariogenic isolates, MDR (multidrug resistant) and non-MDR, of *Streptococcus mutans* were sensitive to garlic extract with the MIC ranging from 4 to 32 µg/mL, whereas chlorhexidine minimum inhibitory concentration (MIC) for MDR and non-MDR *S.*

mutans varied from 2 to 16 µg/mL and from 0.25 to 1 µg/mL, respectively (Fani et al. 2007). The results indicated that mouthwashes or toothpaste containing optimum concentration of garlic extract could be used for prevention of dental caries.

A new, stable, aqueous extract of allicin (extracted from garlic) showed potent in-vitro inhibitory activity against clinical isolates of methicillin-resistant *Staphylococcus aureus* that showed a range of susceptibilities to mupirocin (Cutler and Wilson 2004). Of the strains tested, 88 % had MICs for allicin liquids of 16 µg/mL, and all strains were inhibited at 32 µg/mL. Furthermore, 88 % of clinical isolates had MBCs of 128 µg/mL, and all were killed at 256 µg/mL. The antibacterial activity of crushed fresh garlic cloves and allicin (allyl 2-propenylthiosulfinate), a major antibacterial principle, declined on a daily basis in aqueous and ethanolic solutions at room temperature, showing biological and chemical half-lives of about 6 and 11 days, respectively (Fujisawa et al. 2008). Allicin was more stable in 20 % alcohol than in water, but surprisingly unstable in vegetable oil, with an activity half-life of 0.8 hour, as estimated from its antibacterial activity towards *Escherichia coli*, and a chemical half-life of 3.1 hour.

Garlic oil, Chinese leek (*Allium odorum*) oil and four diallyl sulfides occurring naturally in these oils exhibited in-vitro antimicrobial activity against *Staphylococcus aureus*, methicillin-resistant *S. aureus* (MRSA), *Candida albicans*, *C. krusei*, *C. glabrata*, *Aspergillus niger*, *A. flavus* and *A. fumigatus* (total of 276 clinical isolates) (Tsao and Yin 2001b). The magnitude of activity of the four diallyl sulfides followed the order diallyl tetrasulfide > diallyl trisulfide > diallyl disulfide > diallyl monosulfide. The concentration of four diallyl sulfides in garlic and Chinese leek oils was in the range 41.7–52.7 % of total sulfides. Garlic oil, with a higher concentration of four diallyl sulfides, showed greater antimicrobial activity than Chinese leek oil. Garlic oil at 4 x MIC could reduce original inoculum to < or =2 log₁₀ in both *Pseudomonas aeruginosa* and *Klebsiella pneumoniae* within 8 hours (Tsao and Yin 2001a). The MIC values of four diallyl sulfides from garlic oil against these two pathogens followed the order diallyl monosulfide > diallyl disulfide > diallyl

trisulfide (DAT) > diallyl tetrasulfide (DATS). Most interactions of ceftazidime, gentamicin, imipenem and meropenem with DAT or DATS, determined according to the fractional inhibitory concentration index, showed synergic or additive effects. The results suggested that garlic oil, DAT and DATS may have potential for the prevention or treatment of nosocomial, antibiotic-resistant bacterial infections. Garlic essential oil showed good antimicrobial activity in-vitro against *Staphylococcus aureus* (inhibition zone 14.8 mm), *Pseudomonas aeruginosa* (inhibition zone 21.1 mm) and *Escherichia coli* (inhibition zone 11.0 mm) (Casella et al. 2013). The main constituents of garlic oil were diallyl monosulfide, diallyl disulfide (DADS), diallyl trisulfide and diallyl tetrasulfide, and the results showed that the presence of the allyl group was fundamental for the antimicrobial activity of these sulfide derivatives. DADS had an inhibition zone of 15.9 mm on *S. aureus*, 21.9 mm on *P. aeruginosa* and 11.4 mm on *E. coli*. The dipeptide, (R)-3-(allylthio)-2-((R)-3-(allylthio)-2-aminopropanamido)propanoic acid, isolated from garlic bulb, showed antibacterial activity against the *Staphylococcus aureus* antibiotic-resistant strain (Zhou et al. 2014a).

Except *Enterobacter* sp. and *Klebsiella* sp., *Escherichia coli*, *Pseudomonas aeruginosa*, *Proteus* sp., *Staphylococcus aureus* and *Bacillus* sp. were susceptible when subjected to ethanolic extracts of garlic and ginger (Karuppiah and Rajaram 2012). The highest inhibition zone was observed with garlic (19.45 mm) against *P. aeruginosa* with minimal inhibitory concentration of 67.00 µg/mL. Diallyl disulfide complex exhibited significant antibacterial activity (MIC 100 µg/ mL) and was found to be effective against *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Klebsiella pneumoniae* and *Escherichia coli* (Singh et al. 2012).

Animal Studies

Aqueous garlic extract of garlic and allicin both showed significant in-vitro antibacterial activity against isolates of multiple drug-resistant *Shigella dysenteriae* 1, *Shigella flexneri* Y, *Shigella sonnei* and enterotoxigenic *Escherichia*

coli (Chowdhury et al. 1991). The two agents also showed promising in-vivo antibacterial activity against *Shigella flexneri* Y when tested in the rabbit model of experimental shigellosis, fully curing the infected rabbits within 3 days.

Oral administration of garlic extract, diallyl sulfide and diallyl disulfide possessed multiple protective functions against methicillin-resistant *Staphylococcus aureus* (MRSA) in rats (Tsao et al. 2003). Garlic significantly decreased the viability of MRSA, in the plasma, liver, kidney and spleen in MRSA-infected rats; significantly increased fibronectin and interleukin 6 levels in plasma; significantly enhanced lipid oxidation in plasma and three organs; and showed antioxidant protection in significantly decreasing the malondialdehyde level. The garlic-derived volatile allyl methyl sulfide (AMS) exhibited an antibacterial effect against the pig pathogen *Actinobacillus pleuropneumoniae* serotype 9 (Becker et al. 2012). Feeding garlic to pigs reduced *A. pleuropneumoniae* infection as indicated by the reduced occurrence of characteristic pleuropneumonia lesions (27 % of the lungs affected in the garlic-fed group vs. 47 % in the control group) and significantly lower relative lung weight postmortem in the garlic-fed group.

Diallyl sulfide (DAS) and diallyl disulfide (DADS), from garlic, inhibited methicillin-resistant *Staphylococcus aureus* (MRSA) infection in streptozotocin-induced diabetic mice (Tsao et al. 2007). DAS and DADS significantly decreased MRSA viability in the kidney, with administration of each agent twice showing a greater inhibitory effect than when given once. DAS and DADS treatments also significantly reduced the plasma levels of CRP, fibronectin and fibrinogen and the MRSA-elevated malondialdehyde levels in the kidney and spleen. DAS or DADS given twice significantly decreased the plasma levels of both IL-6 and TNF- α , and significantly increased AT-III and protein C activities. The data suggested that DAS and DADS could provide multiple protective functions against MRSA infection in diabetic mice.

Clinical Studies

Zhou (2003) reported the treatment of acute lymphangitis in 118 cases by moxibustion with garlic. Burning of moxa stick being itself antagonistic to bacteria could also promote the local flow of qi and blood and enhance the antagonistic effect of garlic on bacteria. A 2.5 % garlic mouthwash solution had good antimicrobial activity against *Streptococcus mutans* and other oral microorganisms in a 5-week study of 30 subjects (Groppo et al. 2007). Maintenance of reduced salivary levels of streptococci was observed after 2 weeks at the end of mouthwash use. Unpleasant taste (100 %), halitosis (90 %) and nausea (30 %) after using garlic mouthwash for 5 weeks were reported by subjects after the end of the study. It was concluded that the garlic cloves have antimicrobial properties in-vitro against streptococci and anticariogenic properties against oral microorganism in spite of its adverse effects. In a study involving 45 dental students using garlic extract mouth rinse daily for a week, posttreatment *Streptococcus mutans* counts showed that garlic was effective against *S. mutans* and could be used as an effective remedy in the prevention of dental caries (Chavan et al. 2010). In a clinical study of 100 married women, aged 18–44, whose infection with diagnosed bacterial vaginosis, treatment with micosin vaginal cream (made of garlic) for 7 days appeared to be an appropriate alternative for metronidazole vaginal gel in treatment of bacterial vaginosis (Moori et al. 2010). In a clinical study of 140 burn patients, patients in the group with <45 % but >20 % of total body surface area that received two crushed garlic cloves mixed with yogurt with their daily lunch meal had significantly reduced *Pseudomonas aeruginosa* burn wound infection compared to the group with yogurt only. It seemed that fresh crushed garlic cloves could be used as a supplementary herbal medicinal agent in delaying of *P. aeruginosa* burn wound infection in patients with moderate burn injuries.

The findings from the cross-sectional study of 566 Japanese men aged 50–55 years suggested that fresh vegetables may be protective against *H. pylori* infection but did not support either an increased risk of the infection associated with salty foods or a protective effect of green tea or garlic (Shinchi et al. 1997). The prospective crossover study

in healthy *Helicobacter pylori*-infected adults did not support a role for either garlic or jalapeños in the treatment of *H. pylori* infection (Graham et al. 1999).

Antiviral Activity

Garlic extract prevented infection by influenza B virus and herpes simplex virus but not against Coxsackie virus (Nagai 1973; Tsai et al. 1985). The order for virucidal activity for garlic-derived compounds against selected viruses including herpes simplex virus type 1, herpes simplex virus type 2, parainfluenza virus type 3, vaccinia virus, vesicular stomatitis virus and human rhinovirus type 2 generally was ajoene > allicin > allyl methyl thiosulfinate > methyl allyl thiosulfinate (Hughes et al. 1989; Weber et al. 1992). The 50 % endpoint neutralisation titre for porcine rotavirus strain OSU was 2.4–2.8 µg/mL garlic (Rees et al. 1993). Ajoene was found in oil macerates of garlic but not in fresh garlic extracts. No activity was found for the garlic polar fraction, alliin, deoxyalliin, diallyl disulfide or diallyl trisulfide. Fresh garlic extract, in which thiosulfonates appeared to be the active components, was virucidal to each virus tested. The predominant thiosulfonate in fresh garlic extract was allicin. In addition, concentrations that were virucidal were also toxic to HeLa and Vero cells. Shoji et al. (1993) found that allyl disulfide, allyl alcohol (both found in garlic) and its ester strongly depressed cell proliferation of HIV-1-infected cells. KC_{50} (50 % killing concentration) of the allyl disulfide and the allyl alcohol were 34 µM and 10 µM, respectively. The allyl alcohol, in particular, completely inhibited cell growth of HIV-1-infected cells by a single injection at a concentration of 40 µM, ultimately killing the viable CEM/LAV-1 cells within 96 hours of cultivation. No effect of the allyl alcohol and its esters on cell proliferation of CEM cells, an HIV-1-noninfected human T-cell cell line, was observed at the concentration range of 20–200 µM under the same experimental conditions.

Racemic ajoene inhibited the fusion of H9 cells with HIV-infected H9:RF cells (IC_{50} approximately 45 µM; 16 hours of incubation) and also exhibited antiviral activity (IC_{50}

approximately 5 μM as assessed by the inhibition of HIV-1/CEM/Lav 1 Bru replication in CEM13 cells; 72 hours) (Tatarintsev et al. 1992). Ajoene exhibited differential inhibitory activity in-vitro against human immunodeficiency virus (HIV)-1 (IIIB) (Walder et al. 1997). Ajoene protected acutely infected Molt-4 cells against HIV-1 and blocked further destruction of CD4 T cells in-vitro. Ajoene showed dose-dependent inhibition, with 50 % cytotoxic concentration ($\text{CTC}_{50\%}$) and 50 % effective inhibitory concentration ($\text{EIC}_{50\%}$) values of 1.88 μM and about 0.35 μM , respectively, when the test compound was added before or after HIV-1 infection and incubation carried out at 37 °C for 4 days. Ajoene proved relatively more active than dextran sulfate in blocking HIV-1 virus–cell attachment.

Z-ajoene inhibited human cytomegalovirus in-vitro mediated by an increased number of apoptotic cells after infection (Terrasson et al. 2007). Garlic extract exhibited dose-dependent antiviral activity against human cytomegalovirus (HCMV) in-vitro (Guo et al. 1993). Its bioactive compound allitridin (diallyl trisulfide) dose dependently inhibited the virus with an EC_{50} value of 4.2 $\mu\text{g/mL}$ (Zhen et al. 2006). Allitridin inhibited HCMV replication in the earlier period of viral cycle before viral DNA synthesis. Decrease of viral DNA load in infected cells was also detected under allitridin treatment, probably due to an indirect consequence of the reduction in IE gene transcription. Allitridin was found to effectively suppress the transcription of IE genes (ul122 and ul123) of HCMV AD169 strain, leading to a significant lowering of the mRNA expression (Zhang et al. 2011). It was able to suppress the transcription of IE gene (ul54) and l gene (ul83), indicating that HCMV IE genes may be the key target of allitridin against HCMV. In-vitro studies in HCMV-infected human embryo lung cells, HEL, showed that another mechanism of allitridin, anti-HCMV activity, was by the inhibition of HCMV immediate early antigen (HCMV-IEA) expression (Shu et al. 2003). The maximum tolerant concentration (MTC) of allitridin was 9.60 mg/L. Additionally, allitridin effectively suppressed the transcription of the HCMV IE, HCMV E and HCMV L genes; the

inhibition rates of the transcription of the ul122 and ul123 genes were higher compared with those of ul54 and ul83 mRNA expression, while the expression of the IE genes was not significantly reduced by ganciclovir (GCV) (Zhang et al. 2013b). Further, their results indicated that the IE genes may be the key target of allitridin in its action against HCMV. Among five *Allium* plants tested, shallots exhibited the highest level of antiviral activity for both adenovirus ADV41 and ADV3, followed by garlic and onions (Chen et al. 2011).

In a 12-week, randomised, placebo-controlled study of 146 volunteers, volunteers taking placebo were much more likely to get more than one cold over the treatment period (Josling 2001). An allicin-containing supplement had significantly fewer colds than the placebo group and thus could prevent attack by the common cold virus.

In a self-controlled, longitudinal study nested within the Women's Interagency HIV Study, from October 1994 to April 2009, conducted by Liu et al. (2012a), short-term garlic supplementation was found not to impact on highly active antiretroviral treatment (HAART) adherence level and HAART effectiveness (HIV viral load and CD4+ cell counts) in HIV-infected women. However, 'use garlic as needed', a potential marker of a disease state was significantly associated with higher viral load.

Antithrombotic/Antiplatelet Activity

Anticoagulant factor of garlic extract exhibited anticoagulant activity in-vitro but not in-vivo, and two mechanisms for this activity suggested were by precipitating calcium ions and by causing fibrinolysis (Song et al. 1963a). Addition of essential oil of garlic dose dependently inhibited in-vitro platelet aggregation induced by ADP, epinephrine or collagen (Bordia 1978). Oral administration of garlic also decreased platelet aggregation. Incubation of platelet-rich plasma with garlic bulb extract either in methanol or in homologous platelet-poor plasma inhibited platelet aggregation induced by all of the agonists ADP, epinephrine, collagen, thrombin, arachidonate, PAF and the ionophore A-23187 (Apitz-Castro et al. 1983).

Three pure components isolated from it F1, F2 and F3 also inhibit platelet aggregation; however, F3 was about four times more potent. Thrombin-induced release of ATP from gel-filtered platelets was inhibited by 75–80 % after garlic extract or F3 treatment. Chemical structures of F1, F2 and F3 were provisionally assigned as diallyl trisulfide for F1, 2-vinyl-1,3-dithiane for F2 and allyl 1,5-hexadienyltrisulfide for F3. The data suggest that the antiplatelet effects described might be mediated by a perturbation of the physicochemical properties of the plasma membrane rather than by affecting arachidonate or calcium metabolism in the cells.

Aqueous extracts of onion, garlic and ginger inhibited platelet aggregation induced by several aggregation agents, including arachidonate (AA), in a dose-dependent manner (Srivastava 1984). The three aqueous extracts inhibited the biosynthesis of 6-keto-F1 alpha in rat aortic rings from labelled AA, and they did not reduce prostacyclin production from endogenous AA pool in aortic rings. Aqueous extract of garlic inhibited aggregation induced by ADP, collagen, arachidonate (AA), epinephrine and calcium ionophore A23187 in a dose-dependent manner (Srivastava 1986). It was found that garlic reduced the formation of thromboxane from exogenous AA; garlic inhibited the phospholipase activity; garlic inhibited the formation of thromboxane and lipoxygenase products formed in platelets prelabelled with AA; and garlic inhibited the incorporation of arachidonate into platelet phospholipids. These effects may explain, in part, inhibition of platelet aggregation. Further, garlic was also effective in inhibiting aggregation induced by calcium ionophore A23187 suggesting that the anti-aggregation effect may be related to the intraplatelet mobilisation of calcium. Inhibition of epinephrine-induced aggregation by garlic extract may suggest that it may be inhibiting the uptake of calcium into platelets thereby lowering cytosolic calcium concentrations. Two fractions obtained from the TLC of the aqueous garlic extract were found to be antiaggregatory on epinephrine- and arachidonic acid (AA)-induced aggregation (Srivastava and Justesen 1989). The material extracted in ether (MEE) inhibited the incorporation of labelled AA into platelets in platelet-rich plasma. Garlic extracts (MEE and

material extracted in chloroform, MEC) at higher dosage inhibited the degradation of platelet phospholipids and reduced the formation of thromboxane (TxB₂) and lipoxygenase-derived products from labelled platelets. The two organic extracts at low dosage, while not affecting the degradation of platelet phospholipids, inhibited the cyclooxygenase and lipoxygenase enzymes. A concomitant increase in the amount of released AA was observed in the treated platelets. Adenosine and allicin, from garlic and onions, both inhibited platelet aggregation without affecting cyclooxygenase and lipoxygenase metabolites of arachidonic acid (Makheja and Bailey 1990). The trisulfides inhibited platelet aggregation as well as thromboxane synthesis along with the induction of new lipoxygenase metabolites.

When added to platelet-rich plasma, aqueous extracts of garlic inhibited platelet aggregation and the release reaction (Mohammad and Woodward 1986). The inhibitory component was characterised as allicin. At 10 μ M concentration, allicin inhibited completely platelet aggregation and the release reaction. Mayeux et al. (1988) reported that allicin inhibited human platelet aggregation in-vitro without affecting cyclooxygenase, thromboxane synthase activity or cyclic adenosine monophosphate (AMP) levels and without altering the activity of vascular prostacyclin synthase.

Raw garlic inhibited cyclooxygenase activity non-competitively and irreversibly in rabbit tissues (Ali 1995). A dose-dependent inhibition of cyclooxygenase activity was observed in tissues treated with raw garlic. The garlic concentrations required for 50 % inhibition of platelet, lung and vascular aortic cyclooxygenase activities of rabbits were 0.35, 1.10 and 0.90 mg, respectively. Cyclooxygenase activity of rabbit platelets was more sensitive to inhibition by raw garlic than the enzyme from blood vessels or lungs. Boiled garlic was found to have little effect on cyclooxygenase activity as compared to raw garlic in these tissues. The results indicated that garlic may be beneficial in the prevention of thrombosis if ingested raw rather in a cooked form.

Aged garlic extract (AGE) inhibited platelet aggregation in a concentration-dependent manner, and this achieved

significance between concentrations of 1.56–25 % (v:v) (Allison et al. 2006a). AGE also displayed disaggregatory properties at concentrations of 12.5 and 25 % (v:v). The constituents and the amino acids, when tested as a mixture, displayed disaggregatory properties at concentrations of 0.25 and 1 mmol/L. In contrast, a diethyl ether extract of AGE had no effect on platelet aggregation. When platelets were stimulated with either A23187 or ADP, an increase in intraplatelet Ca^{2+} accompanied platelet aggregation. This increase in Ca^{2+} was abolished in the presence of AGE. It was concluded that AGE acted in a synergistic manner and exerted multiple effects on the biochemical pathways involved in platelet aggregation. Further they reported that aged garlic extract inhibited platelet aggregation either by suppressing the influx of calcium ions by chelating calcium within platelet cytosol or by altering other intracellular second messengers within the platelets (Allison et al. 2006b). Results of studies suggested that odourless garlic not only activated fibrinolytic activity by accelerating tissue-type plasminogen activator (t-PA)-mediated plasminogen activation but also suppressed the coagulation system by downregulating thrombin formation, indicating a beneficial role in preventing pathological thrombus formation in such cardiovascular disorders (Fukao et al. 2007). Garlic exerted antiaggregatory effects in platelets taken from healthy volunteers via inhibition of the adenosine diphosphate (ADP) pathway; its mechanisms of action were comparable to that of the clinically used drug clopidogrel (Hiyasat et al. 2009). Studies showed that garlic extract showed significant fibrinolytic effect in-vitro compared with the control group (Ansari et al. 2012). Various concentrations of garlic extract exhibited significant different rise in the fibrinolytic activity of blood clot in different time. Desirable result was obtained in the lower concentration of (10 $\mu\text{g}/\mu\text{L}$) after 7 hours.

Garlic extracts contained a compound termed ajoene, which was found to be a potent inhibitor of platelet aggregation (Block et al. 1986). Ajoene, the major antiplatelet compound derived from garlic, synergistically potentiated the antiaggregatory action of prostacyclin, forskolin, indomethacin and dipyridamole (Apitz-Castro et al. 1986a). For collagen-

induced platelet aggregation in human platelet-rich plasma, the ID_{50} for ajoene was 95 μM . However, in the presence of the antiaggregatory drugs mentioned above, the ID_{50} for ajoene decreased more than what would be predicted on the basis of simple additive effects. Further, ajoene inhibited the fibrinogen-supported aggregation of washed human platelets ($ID_{50} = 13 \mu M$) and inhibited binding of ^{125}I -fibrinogen to ADP-stimulated platelets ($ID_{50} = 0.8 \mu M$) (Apitz-Castro et al. 1986b). In both cases, the inhibition was of the mixed non-competitive type. Fibrinogen-induced aggregation of chymotrypsin-treated platelets was also inhibited by ajoene in a dose-dependent manner ($ID_{50} = 2.3 \mu M$). Other membrane receptors such as ADP or epinephrine receptors were not affected by ajoene. Ajoene strongly quenched the intrinsic fluorescence emission of purified glycoproteins IIb–IIIa ($ID_{50} = 10 \mu M$). These results suggested that the antiaggregatory effect of ajoene was causally related to its direct interaction with the putative fibrinogen receptor. Ajoene inhibition of platelet aggregation was found to be possibly mediated by modifying the binding interactions of the haemoprotein with ligands (Jamaluddin et al. 1988). Administration of ajoene to heparinised pigs significantly prevented thrombus formation mainly in arterial sites with local low blood shear rates (Apitz-Castro et al. 1994). The results of in-vitro studies suggested that ajoene inhibited platelet release reaction by affecting the plasma membrane internal microviscosity, which impaired the fusion of the granules and plasma membrane, a prerequisite for exocytosis (Rendu et al. 1989). Ajoene was found to inhibit platelet aggregation induced by arachidonic acid (AA), adrenaline, collagen, adenosine diphosphate (ADP) and calcium ionophore A23187; the nature of the inhibition was irreversible (Srivastava and Tyagi 1993). In washed platelets stimulated by labelled arachidonate, ajoene inhibited the formation of thromboxane A₂; 12-lipoxygenase product(s) was reduced at higher ajoene concentrations. Ajoene inhibited the incorporation of labelled AA into platelet phospholipids at higher concentration.

Steroidal saponins isolated from garlic, namely, proto-isoeruboside-B and isoeruboside-B, had no effect on platelet aggregation. Nevertheless, isoeruboside-B inhibited blood coagulation and had a fibrinolysis-promoting effect (Peng et al. 1996) with IC_{50} of 1.5 mg/mL for blood coagulation inhibition and IC_{50} of 19 mg/mL for fibrinolysis promoting activity (Peng and Yao 1996). Proto-isoeruboside-B was found to promote only fibrinolysis (Peng et al. 1996) with IC_{50} of 13 mg/mL (Peng and Yao 1996). Total garlic saponins and garlic adenosine had platelet aggregation activity with IC_{50} of 7.3 mg/mL and 1.87 mg/mL, respectively. Total garlic saponins and garlic adenosine also had fibrinolysis promoting activity with IC_{50} of 13 mg/mL and 25 mg/mL, respectively. *N*-feruloyltyramine isolated from garlic cloves, at the concentration of 0.05 μ M was found to be a very potent compound able to inhibit COX-I and -II enzymes by 43 % and 33 %, respectively (Park 2009). *N*-feruloyltyramine was found likely to inhibit COX enzymes, thereby suppressing P-selectin expression on platelets.

In platelet-rich plasma (PRP) most of the antiaggregatory activity of garlic clove homogenates was due to adenosine; however, in whole blood neither adenosine nor the polar fraction had any effect, and all of the antiaggregatory activity was due to allicin and other thiosulfinates (Lawson et al. 1992). Allicin was equally active in whole blood and PRP. The best garlic powder tablets were equally as active as clove homogenates, whereas steam-distilled oils were 35 % as active and oil macerates (due to low content) only 12 % as active. A garlic product aged many months in aqueous alcohol had no activity. For steam-distilled oils, most of the activity was due to diallyl trisulfide. For the oil macerates, most of the activity was due largely to the vinylthiols. Ajoene, an exclusive component of the oil macerates, had the highest specific activity of all the compounds tested but, because of its low concentration, had only 13 % of the activity of diallyl trisulfide and 3 % of the activity of allicin.

In labelled platelets, on stimulation with either calcium ionophore A23187 or collagen, reduced amounts of

thromboxane and 12-HETE (12-hydroxyeicosatetraenoic acid) were produced in ajoene-treated platelets compared to control platelets. In-vitro, ajoene at concentrations of $>$ or $=75\text{ }\mu\text{g/mL}$ inhibited baboon platelet aggregation by 95 % (ADP assay) and 89 % (collagen assay) (Teranishi et al. 2003). Ajoene also inhibited the aggregation caused by pig growth factor-mobilised peripheral blood leucocytes (containing 1–2 % progenitor cells) (pPBPC) by 33–50 %. In-vivo, platelet aggregation in baboon was completely inhibited for 2 hours by ajoene at 25 mg/kg. Dipyridamole at 0.8 mg/kg reduced aggregation by 20 % for 15 minutes, but the effect was lost by 60 minutes. In combination, the two agents prolonged inhibition marginally.

The antiplatelet activity of methyl allyl trisulfide (MATs), a component commonly present in steam-distilled garlic oil, was demonstrated by Ariga et al. (2000). MATs inhibited arachidonic acid cascade at the reaction site with prostaglandin H (PGH) synthase. However, this enzyme catalysed two successive reactions, from arachidonic acid to prostaglandin G_2 (PGG_2) and from PGG_2 to prostaglandin H_2 (PGH_2). Studies suggested that (1) allicin and thiosulfinates were responsible for in-vitro antiaggregatory activity response, (2) crushing garlic before moderate cooking could reduce the loss of activity and (3) the partial loss of antithrombotic effect in crushed-cooked garlic may be compensated by increasing the amount consumed (Cavagnaro et al. 2007).

A dose-dependent inhibition of rabbit platelet aggregation was observed with garlic (Ali et al. 1999). Garlic showed higher magnitude compared to dose-dependent inhibitory effects on the collagen-induced platelet aggregation than onion. The concentration required for 50 % inhibition of the platelet aggregation for garlic was calculated to be approximately 6.6 mg/mL plasma, whereas the concentration for onion was 90 mg/mL plasma. Boiled garlic and onion extracts showed a reduced inhibitory effect on platelet aggregation. The potency of garlic in inhibiting the collagen-induced platelet aggregation was approximately similar to that of rabbit platelets (8.8 mg/mL produced 50 % inhibition of platelet aggregation). The results showed that garlic was about

13 times more potent than onion in inhibiting platelet aggregation.

Animal Studies

In-vivo studies showed that pretreatment of rabbits with an aqueous extract of garlic (500 mg/kg) provided protection from thrombocytopenia and hypotension (Ali et al. 1990). Synthesis of thromboxane B₂ during infusion of arachidonic acid and collagen was significantly inhibited. The findings showed that garlic may be beneficial in the prevention of thrombosis. Administration of aqueous extracts of garlic and onion, orally or intraperitoneally, daily for a period of 4 weeks exerted an antithrombotic on rats (Bordia et al. 1996).

Thromboxane B₂ (TXB₂) level in the serum was inhibited, but boiled garlic and onion at high concentration (500 mg/kg) had a very little effect on TXB₂ synthesis. Garlic was found to be more potent than onion in lowering the TXB₂ levels. Garlic inhibited the thrombin-induced platelet synthesis of thromboxane B₂ in a dose- and time-dependent manner in rabbits (Thomson et al. 2000). At 24 hours post-garlic infusion, TXB₂ inhibition was reduced to 15 % of the control, and TXB₂ levels were comparable to that of the control values at 72 hours post-garlic infusion. The rapid recovery of platelet cyclooxygenase activity after infusion of a single dose of garlic suggested that garlic should be taken more frequently in order to achieve beneficial effects in the prevention of thrombosis.

Garlic dialysate induced a drop in diastolic blood pressure (DBP) (from 112.5 to 70 mmHg) and a decrease in heart rate (HR) (from 198 to 164 beats/minute) in anaesthetised dog in a dose-dependent manner (Martin et al. 1992). The electrocardiogram (ECG) showed a regular sinus bradycardic rhythm. The addition of garlic dialysate to the isolated left rat atria evoked a decrease in tension development. Frequency, measured by spontaneous beating of the right atria, was also reduced. Both effects were dose dependent. Additionally, the positive inotropism and chronotropism induced by addition of isoproterenol 10^{-9} M were partially antagonised by preincubation of the rat atria with the garlic dialysate. The

findings could be elucidated by a depressant effect on automaticity and tension development in the heart, suggesting a beta-adrenoceptor blocking action produced by the garlic dialysate. Further they found that the negative inotropism of garlic dialysate increased with calcium 0.75 mM; in contrast, high level of calcium (4.5 mM) induced a significant reduction of this depressant effect (Martin et al. 1997). Their findings suggested that the negative inotropic effect of our garlic dialysate was related to $[Ca^{2+}]_O$ availability.

Diallyl trisulfide (DAT)-rich garlic oil at 5 or 50 mg garlic oil/kg body weight fed to Sprague–Dawley rats significantly prolonged the bleeding time and thrombin time and enhanced anticoagulation factor activity, such as antithrombin III and protein C (Chan et al. 2007). In addition, DAT-rich garlic oil benefited blood anticoagulation factors, which might further prevent the development of thrombus formation. However, the intake of garlic oil at high dose significantly increased plasma fibrinogen concentration and affected the levels of several haematological parameters such as erythrocyte count, haemoglobin and platelets. Therefore, the lower concentration of DAT-rich garlic oil should be used.

Clinical Studies

In a randomised, placebo-controlled, double-blind study, garlic consumption was found to improve blood fluidity and to increase fibrinolytic activity (Kiesewetter et al. 1990). In a double-blind, placebo-controlled study on 60 voluntary subjects with cerebrovascular risk factors and constantly increased platelet aggregation, it was demonstrated that the daily ingestion of 800 mg of powdered garlic in tablet form over 4 weeks led to a significant inhibition of the pathologically increased ratio of circulating platelet aggregates and of spontaneous platelet aggregation (Kiesewetter et al. 1993b). Consumption of 10 g of raw garlic daily after breakfast for 2 months elicited a significant decrease in serum cholesterol and an increase in clotting time and fibrinolytic activity in 50 human volunteers (Gadkari and Joshi 1991). In a randomised, double-blind, placebo-controlled crossover study of 12 healthy subjects, Legnani et al. (1993) evaluated the

acute and chronic effects of a preparation of dried garlic powder in a total daily dose of 900 mg on fibrinolysis and platelet aggregation. Total euglobulin fibrinolytic activity and TPA (tissue plasminogen activator) activity were significantly higher 4 and 6 hours after garlic and placebo ingestion, and no differences were recorded between treatments. After 14 days of treatment, TPA activity was significantly higher after garlic, with inter-treatment significance. No significant changes in PAI (plasminogen activator inhibitor) activity and fibrinogen levels were recorded. Platelet aggregation induced by adenosine diphosphate and collagen, and especially beta-thromboglobulin (beta-TG) release, after collagen stimulation was significantly inhibited 2 and 4 hours after garlic ingestion; platelet aggregation values were also significantly lower after 7 and 14 days of garlic treatment. No significant changes were found in adenosine triphosphate release and serum thromboxane B2 levels after acute garlic administration. In another placebo-controlled, double-blind design study of feeding garlic extract to healthy men, no significant differences in platelet aggregation with adenosine diphosphate, platelet activating factor (PAF) or collagen according to treatment group were found (Morris et al. 1995). Serum thromboxane and lyso-platelet activating factor also showed no change related to garlic supplements. In-vitro aggregation with collagen decreased linearly with increasing amounts of garlic extract, but concentrations were higher than those attainable in-vivo. In a study of 60 patients with coronary artery disease (CAD) (30 garlic, 30 placebo), garlic supplementation reduced significantly total serum cholesterol and triglycerides and increased significantly HDL cholesterol and fibrinolytic activity (Bordia et al. 1998). In-vitro, garlic oil inhibited platelet aggregation induced by several platelet agonists and also platelet thromboxane formation. Two important garlic oil constituents, diallyl disulfide (DADS) and diallyl trisulfide (DATS), showed antiplatelet activity and also inhibited platelet thromboxane formation.

Steiner and Lin (1998) found that administration of aged garlic extract (AGE) to moderately hypercholesterolaemic men for 10 months had beneficial effects on lipid profile, blood pressure and platelet function. Supplementation of

subjects with 7.2 AGE per day showed a significant reduction of epinephrine- and, to a lesser degree, collagen-induced platelet aggregation but failed to demonstrate an inhibition of adenosine diphosphate (ADP)-induced aggregation. Platelet adhesion to fibrinogen was reduced by approximately 30 % in subjects taking AGE compared with placebo supplement. A trend towards decreased susceptibility of lipoproteins to oxidation also was noted during AGE administration compared with the placebo period. In a randomised, double-blind, placebo-controlled clinical trial of 152 probationers, continuous intake of high-dose garlic powder dragées reduced significantly the increase in arteriosclerotic plaque volume by 5–18 % or even effected a slight regression within the observational period of 48 months (Koscielny et al. 1999). Also the age-dependent representation of the plaque volume showed an increase between 50 and 80 years that was diminished under garlic treatment by 6–13 % related to 4 years. Further in a randomised, double-blind study of normal healthy individuals ($n = 34$), both men and women, they found that the adherence of platelets was inhibited by AGE in a dose-dependent manner when collagen was the adhesive surface perfused at low shear rates (approximately 30/s) (Steiner and Li 2001). At high shear rates (1,200/s), AGE also inhibited platelet adhesion to collagen but only at higher intake levels. Adhesion to von Willebrand factor was reduced only at 7.2 g/day AGE, but adherence to fibrinogen was potently inhibited at all levels of supplementation.

In a randomised, double-blind, placebo-controlled, crossover study of 14 healthy volunteers, four hours after consuming one large dose of oil derived from 9.9 g garlic, there was little or no effect in the reduction of platelet aggregation (Wojcikowski et al. 2007). Platelet aggregation induced by adrenaline was reduced slightly but significantly (12 % reduction). The oil had no effect on collagen- or ADP-induced aggregation. In a randomised, open-label, placebo-controlled, crossover study of type II diabetic patients, after single- and multiple-dose administration of aged garlic, there was a significant inhibition of platelet aggregation at 2 hours, whereas with cilostazol, the inhibition was significant at all the three time points tested, with 4 hours showing maximum

inhibition (Mateen et al. 2011). Co-administration of aged garlic extract and cilostazol did not enhance the antiplatelet activity compared with individual drugs.

Review Studies

A review of studies of garlic (*Allium sativum*) on serum lipids and blood pressure before and after 1994 found that publications published prior to January 1994 performed better than those published after January 1994, suggesting that allicin may be responsible for the antihypertensive effects of garlic powder tablets (McRae 2005). However, a lack of correlation between changes in total serum cholesterol and blood pressure suggested that other organosulfur compounds may also play a role in the antihypertensive mechanisms of garlic.

Antihypercholesterolaemic Antihyperlipidaemic Activity

In-Vitro Studies

Simultaneous feeding of garlic or onion unsaturated oil and high sucrose for 2 months counteracted the adverse effects of high sucrose in rats (Adamu et al. 1982). Along with a lipid-lowering effect, a modest but significant effect of tissue protein reduction was observed. The crude garlic was found to be more effective than petroleum ether and ethanol garlic extracts in inhibiting the rise of serum cholesterol level in cholesterol-fed rabbits (Rahmani et al. 1988). Ethanol was least effective in suppressing serum cholesterol concentration. Ajoene from garlic was found to be reactive towards sulfhydryl compounds and to inactivate human gastric lipase in-vitro (Gargouri et al. 1989). The results corroborated previous reports on the ability of garlic to lower triacylglycerol blood levels. Garlic-derived organosulfur compounds exerted differential inhibitory effects on cholesterol biosynthesis in primary rat hepatocyte cultures and may provoke multiple inhibition of this metabolic pathway in response to garlic consumption (Gebhardt and Beck 1996). Concerning early steps, allicin significantly inhibited incorporation of

[14C]acetate into nonsaponifiable neutral lipids already at concentrations as low as 10 μ M; diallyl disulfide and allyl mercaptan were effective above 100 μ M only, and the two vinylldithiins started at 500 μ M. If [14C]acetate was replaced by [14C]mevalonate, inhibition due to allicin, diallyl disulfide and allyl mercaptan disappeared suggesting that HMG-CoA reductase was the target of inhibition. Concerning the late step, the potency to exert accumulation of lanosterol presumably by inhibiting lanosterol 14 α -demethylase decreased in the order, allicin > diallyl disulfide > allyl mercaptan = 1,3-vinylldithiin > 1,2-vinylldithiin, the effect of the latter compound being close to zero. With respect to the total inhibition of [14C]acetate labelling of cholesterol, the half-maximal effective concentration value of allicin was determined to be 17 μ M compared to 64 μ M for diallyl disulfide and to 450 μ M for allyl mercaptan. Garlic powdered extract significantly reduced the level of cholesteryl esters and free cholesterol in cultured cells and inhibited their proliferative activity after 24 hours incubation (Orekhov et al. 1995). In addition, the extract significantly reduced cholesterol accumulation and inhibited cell proliferation stimulated by blood serum taken from atherosclerotic patients. Blood serum taken 2 hours after an oral administration of 300 mg garlic powder tablet caused substantially less cholesterol accumulation in cultured cells. This suggested that garlic powder manifested direct antiatherogenic-related action not only in-vitro but also in-vivo. Studies by Slowing et al. (2001) suggested that administration of garlic fractions to rats fed with a high cholesterol could prevent diet-induced hypercholesterolaemia by plasma total cholesterol and LDL and vascular alterations in the endothelium-dependent relaxation associated with atherosclerosis.

Studies in rat primary hepatocyte cultures suggested that the hypocholesterolaemic effect of garlic could be attributed partly from decreased hepatic cholesterologenesis, whereas the triacylglycerol-lowering effect appeared to be due to the inhibition of fatty acid synthesis (Yeh and Yeh 1994). In further studies using cultured rat hepatocytes, Yeh and Liu (2001) found 44–87 % inhibition of cholesterol synthesis by the water-extractable fraction (WEF), methanol-extractable

fraction (MEF) and petroleum ether-extractable fraction (PEF) of fresh garlic and Kyolic (liquid form of AGE). The results suggested that hydrophilic and hydrophobic compounds of garlic were inhibitory to cholesterol synthesis. Among water-soluble compounds, SAC, *S*-ethylcysteine (SEC) and *S*-propyl cysteine (SPC) inhibited cholesterol synthesis by 40–60 % compared with 20–35 % by γ -glutamyl-*S*-allylcysteine (GSAC), γ -glutamyl-*S*-methylcysteine (GSMC) and γ -glutamyl-*S*-propyl cysteine (GSPC). Lipid-soluble sulfur compounds (i.e. diallyl sulfide, diallyl disulfide, diallyl trisulfide, dipropyl sulfide and dipropyl trisulfide) at low concentrations (0.05–0.5 mol/L) slightly (10–15 %) inhibited cholesterol synthesis but became highly cytotoxic at high concentrations (1.0–4.0 mol/L). All water-soluble compounds, except *S*-allylmercaptocysteine, were not cytotoxic, judging from the release of cellular lactate dehydrogenase (LDH) into the culture medium. The results suggested that cholesterol-lowering effects of garlic extract, such as aged garlic extract, emanated in part from inhibition of hepatic cholesterol synthesis by water-soluble sulfur compounds, especially SAC.

Among water-soluble compounds of garlic, *S*-allylcysteine (SAC), *S*-ethylcysteine (SEC) and *S*-propyl cysteine (SPC) inhibited [2-¹⁴C]acetate incorporation into cholesterol in a concentration-dependent manner, attaining 42–55 % maximal inhibition (Liu and Yeh 2000). γ -glutamyl-*S*-allyl cysteine, γ -glutamyl-*S*-methylcysteine and γ -glutamyl-*S*-propyl cysteine were less potent, exerting only 16–29 % maximal inhibitions. Alliin, *S*-allyl-*N*-acetyl cysteine, *S*-allylsulfonyl alanine and *S*-methylcysteine had no effect on cholesterol synthesis. Of the lipid-soluble compounds, diallyl disulfide (DADS), diallyl trisulfide (DATS) and dipropyl disulfide (DPDS) reduced cholesterol synthesis by 10–25 % at low concentrations ($\leq$ 0.5 mmol/L) and abrogated synthesis at high concentrations ($\geq$ 1.0 mmol/L). Diallyl sulfide, dipropyl sulfide and methyl allyl sulfide slightly inhibited [2-¹⁴C]acetate incorporation into cholesterol only at high concentrations. The complete suppression of cholesterol synthesis by DADS, DATS and DPDS was associated with cytotoxicity as indicated by a marked increase in cellular LDH release. There was no apparent increase in LDH secretion by water-soluble

compounds except S-allyl mercaptocysteine, which also negated cholesterol synthesis. Based on maximal inhibition and IC₅₀ (concentration required for 50 % of maximal inhibition) values, SAC, SEC and SPC were equally potent in inhibiting cholesterol synthesis. The results of subsequent studies indicated that SAC, SEC, SPC and gamma-glutamyl-S-methylcysteine inhibited lipid biosynthesis in cultured rat hepatocytes and further suggested that these S-alk(en)yl cysteines of garlic impaired triglyceride synthesis in part due to decreased de novo fatty acid synthesis resulting from inhibition on the lipogenic enzyme fatty acid synthase (Liu and Yeh 2001). Alliin, γ -glutamyl-S-allyl cysteine, γ -glutamyl-S-propyl cysteine, S-allyl-N-acetyl cysteine, S-allylsulfonyl alanine and S-methylcysteine had no effect on fatty acid synthesis. Further, S-allylcysteine (SAC), S-ethylcysteine (SEC) and S-propyl cysteine (SPC) inhibited cholesterol synthesis from [(14)C]acetate but not from [(14)C]mevalonate in cultured rat hepatocytes (Liu and Yeh 2002). The results suggested that S-alk(en)yl cysteines inhibited cholesterol synthesis by deactivating HMG-CoA reductase via enhanced phosphorylation, but not changing levels of mRNA or the amount of the enzyme. Additionally, of the three S-alk(en)yl cysteines tested, only SAC appeared to further decrease the activity of HMG-CoA reductase by increasing sulfhydryl oxidation of the enzyme. Diallyl trisulfide (DATS) inhibited the differentiation of 3T3-L1 preadipocytes into adipocytes (Lii et al. 2012). DATS prolonged ERK activation, which led to the downregulation of adipogenic transcription factor expression during adipogenesis. Their results suggested that garlic may have potential as an antiobesity agent. Khat (*Catha edulis*) and garlic in combination exhibited a synergistic effect in reducing the lipid contents of blood in-vitro (Abdul Aziz et al. 2010). The mechanism of garlic in reducing lipids could be explained by its emulsifying property, while the mechanism of khat by lipolysis.

Animal Studies

Allicin significantly reduced the lipid levels of serum and liver of normal rats on long-term (2 months) administration

(Augusti and Mathew 1974). The effect of allicin was more pronounced in the liver than in the serum and was largely attributed to the decrease in the triglyceride level and free cholesterol. The increased levels of low-density lipoproteins (LDL) and LDL cholesterol in rats fed with the atherogenic diet were partly reversed in rats receiving a supplement of 2 % garlic powder (Kamanna and Chandrasekhara 1982). On a cholesterol-containing diet, high-density lipoprotein (HDL) and HDL cholesterol levels were decreased. Inclusion of garlic powder in the atherogenic diet enhanced the percentage of HDL, whereas no change was observed in HDL cholesterol levels. Commercial garlic pearls (equivalent to 0.15 % garlic powder in the diet) also produced a significant decrease in serum and liver cholesterol levels in rats fed with the atherogenic diet. Feeding of garlic oil exerted hypolipidaemic effects in rats fed with ethanol and a high-fat high-cholesterol diet (Shoetan et al. 1984). Elevated levels of total lipids in the liver, and cholesterol and triglyceride in the serum, liver and kidneys were significantly reduced by garlic oil to levels near to those seen in untreated control rats. Cholesterol-induced hyperlipidaemia in male Sprague–Dawley rats was controlled by garlic feeding for 12 weeks (Chaudhuri et al. 1984). Garlic treatment did not alter the concentrations of circulating thyroid hormones and thyroidal uptake of radioiodine, suggesting that the hypolipidaemic effect of garlic was probably not mediated through the thyroid. Garlic oil extract administered with high-sucrose and high-alcohol diets significantly lowered the high levels of alkaline phosphatase and alcohol dehydrogenase in the serum, liver and kidneys in rats (Adoga and Osuji 1986). This effect was postulated to be due to the reduced biosynthesis of fatty acids as NADPH, required for the process, was utilised for the metabolism of the oil. Garlic ameliorated the signs associated with Cu deficiency, although hepatic lipogenesis was not affected (Fields et al. 1992). Administration of garlic reduced the activity of the lipogenic enzyme glucose-6-phosphate dehydrogenase only in Cu-adequate rats. Consumption of garlic resulted in increased epididymal fat pad and pancreas sizes and higher haematocrit, insulin and thyroxine concentrations. Both garlic protein (16 % of diet) and garlic oil (100 mg/kg body weight/day)

exhibited significant lipid-lowering effects in hyperlipidaemic albino rats (Mathew et al. 1996). The hypolipidaemic action is primarily attributed to a decrease in hepatic cholesterogenesis in the treated rats. Even though garlic oil was found to be more effective, the garlic protein was more palatable and free from an obnoxious smell. Garlic protein (500 mg/kg body wt/day) given to rats exerted significant hypolipidaemic action comparable with a standard dose of gugu-lipid (Rajasree et al. 1999). The hypolipidaemic action was mainly due to an increase in cholesterol degradation to bile acids and neutral sterols and mobilisation of triacylglycerols in garlic-treated rats. Studies show that aqueous fresh garlic extract was beneficial in reducing blood cholesterol, triglyceride levels and systolic blood pressure in hypercholesterolaemic rats (Ali et al. 2000a). The results showed that garlic may beneficially affect two risk factors for atherosclerosis – hyperlipidaemia and hypertension.

Garlic treatment reduced significantly total cholesterol, LDL cholesterol and triglycerides, but not HDL cholesterol in rats with chronic nephrotic syndrome induced by puromycin aminonucleoside (Pedraza-Chaverri et al. 2000). Garlic treatment was unable to modify proteinuria in either acute or chronic nephrotic syndrome. Garlic induced no change in the percentage of sclerotic glomeruli in chronic nephrotic syndrome but decreased significantly the percentage of sclerotic area of these glomeruli. The data indicated that garlic treatment ameliorated hyperlipidaemia and renal damage in chronic nephrotic syndrome which was unrelated to proteinuria or antioxidant enzymes.

Hypercholesterolaemia in rats induced by cholesterol feeding was significantly reduced by garlic (Aouadi et al. 2000). Garlic supplementation increased high-density lipoprotein and decreased low-density lipoprotein in normal and hypercholesterolaemic rats. The reduction in the plasma cholesterol by feeding garlic was in low-density lipoprotein and very-low-density lipoprotein cholesterol fractions. Feeding garlic diet decreased liver weight. Saponin fractions from garlic lowered plasma total and LDL cholesterol concentrations without changing HDL cholesterol levels in a

hypercholesterolaemic animal model (Matsuura 2001). In-vivo studies in rats suggested that long-term dietary supplementation of fresh garlic may exert a lipid-lowering effect partly through reducing intestinal MTP mRNA gene expression, thus, suppressing the assembly and secretion of chylomicrons from the intestine to the blood circulation (Lin et al. 2002). In-vitro, fresh garlic extract reduced MTP mRNA levels in both the human hepatoma HepG2 and intestinal carcinoma Caco-2 cells in a dose-dependent fashion.

Durak et al. (2002) demonstrated that cholesterol supplementation in rabbits led to dense plaque formation in the aortas of the rabbits, while garlic extract supplementation ameliorated blood lipid profile increased antioxidant potential and could significantly reduce plaque surface area in the aorta. Aqueous garlic extract exerted a significant effect on lowering the Triton WR-1339-induced cholesterol and triglyceride in the rat's blood (Sarwar et al. 2005). The hypocholesterolaemic and hypotriglyceridaemic effect of garlic extract was higher than the reference compound nicotinamide, a well-known hypocholesterolaemic and hypotriglyceridaemic compound. In rats rendered hyperlipidaemic by maintaining them on a high-fat diet (30 %) for 8 weeks, incorporation of curcumin (0.2 %) or capsaicin (0.015 %) or garlic (2.0 %) in the diet produced significant hypotriglyceridaemic effect. Plasma cholesterol remained unaffected in high-fat treatment (Kempaiah and Srinivasan 2006). Elevated hepatic triglyceride content in high-fat-fed rats was significantly lowered by the three spices. The altered osmotic fragility of erythrocytes and the reduction in Ca^{2+} , Mg^{2+} -ATPase activity in the erythrocyte membrane in the high-fat-fed rats were all corrected by the three dietary spices. Gorinstein et al. (2006a) found that dietary supplementation of raw and boiled garlic enhanced plasma antioxidant activity and improved plasma lipid metabolism in cholesterol-fed rats. Garlic boiled for 20 minutes had the same bioactivity as raw garlic in its antioxidant and protein spectra. The selenium and copper content of raw garlic was not altered by boiling.

Simultaneous feeding of garlic protein (GP) or soy protein (SP) (500 mg/kg body weight/day for 45 days) to alcohol-fed

rats increased the alcohol-lowered antioxidant enzymes, lecithin cholesterol acyltransferase (LCAT) in plasma, levels of HDL cholesterol in serum, hepatic bile acid production and faecal excretion of neutral sterols (Rajasree et al. 2009). Increase in glutathione content and catalase activity in the liver was significantly higher for the SP-treated group than for the GP-treated group. However, increase in plasma LCAT was significantly higher for the GP-treated group than for the SP-treated group. GP- and SP-treated rats reverted the alcohol-elevated lipid profile and activity of HMG-CoA reductase in the liver and intestine; lipid peroxidation, glucose-6-phosphate dehydrogenase (G6PD), glutathione peroxidase (GPx) and glutathione reductase (GR) in the liver; and incorporation of labelled acetate into liver cholesterol back towards normal. GP feeding showed a better effect than SP in lowering serum and heart total cholesterol, and in maintaining GPx at near normal level, while SP feeding showed a better effect in lowering serum FFA level and maintaining GR activity at near normal level. In suppressing the incorporation of labelled acetate into serum cholesterol, GP feeding showed a better effect than SP. Antiatherogenic and antiperoxidative effects of these proteins may be due to lower lysine/arginine ratio.

Studies showed that garlic significantly reduced total cholesterol (TC), plasma triglyceride (TG), LDL-C, VLDL-C, liver triglyceride, plasma malondialdehyde (MDA) and elevated plasma antioxidant in garlic-treated rats compared to rats fed on a lipogenic diet containing sunflower oil, cholesterol and ethanol only (Heidarian et al. 2011). Also, liver phosphatidate phosphohydrolase activity was decreased in rats fed with garlic and a standard diet. Administration of garlic significantly reduced high-fat diet (HFD)-induced body weight, epididymal fat accumulation, hyperlipidaemia and hypercholesterolaemia in mice (Kim and Kim 2011). Consequently, the atherogenic indices were reduced by 83 % and 91 %, respectively, in the 2 % and 4 % garlic-supplemented group. Liver steatosis induced by HFD was ameliorated by garlic supplementation. Additionally, garlic affected the downregulation of expression patterns of epididymal adipose tissue genes such as peroxisome proliferator-activated receptor γ (PPAR γ), acetyl-CoA

carboxylase (ACC), adipose-specific fatty acid-binding protein (aP2) and glycerol-3-phosphate dehydrogenase (GPDH). The results suggested that garlic may have a potential benefit in preventing obesity. Oral administration of thiacremonone, from garlic, for 3 weeks to db/db mice elicited a loss of body weight and decrease in blood triglyceride and glucose levels compared with the control mice (Ban et al. 2012). Histological analysis further revealed that thiacremonone significantly decreased lipid accumulation in the fatty livers of treated db/db mice. GLUT4 expression and glucose uptake were upregulated by thiacremonone in 3T3-L1 adipocytes. Thiacremonone treatment also suppressed expression levels of acetyl-CoA carboxylase (ACC) and fatty acid synthase (FAS) involved in lipid metabolism, in the liver of db/db mice. Additionally, thiacremonone enhanced the peroxisome proliferator-activated receptor γ (PPAR γ) expression in the fatty liver. Other studies found that supplementation with methanolic extract of black garlic (MEBG) decreased the final body weight, relative masses of the liver and fat tissues, serum triacylglyceride levels and hepatic oxidative stress and increased the faecal lipid contents in high-fat diet (HFD) rats (Chen et al. 2014b). It was found that supplementation with MEBG ameliorated diet-induced obesity via regulating adipogenesis, adipokine biosynthesis and lipolysis. The results suggested that MEBG could be developed as a potential nutraceutical ingredient for the prevention of obesity. Compared with hypercholesterolaemic mice, treatment with garlic extract significantly decreased total cholesterol, low-density lipoprotein cholesterol (LDL-C), triglycerides, very-low-density lipoprotein-cholesterol (VLDL-C), atherogenic index, alanine aminotransferase (ALT) and aspartate aminotransferase (AST) (Mohammadi and Oshaghi 2014). Change in HDL-C levels was not significant in garlic extract-treated animals compared with the hypercholesterolaemic group. Liver X receptor protein α and mRNA in the intestine were increased in the garlic extract-treated group compared with the chow group, while in the liver, only the mRNA of liver X receptor α was increased in the hypercholesterolaemic control mice.

Diallyl disulfide (DADS) analogues were effective in reducing the total lipid levels which could be correlated with a significant decrease in 3-hydroxy-3-methylglutaryl-CoA reductase (HMGR) activity (Rai et al. 2009). DADS analogues strongly inhibited HMGR activity in-vivo in Wistar rats but not in-vitro. These results could be attributed to the significant decrease in the mRNA levels and protein expression of HMGR. Further, DADS analogues significantly inhibited the activation of sterol regulatory element-binding protein-2 (SREBP-2) and interfered with the DNA binding activity of cAMP response element-binding protein (CREB) but not nuclear factor- κ B (NF- κ B), with upstream regulatory sequences of HMGR. DADS analogues were also effective in reducing the levels of oxidised low-density lipoprotein (ox-LDL), lipid peroxidation as well as NF- κ B activity, showing good anti-inflammatory and antioxidant properties.

Clinical Studies

Studies on human subjects found that on a fat-rich diet, the serum cholesterol, serum triglycerides and serum total lipids were significantly increased as compared to normally fed diet for 2 weeks (Bakhsh and Chughtai 1984). When 40 g of garlic was substituted in fat-rich diet for 7 days, garlic significantly reduced the serum cholesterol and serum triglycerides. In a study of 20 patients with hyperlipoproteinaemia over a period of 4 weeks, intake of dried garlic significantly decreased fibrinogen and fibrinopeptide A by 10 % (Harenberg et al. 1988). Streptokinase-activated plasminogen and fibrinopeptide B beta 15–42 were significantly increased by about 10 %. Serum cholesterol levels significantly decreased by 10 %. Systolic and diastolic blood pressure decreased. ADP- and collagen-induced platelet aggregation was not affected. Evidence from the German Association of General Practitioners' multi-centric placebo-controlled double-blind study involving a total of 261 patients of 30 general practitioners in West Germany showed that intake of standardised garlic tablets for 16 weeks was effective in the treatment of hyperlipidaemia by lowering total cholesterol values by an average of 12 % and triglyceride values by an

average of 17 % (Mader 1990a, b). In a double-blind study of 40 hypercholesterolaemic outpatients, the group-administered 900 mg garlic powder per day (equivalent to 2,700 mg of fresh) for 4 months showed significantly lower total cholesterol, triglycerides and blood pressure than those of the placebo group (Vorberg and Schneider 1990). In addition, results of a self-evaluation questionnaire indicated that patients in the drug group had a greater feeling of 'well-being'.

In a randomised, double-blind, placebo-controlled study of 42 healthy adults, it was found that treatment with standardised garlic 900 mg/day produced a significantly greater reduction in serum total cholesterol and LDL-C than placebo (Jain et al. 1993). There were no significant changes in high-density lipoprotein cholesterol, triglycerides, serum glucose, blood pressure and other monitored parameters. The garlic formulation was well tolerated without any odour problems. In a double-blind, placebo-controlled, randomised crossover study of subjects with mild to moderate hypercholesterolaemia, Simons et al. (1995) found no demonstrable effect of garlic ingestion on lipids and lipoproteins. Comparing the period on garlic with that on the placebo, there were no significant differences in plasma cholesterol, LDL cholesterol, HDL cholesterol, plasma triglycerides, lipoprotein(a) concentrations or blood pressure. There was no demonstrable effect of garlic on the oxidisability of LDL, on the ratio of plasma lathosterol/cholesterol (a measure of cholesterol synthesis) nor on the LDL receptor expression in lymphocytes.

In another double-blind crossover study of 41 moderately hypercholesterolaemic men, dietary supplementation with aged garlic extract had beneficial effects on the lipid profile and blood pressure (Steiner et al. 1996). The major findings were a maximal reduction in the total serum cholesterol of 6.1 % or 7.0 % in comparison with the average concentration during the placebo administration or baseline evaluation period, respectively. Low-density lipoprotein cholesterol was also decreased by aged garlic extract, 4 % when compared with average baseline values and 4.6 % in comparison with placebo period concentrations. In addition, there was a 5.5 %

decrease in systolic blood pressure and a modest reduction of diastolic blood pressure in response to aged garlic extract. In a double-blind, randomised 6-month parallel trial involving 115 individuals with a repeat total cholesterol concentration of 6.0–8.5 mmol/L and low-density lipoprotein (LDL) cholesterol of 3.5 mmol/L or above after 6 weeks of dietary advice, garlic was less effective in reducing total cholesterol than suggested by the meta-analyses (Neil et al. 1996). There were no significant differences between the groups receiving garlic and placebo in the mean concentrations of serum lipids, lipoproteins or apo A1 or B. In a meta-analysis which included the results from this trial, garlic was associated with a mean reduction in the total cholesterol of -0.65 mmol/L.

Yeh et al. (1997) showed that aged garlic extract (AGE) supplementation was effective in lowering the plasma concentration of total cholesterol by 7 % and LDL cholesterol by 10 % in hypercholesterolaemic men compared with subjects consuming a placebo. Yeh et al. (1997) showed that aged garlic extract (AGE) supplementation was effective in lowering the plasma concentration of total cholesterol by 7 % and LDL cholesterol by 10 % in hypercholesterolaemic men compared with subjects consuming a placebo. Gardner et al. (2007) found no statistically or clinically significant effects on LDL-C or other plasma lipid concentrations in adults with moderate hypercholesterolaemia when given raw garlic, powdered garlic supplement and aged garlic extract supplement at an approximate dose of a 4 g clove per day, 6 day/week for 6 months. In a single-blind, placebo-controlled study of 150 hyperlipidaemic patients, supplementation of coated garlic powder tablet (equal to 400 mg garlic, 1 mg allicin) twice daily for 6 weeks decreased total cholesterol and LDL cholesterol but increased HDL cholesterol (Kojuri et al. 2007).

Intake of *Monascus pilosus* garlic-fermented extract (MGFE) containing characteristic compounds such as dimerumic acid and monacolin, by hyperlipidaemic subjects, significantly reduced serum total cholesterol (TC) and low-density lipoprotein cholesterol levels 2 and 4 weeks after the start of MGFE intake as compared with the baseline (Sumioka

et al. 2006). Although the level of high-density lipoprotein cholesterol (HDL-C) was unaffected at any time, the atherogenic index calculated from the value of total cholesterol and HDL-C was significantly reduced 2 and 4 weeks after the start of MGFE intake. In a more recent randomised, double-blind, placebo-controlled, parallel-group trial, the intake of MGFE for 12 weeks decreased triglyceride and cholesterol in serum with no appreciable adverse effects in normal to mildly hyperlipidaemic individuals, suggesting that it may be effective to improve and prevent the metabolic syndrome (Higashikawa et al. 2012). In a recent double-blind, randomised, placebo-controlled trial involving patients with mild hypercholesterolaemia (28 aged black garlic administered, 22 placebo treated), aged black garlic (ABG) supplementation reduced atherogenic markers and thus may have a cardioprotective effect beyond the gold standard medication (Jung et al. 2014). ABG increased high-density lipoprotein cholesterol levels compared with the placebo group at the end of the study. Moreover, a significant decrease in the levels of apolipoprotein B and a significant increase in the ratio of low-density lipoprotein cholesterol/apolipoprotein B were observed in the ABG group. No adverse effects were reported in any of the patients.

In a double-blind, randomised, placebo-controlled trial of 25 patients (mean age, 58 years) with moderate hypercholesterolaemia, commercial garlic oil preparation administered for 12 weeks had no influence on serum lipoproteins, cholesterol absorption or cholesterol synthesis (Berthold et al. 1998). In a multi-centre, randomised, placebo-controlled trial involving patients with hypercholesterolaemia (28 garlic treated, 22 placebo treated), garlic powder (900 mg/day) treatment for 12 weeks was ineffective in lowering cholesterol levels (Isaacsohn et al. 1998). The pilot study of moderately hypercholesterolaemic volunteers by Byrne et al. (1999) did not support the hypothesis that dietary garlic supplementation decreased the susceptibility of isolated LDL to oxidation and that patterns of LDL fractions in plasma might be involved. Levels of lipoprotein(a) in plasma were also not changed. Other mechanisms of cardiovascular benefit were however not excluded. In a double-blind, randomised,

placebo-controlled trial of fifty moderately hypercholesterolaemic subjects, garlic treatment for 3 months resulted in no significant change in total cholesterol, LDL cholesterol, HDL cholesterol, HDL subclass distribution, postprandial triglycerides, apolipoprotein B, lipoprotein (a) (Lp[a]), LDL peak particle diameter or LDL subclass distribution (Superko and Krauss 2000). Garlic may have a greater effect on LDL particle diameter in LDL pattern A compared with pattern B subjects. This difference was not selected in other lipid measurements. In a 16-week prospective double-blind placebo-controlled study of 33 adult patients (13 garlic, 20 placebo) with primary hypercholesterolaemia, administration of garlic in the form of alliin 22.4 mg/day did not affect either lipid levels or various psychopathologic parameters (Peleg et al. 2003).

Review/Meta-analysis Studies

Meta-analysis of the controlled trials of garlic to reduce hypercholesterolaemia showed a significant reduction in total cholesterol levels (Warshafsky et al. 1993). The best available evidence suggested that garlic, in an amount approximating one half to one clove per day, decreased total serum cholesterol levels by about 9 % in the groups of patients studied. In the systematic review and meta-analysis conducted by Silagy and Neil (1994b), garlic therapy elicited a 12 % reduction in total cholesterol level compared with placebo. The reduction was evident after 1 month of therapy and persisted for at least 6 months. In the dried garlic powders, in which the allicin content was standardised, there was no significant difference in the size of the reduction across the dose range of 600–900 mg daily. Dried garlic powder preparations also significantly lowered serum triglyceride compared to placebo. The meta-analysis of 13 randomised, double-blind, placebo-controlled trials conducted by Stevinson et al. (2000) suggested garlic to be superior to placebo in reducing total cholesterol levels. However, the size of the effect was modest, and the robustness of the effect was debatable. The meta-analysis conducted by Ackermann et al. (2001) that covered 1,798 pertinent records, 45 randomised

trials (4 weeks or more) and 73 additional studies reporting adverse events found that compared with placebo, garlic preparations may lead to small reductions in the total cholesterol level at 1 and 3 months but not 6 months. Changes in low-density lipoprotein levels and triglyceride levels paralleled total cholesterol level results; no statistically significant changes in high-density lipoprotein levels were observed. Trials also reported significant reductions in platelet aggregation and mixed effects on blood pressure outcomes. No effects on glycemic-related outcomes were found. Proven adverse effects included malodorous breath and body odour. Other unproven effects included flatulence, oesophageal and abdominal pain, allergic reactions and bleeding.

In the meta-analysis conducted by Khoo and Aziz (2009) that involved 13 trials and 1,056 subjects, the available evidence from the randomised controlled trial did not demonstrate any beneficial effects of garlic on serum cholesterol.

Antiatherosclerotic Activity

In-Vitro Studies

Incubation of primary human coronary artery endothelial cell with garlic extract significantly decreased intercellular adhesion molecule-1 (ICAM-1, CD54) and vascular cell adhesion molecule-1 (VCAM-1, CD 106) expression induced by interleukin IL-1 α (Rassoul et al. 2006). In addition the presence of garlic extract significantly inhibited the adhesion of monocytes to interleukin IL-1 α -stimulated endothelial cells. The results indicated that garlic extract modulated the expression of ICAM-1 and VCAM-1, thus potentially contributing to the beneficial antiatherogenic effects traditionally attributed to garlic. Aged garlic extract (AGE) inhibited Ox-LDL-induced peroxides in bovine pulmonary artery endothelial cells, suppressed peroxides in murine macrophage (J774 cells) dose dependently and also inhibited NO production in J774 cells (Ide and Lau 1999). Pretreatment with AGE reverted the increase of LDH release and depletion of GSH caused by oxidised LDL. In a cell-free system, AGE

was shown to scavenge H_2O_2 dose dependently. The data suggested AGE to be a useful protective agent against cytotoxicity associated with Ox-LDL and NO, and it may thus be useful for the prevention of atherosclerosis and cardiovascular diseases. Alcoholic garlic extract increased the ATP-binding cassette transporter A1 (mRNA (20–23 %) and protein expression (18–37 %) in THP-1 macrophage cells compared with the controls (untreated cells) (Malekpour-Dehkordi et al. 2011). The results indicated the possibility of using alcoholic garlic extract to promote reverse cholesterol efflux in macrophages and prevent atherosclerosis. Yamaji et al. (2004) found that egg yolk-enriched garlic powder (EGP) inhibited copper-induced LDL oxidation in a dose-dependent manner. They observed that pretreatment of EGP significantly suppressed the production of peroxides in HL60 cells and protected endothelial cells from hydrogen peroxide-induced cell injury. These findings suggested that EGP might be useful in the prevention of atherosclerosis.

Cell counting, DNA synthesis and cell cycle analysis showed that ajoene, at 1–50 μM , interfered with the progression of the G1 phase of the cell cycle and inhibited rat smooth muscle cell (SMC) proliferation (Ferri et al. 2003). Additionally, ajoene was shown to inhibit cholesterol biosynthesis by affecting 3-hydroxy-3-methyl-glutaryl coenzyme A (HMG-CoA) reductase and late enzymatic steps of the mevalonate (MVA) pathway. Labelling of smooth muscle cell cellular proteins with farnesol (FOH) and geranylgeraniol (GGOH) was significantly inhibited by ajoene. In-vitro assays for protein farnesyltransferase (PFTase) and protein geranylgeranyltransferase type I (PGGTase-I) confirmed that ajoene inhibited protein prenylation. Ajoene interference with the protein prenylation reaction may contribute to its inhibition of SMC proliferation. Diallyl trisulfide (DAT), a natural organosulfur compound in garlic, protected vascular endothelium impairments from high-glucose-induced or hyperglycaemia-induced injury in endothelial cells in-vitro and in-vivo in obese diabetic rats by reducing mitochondrial oxidative stress and considerably improved mitochondrial respiration function (Liu et al. 2014).

The findings provided a novel insight for DAT to potentially treat the oxidative stress diseases, i.e. atherosclerosis, diabetes and neurodegenerative diseases.

Animal Studies

Bordia et al. (1975a) found that the marked rise in serum cholesterol and blood coagulability that followed 3 months of cholesterol feeding (0.2 g/kg/day) was significantly reduced by the essential oils of both onion and garlic in rabbits. Fibrinolytic activity was actually increased even above the normal control levels. The essential oils of onion and garlic (equivalent to 1 g/kg/day of raw bulbs) proved more effective than clofibrate in the usual clinical dose of 33 mg/kg/day. Garlic was even more effective than onion. Addition of cholesterol in the diet of male albino rabbits produced hypercholesterolaemia, increased tissue cholesterol and atheromatous changes in the aorta, but supplementation of garlic oil along with cholesterol significantly inhibited the hypercholesterolaemia and decreased tissue cholesterol and minimised the atheromatous changes in the aorta (Jain and Konar 1978). The results indicated that the active constituent(s) in garlic responsible for its antiatherogenic action was present in the oily fraction of garlic.

Garlic supplementation to cholesterol-rich diet retarded the development of atherosclerosis in rabbits as indicated by biochemical and histological studies (Mirhadi et al. 1991). Oral administration of petroleum ether extract of *Allium sativum*, in albino rats, significantly prevented rise in serum cholesterol and serum triglyceride level, caused by atherogenic diet (Lata et al. 1991). It also conferred significant protection against atherogenic diet-induced atherosclerosis. Two bioactive garlic compounds, ajoene (IC₅₀ 2.5–5 µM) and allicin (IC₅₀ 15–20 µM), dose dependently reduced nitrite accumulation, a parameter for NO synthesis, in supernatants of lipopolysaccharide (LPS)-stimulated RAW 264.7 macrophages (Dirsch et al. 1998). Both compounds markedly reduced inducible nitric oxide synthase (iNOS) protein as well as mRNA levels. iNOS had recently been shown to be present in

human atherosclerotic lesions and to promote the formation of deleterious peroxynitrite. Both allicin and ajoene could contribute to the beneficial effects of garlic in atherosclerosis. Garlic protein diet or daily administration of garlic oil to 2 % cholesterol-fed rats controlled significantly the increases in sulfated glycosaminoglycans in their heart and aorta (Mathew and Augusti 1996). However hyaluronic acid level increased, uridine diphosphoglucose dehydrogenase decreased and several degrading enzymes increased in the aorta on garlic treatment. The effects of garlic treatment were just the reverse in the liver.

The hypercholesterolaemic diet of rabbits caused an increase in aortic arch cholesterol (2.1 mg cholesterol/g tissue) which was significantly reduced by aged garlic extract 'Kyolic' supplementation (1.7 mg cholesterol/g tissue) (Efendy et al. 1997). 'Kyolic' significantly inhibited the development of thickened, lipid-filled lesions in the preformed neointimas produced by balloon catheter injury of the right carotid artery in cholesterol-fed rabbits but had little effect in rabbits on a standard diet. In-vitro studies showed that 'Kyolic' had a direct effect on the inhibition of smooth muscle proliferation. The data showed that 'Kyolic' treatment reduced the fatty streak development, vessel wall cholesterol accumulation and development of fibrofatty plaques in the neointimas of cholesterol-fed rabbits, thus providing protection against the onset of atherosclerosis.

On incorporation of 5 % garlic, amla or onion separately in the animal fat (butter fat, beef) diets to albino rats for 3 months, each of them ameliorated the deleterious effects of the animal fats (Augusti et al. 2001a). Butter fat was found to be more atherogenic than beef. The order of the ameliorative effects of the vegetables was garlic > amla > onion. The better hypolipidaemic effects and correction of elevated levels of certain enzymes shown by garlic and amla may be due to the facts that they contained comparatively better active principles than that found in onions. When 5 % garlic was incorporated with any of the high-fat diets containing 40 % by weight of coconut kernel or groundnut with and without 2 % cholesterol, the lipid parameters, their peroxidation and alterations in

enzyme activities in serum and tissues of rats were significantly decreased (Augusti et al. 2001b). The results showed that garlic contained some principles that counteracted the atherogenicity of the above oil seeds. Further they (Augusti et al. 2005) found that feeding rats with a polar fraction of garlic oil at a dosage of 100 mg/kg along with diets containing 20 % of sesame oil or coconut oil along with 2 % cholesterol for 2 months counteracted significantly the hyperlipidaemic, oxidant and also most of the other deleterious effects of the oils like raised lipid levels in serum and tissues, raised serum levels of AST and tissue levels of HMG-CoA reductase and the lowered serum and tissue levels of glutathione reductase. The results supported the claims that ajoene, the major polar compound of garlic oil, had very good biological action. In-vivo studies showed that daily dietary supplementation of allicin reduced the atherosclerotic plaque area by 68.9 and 56.8 % in apolipoprotein E-deficient and low-density lipoprotein (LDL) receptor knockout mice, respectively, as compared with the control mice (Gonen et al. 2005). LDL isolated from allicin-treated groups was more resistant to CuSO₄-induced oxidation *ex vivo* than LDL isolated from the control mice. They also demonstrated reduced Cu(2+) binding to LDL following allicin treatment. LDL treatment with allicin significantly inhibited both native LDL and oxidised LDL degradation by isolated mouse macrophages. A notable restoration of arterial blood pressure was seen in rats on garlic- and turmeric-supplemented diet (Zahid Ashraf et al. 2005). Animals on supplemented diet showed a significantly enhanced vasorelaxant response to adenosine, acetylcholine and isoproterenol, and contractile effect of 5-hydroxytryptamine was significantly attenuated. The present study demonstrated that garlic and turmeric were potent vasorelaxants and possessed antiatherogenic properties in reducing cholesterol.

Studies in albino rats showed that moderate and high doses of garlic homogenate possessed potential antiatherosclerotic property that was significantly attenuated by propranolol (PRO) and hydrochlorothiazide (HYD) (Asdaq et al. 2009). However, garlic homogenate antihyperlipidaemic activity was augmented by captopril (CAP). It was concluded that

administration of PRO and HYD decreased the hypolipidaemic effect of garlic homogenate and administration of garlic homogenate along with CAP augmented the hypolipidaemic effect of garlic homogenate. Espirito Santo et al. (2004) found that dietary supplementation of APOE*3-Leiden transgenic mice with the garlic formulation Printanor or garlic Kyolic (fermented garlic) for 28 weeks did not produce hypolipidaemic, anti-inflammatory or antiatherosclerotic properties.

Clinical Studies

In a study of ten healthy subjects, garlic and onion administered randomly on four different days during a 1-week period exerted a significant protective action against fat-induced increases in serum cholesterol and plasma fibrinogen and decreases in coagulation time and fibrinolytic activity (Bordia et al. 1975b). The essential oil fraction, which contains all the taste and odour, exactly duplicated the beneficial effects of whole garlic and onion. Results of a study suggested that the addition of garlic in the diet of six male subjects for 3 weeks resulted in significantly lower levels in serum triglyceride and an increase in fibrinolytic activity of blood at the end of the second and third weeks (Jain 1977). The levels of total serum cholesterol and β -lipoprotein cholesterol when compared with the initial values were lower at the end of the first, second and third weeks. However, whole blood coagulation time did not show any alteration after the addition of garlic. In a study of males of the age group of 18–35, daily ingestion of 10 g garlic for 2 months caused a significant decrease in blood cholesterol levels (Bhushan et al. 1979).

An increase in plasma cholesterol and fibrinogen and a decrease in blood fibrinolytic activity (BFA) were observed during alimentary lipaemia produced by an ingestion of a fatty breakfast by healthy volunteers (Sharma et al. 1978). Addition of garlic in its both raw and boiled forms to fatty breakfast was found to prevent the rise in cholesterol and fibrinogen in blood and to produce an enhancement of BFA. Fibrinolytic enhancing effect of garlic appeared to be mediated through an

increase in the blood activator of fibrinolysis. A decrease in blood cholesterol may also contribute to this action indirectly as increased concentration of this lipid was found to decrease the BFA.

A weak clinical efficacy of a 12-week therapy with garlic powder (daily dose, 800 mg) was demonstrated in patients with peripheral arterial occlusive disease stage II (Kiesewetter et al. 1993a). The increase in walking distance in the garlic group by 46 m (from 161.0 to 207.1 m) was significantly higher than in the placebo group (by 31 m, from 172.0 to 203.1). The diastolic blood pressure, spontaneous thrombocyte aggregation, plasma viscosity and cholesterol concentration also decreased significantly in the garlic group (Kiesewetter et al. 1991). Body weight was maintained. In a 2-week, placebo-controlled, randomised, double-blind crossover trial of ten healthy volunteers receiving 600 mg/day of garlic powder, Phelps and Harris (1993) found that although serum lipid and lipoprotein levels were not lowered in this short time period, the ex-vivo susceptibility of apolipoprotein B-containing lipoproteins to oxidation was significantly decreased (−34 %). Garlic had been reported to beneficially affect serum lipid levels, platelet function, fibrinolysis and blood pressure, and this additional effect of retarding lipoprotein oxidation may contribute to the potential antiatherosclerotic effect of garlic.

In a cross-sectional observational study of healthy elderly adults ($n = 101$; age, 50–80 years), chronic garlic powder intake was found to attenuate age-related increases in aortic stiffness (Breithaupt-Grögler et al. 1997). The data strongly supported the hypothesis that garlic intake had a protective effect on the elastic properties of the aorta related to ageing in humans. In a single-blind, placebo-controlled crossover study of 40 consecutive subjects with lipid profile abnormalities, the combination of fish oil and garlic oil caused favourable shifts in the lipid subfractions within 1 month (Morcos 1997). Triglycerides were affected to the largest extent. The cholesterol lowering and improvement in lipid/HDL risk ratios suggested that these combinations may have antiatherosclerotic properties and may protect against the development of coronary artery disease. In a 1-year, placebo-

controlled, double-blind, randomised pilot study, where 19 patients completed the study, administration of aged garlic extract was found to inhibit the rate of progression of coronary arterial calcification in atherosclerosis, as compared to placebo (Budoff et al. 2004). Lau (2006) reported that in a double-blind, placebo-controlled, crossover study involving 20 subjects (10 men and 10 women; mean age, 64 years), short-term supplementation of garlic demonstrated an increased resistance of LDL to oxidation. He also reported that aged garlic extract and its constituents SAC and allixin also suppressed LDL oxidation in-vitro. Oxidation of LDL had recently been recognised as playing an important role in the initiation and progression of atherosclerosis.

In a study of 112 patients (40–60 years old) with atherogenic dislipoproteidemy, 6 months therapy of garlic Allicor tablets resulted in a moderate hypolipidaemic and antioxidative effect (Gromnatskiĭ et al. 2007). They reported that a dosage of 600 mg per day decreases individual 10-year chance of fatal cardiovascular complications at patients with clinical signs of atherosclerosis, whereas for patients with no signs of atherosclerosis, the complications decrease with dosage of 300 mg per day.

In a placebo-controlled, double-blind, randomised trial of 65 intermediate risk firefighters (age 55 ± 6 years), daily treatment of a capsule containing aged garlic extract (1,200 mg) and coenzyme Q10 (120 mg) for a year was found to have beneficial effects on inflammatory markers and reduced progression of coronary atherosclerosis compared to the placebo-treated group (Zeb et al. 2012).

Hypotensive/Antihypertensive Activity

In-Vitro Studies

Garlic and garlic-derived bioactives possessed significant medicinal properties with the potential for ameliorating hypertension and associated morbidity (Shouk et al. 2014). They recently reviewed the role of garlic bioactives, S-allylcysteine and allicin, in modulating various parameters

such as oxidative stress, nitric oxide bioavailability, hydrogen sulfide production, angiotensin-converting enzyme activity, expression of nuclear factor- κ B and the proliferation of vascular smooth muscle cells implicated in the pathogenesis of hypertension. Garlic organosulfur compounds S-allylcysteine, alliin and diallyl sulfides had no effect on epithelial sodium channel (ENaC) (Krumm et al. 2012). By contrast, the thiol-reactive garlic compound allicin significantly inhibited ENaC to a similar extent as garlic extract. Dysregulated activity of ENaC had been reported to be associated with human diseases such as hypertension, the salt-wasting syndrome pseudohypoaldosteronism type 1, cystic fibrosis, pulmonary oedema or intestinal disorders.

Garlic caused dose-dependent relaxations in isolated rat aorta which were attenuated by the removal of endothelium as in the case of acetylcholine (Öztürk et al. 1994). The vasorelaxant effects of acetylcholine and garlic revealed that the mechanism(s) of the effect of garlic may be different from that of acetylcholine. The findings obtained strongly suggested that the vasorelaxant effect of garlic was important in its hypotensive activity and mediated by the production of endothelium- and/or muscle-derived relaxing factors. Studies showed that the single dose of garlic used had a maximum antihypertensive effect 2–6 hours after oral administration to 2K-1C rats (Al-Qattan et al. 1999). The multiple dose of garlic appeared to be effective in restraining the expected rise in blood pressure that normally occurred in 2K-1C rats. The study suggested that garlic possessed an effective antihypertensive ability and may be used as a supplementary and natural remedy in cases of unilateral renovascular hypertension.

Fractions of garlic aqueous extract with high angiotensin I-converting enzyme (ACE) inhibitory activity yielded seven dipeptides with ACE inhibitory properties (Suetsuna 1998). These dipeptides were identified as Ser–Tyr, Gly–Tyr, Phe–Tyr, Asn–Tyr, Ser–Phe, Gly–Phe and Asn–Phe, with IC_{50} (the amount of peptide needed to inhibit ACE activity) values of 66.3, 72.1, 3.74, 32.6, 130.2, 277.9 and 46.3 μ M, respectively. The presence of these dipeptides in garlic suggested that these

compounds may, at least in part, be responsible for the observed antihypertensive effect of garlic (or garlic extracts) in animals and humans. Further, long-term use of dietary garlic may have a protective effect against rise in blood pressure.

Castro et al. (2010) demonstrated that allyl methyl sulfide (AMS) and diallyl sulfide (DAS) inhibited aortic smooth muscle cell angiotensin II-stimulated cell cycle progression and migration. Their inhibitory effects were associated to the prevention of the cell cycle inhibitor p27(Kip1) (p27) downregulation and the reduction of extracellular signal-regulated kinase 1/2 phosphorylation. Also, both organosulfur compounds inhibited angiotensin II-reactive oxygen species generation. The results showed that AMS and DAS could be effective antioxidants targeted at the arterial remodelling seen in hypertension.

Animal Studies

It was found that garlic extract exhibited a hypotensive effect only in-vivo, while both in-vivo and in-vitro, it exerted a hypocalcaemic effect (Song et al. 1963b). Garlic hypotensive effect in atropinised rabbits and in ganglionic blocked rabbits (hexamethonium) was the same as the effect found in rabbits which had not been drugged. Epinephrine also did not change the hypotensive effect of garlic. The hypocalcaemic effect of garlic extract was due to the combining of garlic with blood calcium, and the muscular activity may be secondary to hypocalcaemia.

Allicin, (1, 2.5 or 10 µg), topically applied, but not the precursor, alliin (10 µg), lowered intraocular pressure unilaterally in normal rabbits, but no change occurred in sympathectomised rabbit eyes (Chu et al. 1993). Moreover, allicin (0.01, 0.1 or 1 µM) caused 40, 40 or 52 % inhibition, respectively, of 3H-norepinephrine overflow in response to electrical field stimulation and inhibited isoproterenol-stimulated cAMP accumulation by 40 % and 23 % in rabbit iris-ciliary body and cultured nonpigmented epithelial ciliary body cells, respectively.

Aqueous garlic extract when administered intravenously to normotensive dogs produced a significant fall in their mean blood pressure (Malik and Siddiqui 1981). This effect was not antagonised by atropine or antihistamines but was blocked by diamantane. Gastric administration of encapsulated garlic powder to anaesthetised dogs induced dose-dependent (2.5–15 mg/ kg) natriuretic and diuretic responses which reached a maximum 30–40 minutes after garlic administration and decreased to basal levels after 100–150 minutes (Pantoja et al. 1991). A simultaneous decrease in arterial blood pressure was observed which continued past the 250 minutes mark. High garlic doses (15 and 20 mg/kg) provoked bradycardia and T wave inversion during the first 10–15 minutes with recordings returning to normal and staying normal throughout the remainder of the experiment. In-vivo studies demonstrated that garlic blocked hypoxic pulmonary hypertension in rats, exhibiting a combination of endothelium-dependent and endothelium-independent mechanisms for the effect in pulmonary arterial rings (Fallon et al. 1998). The administration of NG-nitro-L-arginine methyl ester (a nitric oxide synthase inhibitor) inhibited the vasodilatory effect of garlic by 80 %.

In another in-vivo study of Sprague–Dawley rats in which high-fructose feeding elicited hyperinsulinaemia, hypertension and hypertriglyceridaemia, administration of allicin for 5 weeks lowered blood pressure, triglyceride and insulin levels (Elkayam et al. 2001). The similar effect of allicin and the antihypertensive drug enalapril on BP, insulin and triglycerides reinforced the trend towards combining the nonpharmacological approach with drug therapy.

Garlic treatment reduced the induction of Na/H exchanger (NHE)-1 only in the unclipped 2K-1C hypertensive rat kidneys, whereas garlic treatment increased the sodium pump activity in both clipped and unclipped 2K-1C kidneys (Al-Qattan et al. 2003). 2K-1C hypertensive animals showed high blood pressure, increased serum concentration of prostaglandin PGE₂ and thromboxane TxB₂ and hypertrophy of the unclipped kidneys, but not in the clipped kidneys. Sodium pump activity was decreased in the clipped kidneys,

but remained unchanged in the unclipped kidneys. The findings demonstrated that the antihypertensive action of garlic was associated with a reversal of NHE-1 induction in the unclipped kidneys. These findings indicated the potential use of garlic in the treatment of hypertension. Garlic reduced blood pressure in two-kidney, one-clip (2K-1C) rats and enhanced nitric oxide (NO) synthesis in in-vivo and in-vitro experiments (Al-Qattan et al. 2006). Garlic counteracted the hypertensive effect of L-NITROARGININE-METHYL ester (L-NAME) in normal, unclipped as well as 2K-1C rats. It was concluded that the blood pressure-lowering effect of garlic in the rat 2K-1C model may be partly mediated through the NO pathway. Nwokocha et al. (2011) reported that aqueous garlic extract caused a decrease in blood pressure and bradycardia by direct mechanism not involving the cholinergic pathway in both normotensive and 2K-1C rats, suggesting a likely involvement of the peripheral mechanism for hypotension. Studies showed that aged garlic extract improved blood pressure in spontaneously hypertensive rats more safely than raw garlic (Harauma and Moriguchi 2006). Harmful effects were observed in rats fed with raw garlic, including a decrease in erythrocytes, increase in reticulocytes and generation of papilloma in the forestomach.

Studies found that administration of hydrochlorothiazide (HCTZ) in garlic homogenate pretreated rats with isoproterenol-induced myocardial injury and decreased the QRS duration, RR interval, QT segment, systolic blood pressure, heart rate, serum potassium level, serum lactate dehydrogenase and serum CK-MB (creatin phosphokinase MB) activities and kaliuresis significantly; in contrast, the diuretic effect of HCTZ was significantly increased in presence of garlic (Asdaq and Inamdar 2009).

Pharmacokinetic studies showed that garlic increased the bioavailability and half-life, along with a decrease in clearance and elimination rate of HCTZ when administered orally. This could be important in reducing the dose of HCTZ to achieve enhanced therapeutic effect with minimal adverse effect. Studies showed that addition of hydrochlorothiazide (HCTZ) and captopril (CAP) to rats fed with low to moderate doses of garlic elicited synergistic effects in the biochemical,

antioxidant profile and myocardium integrity (Asdaq and Inamdar 2010a). Adding HCTZ/CAP ameliorated the toxic effects of high-dose 500 mg/kg of garlic homogenate. Garlic homogenate at 125 and 250 mg/kg was found to be protective by decreasing the MDA, GSHPx, LDH and CK-MB levels in serum and elevating SOD, CAT, LDH and CK-MB activities in heart tissue homogenate. Addition of HCTZ or CAP was found to augment the garlic homogenate efficacy by keeping the integrity of the myocardium intact. The antioxidant behaviour could be attributed to sulfur-containing compounds such as S-allylcysteine sulfoxide and S-allyl mercaptocysteine sulfoxide in garlic homogenate. They found that incorporation of captopril during garlic homogenate administration provided further antioxidant protection to isoproterenol-myocardium injury in rats (Asdaq and Inamdar 2010b). However, higher dose of GH alone or with captopril failed to prevent the damaging effect of isoproterenol. However, higher dose of garlic homogenate alone or with captopril failed to prevent the damaging effect of isoproterenol. The combined therapy of fresh garlic homogenate (FGH) 250 mg/kg and captopril (CAP) was more effective in reducing systolic blood pressure, cholesterol, triglycerides and glucose in albino rats (Asdaq and Inamdar 2010c). The SOD and catalase activities in heart tissue were significantly elevated in rats treated with FGH, S-allylcysteine sulfoxide (SACS), CAP, FGH+CAP and SACS+CAP. Further, combined therapy of FGH 250 mg/kg and CAP caused significant fall in LDH and CK-MB activities in serum and elevation in heart tissue homogenate. SACS in low dose was less effective than low dose of FGH; similarly, high dose of FGH was more efficacious than high dose of SACS. Corroborating with this, combined therapy of garlic (250 mg/kg) with CAP demonstrated higher synergistic action than combination of SACS (0.222 mg/kg). Moreover, combination of SACS and CAP exerted super-additive (synergistic) interaction with respect to fall in blood pressure and angiotensin-converting enzyme inhibition. They also found that garlic in moderate dose (250 mg/kg) with added HCTZ possessed synergistic cardioprotective and antihypertensive properties against fructose- and isoproterenol-induced toxicities in albino rats (Asdaq and

Inamdar 2011b). They also reported that the bioavailability and half-life of propranolol were significantly enhanced by two- and threefold, respectively, in animals pretreated with 250 mg/kg garlic homogenate (Asdaq and Inamdar 2011a). The combined therapy of garlic 250 mg/kg and propranolol was found to be the most effective in reducing systolic blood pressure, cholesterol, triglycerides and glucose.

Fructose-fed rats showed an increase of systolic blood pressure, aortic NAD(P)H oxidase activity, plasma thiobarbituric acid reactive substances and vascular remodelling that was significantly reduced after aqueous garlic administrations (Vazquez-Prieto et al. 2010). Aqueous garlic extracts prevented oxidative stress and vascular remodelling in rats with metabolic syndrome. In an in-vivo study of Cohen–Rosenthal diabetic hypertensive rats, administration of S-allyl-mercapto-captopril (CPSSA), a conjugate of captopril with allicin, for 2 months was effective in attenuating the systolic and diastolic BP as well as significantly reducing glucose levels and preserving weight gain (Younis et al. 2010). The authors concluded that the combined molecule CPSSA integrated the antihypertensive feature of both allicin and captopril, making it a potential antidiabetic and cardiovascular protective agent.

Intravenous administration of garlic, onion and ginkgo extracts produced dose-dependent and reversible hypotensive and bradycardic effects in anaesthetised normotensive rats (Brankovic et al. 2011). The most effective in reducing arterial blood pressure and heart rate was garlic extract. Processed garlic was found to effectively reduce the blood pressure of spontaneously hypertensive rats after 4, 6 and 8 weeks with a single daily dose of 30 and 50 mg/kg (Han et al. 2011). Animal studies found that the serum antioxidant levels of rats after 3 weeks of garlic treatment were significantly higher than the pretreatment levels in both diabetic and hypertensive rats (Drobiova et al. 2011). The increased serum antioxidant levels were paralleled by a decrease in serum glucose in the garlic-treated diabetic rats and lowered systolic blood pressure in the garlic-treated hypertensive rats. Studies by Hara et al. (2013) found that aged garlic extract (AGE) significantly reduced left

ventricular interstitial fibrosis in Dahl salt-sensitive (DS) rats of 12 and 18 weeks of age. Chronic AGE intake attenuated left ventricular diastolic dysfunction and fibrosis without significantly decreasing systolic blood pressure in hypertensive DS rats.

Clinical Studies

In a randomised, placebo-controlled, double-blind trial of 47 non-hospitalised patients with mild hypertension, garlic intake for 12 weeks resulted in significant differences between the placebo and the garlic group that were found during the course of therapy (Auer et al. 1990). Supine diastolic blood pressure in the group having garlic treatment fell from 102 to 91 mmHg after 8 weeks and to 89 mmHg after 12 weeks. The serum cholesterol and triglycerides were also significantly reduced after 8 and 12 weeks of garlic treatment. A 61-year-old male patient taking garlic 500 mg three times a day for 3 weeks registered a decrease in mean systolic blood pressure by 2 mmHg and a decrease in diastolic blood pressure by 2.4 mmHg (Estrada and Young 1993). The treatment effect of garlic was small, but the patient believed that continuing garlic for the management of his hypertension was justified. In a study of patients with essential hypertension, a moderate decline in blood pressure and a significant reduction in 8-hydroxy-2'-deoxyguanosine, NO levels and lipid peroxidation were observed in patients with garlic pearl supplementation (Dhawan and Jain 2005). Further, a significant increase in vitamin levels and total antioxidant status was also observed in this garlic group as compared to the control subjects. The findings highlighted the beneficial effects of garlic supplementation in reducing blood pressure and counteracting oxidative stress, and thereby, offering cardioprotection in essential hypertensives. In a 4-month study of 23 volunteer subjects with high blood cholesterol (>5.98 mmol/L) comprising 13 hypertensive and ten normotensive patients, garlic extract supplementation improved blood lipid profile, strengthened blood antioxidant potential and produced significant reductions in systolic and diastolic blood pressures (Durak et al. 2004). It also led to a decrease in the level of

oxidation product (malondialdehyde) in the blood samples, which demonstrated reduced oxidation reactions in the body. Sobenin et al. (2009) conducted a double-blind, placebo-controlled trial with an active control arm, and the hypotensive action of time-released garlic powder tablets (Allicor) was compared with that of regular garlic pills (Kwai) in 84 men with mild or moderate arterial hypertension. The results revealed that time-released garlic powder tablets were more effective for the treatment of mild and moderate arterial hypertension than regular garlic supplements. In a double-blind, parallel, randomised, placebo-controlled trial involving 50 patients, administration of garlic extract (960 mg containing 2.4 mg *S*-allylcysteine) daily for 12 weeks was found to be superior to placebo in lowering systolic blood pressure similarly to current first-line medications in patients with treated but uncontrolled hypertension (Ried et al. 2010). In a placebo-controlled trial of 44 hypertensive subjects over a period of 8 weeks, ingestion of 500 mg capsules of processed garlic significantly lowered the blood pressure (SBP) after only 2 weeks, while a significant reduction in diastolic blood pressure (DBP) took 8 weeks (Han et al. 2011).

In a prospective and uncontrolled clinical study of 70 subjects aged 30–60 years with primary arterial hypertension, including 38 females and 32 males, garlic administration was found to significantly lower lipid level and the level of lipid peroxidation products in the blood (Duda et al. 2008). It markedly increased vitamin E concentration in the serum, whereas the increases in the levels of other antioxidant vitamins and glutathione peroxidase activity proved insignificant. The product did not affect arterial blood pressure in the study subjects.

Reviews/Meta-analysis Studies

Results of a systematic review and meta-analysis conducted by Silagy and Neil (1994a) suggested that garlic powder preparation may be of some clinical use in subjects with mild hypertension. However, there was still insufficient evidence to recommend it as a routine clinical therapy for the treatment of hypertensive subjects. The meta-analysis of 11 of 25 review

studies conducted by Ried et al. (2008) suggested that garlic preparations were superior to placebo in reducing blood pressure in individuals with hypertension. Stabler et al. (2012) conducted a systematic review of randomised, placebo-controlled trials of any garlic preparation versus placebo for the treatment of hypertension. From 2 trials in 87 hypertensive patients, it was suggested that garlic reduced mean supine systolic and diastolic blood pressure by approximately 10–12 mmHg and 6–9 mmHg, respectively, over and above the effect of placebo, but the confidence intervals for these effect estimates were not precise, and this difference in blood pressure reduction fell within the known variability in blood pressure measurements. There was insufficient evidence to determine if garlic provided a therapeutic advantage versus placebo in terms of reducing the risk of mortality and cardiovascular morbidity in patients diagnosed with hypertension.

Cardioprotective Activity

Cardioprotective effects of dietary garlic had been reported to be mediated in large part via the generation of hydrogen sulfide (H_2S) (Ginter and Simko 2010; Lavu et al. 2011).

Garlic-derived organic polysulfides were reported to be converted by erythrocytes into hydrogen sulfide which relaxed the vascular smooth muscle, inducing vasodilation of blood vessels and significantly reducing blood pressure. Despite the controversial role of H_2S in blood pressure regulation and interaction with nitric oxide, H_2S , through its antiapoptotic, anti-inflammatory and antioxidant effects, had demonstrated significant cardioprotection (Lavu et al. 2011). Extensive studies had been reported indicating that garlic and its constituents reduced cardiovascular risk, including abnormal plasma lipids, oxidised low-density lipoproteins (LDL), abnormal platelet aggregation and high blood pressure (Ginter and Simko 2010). Stimulation of nitric oxide generation in endothelial cells appeared to be the critical preventive mechanism, and garlic may promote an anti-inflammatory environment by cytokine modulation in human blood. Also data on the potential ability of garlic to inhibit the rate of

progression of coronary calcification had been reported. Epidemiological studies show an inverse correlation between garlic consumption and progression of cardiovascular disease (Rahman and Lowe 2006). Numerous in-vitro studies have confirmed the ability of garlic to reduce serum total cholesterol, LDL and LDL oxidation, platelet aggregation, hypertension and smoking and to increase antioxidant status.

In-Vitro Studies

Allicin, from garlic, markedly inhibited nitrite production in lipopolysaccharide (LPS)-stimulated rat cardiac myocytes (Schwartz et al. 2002). A low concentration of allicin (10 μ M) was significantly more potent in abrogating the effect of LPS on nitrite production than a higher concentration (40 μ M). Allicin decreased steady-state iNOS mRNA levels, and this effect was maximal when a lower concentration was used (10 μ M compared with 40 μ M). Allicin inhibited the uptake of 1 mM extracellular arginine in a concentration-dependent manner in rat cardiac myocytes. A concentration of 200 μ M allicin abolished the expression of CAT-2 mRNA, 100 μ M significantly attenuated it, whereas 50 μ M had no effect. The results suggested that allicin inhibited iNOS activity through two different mechanisms: at lower concentrations it decreased iNOS mRNA levels, whereas at higher concentrations it inhibited arginine transport through downregulation of cationic amino acid transporter-2 (CAT-2) mRNA. Benavides et al. (2007) showed that human RBCs converted garlic-derived organic polysulfides into hydrogen sulfide H₂S, an endogenous cardioprotective vascular cell signalling molecule. Intact aorta rings, under physiologically relevant oxygen levels, also metabolised garlic-derived organic polysulfides to liberate H₂S. The vasoactivity of garlic compounds was synchronous with H₂S production, and their potency to mediate relaxation increased with H₂S yield, strongly supporting the hypothesis that H₂S mediated the vasoactivity of garlic.

Allitridin (diallyl trisulfide, DATS) from garlic inhibited multiple cardiac potassium channels strongly of hKv4.3 and

weakly of hKv1.5, hERG and hKCNQ1/hKCNE1 channels expressed in HEK 293 cells (Xu et al. 2012). These effects may account for its anti-arrhythmic effect observed in experimental animal models. Allitridin (diallyl trisulfide) of garlic and amiodarone exhibited similar effects on the cardiac conduction system and on the electrophysiology without RUD (reverse use dependence) in the isolated hearts of normal rats and rats with myocardial infarction (Xing et al. 2012). These effects may be the result of the use of multi-channel blockers, such as calcium channel blockers and IKr and IKs channel blockers. The data indicated that allitridin may be a promising anti-arrhythmic drug.

Animal Studies

Studies showed that chronic garlic intake (125–500 mg/kg) in rats dose dependently augmented endogenous antioxidants SOD (superoxide dismutase), catalase, GPx (glutathione peroxidase) and GSH (reduced glutathione) and lowered myocardial TBARS (thiobarbituric acid reactive substances), and all these may have important direct cytoprotective effects on the heart, especially in the event of oxidant stress-induced injury (Banerjee et al. 2002). Chronic oral administration of raw garlic provided protection against isoproterenol-induced myocardial necrosis and associated oxidative stress in Wistar albino rats (Banerjee et al. 2003). Significant preservation of myocardial SOD activity and significant reduction in plasma TBARS and LDH levels were observed in garlic-treated rats. Isoproterenol-induced myocardial morphological changes were least in the 250 and 500 mg/kg garlic-treated groups. Administration of garlic oil produced a marked reversal of the adverse metabolic changes related to myocardial infarction induced by isoproterenol in rats (Saravanan and Prakash 2004). These adverse metabolic changes induced by isoproterenol included significant increase in lipid peroxide levels and serum iron content with a significant decrease in plasma iron binding capacity, ceruloplasmin activity and glutathione (GSH) level and a significant decrease in antioxidant enzymes like superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPX), glutathione S-

transferase (GST) and glutathione reductase (GRD) in the heart. Medicinal garlic was found to have potential to ameliorate the myocardial damage induced by isoprenaline in rats (Vibha et al. 2011). It caused significant elevation in superoxide dismutase and catalase activities and reduction in thiobarbituric acid reactive species levels compared to isoprenaline control. Lactate dehydrogenase (LDH) and creatine phosphokinase-MB (CK-MB) activities were decreased in serum and elevated in the heart tissue of animals treated with low and high doses of medicinal garlic. Studies showed that adenosine was involved in the cardioprotective and cardiodepressant activities of aqueous garlic extract in ischaemic preconditioning and myocardial ischaemia–reperfusion-induced cardiac injury and was mediated by the modulation of nitric oxide in rats (Sharma et al. 2012). The cardioprotective effect of ischaemic preconditioning and garlic cardioprotection was significantly attenuated by theophylline (1,000 $\mu\text{mol/L}$) and 8SPT (10 mg/kg, i.p.) and expressed by increased myocardial infarct size, increased LDH level and reduced nitrite and adenosine levels.

Aged garlic extract showed dose-dependent cardioprotection in isoproterenol-induced cardiac toxicity in rats (Avula et al. 2014). Aged garlic extract (AGE) and its constituent, S-allylcysteine (SAC), administration caused a decrease in serum lactate dehydrogenase (LDH) and creatinine kinase-MB (CK-MB) activities and an elevation of LDH and CK-MB activities in heart tissue homogenate. The isoproterenol-induced ECG changes were restored to normal in all treated groups. However, concurrent administration of SAC with atenolol (6 mg/kg, p.o) combated more effectively the myocardial dysfunction during isoproterenol-induced cardiotoxicity in rats. Garlic extract at both concentrations significantly decreased the plasma insulin, total cholesterol, homeostasis model assessment index and oxidative stress levels in obese insulin-resistant rats caused by a high-fat diet for 12 weeks (Supakul et al. 2014). Furthermore, garlic extract at both doses (250 or 500 mg/kg/ day) restored the heart rate variability, cardiac function and cardiac mitochondrial function. The study by Padiya et al. (2014) demonstrated that the raw garlic homogenate was effective in reducing cardiac

hypertrophy and fructose-induced myocardial oxidative stress through PI3K/AKT/Nrf2-Keap1 dependent pathway in fructose-fed diabetic rats.

Clinical/Epidemiological Studies

In a pilot questionnaire study of 101 adult subjects, in Karachi, Pakistan, Qidwai et al. (2000) found that 67 % of the subjects used garlic in cooked food, while the rest used either in the raw form or in pickles. 59 % thought that dietary use of garlic was healthy. Subjects with blood pressure on the lower side were found to consume more garlic in their diets.

Administration of garlic oil (four capsules twice daily for 6 weeks) to 30 patients of coronary artery disease significantly reduced heart rate at peak treadmill exercise and also significantly reduced the workload upon the heart resulting in better exercise tolerance as compared to the initial test (Verma et al. 2005). Garlic appeared to be a good adaptogen to be utilised in patients with coronary artery disease.

In a double-blind, crossover, randomised, placebo-controlled clinical trial on subjects with metabolic syndrome, administration of aged garlic extract (AGE) for 12 weeks increased plasma adiponectin levels (Gómez-Arbeláez et al. 2013). The data that AGE might be a useful, novel, nonpharmacological therapeutic intervention to increase adiponectin and to prevent cardiovascular (CV) complications in individuals with metabolic syndrome.

Antihyperglycaemic/Antidiabetic Activity

In-vivo studies suggested that garlic reduced lipid synthesis and influenced glycogen metabolism in the liver of rats (Chang and Johnson 1980). Nyner et al. (1989) found that the petroleum ether garlic extract and crude garlic juice had some hypoglycaemic effect on the induced hyperglycaemia in experimental rabbits, whereas no effect was observed on the group fed on ethanol garlic extract. The hypoglycaemic effect of garlic appeared to be associated with the increase of insulin level. Administration of S-allylcysteine sulfoxide (SACS), a

garlic sulfur-containing amino acid, at a dose of 200 mg/kg body weight decreased significantly the concentration of serum lipids, blood glucose and activities of serum enzymes like alkaline phosphatase, acid phosphatase and lactate dehydrogenase and liver glucose-6-phosphatase in alloxan-induced diabetic rat (Sheela and Augusti 1992; Augusti and Sheela 1996). It increased significantly liver and intestinal HMG-CoA reductase activity and liver hexokinase activity. SACS ameliorated the diabetic condition almost to the same extent as did glibenclamide and insulin. In addition, SACS controlled lipid peroxidation better than the other two drugs. Furthermore, SACS significantly stimulated in-vitro insulin secretion from B cells isolated from normal rats. Hence it was suggested that the beneficial effects of SACS could be due to both its antioxidant and its secretagogue actions. Oral administration of onion and garlic sulfoxide amino acids, viz. S-methylcysteine sulfoxide (SMCS) and S-allylcysteine sulfoxide (SACS) to alloxan-induced diabetic rats for a month, ameliorated their diabetic condition, being characterised by glucose intolerance, weight loss, depletion of liver glycogen, etc., and was ameliorated as comparable to rats treated with glibenclamide and insulin (Sheela et al. 1995).

Intraperitoneal administration of aqueous garlic extract for 8 weeks significantly improved the impaired endothelium-dependent relaxations and decreased the enhanced contractile response to phenylephrine in streptozotocin-induced diabetic rats (Baluchnejadmojarad et al. 2003). It was concluded that intraperitoneal administration of aqueous garlic extract could improve endothelial dysfunction in the insulin-dependent model of uncontrolled diabetes. Also they demonstrated that garlic extract treatment partially attenuated the increased contractile responses of aortic rings exposed to acetylcholine in 8-week streptozotocin-induced diabetic rats (Baluchnejadmojarad and Roghani 2003).

Oral administration of garlic or onion juice daily for 4 weeks to alloxan-induced diabetic rats reverted the adverse biochemical changes induced by alloxan such as significant elevation of plasma levels of glucose, urea, creatinine and bilirubin; significant increase of aspartate aminotransferase

(AST), alanine aminotransferase (ALT), lactate dehydrogenase (LDH) and alkaline and acid phosphatase (ALP, AcP) activities in plasma and testes and their reduction in the liver; significant increase in brain LDH; and increase in the concentration of thiobarbituric acid reactive substances and activity of glutathione S-transferase in the plasma, liver, testes, brain, and kidney (El-Demerdash et al. 2005). Compared to the consumption of fenugreek and onion, only the consumption of garlic by alloxan-induced diabetic rats was able to reduce blood glucose significantly compared with the control group (Jelodar et al. 2005). In the control positive group, all the mentioned morphometric factors, volume density of B cells, volume density of islets, percent of B cells, number of islets per square millimeter, average area of islets and average volume density of B cell in the whole pancreas, were significantly changed in comparison with the control negative (normal health) group, but the same did not show significant change between treated and untreated diabetics. Oral administrations of garlic extract significantly decreased serum glucose, total cholesterol, triglycerides, urea, uric acid, creatinine and AST and ALT levels, but increased serum insulin in streptozotocin-induced diabetic rats, but not in normal rats (Eidi et al. 2006). The antidiabetic effect of the extract was more effective than that observed with glibenclamide.

Both garlic oil and diallyl trisulfide improved glycaemic control in streptozotocin-induced diabetic rats through increased insulin secretion and increased insulin sensitivity (Liu et al. 2005). They also found that long term (16 weeks) of streptozotocin-induced diabetic rats with garlic oil could improve oral glucose tolerance and renal function (proteinuria) but not through the action of diallyl disulfide (DADS) (Liu et al. 2006). High doses of DADS may further complicate the metabolic disturbances in diabetes.

Zn(II) complex ($\text{Zn}(\text{alx})_2$) with allixin (Halx) isolated from garlic exhibited the relatively high in-vitro insulin-mimetic activity, as determined by the inhibition of free fatty acid (FFA) release in isolated rat adipocytes treated with epinephrine (Adachi et al. 2006b). In type 2 diabetic KKA^y

mice, $\text{Zn}(\text{alx})_2$ exhibited higher antidiabetic activity than $\text{Zn}(\text{ma})_2$ by daily intraperitoneal injections for 2 weeks. In addition, daily oral administrations of $\text{Zn}(\text{alx})_2$ lowered the high blood glucose levels in KKA^y mice; however, the effect was not so high. Three $\text{Zn}(\text{alx})_2$ -related complexes were newly prepared, and a Zn(II) complex ($\text{Zn}(\text{tanm})_2$) with 1,6-dimethyl-3-hydroxy-5-methoxy-2-pentyl-1,4-dihydropyridine-4-thionato was found to have extremely high in-vitro insulin-mimetic activity. They also found that $\text{Zn}(\text{alx})_2$ and $\text{Zn}(\text{ma})_2$ normalised hyperglycaemia in KK-A(y) mice after a 14-day course of daily intraperitoneal injections (Adachi et al. 2004). However, $\text{Zn}(\text{alx})(2)$ improved glucose tolerance in KK-A(y) mice much more than did $\text{Zn}(\text{ma})(2)$, indicating that $\text{Zn}(\text{alx})(2)$ possessed greater in-vivo antidiabetic activity than $\text{Zn}(\text{ma})(2)$. In addition, $\text{Zn}(\text{alx})(2)$ improved leptin resistance and suppressed the progress of obesity in type 2 diabetic KK-A(y) mice. On the basis of these observations, it was concluded that the $\text{Zn}(\text{alx})(2)$ complex may be a novel potent candidate for the treatment of type 2 diabetes mellitus. Following in-vitro and in-vivo studies on a group of bis(3-hydroxy-4-pyronato)oxovanadium(IV) complexes with VO coordination mode, bis(allixinato)oxovanadium(IV) containing allixin, a garlic component, was found to be the most potent antidiabetic agent among them (Adachi et al. 2006a). This allixin-containing complex with a high in-vitro insulin-mimetic activity in terms of both free fatty acid (FFA) release inhibitory and glucose uptake-enhancing activities in isolated rat adipocytes exhibited a high hypoglycaemic effect in type 1 diabetic model mice by both intraperitoneal injections and oral administrations. Bis(allixinato)oxovanadium(IV) was thus proposed to be one of the most effective candidates for antidiabetic therapy. In an animal model of type 2 diabetes, feeding of db/db mice for 7 weeks with aged black garlic exerted stronger antioxidant activity than normal garlic indicating the usefulness of black garlic in diabetic complications (Lee et al. 2009b). Consumption of aged black garlic significantly decreased hepatic thiobarbituric acid reactive substances (TBARS) level compared with the garlic group which showed lower TBARS level than the control

group. Activities of superoxide dismutase (SOD) and glutathione peroxidase (GSH-Px) of garlic and aged black garlic group were significantly elevated compared to the control group. Catalase (CAT) activity of aged black garlic group was increased compared with the control group. The antioxidant activity of garlic and aged black garlic as measured in scavenging free radicals by the Trolox equivalent antioxidant capacity (TEAC) assay was 13.3 and 59.2 $\mu\text{mol/g}$ wet weight, respectively. In-vivo studies showed that fasting serum glucose and blood glycated haemoglobin levels were significantly decreased, and insulin level was significantly increased in db/db mice fed with garlic compared with the control group (Seo et al. 2009). Consumption of aged black garlic significantly decreased the homeostasis model assessment for insulin resistance (HOMA-IR) and tended to decrease serum glucose. Garlic consumption significantly decreased total cholesterol, while aged black garlic significantly reduced serum total cholesterol and triglyceride and increased HDL cholesterol levels. These results suggested that garlic exerted hypoglycaemic and hypocholesterolaemic effect, and aged black garlic improved insulin sensitivity and dyslipidaemia in db/db mice.

Compared to non-treated diabetic rats, garlic- or ginger-treated diabetic rats' serum glucose and protein clearance levels decreased by 45 % and 50 %, respectively (Al-Qattan et al. 2008). Images of non-treated diabetic kidneys showed characteristic histopathological changes (e.g. capsular space shrinkage, glomerular hypertrophy and diffusion, glomerular and microvascular eosinophilic precipitation and cytoplasm fragmentation and retraction). In garlic- or ginger-treated rats, these renal nephropathic structural changes although evident were less prominent. Garlic and ginger ameliorated the biomarkers of diabetes and diabetic nephropathy in streptozotocin-induced diabetic rats (Thomson et al. 2013). Garlic treatment of diabetic animals resulted in a modest weight gain and decreased food (but not water) intake and urine output. Blood glucose and serum creatinine, fructosamine and uric acid were significantly elevated in diabetic rats and were significantly lowered by ginger and garlic. In contrast, serum protein, albumin and insulin levels

decreased significantly in diabetic rats, while the ginger- and garlic-treated diabetic rats had increased serum levels of protein, albumin and insulin. Garlic and ginger treatment significantly decreased the elevated total urine protein, albumin and albumin/creatinine ratio and glycated haemoglobin levels in diabetic animals.

Aqueous garlic extract was found to attenuate glomerular glycation in streptozotocin-induced diabetic rats (Al-Qattan et al. 2013). This effect could be partially mediated via euglycaemia induced by revitalisation of endogenous insulin. Serum glucose, triglycerides, total lipids, total cholesterol, low-density lipoprotein (LDL) and very-low-density lipoprotein (VLDL) cholesterol in alloxan-induced diabetic rats treated with alliin produced from leaves of in situ-grown garlic plants elicited significant reduction of ~54 %, 15 %, 14 %, 20 %, 24 % and 15 %, while 35 %, 14 %, 10 %, 12 %, 17 % and 11 % reduction was noted in diabetic rats treated with alliin produced from ex situ-grown plants in comparison with those administered with distilled water (Nasim et al. 2011). High-density lipoprotein (HDL) cholesterol did not show any significant change. Leaf extract of plants lowered serum enzyme levels (alkaline phosphatase, aspartate aminotransferase and alanine aminotransferase) towards the norm better than glibenclamide. The histopathological alteration in the pancreas caused by alloxan was also reduced by the leaf extract. Treatment with garlic extract significantly reduced the elevated blood glucose level and augmented the decreased catalase activity in streptozotocin-induced diabetic rats (Mahmoud and Abdalla 2011). Garlic extract also significantly increased reduced glutathione content and decreased caspase-3 protein in the pancreatic tissue. The results revealed that the aqueous extract of raw garlic may have antioxidant and antiapoptotic activity in the treatment of diabetes mellitus.

Administration of garlic juice 3 weeks before streptozotocin injection prevented and ameliorated the deleterious biochemical and histopathological effects in the pancreas and liver in streptozotocin (STZ)-induced diabetic rats (Masjedi et al. 2013). Administration of S-allylcysteine, a

garlic derivative to streptozotocin (STZ)-induced diabetic rats, led to a decrease in the levels of glucose, CYP2E1 activity, TBARS and ceruloplasmin (Saravanan and Ponmurugan 2013). Additionally, the levels of plasma insulin and enzymatic and nonenzymatic antioxidants leptin and adiponectin were increased in SAC-treated diabetic rats.

The garlic extract was found to be effective in improving the high fructose-induced oxidative stress, inflammation and insulin resistance in male Wistar rats (Sivaraman et al. 2013). *Allium sativum* and *Allium porrum* inhibited significantly the active transport of D-glucose across rat enterocytes in the rat everted intestinal sac experiment (Belemkar et al. 2013). Increased concentrations of both at 2.2 and 5.0 mg/mL in the mucosal solution significantly decreased the absorption as well as transport across the rat intestine. D-glucose absorption along with transport was significantly inhibited at 2.5 and 5 mg/mL of garlic and leek compared to the control experiment groups. *A. porrum* showed more potent action.

Immunomodulatory/Haemagglutination Activity

A mannose-binding lectin ASA was isolated from garlic (Kaku et al. 1992). ASA reacted strongly with a synthetic linear (1→3)- α -D-mannan and *Saccharomyces cerevisiae* mannan, weakly with a synthetic (1→6)- α -D-mannan, and failed to precipitate with galactomannans from *Torulopsis gropengiesseri* and *T. lactis-condensi*, a linear mannopentaose, and murine IgM. The N-terminal amino acid sequence of ASA exhibited 79 % homology with that of ransom (*Allium ursinum*) lectin AUA and moderately high homology (53 %) with that of snowdrop bulb lectin, also an α -D-mannosyl-binding lectin. Fraction 4 (F4), a protein fraction isolated from aged garlic extract, enhanced the cytotoxicity of human peripheral blood lymphocytes (PBL) against both natural killer (NK)-sensitive K562 and NK-resistant M14 cell lines (Morioka et al. 1993). Administration of F4 (5 μ g/mL) with 10 U/mL interleukin IL-2 generated lymphokine-activated killer activity equivalent to that produced by 100 U/mL IL-2 alone

against M14. F4 also enhanced concanavalin A-induced IL-2 receptor (Tac) expression and IL-2 production of human peripheral blood lymphocytes. The results indicated F4 to be a very efficient immunopotentiator and may be used for immunotherapy.

Alliin exerted an immunomodulatory effect on certain functions of the peripheral blood mononuclear cells in-vitro (Salman et al. 1992). When macrophages were treated with various doses (1, 10, 100 ng/mL) of allicin from garlic, for 20 hours, allicin induced tumouricidal activity and increased the production of tumour necrosis factor (TNF- α) and nitric oxide (NO) in a dose-dependent manner (Kang et al. 2001). However, there was a little alteration on phagocytosis and the production of hydrogen peroxide (H₂O₂), interleukin 1 (IL-1) and IL-6. The results indicated that NO and TNF- α were likely major mediators of tumouricidal activity in allicin-treated macrophages and suggested allicin to be an efficient immunomodulator of macrophage secretory and cellular activities, showing a differential effect on the production of cytokines and cytotoxic molecules. Garlic aqueous and ethanolic extracts significantly modulated lymphocyte proliferation, triggered by the potent T-cell mitogen concanavalin A (Con A) (Čolić et al. 2002). Generally, higher concentrations of the extracts showed inhibitory effects, whereas lower concentrations significantly augmented the proliferation of lymphocytes. The stimulatory effect of aqueous extract was stronger using splenocytes and suboptimal concentrations of Con A as a consequence of increased interleukin 2 (IL-2) production as well as the expression of IL-2 receptor α (IL-2R α). The inhibitory effect of aqueous extract correlated with a decrease in IL-2 production, but was not followed by the downregulation of IL-2R α expression. Studies demonstrated that immune-mediated, concanavalin A (Con A)-induced liver damage in mice could be prevented by allicin, probably because of its immunomodulatory effects on T cells and adhesion molecules and inhibition of NF- κ B activation (Bruck et al. 2005). In-vitro studies showed that allicin inhibited the apoptosis of macrophages in a depleted nutritional state through the

mitogen-activated protein kinase/extracellular signal-regulated kinase–kinase pathway and increasing the level of ERK1/2 phosphorylation (Cho et al. 2006).

Two major proteins (12–14 kDa) were detected in aged garlic extract; the purified protein components QA-1, QA-2 and QA-3 displayed immunomodulatory and mannose-binding activity (Chandrashekar and Venkatesh 2009). QA-2 showed the highest mitogenic activity. The identity of QA-2 and QA-1 proteins with the garlic lectins ASA I and ASA II, respectively, had been confirmed by haemagglutination analysis. QA-3 exhibited mitogenic activity, but no haemagglutination activity. Aged garlic had been reported to have more potent immunomodulatory effects than raw garlic, and these effects had been attributed to the transformed organosulfur compounds. The study here showed that immunomodulatory proteins could also contribute to the immunomodulatory activity of aged garlic extract. A 14 kDa protein molecule isolated from garlic suppressed indoleamine 2, 3-dioxygenase metabolites in mononuclear cells and increased the proliferation responses of mononuclear in-vitro (Nikoo et al. 2008).

Three immunomodulatory protein components of molecular weight ~13 kD (QR-1, QR-2 and QR-3 in the ratio 7:28:1) were separated from raw garlic extract (Clement et al. 2010). All the 3 proteins exhibited mitogenic activity towards human peripheral blood lymphocytes, murine splenocytes and thymocytes. The mitogenicity of QR-2 was the highest among the three immunomodulatory proteins. QR-1 and QR-2 displayed haemagglutination and mannose-binding activities; QR-3 showed only mannose-binding activity. Immunoreactivity of rabbit anti-QR-1 and anti-QR-2 polyclonal antisera showed specificity for their respective antigens as well as mutual cross-reactivity; QR-3 was better recognised by anti-QR-2 (82 %) than by anti-QR-1 (55 %). QR-2 induced a 2-fold higher histamine release in-vitro from leucocytes of atopic subjects compared to that of nonatopic subjects. In all functional studies, QR-2 was more potent compared to QR-1. The results indicated that the two major proteins QR-2 and QR-1 present in a ratio of 4:1 in raw garlic

contribute to garlic's immunomodulatory activity, and their characteristics were markedly similar to the abundant *Allium sativum* agglutinins (ASA) I and II, respectively. Garlic lectins ASA I and ASA II were moderately stable in simulated gastric fluid for up to 30 minutes; while they retained haemagglutination activities, immunoreactivity with the respective rabbit antiserum decreased immediately (0.5 minutes) to 10–30 % (Clement and Venkatesh 2010). ASA I retained ~80 % haemagglutination activity in the pH range 2–12; however, ASA II retained only 40 % in the pH ranges 2–4 and 10–12. Garlic lectins exposed to 60 °C (30 minutes) and pepsin (1 and 2 minutes) retained haemagglutination and phagocytic activities. Garlic lectins were found to be immunogenic upon oral feeding in BALB/c mice. A lectin-specific serum IgG response was seen in mice comparable to the oral immunogen, phytohaemagglutinin. The recovered lectin in faeces of mice administered with garlic lectins showed antigenicity identical to that of the administered proteins. The stabilities of the garlic lectins, their ability to withstand the gastrointestinal passage and their recognition by the immune system upon oral feeding reinforced the reported presence of natural antibodies to garlic proteins in normal human sera. Garlic extract (GaE) is protected against methylmercury (MeHg)-induced cytotoxic effects and MeHg-induced inhibition of adenosine deaminase activity on human leucocytes under in-vitro conditions (Abdalla et al. 2010). The protective effects of garlic extract against MeHg-induced leucocyte damage were related to the removal of oxidant species generated in the presence of MeHg due to the antioxidant efficacy of garlic constituents. 14-kDa and 47-kDa protein molecules of aged garlic extract were able to suppress NO production from peritoneal macrophages (Daneshmandi et al. 2011). These molecules had no cytotoxic effect on macrophages and did not increase tumouricidal property of macrophages. 14-kDa and 47-kDa protein molecules of aged garlic extract were able to suppress NO production from peritoneal macrophages (Daneshmandi et al. 2011). These molecules had no cytotoxic effect on macrophages and did not increase tumouricidal property of macrophages.

A dual function protein with proteolytic and haemagglutinating activities was isolated from garlic bulbs (Parisi et al. 2008). It had a molecular mass of 25–26 kDa and comprised of two polypeptide chains of 12.5 kDa. The N-terminus of the protein displayed a 100 % sequence similarity to the sequences of a mannose-binding lectin isolated from garlic bulbs. It exhibited characteristics similar to cysteine peptidase. The enzyme exhibited substrate specificity and hydrolysed natural substrates such as α -casein, azocasein, haemoglobin and gelatin. It also showed a high affinity for synthetic peptides such as Cbz-Ala-Arg-Arg-OMe- β -Nam. The purified protein was able to agglutinate trypsin-treated rabbit red cells. Both high molecular weight (>3.5 kDa; HF) and low molecular weight (<3 kDa; LF) fructans isolated from aged garlic extract exhibited immunomodulatory activity, namely, lymphocyte proliferation and macrophage activation including phagocytosis (Chandrashekar et al. 2011). These activities were comparable to that of known polysaccharide immunomodulators such as zymosan and mannan.

Studies revealed that CD4 and total white blood cell (WBC) counts were significantly increased in a dose-dependent manner in both onion- and garlic-treated rats when compared to the zero control (Mirabeau and Samson 2012). Extract of garlic at 750 mg/Kg/day significantly increased the CD4 cells and total white cell count when compared to other concentrations. However, no significant effect was observed on these parameters when extracts were combined. The results from this study revealed the immune-boosting capabilities of onion and garlic, but underscored their synergistic activities. In contrast to control rats, garlic essential oil-treated gastric rats dose dependently and significantly increased the percent of CD3 and CD4 leucocytes in garlic-treated rats (Li et al. 2010). The detection of a significant increment in the ratio of CD4/CD8 leucocytes in the serum of rats after administration of garlic essential oil indicated that garlic essential oil may be useful for treatment of patients with inflammatory disease, e.g. gastric cancer.

Garlic consumption in mice not only caused increased energy demand from the faster RBC turnover but also

increased the production of CO, which in turn stimulated splenic erythropoiesis by an erythropoietin-independent mechanism, thus completing the sequence of feedback regulation for RBC metabolism (Akgül et al. 2010). Dietary garlic supplementation and CO treatment showed additive effects on reducing plasma erythropoietin levels in mice. Studies showed that gavage administration of male Wistar rats with garlic solution may enhance lymphocyte proliferation in the spleen and thymus from the rat immune system (Zamani et al. 2011). In spite of a decline in the average nuclear area and nuclear length of thymocytes from garlic-treated rats, total AgNORs (argyrophilic nucleolar organiser regions) and total AgNORs length increased significantly in the splenocytes and thymocytes of the garlic-treated rats. Treatment of dendritic cells from the spleen of BALB/c mice with 47 kDa protein isolated from aged garlic lowered the expression of dendritic cell maturation markers including: CD40, CD86 and MHC-II which was similar to tolerogenic dendritic cell phenotype (Ahmadabad et al. 2012). The study demonstrated that 47 kDa protein purified from aged garlic could be considered as a potential candidate to generate tolerogenic dendritic cells in-vitro. The 70 % ethanol black garlic extracts (BGE) at 70 °C for 12 hours showed the strongest antioxidant and anticancer activities (Purev et al. 2012). It was found that the cell proliferation, TNF- α and NO production of primary immune cells obtained from volunteers' blood treated with 70 % raw garlic extract (70 % RGE) were significantly different; however, little difference was observed for the 70 % BGE treatment. BGE showed stronger immunostimulatory activities than RGE.

Administration of aged garlic fructans produced a significant humoral (serum IgG) response to ovalbumin antigen in BALB/c mice though the immunoadjuvant response was delayed (Chandrashekar and Venkatesh 2012). Garlic polysaccharide was modified by HNO₃-Na₂SeO₃ method to obtain nine selenising garlic polysaccharides, sGPS1–sGPS9 (Qiu et al. 2014). The results showed that sGPSs could significantly promote lymphocyte proliferation in-vitro, with sGPS3, sGPS5 and sGPS6 presenting stronger efficacy. In-vivo, 14-day-old chickens injected, respectively, with sGPS3,

sGPS5 and sGPS6 could significantly promote lymphocyte proliferation and enhance serum antibody titre, IFN- γ and IL-2 contents. The results indicated that selenylation modification could significantly enhance the immune-enhancing activity of GPS, with sGPS6 possessing the best efficacy and could be as a candidate drug of immunoenhancer.

In a randomised study of 60 healthy volunteers, oral intake of 1 and 3 g doses of garlic traditionally used for daily supplementation increased urinary levels of interleukin IL-12, a potent stimulator of T helper cell 1 (Th-1) immune responses (Alma et al. 2014).

Anti-inflammatory Activity

Garlic oil exhibited anti-inflammatory activity, and it suppressed rat paw edema inflammation induced by formalin and histamine (Nemat et al. 2013). It was as effective as the nonsteroidal anti-inflammatory drug indomethacin. Using a chemotactic gradient Labchip to study cell migration, garlic oil was found to be a potential inhibitor for neutrophil-like cell migration and chemotactic responsiveness (Shih et al. 2010). Garlic oil treatment lowered the values of chemotactic index (CI) and motility index (MI) and reduced the average speed of cell migration from 13 to 8 $\mu\text{m}/\text{minute}$. The authors also suggested that the anti-inflammatory activity exhibited by garlic oil was mainly through inhibiting the assembly–disassembly processes of the cytoskeleton.

Studies by Lee et al. (2011) showed that aged black garlic possessed anti-inflammatory activity and may have a potential therapeutic use for the prevention and treatment of vascular diseases such as atherosclerosis through mechanisms involving the inhibition of VCAM-1 expression and NF- κB activation in vascular endothelial cells. The chloroform extract of aged black garlic significantly inhibited TNF- α -induced reactive oxygen species (ROS) formation and suppressed TNF- α -induced mRNA expression of VCAM-1 in human umbilical vein endothelial cells (HUVECs). In addition, treatment of HUVECs with CEABG markedly reduced THP-1

monocyte adhesion to TNF- α -stimulated HUVECs and significantly inhibited NF- κ B transcription factor activation.

Aged red garlic (ARG) treatment markedly reduced LPS-induced nitrite production in RAW 264.7 macrophages and reduced inducible nitric oxide synthase (iNOS) expression (Park et al. 2012a). Treatment of cells with ARG led to a significant increase in haeme oxygenase-1 (HO-1) protein expression, which was mediated by stimulating the expression of nuclear factor erythroid 2-related factor 2 (Nrf2). In LPS-induced inflammatory mice, ARG treatment downregulated iNOS and COX-2 expressions, while it upregulated HO-1 expression.

Ajoene, from garlic, dose dependently inhibited the release of lipopolysaccharide (LPS) (1 μ g/mL)-induced prostaglandin E₂ in RAW 264.7 macrophages (IC₅₀ value: 2.4 μ M) (Dirsch and Vollmar 2001). This effect was found to be due to an inhibition of COX-2 enzyme activity by ajoene (IC₅₀ value: 3.4 μ M). The effect of ajoene was found to be similar to that of indomethacin. Allicin (20–100 μ M) inhibited the SDF-1 α (CXCL12)-induced T-cell migration through fibronectin by the downregulation of (1) the reorganisation of cortical actin and the subsequent T-cell polarisation and (2) T-cell adhesion to fibronectin (Sela et al. 2004). Allicin also inhibited T-cell adhesion to endothelial cells and transendothelial migration. These inhibitory effects of allicin were associated with its ability to downregulate the phosphorylation of Pyk2 and to reduce the expression of the VCAM-1- and FN-specific α 4 β 1 integrin (VLA-4). The data suggested the beneficial biological effects of allicin in processes where T cells play an important role and suggested that allicin may be used therapeutically with chronic inflammatory diseases. Studies suggested that allicin exerted an inhibitory immunomodulatory effect on intestinal epithelial cells and suggested that allicin may have the potential to attenuate intestinal inflammation (Lang et al. 2004). Allicin markedly inhibited the spontaneous and TNF- α -induced secretion of interleukin IL-1 β , IL-8, IP-10 and MIG from HT-29 and Caco-2 cell lines in a dose-dependent manner and suppressed the expression of IL-8 and IL-1 β mRNA levels.

Thiacremonone from garlic decreased lipopolysaccharide (LPS)-induced memory impairment, glial activation, proinflammatory mediators' expression and amyloidogenesis in ICR mice (Lin et al. 2012a). In an in-vitro study, similar results, with thiacremonone (1, 2 and 5 $\mu\text{g/mL}$), effectively decreased LPS (1 $\mu\text{g/mL}$)-induced glial activation and inflammatory mediator generation which are implicated in amyloidogenesis. Thiacremonone inhibited LPS-induced amyloidogenesis in cultured astrocytes and microglial BV-2 cells. NF- κB , a critical transcriptional factor regulating not only inflammation but also amyloid- β generation, was inhibited by thiacremonone via the blocking of phosphorylation of I $\kappa\text{B}\alpha$ in mice brain as well as cultured astrocytes and microglial BV-2 cells. The results indicated that the anti-inflammatory compound, thiacremonone, inhibited neuroinflammation and amyloidogenesis through inhibition of NF- κB activity and thus could be applied for intervention of inflammation-related neurodegenerative disease including Alzheimer's disease.

Ethyl linoleate (ELA), isolated from the garlic cloves, downregulated inducible nitric oxide synthase (iNOS) and cyclooxygenase-2 (COX-2) expression and reduced nitric oxide (NO) and prostaglandin E2 production in lipopolysaccharide (LPS)-activated RAW 264.7 cells (Park et al. 2014). These effects were mediated by impaired translocation of nuclear factor (NF)- κB and inhibition of phosphorylation of mitogen-activated protein kinases. Further, ELA exerted its anti-inflammatory activity by inducing haeme oxygenase-1 (HO-1) expression. In lipopolysaccharide (LPS)-stimulated 3T3-L1 adipocytes, alliin was able to suppress the LPS inflammatory signals by generating an anti-inflammatory gene expression profile and by modifying adipocyte metabolic profile (Quintero-Fabián et al. 2013). Studies demonstrated that diallyl sulfide (DAS), from garlic, inhibited tumour necrosis factor- α (TNF- α)- and histamine-induced inflammation, suggesting that DAS might be an effective dietary agent for the prevention of oxidative stress-induced inflammation of the airway (Ho et al. 2014).

Fresh and aged black garlic extracts exhibited anti-allergic activity in-vitro (Kim et al. 2012). Markedly higher suppression of β -hexosaminidase release was found in fresh garlic extract at lower concentration compared with that of the black garlic. Aged black garlic (ABG), ethyl acetate extract (EBG) of ABG and BG10, an active fraction of EBG, suppressed the allergic response in RBL-2H3 cells, and the mechanism for its anti-allergic action may involve suppressions of release of β -hexosaminidase and TNF- α and suppression of Syk, cPLA₂, 5-LO and COX-2 (Yoo et al. 2014c). BG10 also significantly inhibited the passive cutaneous anaphylaxis reaction in mice. The anti-allergic actions of ABG, EBG or BG10 suggested that they may be useful as functional foods for allergic diseases.

Neuroprotective Activity

Administration of S-allylcysteine (SAC), an aged garlic constituent, prior to ischaemic insult, attenuated rat ischaemic brain damage (Numagami et al. 1996). Infarct volume and water content of both ischaemic and contralateral hemispheres were reduced by SAC, but neither allyl sulfide nor allyl disulfide was effective. Both SAC and 7-nitro indazole, a nitric oxide synthase inhibitor, did not attenuate the amount of ROS produced at the first peak, but did so in the second peak. A possible involvement of peroxynitrite, which may be formed from superoxide and nitric oxide and known to be highly toxic in ischaemia–reperfusion injury of the brain, was suggested. Dietary aged garlic extract (AGE) (2 %) and its prominent constituents, i.e. S-allylcysteine (SAC) (20 mg/kg) and diallyl disulfide (DADS) (20 mg/kg), modulated beta-amyloid precursor protein processing and tau phosphorylation in an Alzheimer's transgenic model Tg2576 (Chauhan 2006). Ameliorative effects of dietary interventions were found to be in the order of AGE > SAC > DADS.

Studies by Saleem et al. (2006) suggested that aqueous garlic extract (AGE) effectively modulated neurobehavioural and neurochemical changes in focal ischaemia, most probably by virtue of its antioxidant properties. Aged garlic extract

delayed the effects of ischaemia–reperfusion-induced neuronal injury in an animal cerebral ischaemia model possibly by controlling free-radical burst induced by reperfusion, preservation of antioxidant enzyme activity and delay of other pathophysiological processes (Aguilera et al. 2010). Ray et al. (2011) found significant neuroprotective and neurorescue properties of AGE and one of its ingredients, SAC, from ROS (H₂O₂)-mediated insults to neuronal cells. Treatment of AGE and SAC were found to protect neuronal cells when they were independently co-treated with ROS. Additionally, a novel neuropreservation effect of AGE was detected in that pretreatment with AGE alone and protected ~80 % neuronal cells from ROS-mediated damage. AGE was also found to preserve presynaptic protein synaptosomal associated protein of 25 kDa (SNAP25) and synaptophysin from ROS-mediated insult in Alzheimer's amyloid precursor protein-transgenic mice. The results suggested that the neuroprotective, including preservation of presynaptic proteins by aged garlic extract and SAC, could be utilised in future drug development in Alzheimer disease. In-vivo studies suggested that the neuroprotective effect of AGE was associated not only to its antioxidant properties but also with its anti-inflammatory capacity to diminish the increase in TNF- α levels and COX-2 protein expression and activity in mouse with cerebral ischaemia (Colín-González et al. 2011). Garlic administration accompanying radiofrequency electromagnetic radiation (RF-EMR) significantly reduced advanced oxidation protein product (AOPP) levels in the brain tissue of Wistar albino rats (Avci et al. 2012). In the group for which garlic administration accompanied that of RF-EMR, there was no difference in serum NO levels compared with the RF-EMR exposed group. AGE demonstrated neuroprotective effects in rats with spinal cord injury via its antioxidant activity (Cemil et al. 2012). Aged garlic extract (AGE) and of 20 % hydroethanolic fresh extracts from garlic clove (GCE) and skin (GSE) protected against cerebral ischaemia-induced injuries in rats (Cervantes et al. 2013). The results indicated that antioxidants such as SAC present in garlic extracts may regulate ROS concentrations during ischaemia, favour pro-survival pathways and attenuate mitochondrial dysfunction.

In-vitro studies showed that aged garlic extract (AGE) and S-allylcysteine (SAC) reduced Abeta(25-35)-induced apoptosis and reactive oxygen species (ROS) generation in a rat pheochromocytoma (PC12) cell line by enhancing the endogenous antioxidant defences (Peng et al. 2002). AGE and SAC not only suppressed the generation of ROS but also attenuated caspase-3 activation, DNA fragmentation, PARP cleavage and eventually protected against Ab-induced apoptosis. S-allyl-L-cysteine (SAC) was found to selectively protect neuronal cell death induced by amyloid beta-protein (Abeta) and tunicamycin, which may be triggered by endoplasmic reticulum (ER) dysfunction in nerve growth factor-differentiated PC12 neuronal cells (Ito et al. 2003b) and in the hippocampus, but it had no effect on neuronal cell death that was dependent upon the caspase-3-mediated pathway (Kosuge et al. 2003). Ito et al. (2003a) found that SAC and L-glutamate protected neuronal cell death in hippocampal neurons in the CA3 area and the dentate gyrus of the hippocampus induced by amyloid beta-peptide and ibotenic acid. Pérez-Severiano et al. (2004) found that SAC ameliorated quinolinic acid striatal toxicity in rats by its ability to scavenge free radicals, to decrease oxidative stress and to preserve the striatal activity of Cu, Zn-superoxide dismutase (Cu, Zn-SOD). SAC exerted protective effects against 3-nitropropionic acid-induced lipid peroxidation and mitochondrial dysfunction in the rat brain synaptosomes via its antioxidant properties (Pérez-De La Cruz et al. 2006). Under aggregating conditions in-vitro, SAC dose dependently inhibited Abeta fibrillation and also destabilised preformed Abeta fibrils (Gupta and Rao 2007). Further, circular dichroism and fluorescence quenching studies supported the binding ability of SAC to Abeta and inducing a partially folded conformation in Abeta. Peritoneal administration of SAC diminished cerebral ischaemia-induced mitochondrial dysfunctions in hippocampus of treated rats (Atif et al. 2009). Studies in C57BL/6J mice suggested SAC attenuated 1-methyl-4-phenylpyridinium (MPP (+))-induced neurotoxicity (Parkinsonism) in the striatum and that an antioxidant effect against oxidative stress may be partly responsible for its observed neuroprotective effects (Rojas et al. 2011).

Behavioural analyses showed that SAC improved MPP(+)-induced impairment of locomotion (35 %). The protective effects of AGE and SAC were reported to be associated with antioxidant mechanisms such as scavenging of free radicals and pro-oxidant species, induction of antioxidant enzymes, activation of Nrf2 factor, inhibition of pro-oxidant enzymes and chelating effects (Colín-González et al. 2012). They also reported that SAC had ability to Nrf2 factor – a master regulator of the cellular redox state in the cerebral cortex. Studies by Ashafaq et al. (2012) suggested that SAC exhibited exuberant neuroprotective potential in the rat ischaemia–reperfusion model. SAC treatment significantly reduced ischaemic lesion volume, improved neurological deficits, combated oxidative loads and suppressed neuronal loss. The increase in glial fibrillary acidic protein and the inducible nitric oxide expression associated with focal cerebral ischaemia were markedly inhibited by the treatment with SAC. SAC significantly protected cultured rat hippocampal neurons against endoplasmic reticulum (ER) stress-induced neurotoxicity (Imai et al. 2014). It was found that the protective effects of SAC against ER stress-induced neuronal cell death were not attributable to antioxidant activity, but to the suppression of calpain (a Ca^{2+} -dependent cysteine protease) through the interaction with its Ca^{2+} -binding site.

Low concentration of diallyl disulfide (DADS) had protective effects on oxidative stress-injured neuronally differentiated PC12 cells by activating PI3K/Akt and by inhibiting GSK-3 activation, cytochrome c release, caspase-3 activation and PARP cleavage, whereas high concentration was rather cytotoxic (Koh et al. 2005). Studies showed that rats with induced ischaemia–reperfusion, pretreated with DAS, had significantly lower infarct volume the percentage of terminal dUTP nick-end labelling-positive cells than those untreated (Lin et al. 2012b). The neuroprotective effect of Das was partially attributed to its antiapoptotic effects. Oral administration of diallyl trisulfide (DATS) beginning at clinical onset stage significantly prolonged disease duration and extended life span by about a week of SOD1-G93A transgenic mouse with amyotrophic lateral sclerosis (Guo et al.

2011). DATS treatment induced HO-1 and reduced GFAP expression in the lumbar spinal cord of SOD1-G93A transgenic mice.

Allixin, a phytoalexin of garlic and its analogue 2,6-dimethyl-3-hydroxy-4H-pyran-4-one (DHP) exhibited neurotropic activity (Moriguchi et al. 1997). Addition of allixin (1–100 ng/mL) to medium significantly promoted the survival of neurons derived from various regions of brain and increased the number of branching points per axon in hippocampal neurons. Allixin, however, was cytotoxic at higher concentrations (>1 µg/mL). Its analogue DHP possessed potent neurotrophic activity at concentrations over 10 ng/mL without any obvious cytotoxicity up to 10 µg/mL. DHP also retained the activity to promote axonal branching. This compound may be a useful prototype leading chemical for developing therapeutic and/or prophylactic drugs for neurodegenerative disorders.

Studies demonstrated that allicin exerted neuroprotection against spinal cord ischaemia–reperfusion injury in rabbits, which may be associated with the improvement of the function of mitochondria respiratory chain complexes and inhibition of ROS production and the release of mitochondrial cytochrome c in the spinal cord (Zhu et al. 2012). In an in-vitro model of traumatic brain injury (TBI) using primary cultured rat cortical neurons, treatment with allicin significantly reduced mechanical trauma-induced lactate dehydrogenase (LDH) release and inhibited apoptotic neuronal death in a dose-dependent manner (Zhou et al. 2014b). The results demonstrated that allicin treatment may be an effective therapeutic strategy for traumatic neuronal injury and that the potential underlying mechanism involved Akt- and ERK-mediated regulation of NOS pathways. Allicin treatment (10 and 50 mg/kg, not 1 mg/kg) significantly reduced brain edema and motor functional deficits, as well as apoptotic neuronal cell death in injured cortex of rats with traumatic brain injury (Chen et al. 2014a). Further, allicin treatment decreased the expression levels of MDA and protein carbonyl, preserved the endogenous antioxidant enzyme activities and suppressed the expression of inflammatory cytokines. The results showed that

allicin neuroprotective effect against traumatic brain injury was mediated via Akt/eNOS pathway-mediated anti-inflammatory and antioxidative activities. Z-ajoene, a major compound in oil-macerated garlic products, is protected against ischaemia–reperfusion-induced delayed neuronal death and gliosis by reducing lipid peroxidation in the gerbil hippocampal CA1 region (Yoo et al. 2014b).

Studies found that garlic oil exhibited neuroprotective effects on n-hexane-induced neurotoxicity in rats via inhibition of hepatic alcohol dehydrogenase (ADH) activity (Bi et al. 2011). The gait scores and the staying time on the rotating rod were significantly improved, the levels of malondialdehyde and ADH significantly decreased and the activities of glutathione peroxidase (GSH-Px), total antioxidation capacity and the ability of inhibition of $\cdot\text{OH}$ markedly increased.

Hepatoprotective Activity

Garlic bulb extract inhibited hepatic and serum glutamic-oxaloacetic transaminase, glutamic-pyruvic transaminase, lactic dehydrogenase and cholinesterase in-vitro (Bogin and Abrams 1976). The garlic extract stimulated the activity of liver adenosine triphosphatase in intact mitochondria, but had no effect on this enzyme after disruption of the mitochondria. Oral administration of garlic extract exerted a therapeutic effect on the carbon tetrachloride-intoxicated liver injury in mice (Kagawa et al. 1986). The increased conjugated diene level was diminished significantly to 82 % by the 100 mg/kg garlic extract, and also thiobarbituric acid reactivity was inhibited by all the doses of the extract. Also the high doses (100 and 500 mg) of garlic extract lowered the hepatic triglyceride and lipid contents. Marked inhibitory activity was found with garlic volatile oil, *S*-allylmercaptocysteine (ASSC) and *S*-methylmercaptocysteine (MSSC) in carbon tetrachloride (CCl_4)- and galactosamine (GalN)-induced cytotoxicity in primary cultured rat hepatocytes (Hikino et al. 1986). ASSC exhibited a remarkable inhibitory action and the volatile oil, alliin and MSSC showed tendencies to elicit protective actions in GalN-produced liver lesion in rats. The volatile oil inhibited

CCL₄-induced free radical formation and lipid peroxidation, indicating that antioxidative activity participated in the inhibitory effect of the volatile oil in CCL₄-evoked liver damage.

Studies showed that diallyl sulfide (DAS) (25–100 mg/kg) completely prevented rat's liver necrosis by 1,2-dimethylhydrazine (DMH) (200 mg/kg) (Hayes et al. 1987). DAS substantially reduced macromolecular binding of [14C]DMH in cultured liver cells, but had no effect on their levels of glutathione S-transferase, glutathione reductase or glutathione peroxidase at 18 hours. The data suggested that DAS inhibited hepatocarcinogenicity by reducing the promoting influences of post-necrotic regeneration than by preventing initiation. Pretreatment of rats with garlic alone, or in combination with *Crataegus*, resulted in dose-dependent protective effects on isoprenaline-induced necroses of the heart, liver and pancreas (Ciplea and Richter 1988). The following parameters were used to evaluate the protective effect: clinical signs, qualitative histological and histoenzymatical findings, as well as quantitative microphotometric determination of enzymatic activities of succinate dehydrogenase, NADH-NBT reductase, acid phosphatase and glucose-6-phosphate dehydrogenase in cardiac, hepatic and pancreatic tissues. Intraperitoneal administration of garlic (50 mg/animal, 14 days) along with cyclophosphamide reduced the toxicity of the latter considerably with an increase in murine life span of more than 70 % (Unnikrishnan et al. 1990). The administration of garlic extract did not improve the lymphopenia produced by cyclophosphamide or liver alkaline phosphatase, but there was a significant reduction in liver glutamic-pyruvic transaminase. Moreover, garlic extract reduced the level of lipid peroxidation induced in the liver by cyclophosphamide administration.

Ajoene, a garlic-derived sulfur-containing compound, exhibited a dose-dependent (20–100 mg/kg) hepatoprotective effect against acetaminophen-induced liver injury in mice (Hattori et al. 2001). A pretreatment with ajoene suppressed the rise in serum glutamic-pyruvic transaminase activity and the reduction in the hepatic reduced glutathione level.

Pretreatment by ajoene also suppressed the decrease in hepatic protein thiol content resulting from acetaminophen administration.

Studies showed that concomitant administration of garlic extracts in mice prevented arsenic-induced hepatic apoptosis by its strong antioxidant property (Flora et al. 2009). The generation of reactive oxygen species (ROS) in hepatic tissue reverted to normal values after co-administration of garlic extracts. Studies showed that cadmium-induced oxidative damage in rat liver was amenable to attenuation by pretreatment of high dose of onion and moderate dose of garlic extracts possibly via reduced lipid peroxidation and enhanced antioxidant defence system (Obioha et al. 2009). Animal studies showed that though both ascorbic acid and heated garlic juice were efficient in preventing cadmium-induced damage in the rat liver, ascorbic acid appeared to be a more powerful antioxidant than heated garlic juice in preventing cadmium-induced oxidative damage in liver, and its action may be mediated in parts via the Nrf2-Keap1 pathway (Lawal et al. 2011). Nwokocha et al. (2012) found that administration of raw garlic to rat chow offered more hepatoprotective effect to cadmium (200 ppm) followed by mercury (10 ppm) and the least protection to lead (100 ppm) administered in the drinking water to rats.

In-vivo studies showed that the combination of meso 2,3-dimercaptosuccinic acid (DMSA) and garlic extract possessed the greatest protective effect against sodium arsenite-induced hepatotoxicity in rats as evidenced by low serum levels of alanine aminotransferase (ALT) and aspartate aminotransferase (AST) when compared to other treated animal groups (Hegazy and Ghaleb 2011). Studies demonstrated that diallyl disulfide (DADS) could induce the activation of HO-1/Nrf-2 pathway, which may contribute to the protective effects of DADS against ethanol-induced liver injury (Zeng et al. 2013b). DADS significantly suppressed ethanol-induced elevation of lactate dehydrogenase (LDH) and aspartate transaminase (AST) activities, decrease of glutathione (GSH) level, increase of malondialdehyde (MDA) levels and apoptosis of LO2 cells. In mice, DADS effectively

suppressed acute ethanol-induced elevation of aminotransferase activities and improved liver histopathological changes.

Garlic-derived S-allylmercaptocysteine (SAMC) exhibited hepatoprotective effect in non-alcoholic fatty liver disease (NAFLD) in rats (Xiao et al. 2013). Co-treatment of SAMC attenuated NAFLD-induced liver injury, fat accumulation, collagen formation and free fatty acids (FFAs). At the molecular level, SAMC decreased the lipogenesis marker and restored the lipolysis marker. SAMC also reduced the expression levels of pro-fibrogenic factors and diminished liver oxidative stress partly through the inhibition in the activity of cytochrome P450 2E1-dependent pathway. NAFLD-induced inflammation was also partially mitigated by SAMC treatment via reduction in the proinflammatory mediators, chemokines and suppressor of cytokine signalling. The results of studies by Ademiluyi et al. (2013) suggested that dietary inclusion of garlic powder in rats could protect against gentamicin-induced hepatotoxicity, improve antioxidant status and modulate oxidative stress, a function attributed to their phenolic constituents. In-vivo studies showed that diallyl trisulfide (DATS), the primary component of garlic, protected the rat liver from CCL₄-caused injury and fibrogenesis (Zhu et al. 2014). The hepatoprotective effect was associated with the inhibition of hepatic stellate cell activation in the rat fibrotic liver, attenuation of collagen deposition and attenuation of oxidative stress. DATS ameliorated hepatic oxidative stress by diminishing the levels of lipid peroxides and malondialdehyde and enhancing glutathione content. Oral pretreatment of diallyl disulfide (DADS) protected against carbon tetrachloride (CCl₄)-induced oxidative hepatic damage and inflammatory response in rat liver (Lee et al. 2014b). DADS increased the expression of phase II/antioxidant enzymes and simultaneously decreased the expression of inflammatory mediators in CCL₄-induced liver injury. The findings suggested that DADS induced antioxidant defence mechanism by activating the Nrf2 pathway and reducing inflammatory response by inhibiting NF-κB activation.

Renoprotective Activity

Prophylactic treatment of rats with garlic oil before the administration of ferric nitrilotriacetate (Fe-NTA), a potent nephrotoxic agent, resulted in the diminution of Fe-NTA mediated injury (Iqbal and Athar 1998). The enhancement of renal lipid peroxidation (LPO) and hydrogen peroxide generation was decreased. In addition, there was a recovery of glutathione depletion and inhibition of the activities of antioxidant enzymes. Similarly, in animals given the higher dose of garlic oil (100 mg/kg body weight), the enhanced blood urea nitrogen and serum creatinine levels, which were indicative of renal injury, showed a reduction of about 30 % and 40 %, respectively, in comparison with the group treated with Fe-NTA alone. Pretreatment with garlic oil also ameliorated the Fe-NTA-mediated induction of renal ornithine decarboxylase activity and enhancement of [3H]thymidine incorporation into DNA in a dose-dependent manner.

Administration of S-allylcysteine (SAC), a garlic derivative, prevented gentamicin-induced oxidative stress and renal damage in rats (Maldonado et al. 2003). SAC ameliorated the gentamicin-induced acute renal failure by a mechanism related, partly, to its ability to decrease oxidative stress and to preserve antioxidant enzyme activity in the renal cortex. SAC treatment was able to ameliorate the increase in blood urea nitrogen (BUN) and serum creatinine and to decrease the structural damage induced by ischaemia and reperfusion in rats (Segoviano-Murillo et al. 2008). It was concluded that the antioxidant properties of SAC were involved in its protective effect on renal ischaemia and reperfusion injury.

In nephrectomised rats SAC and aged garlic extract (AGE) reduced hypertension, renal damage and abundance of inducible nitric oxide synthase, 3-nitrotyrosine, poly(ADP-ribose), p22phox and gp91phox and increased SOD activity (Cruz et al. 2007). Data suggested that the antihypertensive and renoprotective effects of SAC and AGE were associated with their antioxidant properties and that they may be used to ameliorate hypertension and delay the progression of renal damage.

In another animal study, significant restoration of depleted renal glutathione and its dependent enzymes (glutathione reductase and glutathione S-transferase) was observed in diallyl sulfide (DAS)-pretreated rats (Ansar et al. 2014). DAS also attenuated Fe-NTA-induced increase in LPO, hydrogen peroxide generation and protein carbonyl formation. The results indicated that DAS may be beneficial in ameliorating the Fe-NTA-induced renal oxidative damage in rats. The study of Suru (2008) suggested against that onion and garlic extracts may exert their protective effects, cadmium-induced nephrotoxicity, in rats via reduction in renal lipid peroxidation and enhanced antioxidant defence. While treatment with high dose of onion extract exerted a significant dose-dependent restoration of the cadmium-induced decrease in antioxidant activities, treatment with high dose of garlic elicited a pro-oxidant effect, relative to their respective low dose. In dyslipidaemic rats, interaction studies on the kidney indicated that administration of high dose of atorvastatin and garlic had a negative safety profile when compared with groups administered with low dose of atorvastatin and high dose of garlic (Reddy et al. 2010). Studies suggested that aqueous garlic extract as a supplementary to diet may have a potential therapeutic effect in delimitating the systemic oxidant effects of chronic renal failure (CRF) in rats (Deniz et al. 2011). Garlic treatment alleviated CRF-induced oxidative changes in the injured tissues, inhibited neutrophil infiltration and reduced CRF-induced elevations in the blood levels of the proinflammatory cytokines and lactate dehydrogenase. Post-administration of garlic after gentamicin treatment or co-administration of garlic and gentamicin significantly attenuated gentamicin-induced nephrotoxicity in Wistar rats (Nasri et al. 2013). Garlic had regenerative potential after tubular injury induced by gentamicin. Studies showed that aged garlic extract exhibited the ability to ameliorate kidney damage in streptozotocin-induced diabetic rats, and its renoprotective effect may be attributed to its anti-glycation and hypolipidaemic activities (Shiju et al. 2013). The efficacy of the extract was substantiated by the histopathological changes in the kidney. Administration of metformin, garlic or their combination with or after injection of gentamicin (high doses)

could attenuate serum blood urea nitrogen (BUN) and creatinine in rats indicating curative and protective activity against gentamicin nephrotoxicity (Kopaei et al. 2013).

Gastroprotective Activity

Recent studies indicated that diallyl disulfide (DADS) prevented gastric mucosal damage induced by acute ethanol administration in rats and that the protective effects of DADS may be due to its potent antioxidant and anti-inflammatory activities (Lee et al. 2014a). DADS effectively suppressed the production of proinflammatory mediators induced by ethanol and prevented the formation of gastric malondialdehyde and the depletion of reduced glutathione content and restored antioxidant enzyme activities, such as catalase, glutathione peroxidase and glutathione reductase in the gastric tissues of ethanol-treated rats. Aged garlic extract (AGE) especially at 200 mg/kg protected against indomethacin (IN)-induced gastric inflammation in male rats as reflected by significant gastric mucosal healing of damage and reduction in the total microbial induced due to indomethacin administration (Badr and Al-Mulhim 2014). Further AGE normalised the significant increase in malondialdehyde (MDA), myeloperoxidase (MPO), tumour necrosis factor- α (TNF- α) values and the significant decrease in the total glutathione (tGSH), superoxide dismutase (SOD) and catalase (CAT) values induced by indomethacin.

Antihyperthyroidic Activity

The combined effects of *Trigonella foenum-graecum* and *Allium sativum* extracts at 200 and 500 mg/kg body wt., respectively, were equipotent as compared to the individual extracts in lowering the serum concentrations of serum triiodothyronine (T₃) and thyroxine (T₄) in hyperthyroidic rats and not synergistic (Tahiliani and Kar 2003). It was thus suggested that *Trigonella foenum-graecum* and *Allium sativum* extracts may be used individually and not together in the regulation of hyperthyroidism.

Diuretic and Natriuretic Activity

Intravenous administration of purified fractions of garlic (2, 4 and 6 µg/kg dry weight) to anaesthetised rabbits elicited dose-dependent diuretic–natriuretic responses which reached a maximum 60 minutes after injection and return to basal levels after 90 minutes (Pantoja et al. 1996). A gradual decrease in heart rate, but not in arterial blood pressure, was observed during the course of the experimental periods. Further, intravenous administration of a purified garlic fraction (6 µg/kg) to anaesthetised dogs elicited a significant biphasic diuretic and natriuretic response which reached a maximum at 180 minutes after injection (Pantoja et al. 2000). Chloride, but not potassium ions, followed the natriuretic profile. No changes were observed in arterial blood pressure or in the electrocardiogram. The purified garlic fraction also induced an inhibitory dose-dependent effect on the kidney Na, K-ATPase.

Antispasmodic Activity

Garlic juice inhibited the contractions of rabbit and guinea pig aortic rings induced by norepinephrine in Ca^{2+} -free and Ca^{2+} -containing Krebs–Henseleit solutions (Aqel et al. 1991). Also, garlic juice inhibited the contractions of rabbit and guinea pig tracheal smooth muscles induced by acetylcholine and histamine, respectively, in both Ca^{2+} -free and Ca^{2+} -containing Krebs–Henseleit solutions. Furthermore, garlic juice inhibited the spontaneous movements of rabbit jejunum and guinea pig ileum and inhibited the force of contraction of isolated rabbit hearts in a concentration-dependent manner. All inhibitions were reversible. Aqueous extracts of fresh garlic (5, 12.5, 25 and 50 mg/mL) were shown to inhibit the synthesis of the prostanoids in a dose-dependent manner (Ali et al. 1993). Fresh garlic extracts (1, 2.5, 5 and 10 mg/mL) also dose dependently inhibited spontaneous rhythmic contractions of the isolated ureter. Boiled garlic (5, 12.5, 25 and 50 mg/mL) had no effect on either ureteral motility or the prostaglandin-synthesising capacity of the sheep ureter. The addition of garlic extracts to isolated rat atria evoked negative inotropic and chronotropic effects (Radenkovic et al. 2010). Ethanolic

garlic extract exerts much stronger negative inotropic (58.33 %) effects than the aqueous extract (43.66 %). Aqueous garlic extract very slightly affected the frequency, while ethanolic extract reduced it by more than 40 %. In addition to these effects, the positive inotropism and chronotropism induced by the addition of noradrenaline were much more antagonised by ethanolic garlic extract than by aqueous extract. Moreover, ethanolic garlic extract established sinus rhythm in the atria with extrasystoles induced by noradrenaline.

Studies by Grman et al. (2011) found that aqueous garlic, onion and leek extracts released nitric oxide from S-nitrosoglutathione (GSNO) in the order: garlic > onion > leek. Garlic extract (0.045 mg/mL) prolonged relaxation time of aortic rings induced by GSNO (50 nmol/L) and inhibited intracellular chloride channels. It was suggested that NO-releasing properties of the garlic, onion and leek extracts and their interaction with cysteine and glutathione were involved in NO-signalling pathway which contributed to some of its numerous beneficial biological effects.

Antilithogenic Activity

Dietary garlic and onion reduced the cholesterol gallstone incidence by 15–39 % in mice, the effect being maximum in the heat-processed onion group (Vidyashankar et al. 2009). Dietary garlic and onion markedly reduced biliary cholesterol. The cholesterol–phospholipid ratio and biliary cholesterol saturation index were reduced to 0.73–0.96 in the garlic and onion groups. Hepatic hydroxymethylglutaryl-CoA reductase activity was lowered in the lithogenic diet-fed group, while dietary garlic or onion countered this alteration and also increased the activities of hepatic cholesterol 7 α -hydroxylase and sterol 27-hydroxylase. Serum and liver cholesterol were decreased by feeding garlic or onion compared to the lithogenic diet. Thus, dietary *Allium* spicy garlic and onion exerted antilithogenic influence by decreasing the cholesterol hypersecretion into bile and increasing the bile acid output thus decreasing the formation of lithogenic bile in experimental mice. Apart from the beneficial modulation of biliary cholesterol saturation index, dietary garlic and onion

also influenced cholesterol-nucleating and cholesterol-antinucleating protein factors that contribute to their antilithogenic potential (Vidyashankar et al. 2010a). Dietary garlic and onion, either raw or heat processed administered for 10 weeks, regressed preformed cholesterol gallstone in mice up to 53–59 %, whereas the regression in the basal control diet group was only 10 % (Vidyashankar et al. 2010b). The antilithogenic potency of garlic was decreased by its heat processing, but not in the case of onion. Biliary cholesterol was significantly decreased in garlic- and onion-fed animals. Biliary cholesterol saturation index and hydrophobicity index were significantly lowered by dietary garlic and onion. Serum and liver cholesterol levels were decreased by feeding these spices during the post-cholesterol gallstone induction period.

Dietary garlic and onion reduced the cholesterol gallstone incidence by 15–39 % in mice, the effect being maximum in the heat-processed onion group (Vidyashankar et al. 2009). Dietary garlic and onion markedly reduced biliary cholesterol. The cholesterol–phospholipid ratio and biliary cholesterol saturation index was reduced to 0.73–0.96 in the garlic and onion groups. Hepatic hydroxymethylglutaryl-CoA reductase activity was lowered in the lithogenic diet-fed group, while dietary garlic or onion countered this alteration and also increased the activities of hepatic cholesterol 7 α -hydroxylase and sterol 27-hydroxylase. Serum and liver cholesterol were decreased by feeding garlic or onion compared to the lithogenic diet.

Female/Male Fertility Activity

In the Norwegian Mother and Child Cohort of 18,888 women of whom 950 (5 %) underwent spontaneous preterm delivery (PTD) (<37 gestational weeks), intake of food such as garlic with antimicrobial and prebiotic compounds may be of importance to reduce the risk of spontaneous PTD (Myhre et al. 2013). *Allium* (garlic, onion, leek and spring onion) (odds ratio (OR): 0.82) was associated with a decreased risk of spontaneous PTD. Intake of *Allium* was related to a more pronounced risk reduction in early spontaneous PTD (gestational weeks 28–31) [OR: 0.39]. The strongest

association in this group was with garlic (OR: 0.47), followed by cooked onions. The strongest association with preterm prelabor rupture of membranes (PPROM) in the *Allium* group was with garlic (odds ratio: 0.74).

There are mixed views on the impact of garlic on the male reproductive system. Some studies had reported that garlic improved male sexual function with beneficial effect in the recovery of testicular functions (Hammami and El May 2013). Others reported that garlic impaired testicular functions (such as inhibition of testosterone production) and had spermicidal effect on spermatozoa.

Dixit and Joshi (1982) reported that garlic impaired testicular function. Garlic decreased body weight after treatment with a powder garlic preparation by daily gavage and caused a reduction in accessory gland weight and hypospermatogenesis. In-vitro studies showed that sperm motility was inhibited dose dependently by allitridum, from garlic, at different intervals ranging from 20 seconds to 200 minutes as compared to the control (Qian et al. 1986). Immobilisation of spermatozoa occurred at 7.5 mg/mL of allitridum. Crude aqueous garlic bulb extract exhibited instant immobilisation of the ram epididymal sperm at 0.25 g/mL and human ejaculated sperm at 0.5 g/mL (Chakrabarti et al. 2003). Sperm-immobilising effects were irreversible, and the factor of the extract responsible for immobilisation was thermostable up to 90 °C, and on boiling at 100 °C for 10 minutes, the activity was markedly reduced. Moreover, this extract was able to cause aggregation of ram sperms into small clusters after 30 minutes of incubation at 37 °C but not human spermatozoa. More than 50 % reduction in sperm viability and hypo-osmotic swelling occurred in treated sperm as compared with the controls, indicating the possibility of plasma membrane disintegration which was further supported by the significant reduction in the activity of membrane-bound 5'-nucleotidase and acrosomal acrosin. Animal studies showed that crude garlic consumption during 1 month reduced testosterone secretion, phosphatase acid activity, seminal vesicle weight and altered spermatogenesis at 10, 15 and 30 % doses (Hammami et al. 2008). At the higher two dosages, a

significant decrease was observed in the body weight and prostate weight of male rats. Testicular histology showed a dose-dependent increase in the percentage of empty seminiferous tubules. Chronic crude garlic consumption for 2–4 months induced testicular apoptosis in Sertoli cells, germ cells and peritubular tissue including interstitial Leydig cells and myoid cells with disruption in the spermatogenesis in adult male rats (Abdelmalik 2011). Two theories were proposed: garlic being an antihypercholesterolaemic agent, it might inhibit steroidogenesis resulting in a decrease in testosterone level, and being one of the famous phytoestrogens, it possibly had direct oestrogen-like actions on adult male rat testes. Recent studies found that seminiferous tubules of rats treated with garlic fractions showed an increased number of tubules deprived of spermatozoa (Hammami et al. 2013). In addition, garlic fractions induced apoptosis of testicular germ cells and a decrease of serum testosterone levels and seminiferous tubule DNA concentrations. The results suggested that one or several garlic substances, soluble in water and precipitated by alcohol, impaired spermatogenesis.

Administration of garlic aqueous extract in the drinking water to male and female mice (100 mg/kg/day) for 3 months elicited a significant increase in the weight of seminal vesicles and epididymis of male animals as compared to controls, and the sperm count was significantly elevated (Al-Bekairi et al. 1990). There was no increase in the body weight of the test animals, and weights of the heart, liver and spleen were reduced as compared to controls. Haematological studies revealed an increase in WBC and a decrease in RBC levels of the test animals. Three-day intraperitoneal treatment (500 mg/kg) with the *A. sativum* extract failed to exhibit any oestrogenic or antioestrogenic activity. After 28 days of feeding, testosterone contents in the testis were significantly higher, and plasma corticosterone concentrations were significantly lower in rats fed with 40 and 25 % casein diets with garlic powder than in those fed with the same diets without garlic powder (Oi et al. 2001). Urinary excretion of 17-ketosteroid (an index of testosterone), nitrogen balance and hepatic arginase activity were significantly higher in rats fed

with the 40 % casein diet with garlic powder than in the 40 % casein controls. In a subsequent experiment, plasma luteinising hormone concentration increased dose dependently after administration of diallyl disulfide (a garlic volatile) to anaesthetised rats. The results suggested that dietary supplementation with 0.8/100 g garlic altered hormones associated with protein anabolism by increasing testicular testosterone and decreasing plasma corticosterone in rats fed with a high protein diet.

Oral administration of onion and garlic extracts to rats successfully attenuated the adverse effects of cadmium-induced testicular damage and spermiotoxicity possibly reducing lipid peroxidation and increasing the antioxidant defence mechanism in rats (Ola-Mudathir et al. 2008). Cd caused a marked rise in testicular lipid peroxidation (LPO) and glutathione S-transferase (GST) levels and a decline in levels of glutathione (GSH), superoxide dismutase (SOD), catalase (CAT) and alkaline phosphatase (ALP). Cd intoxication significantly decreased epididymal sperm concentration and sperm progress motility and increased percent total sperm abnormalities and live/dead count. Decreases in rat body weight gain and testicular weight induced by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) were greatly attenuated by ethanol garlic extract (Lee et al. 2009a). TCDD-induced decreases in spermatogenesis-related panels, Johnsen's score, seminiferous tubular size, ratio of tubules with sperm and sperm count/tubule were greatly improved by garlic treatment in a dose-dependent manner in the rats. TCDD-induced increases in serum cholesterol and triglyceride levels and glutamic oxaloacetate activity were also suppressed by garlic extract. The results indicated that administration of garlic to TCDD-exposed rats attenuated testicular and hepatic damage, suggesting that garlic might be a useful agent that can protect human health from toxic responses induced by environmental pollutants.

Garlic was found to be good substitute for certain nitric oxide-based market preparations for use in erectile dysfunction (Parveen et al. 2010). Garlic also had more or less similar effects and mode of action. The only step that differs was that

most of the market preparations increase blood GMP (3',5' guanosine monophosphate) level by inhibiting its degrading enzyme phosphodiesterase-5, while garlic acted by the activation of guanylyl cyclase enzyme and thus by increasing the production of GMP in the body. Garlic could have potential as an economic, safe, easily available substitute to market preparations and unstandardised adulterated herbal formulations.

Lindane poisoning in rats was characterised by a decreased weight of testes, epididymides, prostate gland and seminal vesicles; a decrease of spermatozoa count and motility; an increased level of free thyroxine; decreased levels of TSH (thyroid-stimulating hormone) and FSH (follicle-stimulating hormone) in the serum and lindane oxidative stress as revealed by the increased level of lipid peroxidation (TBARS); an increase of superoxide dismutase activity in the testes; and a decrease of glutathione peroxidase and catalase activities in the testes and brain (Hfaiedh et al. 2011). All these lindane-induced changes were almost reversed to normal in animals injected with a garlic extract (an amount corresponding to 300 mg fresh garlic/kg/day).

Antihyperhomocysteinaemia Activity

Rats fed with AIN-93G diet devoid of folic acid exhibited mild folate deficiency and had a plasma level of total homocysteine higher than that for those fed with AIN-93G diet containing folic acid (Yeh et al. 2005). Supplementation of aged garlic extract (AGE, 4 %) to the folate-deficient L-amino acid diet of rats reduced plasma protein-bound, free and total homocysteine by 28–33 %. The supplementation did not change plasma cysteine, cysteinylglycine or glutathione concentrations. Liver concentration of S-adenosylmethionine was elevated by 26 %, and S-adenosylhomocysteine was lowered by 15 % in the AGE-supplemented group.

Cognitive Enhancement Activity

In the acute study, commercial formulation of crude garlic extract (Lasuna) (65 mg/kg, po) partially reversed the

scopolamine-induced amnesia but failed to improve learning and memory in untreated animals (Mukherjee and Banerjee 2013). Chronic administration of Lasuna (40 mg/kg/day for 21 days) significantly improved learning both in control and scopolamine-induced amnesic animals. Chronic administration of Lasuna inhibited cortical acetylcholinesterase, while increasing cortical acetylcholinesterase levels. Thus the results indicated that long-term administration of crude garlic extract may improve learning and memory in mice, while the underlying mechanism of action may be attributed to the anti-acetylcholinesterase activity and antioxidant property of garlic.

Antiosteoporotic Activity

Garlic oil was found to have a positive role in suppressing ovariectomy-induced bone resorption in ovariectomised rats (Mukherjee et al. 2004). Garlic oil extract supplementation, apart from its unique influence in lowering blood cholesterol, could also prevent ovariectomy-induced low bone density, high rate of bone turnover and osteoporosis characterised by significant alteration of serum alkaline phosphatase activity, serum tartrate-resistant acid phosphatase activity, urinary excretion of calcium, phosphate, hydroxyproline and urinary calcium to creatinine ratio. Further studies in ovariectomised rat model of osteoporosis showed that 17β -oestradiol, garlic oil and lovastatin were effective in suppressing bone loss owing to oestrogen deficiency, and their efficacy in the order of lower to higher was garlic < lovastatin < 17β -oestradiol (Mukherjee et al. 2006a). The results revealed that all three compounds significantly protected the hypogonadal bone loss as reflected by higher bone densities and higher bone mineral contents than the ovariectomised group of animals. They found that in ovariectomised rat, oil extract of garlic promoted intestinal transference of calcium by modulating the activities of both intestinal alkaline phosphatase and Ca^{2+} -activated ATPase (Mukherjee et al. 2006b). Also the observed low bone mineral content and low bone tensile strength in these rats were significantly restored by garlic oil supplementation. Further, garlic oil supplementation was able to revive partially the bilateral ovariectomy-induced decrease in the serum

oestrogen titre. The garlic oil supplemented partial recovery in the serum oestrogen titre in bilaterally ovariectomised rat was found to be persistently associated with enhanced calcium transference and better preservation of bone mineral content. They also found that hypogonadism-induced oxidative stress of peritoneal macrophages and lymphocytes could be reduced by supplementation with garlic oil extract (Mukherjee et al. 2007). The hypogonadism-induced increase in the serum levels of interleukin IL-6 and TNF- α was significantly reduced by garlic oil. Further, garlic supplementation could revive the hypogonadism-induced decrease in the serum oestrogen titre and counterbalance the increase in bone turnover as determined by low bone tensile strength and alterations in bone-related biochemical variables such as urinary calcium, hydroxyproline, calcium to creatinine ratio and serum tartrate-resistant acid phosphatase activity (TRAP).

Prebiotic Activity

Garlic fructans A (DP 16, molecular weight (MW) 2,567) and B (DP 21 mw 3,345) were found to selectively stimulate the growth of beneficial *Bifidobacterium* from human intestinal microflora (Zhang et al. 2013a). The prebiotic effectiveness of garlic fructans suggested the potential for the use of garlic as a way to prevent some gastrointestinal diseases.

Wound/Wart Healing Activity

Twenty-eight patients with 2–96 warts, nine patients with 1–2 corns and a control group consisting of five patients with 7–35 warts were included in the study after obtaining a written informed consent. A study on 28 patients showed positive effect of garlic extracts in the treatment of warts and corns (Dehghani et al. 2005). With the lipid garlic extract, full recovery was achieved in all the patients with warts in 1–2 weeks, and it took 2–3 weeks for full recovery of approximately 80 % of the corns. However, for the aqueous extract, the duration of treatment, which only caused a partial recovery, was 1 month for warts and approximately 2 months for corn.

Intra-abdominal administration of *Allium sativum* (garlic) oil prevented the formation of postoperative peritoneal adhesions in the rat (Sahbaz et al. 2014). This was attributed to the anti-inflammatory, antibacterial, fibrinolytic, antithrombotic and wound healing effects of garlic, and garlic may be effective and cheap when used to prevent such adhesions in humans.

Radioprotective Activity

Hairless mice fed with 4 % aged garlic extract was protected from UVB radiation-induced suppression of contact hypersensitivity (Reeve et al. 1993). Replacing UVB with topical application of lotion containing urocanic acid, when mice were fed with a diet containing 1 % aged garlic extract, they were partially protected from *cis*-urocanic acid-induced suppression of contact hypersensitivity, with greater protection from the lower concentrations of urocanic acid. Mice fed with a diet containing 4 % aged garlic extract were protected from all the concentrations of urocanic acid. The results indicated that aged garlic extract contained an ingredient(s) that is protected from UVB-induced suppression of contact hypersensitivity and suggested that the mechanism of protection was by antagonism of the *cis*-urocanic acid mediation of this form of immunosuppression.

Diallyl sulfide (DAS) from garlic significantly inhibited nuclear aberration formation (a measure of nuclear damage) over gamma ray radiation dose range of 0.5–10 Gy in female C57BL/6J mice (Baer and Wargovich 1989). The degree of protection was related to the dose of DAS, and the compound was ineffective if given after irradiation.

Difluoromethylornithine added to the drinking water of animals 24 hours prior to and following radiation treatment abolished the ability of DAS to reduce colonic nuclear damage caused by radiation exposure. Thus DAS was protected against colonic radiation injury via a polyamine-dependent pathway.

Animal studies showed that pretreatment by gavage with freshly prepared garlic extract could lead to significant dose-related reductions in the frequencies of gamma radiation-

induced (2 Gy) micronucleated polychromatic erythrocytes (Singh et al. 1995). The anticlastogenic effect of garlic extract was observed against lower radiation doses of 0.5 and 1 Gy, but not 0.25 Gy. The irradiated garlic extract-pretreated animals showed a significant reduction in sulfhydryl content and glutathione S-transferase activities. They also reported that pretreatment with garlic extract was effective in reducing gamma radiation-induced chromosomal damage in mice (Singh et al. 1996a). Against 0.25 Gy gamma radiation, a high dose of 500 mg/kg bw garlic extract was required to significantly reduce the chromosomal damage. All the three doses of garlic extract were effective in exerting a protective effect against 0.5, 1.0 and 2.0 Gy gamma radiation. S-allylcysteine sulfoxide (SAC), of garlic, was found to show significant radioprotective effect in albino rats irradiated with 400 rads of irradiation by cobalt 60 source (Jaiswal and Bordia 1996). It markedly reduced the radiation-induced mortality and showed significant protection against the tissue damaging effects of irradiation in the histopathological sections of the liver and lung. Studies in H22 tumour xenograft mice model showed that garlic oil did not increase the tumour inhibitory rate of cyclophosphamide/radiation, which indicated that garlic oil could not enhance the chemo/radiosensitivity of cancer cells (Zeng et al. 2013a). However, the decrease of the peripheral total white blood cell (WBC) count induced by cyclophosphamide/radiation was significantly suppressed by garlic oil co-treatment. Further, garlic oil co-treatment significantly inhibited the decrease of the DNA contents and the micronuclei ratio of the bone marrow and reduction of the endogenous spleen colonies induced by CTX/radiation. The findings supported the idea that garlic oil consumption may benefit for the cancer patients receiving chemotherapy or radiotherapy.

Antihypoxic Activity

Aqueous and methanolic garlic extracts exhibited dose-dependent antihypoxic effect in mice (Hosseinzadeh and Sadati 2003). The minimum effective doses of aqueous and methanolic extracts were 0.2 g/kg and 5.12 g/kg, respectively.

The high doses of aqueous (16.9 g/kg) and methanolic (12.8 g/kg) extracts increased survival time up to 73.17 and 68.41, respectively.

Anti-anaemic Activity

Administration of aged garlic extract (AGE) (5 mL/day for 4 weeks) to five patients with sickle cell anaemia caused a decline in the number of Heinz body suggesting a significant antioxidant activity of AGE on sickle red blood cells (Takasu et al. 2002, 2006).

Haemolytic Activity

The degree of haemolysis of albino Wistar rat erythrocyte was greater in the treatment group compared to the control, and the percentage haemolysis was greater in blood samples with onion and garlic compared to the onion alone group (Salami et al. 2012). The same observation was made in the in-vitro study, but the degree of haemolysis was significantly higher in in-vitro than in the in-vivo experiments. It was concluded that onion and garlic increase the osmotic fragility of red blood cells in albino rats.

Antiurotoxic Activity

Pretreatment of rats with diallyl disulfide (DADS) significantly attenuated the cyclophosphamide-induced urotoxic effects, including oxidative damage, histopathological lesions, apoptotic changes and accumulation of acrolein–protein adducts in the bladder (Kim et al. 2014). DADS also significantly increased expression of cytochrome CYP2B1/2, CYP3A1, Nrf-2, NQO-1 and HO-1 and significantly decreased expression of CYP2C11. The protective effects of DADS may be due to its ability to decrease metabolic activation of cyclophosphamide by inhibiting CYP2C11 and inducing CYP3A1, and its potent antioxidant activity and antiapoptotic effects occurred via the Nrf2-antioxidant response element pathway.

Anti-ototoxic Activity

A garlic-supplemented diet appeared to attenuate gentamicin-induced hearing loss in male Wistar rats and may be beneficial in the prevention of ototoxicity (Uzun et al. 2012).

Protective Effects Against Chemical Toxicity

Oral administration of garlic extract at three 100 (low), 200 (medium) and 400 mg (high) per kg body weight to rats was found to reduce lead concentration considerably in the liver, kidney, brain and bone indicating the potential therapeutic activity of garlic against lead (Senapati et al. 2001). Studies found that separate administration of garlic juice and ascorbic acid during pregnancy and lactation may protect lead-induced neural damage in rat offspring hippocampus (Sadeghi et al. 2013). In a comparative study on the therapeutic effects of garlic and compared with d-penicillamine in 117 car battery workers with chronic lead poisoning, clinical improvement was significant in a number of clinical manifestations including irritability, headache, decreased deep tendon reflex and mean systolic blood pressure after treatment with garlic, but not d-penicillamine (Kianoush et al. 2012). Blood lead levels were reduced significantly in the garlic and d-penicillamine groups, with no significant difference between the two groups. The frequency of the side effects was significantly higher in d-penicillamine than in the garlic group. Thus, garlic appeared safer clinically and as effective as d-penicillamine.

Aqueous garlic extract (2 mg/mL) co-administered with 10 μ M NaAsO₂-attenuated arsenite-induced cytotoxicity reduced intracellular reactive oxygen species (ROS) level in human malignant melanoma cells (A375), human keratinocyte cells (HaCaT) and cultured human normal dermal fibroblast cells (Chowdhury et al. 2008). In addition garlic extract application in NaAsO₂-intoxicated Sprague–Dawley rats resulted in a marked inhibition of tissue lipid peroxide generation and enhanced level of total tissue sulfhydryl groups and

glutathione and also increased the activities of antioxidant enzymes, superoxide dismutase and catalase to near normal. An increase in blood ROS level and myeloperoxidase activity in arsenic-intoxicated rats was effectively prevented by garlic administration. Garlic extract was also able to counter arsenic-mediated incongruity in blood haematological variables and glucose level. The restorative property of garlic extract was attributed to its antioxidant activity, chelating efficacy and/or oxidising capability of trivalent arsenic to its less toxic pentavalent form. The results indicated that garlic extract could be a potential protective regimen for arsenic-mediated toxicity.

Nitrate-induced toxicity in male mice was characterised by a significant decline in total erythrocyte count, total leucocyte count, neutrophil content, haemoglobin concentration, lymphocyte and monocyte content, viability of macrophage, phagocytic index and immunoglobulin level and plaque count; a significant escalation in thiobarbituric acid reactive substances level, aspartate transaminase, alanine transaminase, acid phosphatase and alkaline phosphatase; and depletion in reduced glutathione content and antioxidant enzymes, namely, superoxide dismutase and catalase in the kidney and brain (Sharma et al. 2010). Oral administration of garlic extracts to lead nitrate-treated rats attenuated the above deranged haematological, biochemical and immunological parameters to some extent.

Enzyme Inhibitory Activity

Garlic extract had been reported to inhibit urease and succinic dehydrogenase enzymes (Szymona 1952). Allicin, a major compound of garlic, had been reported to inhibit urease (Agarwala et al. 1952) and papain and amylase (Rao et al. 1946). Aqueous crushed garlic extract inhibited succinic oxidase and urease, but trypsin, amylase and lipase were unaffected (Wills 1956). Enzyme inhibitory effects observed with garlic extracts were attributed to allicin. Enzymes inhibited by allicin included succinic dehydrogenase, urease, papain, xanthine oxidase (cream), xanthine oxidase (liver), choline oxidase, hexokinase, cholinesterase, glyoxalase, triose

phosphatase dehydrogenase, alcohol dehydrogenase, lactic dehydrogenase tyrosinase and alkaline phosphatase; enzymes unaffected include cytochrome oxidase, lipase, rennin, pepsin, trypsin, invertase, α -amylase, esterase (serum), D-amino acid oxidase, ascorbic acid oxidase, catalase, carbonic anhydrase, carboxylase, β -amylase and adenosine triphosphatase (Wills 1956). Enzymes strongly inhibited by allicin were succinic dehydrogenase, triose phosphatase dehydrogenase and xanthine oxidase (in cream). Alliin did not inhibit the enzymes tested. Also, yeast fermentation of glucose, respiration of yeast in the presence of glucose and endogenous respiration of rat-liver homogenate and rat muscle homogenate were all inhibited by allicin but unaffected by alliin. Garlic bulb extract was shown to inhibit hepatic and serum glutamic-oxaloacetic transaminase, glutamic-pyruvic transaminase, lactic dehydrogenase and cholinesterase in-vitro (Bogin and Abrams 1976). The extract stimulated the activity of liver adenosine triphosphatase in intact mitochondria, but had no effect on this enzyme after disruption of the mitochondria. Allicin was shown to be a specific inhibitor of the acetyl-CoA synthetases from plants, bacteria, yeast and mammals (Focke et al. 1990). The bacterial acetyl-CoA-forming system, consisting of acetate kinase and phosphotransacetylase, was also inhibited. A concentration-dependent inhibition of 3-hydroxy-3-methylglutaryl-CoA (HMG-CoA) reductase was found on the preincubation of microsomal preparations with diallyl disulfide, a component of garlic oil (Kumar et al. 1991). The garlic-derived diallyl disulfide was the most effective among the sulfides tested for the inhibition of HMG-CoA reductase.

Oral administration of garlic to lactating Swiss albino mice for 14 or 21 days postpartum was found to differentially impact on hepatic xenobiotic-metabolising enzymes in the F₁ generation mouse pups (Chharbra and Rao 1994). Cytochrome b₅ content was not affected with garlic treatment in dams and most of the pups but increased in the 14-day-old female pup translactationally exposed to the higher dose of garlic. Hepatic cytochrome P450 content and glutathione S-transferase activity remained unchanged in dams and pups exposed to garlic. Glutathione reductase decreased significantly in the

liver of dams which received the lower garlic dose for 14 or 21 days and in the 21-day-old pups. Glutathione peroxidase activity decreased in dams and pups which were exposed to 400 mg garlic/kg bw for 21 days.

In acetone-treated adult male Sprague–Dawley rats, the activity of p-nitrophenol (pNP) hydroxylase was significantly decreased by all garlic compounds (diallyl sulfide (DAS), diallyl disulfide (DADS) and allyl methyl sulfide (AMS)), whereas benzphetamine N-demethylase and ethoxyresorufin O-deethylase activities were not changed (Reicks and Crankshaw 1996). The activity of pNP hydroxylase was decreased to 31 %, 54 % and 65 % of control activity, and immunodetectable CYP2E1 protein levels were decreased in a similar manner by DAS, DADS and AMS, respectively. Also, pNP hydroxylase activity was decreased to 73 %, 78 % and 67 % of control levels by DAS, DADS and AMS, respectively. DAS treatment of male Sprague–Dawley rats decreased hepatic catalase activity (Chen et al. 1999). DAS treatments resulted in the corresponding decreases in the liver catalase protein level. No significant change in the catalase activity in the kidney, lung and brain was observed with the treatments, but a slight decrease in the heart catalase activity was observed. These treatments did not cause significant changes in superoxide dismutase and glutathione peroxidase activities in these tissues. Treatment of rats with fresh garlic homogenates (2 or 4 g/kg, i.g., daily for 7 days) caused a 35 % decrease in liver catalase activity. A/J mice treated with DAS and garlic homogenates also showed a decrease in the liver catalase activity. Diallyl sulfone (DASO₂), a DAS metabolite, however, did not effectively decrease catalase activity in mice.

Nuclei Acid Activity

Feeding male albino rats with low and medium dose (1 and 2 mL/kg body weight) of garlic produced significant increase in DNA and RNA levels, but when rats were fed with 4 mL/kg body weight of garlic extract, a significant decrease in DNA and RNA levels was observed (Srivastava and Pathak 2012). It was concluded that garlic may be a building block of nucleic acids at a proper dose and time period.

Antiparasitic Activity

In-Vitro Studies

Whole garlic extract and some of its components exhibited anti-giardial activity against the microaerophilic flagellate *Giardia intestinalis* (Harris et al. 2000). Whole garlic extract gave an IC_{50} at 24 hours of 0.3 mg/mL, and allyl alcohol and allyl mercaptan had IC_{50} values of 7 μ g/mL and 37 μ g/mL, respectively. Whole, freeze-dried garlic and *Allium*-derived compounds had an inhibitory effect on gas metabolism, exponential growth rate and final growth yield of the flagellated parasite *Spironucleus vortens* in Keister's modified TY-I-S33 culture medium (Millet et al. 2011). Of all the *Allium*-derived compounds tested, the ajoene-free mixture of dithiins and thiosulfinates were the most effective with a minimum inhibitory concentration (MIC) of 107 μ g/mL and an inhibitory concentration at 50 % (IC_{50}) of 58 μ g/mL. It was followed by ajoene (MIC = 83 μ g/mL, IC_{50}) = 56 μ g/mL) and raw garlic (MIC >20 mg/mL, IC_{50}) = 7.9 mg/mL), allicin being significantly less potent with an MIC and IC_{50} above 160 μ g/mL.

Animal Studies

Diallyl sulfide, a flavour component from garlic, attenuated lipid peroxidation in mice infected with *Trichinella spiralis* (Grudzinski et al. 2001). Diallyl sulfide decreased TBARS thiobarbituric acid reactive substances (TBARS) but did not have any effect(s) on the total antioxidant status of blood in *Trichinella*-infected mice. The results suggested that diallyl sulfide may be an effective antioxidant candidate and may play a significant role in the defence against lipid peroxidation in trichinellosis. Studies demonstrated that after administration of Alchinal (a complex preparation of *Echinacea purpurea*, garlic and cocoa), the number of adult forms (10 dpi – days postinfection) of *Trichinella spiralis* and muscular larvae (36 dpi) significantly decreased in infected mice (Bany et al. 2003). Results of studies indicated that garlic may be a

promising phytotherapeutic agent for the protection against trichomoniasis caused by *Trichomonas gallinae* in pigeons (Seddiek et al. 2014). Pigeons protected with aqueous garlic extract showed increased body weight and reduced mortality percentage.

Ajoene inhibited the proliferation of both epimastigotes and amastigotes of *Trypanosoma cruzi*, the causative agent of Chagas' disease (Urbina et al. 1993). Concomitant with the antiproliferative effects was the alteration of the phospholipid composition of the treated cells and inhibition of phosphatidylcholine and neutral lipid biosynthesis in particular of sterols in the epimastigotes. Diallyl trisulfide (DATS) from garlic exhibited antiparasitic activity in-vitro against human and animal protozoan parasites (Lun et al. 1994). The IC₅₀ values for *Trypanosoma brucei brucei*, *Trypanosoma brucei rhodesiense*, *Trypanosoma brucei gambiense*, *Trypanosoma evansi*, *Trypanosoma congolense* and *Trypanosoma equiperdum* were in the range of 0.8–5.5 µg/mL. IC₅₀ values were 59 µg/mL for *Entamoeba histolytica* and 14 µg/mL for *Giardia lamblia*. Ajoene was found to be an inhibitor and a substrate of human glutathione reductase (GR) and *Trypanosoma cruzi* trypanothione reductase (Gallwitz et al. 1999). The antiparasitic and cytostatic actions of ajoene were found to be partly due to the multiple effects on key enzymes of the antioxidant thiol metabolism. Allicin and its derivatives were found to be cysteine protease inhibitors with antiparasitic activity (Waag et al. 2010). The compounds inhibited the CAC1 cysteine proteases falcipain 2, rhodesain, cathepsin B and cathepsin L in the low µmolar range. Some showed potent antiparasitic activity against *Plasmodium falciparum* and *Trypanosoma brucei brucei*.

Ajoene showed a potent leishmanicidal activity in-vitro against *Leishmania mexicana*, *Leishmania mexicana venezuelensis*, *Leishmania mexicana amazonensis* and *Leishmania donovani chagasi* (Ledezma et al. 2002). Concentrations higher than 0.3 µM led to total inhibition of growth, and 10 µM induced 100 % lysis of *Leishmania* after 96 hours of incubation in a chemically defined culture medium. The 50 % inhibitory concentration (IC₅₀) for lysis,

for all species, was about 2 μ M. The effect was dose dependent, and a threefold increase in concentration (30 μ M) produced 100 % lysis of cultured forms after 72 hours. Intraperitoneal injection of garlic extract (20 mg/kg) or its protein fraction (0.04 mg/kg) to BALB/c mice augmented engulfment and destruction of intracellular amastigotes of *Leishmania major* by macrophages (Ghazanfari et al. 2006). A single dose of 20 mg/kg garlic extract intraperitoneally (i.p.) altered the number of peritoneal macrophages for at least 2 weeks. Garlic extract reduced footpad lesions in *Leishmania mexicana*-infected BALB/c mice by inducing IFN- γ production from T cells (Gamboa-León et al. 2007). In-vitro, garlic extract reduced macrophage infection through the induction of nitric oxide (NO) production. A 10- to 14-kDa fraction was identified as responsible for the in-vitro effect of the whole extract. Garlic extract exhibited higher leishmanicidal activity against *Leishmania major* (IC₅₀ 34.22 μ g/mL) and *Leishmania donovani* (IC₅₀ 37.41 μ g/mL) than pentostam (Wabwoba et al. 2010). However, the activity was significantly lower than that of amphotericin B against both the species. At a concentration of 250 μ g/mL, the extract induced the production of 60 μ M of nitric oxide, a tenfold upregulation in activated macrophages. The multiplication indices for *L. major* amastigotes treated in 100 μ g/mL were significantly different. Treatment with the extract, daily for 28 days, led to a significant reduction in footpad swelling in BALB/c mice; similar activity is noticed in the treatment with standard drugs. Studies showed that the mixture of *Tridax procumbens* and *A. sativum* extracts was more effective in controlling *Leishmania mexicana* infection while not being toxic when tested in the acute oral toxicity assay in mice (Gamboa-Leon et al. 2014). An increase in the ratio of IgG2a/IgG1 immunoglobulins indicated a tendency to raise a Th1-type immune response in mice treated with the mixture.

Feeding *Biomphalaria alexandrina* with onion and garlic powder separately exerted some biological and biochemical changes that reduced the snails' fecundity that in turn disturbed the life cycle of *Schistosoma mansoni* parasite (Mantawy 2001; Mantawy and Mahmoud 2002). Glucose and

glycogen were decreased significantly after feeding on onion and garlic. Also phenol oxidase activity was highly significantly decreased after 2 and 7 days of feeding on garlic, while feeding on onion decreased the activity of the enzyme at all periods. Alkaline phosphatase was highly significantly reduced in the haemolymph of snails that fed on either onion or garlic. Also, alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were highly significantly reduced in the haemolymph of snails that were fed on onion, while those fed on garlic showed no change in ALT activity and a high significant increase in AST activity. Total proteins were significantly decreased in the haemolymph of all treated snails, whereas variations in free amino acid contents were also observed. In another study, administration of onion and garlic extract individually and mixed either with or without the currently used drug, praziquantel, to *Schistosoma mansoni*-infected mice significantly reduced parasite burden, hepatic and intestinal eggs and oogram count (Mantawy et al. 2011). The extracts ameliorated the increase in IgM, IgG, interleukins 2 and 6 (IL-2 and 6) and tumour necrosis factor (TNF- α) and catalase enzyme, accompanied with a decrease in GPX and SOD antioxidant enzyme activities caused by the parasite. Results of in-vitro studies indicated their strong biocidal effects against all stages of *Schistosoma mansoni* miracidia, schistosomula, cercaria and adult worms and also showed a scavenging inhibitory effect on 2,2-diphenyl-1-picrylhydrazyl (DPPH) and nitric oxide (NO) (Mantawy et al. 2012). Allicin exhibited antiparasitic activity against adult *Schistosoma mansoni* worms (Lima et al. 2011). A concentration of 5 mg/mL caused wrinkling in the tegument; a concentration of 10 mg/mL resulted in changes to tubercles and loss or modification of spines. With 15 and 20 mg/mL, increasing damage to the tegument could be seen, such as vesicle formation and the presence of ulcers.

Animal studies demonstrated garlic to have a convenient prophylactic and promising therapeutic agent for cryptosporidial infection (Gaafar 2012). Garlic successfully eradicated the *Cryptosporidium* oocysts from stool and intestinal sections of the infected immunocompetent subgroup of mice receiving garlic 2 days before the infection. Besides,

the oocysts were significantly reduced in all other infected experimental subgroups in comparison to the corresponding infected control subgroups. The intestinal sections of all subgroups received garlic before or after the infection revealed a more or less normal architecture. Reduction in the level of myeloperoxidase activity was also detected in all treated subgroups.

Allicin dose dependently inhibited the in-vitro growth of *Babesia bovis*, *Babesia bigemina*, *Babesia caballi* or *Theileria equi* with IC₅₀ values of 818, 675, 470 and 742 µM, respectively (Salama et al. 2014). Moreover, allicin significantly inhibited the invasion of *B. bovis*, *B. bigemina*, *B. caballi* and *T. equi* into the host erythrocyte. In-vivo, mice treated with 30 mg/kg of allicin for 5 days significantly reduced the parasitaemia of *Babesia microti* over the period of the study. Also, combinations of diminazene aceturate with allicin synergistically potentiated its inhibitory effects in-vitro and in-vivo.

Studies indicated that garlic treatment significantly attenuated the inflammation and injury of the liver induced by the protozoan parasite *Eimeria papillata* infections in male BALB/c mice (Dkhil et al. 2011). In particular, garlic counteracted the *E. papillata*-induced loss of glutathione and the activities of catalase and superoxide dismutase. Coppi et al. (2006) found that at low concentrations, allicin was not toxic to either *Plasmodium* sporozoites or mammalian cells. At these concentrations, allicin inhibited circumsporozoite protein processing and prevented sporozoite invasion of host cells in-vitro. In-vivo, mice injected with allicin had decreased *Plasmodium* infections compared to controls. When sporozoites were treated with allicin before injection into mice, malaria infection was completely prevented. A 4-day regimen of allicin administered either orally or intravenously significantly decreased parasitaemias and increased the survival of infected mice by 10 days. Allicin was found to be active against the malarial protozoan parasite, *Plasmodium yoelii* (Feng et al. 2012). Allicin treatment of malarial-infected mice reduced parasitaemia and prolonged the survival of the host in a dose-dependent manner. This effect was at least

partially due to improved host immune responses. Results showed that allicin treatment enhanced the production of proinflammatory mediators such as IFN- γ , TNF, IL-12p70 and NO. The absolute numbers of CD4⁺ T cells, DCs and macrophages were significantly higher in allicin-treated mice. In addition, allicin promoted the maturation of CD11c⁺ DCs, whereas it did not cause major changes in IL-4 and the level of anti-inflammatory cytokine IL-10.

Clinical Studies

Aqueous garlic extract 5/100 mL in two doses per day or commercial garlic preparation (0.6 mg capsules) two capsules twice/day for 3 days was found to be an effective, safe and short-duration treatment for *Hymenolepis nana* infection in ten children and *Giardia lamblia* infection in 26 children (Soffar and Mokhtar 1991).

In a study of Chinese patients with *Cryptosporidium parvum* positive in baseline stool samples and clinically significant diarrhoeal disease, twice daily administration of a high-dose garlic concentrate ('Allicin', 30 mg) appeared to be a feasible therapeutic regimen to consider for HIV⁺ patients with CD4 counts less than 100 (Fareed et al. 1996). At 6 weeks, 10 of 16 evaluable patients continued to show a reduction in stool frequency and a further stabilisation or increase in body weight. Among the 8 patients who have remained on the high-dose allicin treatment for greater than 8 weeks, *Cryptosporidium parvum* stool exams have been repeatedly negative in four of the patients. The preparation was apparently well tolerated in a majority of patients.

Insecticidal Activity

The crude methanol garlic extract was inhibitory to mosquitoes; the LC₅₀ value for the third-instar larvae was 34 ppm for *Culex peus*, 25 ppm for *Culex tarsalis*, 33 pp for *Aedes aegypti* and 62 ppm for *Aedes triseriatus* and *Aedes nigromaculis* (Amonkar and Reeves 1970). The corresponding LC₅₀s of garlic oil fraction, which was obtained from the

reconstituted dehydrated garlic by steam distillation, were 2.1, 2, 5.6, 4 and 2.8 ppm. When a wide range of concentrations of the oil fraction was tested against third-instar larvae of *A. sierrensis*, a concentration of 10 ppm caused 8 % mortality and 20 ppm 54 %. The larvicidal principles of garlic were isolated and identified as diallyl disulfide and diallyl trisulfide; both compounds were fatal at 5 ppm to *Culex pipiens quinquefasciatus* (Amonkar and Banerji 1971). Garlic oil as well as the active larvacidal principle from it, viz. diallyl disulfide, inhibited significantly the synthesis of the 3rd larval instar proteins of *Culex pipiens quinquefasciatus* (George et al. 1973). The maximum reduction in incorporation was observed during the first hour of treatment. The incorporation of [¹⁴C]phenylalanine was also inhibited by garlic oil, and the effect was irreversible. Aqueous extracts of garlic inhibited the hatching of *Aedes aegypti* eggs (Jarial 2001). No larvae were observed either alive or dead in the garlic extracts, suggesting that the embryos were disabled before they could escape from their eggshells as viable larvae. Ethanol garlic extract exhibited larvicidal activity against the filarial mosquito *Culex quinquefasciatus* (Kalu et al. 2010). The larval mortality was observed after 24 hour treatment. The LC₅₀ values calculated for the second, third and fourth larval instars were 144.543, 165.70 and 184.18 ppm, respectively. Horseradish and garlic preparations showed also an interesting and significant insecticidal activity against larvae of *Aedes albopictus*, with LC₅₀ values of 2.34 g/L and 4.48 g/L, respectively (Tedeschi et al. 2011). Crude and chloroform–methanol (1:1 v/v) extracts of *Cuminum cyminum*, *Allium sativum*, *Zingiber officinale*, *Curcuma longa* and vegetable waste (*Solanum tuberosum* germinated tuber) exhibited larvicidal activities against *Anopheles stephensi* and *Culex quinquefasciatus* mosquito larvae (Singha and Chandra 2011). Relative mortality rate of both larval mosquito species was recorded in the following sequences: *Cuminum cyminum* > *Allium sativum* > *Zingiber officinale*, *Curcuma longa* > *Solanum tuberosum* germinated tuber for crude extract, and efficacy of chloroform–methanol (1:1 v/v) extract was as follows: *Curcuma longa* > *Zingiber officinale* > *Solanum tuberosum* germinated tuber > *Cuminum cyminum* > *Allium sativum*.

Garlic oil exerted significant protection against sand fly *Phlebotomus papatasi* by topical application on the skin of volunteers being 100 % and 30 % at 0.01 % and 0.005 % dilution, respectively (Valerio and Maroli 2005). Garlic also showed antifeeding effect when tested on artificial membrane and was dose dependent, being 100 % at 0.1 %. Garlic juice exhibited insecticidal activity against two Dipteran pests *Delia radicum* and *Musca domestica* (Gareth et al. 2006). LC₅₀ values recorded for *D. radicum* were eggs (7-day exposure) 0.8 %, larvae (24 hour exposure) 26.4 %, larvae (48 hour exposure) 6.8 % and adults (24 hour exposure) 0.4 %. LC₅₀ values recorded for *M. domestica* were eggs (7-day exposure) 1.6 %, larvae (24 hour exposure) 10.1 %, larvae (24 hour exposure) 4.5 % and adults (24 hour exposure) 2.2 %.

Larvae of *Ixodes ricinus* tick were killed in 25 minutes when exposed to garlic bulb vapour (Olenev 1950). Garlic extract was found to be effective in controlling red mite *Dermanyssus gallinae* infestation in a layer farm in Babol, north Iran (Faghihzadeh Gorji et al. 2014). Ninety-six percent control was achieved after two successive sprays. Crude garlic extracts caused 100 % mortality of adult goat lice *Damalinia caprae* at a concentration of 100 mg/mL at 32 hour postexposure, whereas at 50 mg/mL, the same mortality was observed at 48 hour postexposure (Lakshmanan et al. 2013).

Dichloromethane (DCM) extract of *A. sativum* was found to have anti-tick activity (Nchu et al. 2005). In the Type A contact toxicity bioassay, DCM garlic extract demonstrated a high acaricidal bioactivity against *Hyalomma marginatum rufipes* with 100 % of ticks killed in less than an hour, and toxicity persisted to the second day. A weak acaricidal activity of aqueous extracts of *A. sativum* was observed in the Type B contact toxicity bioassay. In the Type C contact toxicity bioassay, a concentration of 24 % w/v of DCM extracts of garlic in sunflower oil killed 100 % of *Hyalomma marginatum rufipes* (LC₅₀ = 5.9 % w/v) and *Rhipicephalus pulchellus* (LC₅₀ = 10.3 % w/v) by 24 hours posttreatment of ticks. Garlic and onion oils exerted acaricidal effect on all stages of *Boophilus annulatus* hard tick at concentrations higher than 5

% (Aboelhadid et al. 2013). Only garlic oil could kill 100 % of adult ticks at concentrations from 5 % in alcohols. Studies showed that both Mexican oregano and garlic essential oils had very similar activity, producing high mortality (90–100 %) in all tested concentrations on 10-day-old *Rhipicephalus (Boophilus) microplus* tick larvae (Martinez-Velazquez et al. 2011). Crude extracts of garlic cloves and papaya seeds were found to have very good acaricidal properties and could be a potential component of alternative *Rhipicephalus (Boophilus) microplus* cattle tick control strategy (Shyma et al. 2014). Garlic cloves and papaya seed extract produced complete failure of eclosion of eggs from the treated ticks even at lower concentrations and induced significant larval mortality.

Molluscicidal Activity

Aqueous garlic extract exhibited high molluscicidal activity against the snail *Lymnaea acuminata* (Singh and Singh 1993). Allicin (allyl 2-propenethiosulfinate) was identified as the active moiety in garlic causing death of snails *Lymnaea acuminata* and *Indoplanorbis exustus* (Singh and Singh 1995). Allicin inhibited the activity of acetylcholinesterase (AChE), lactic dehydrogenase (LDH) and alkaline phosphatase (AP) in in-vivo and in-vitro exposure against *Lymnaea acuminata* (Singh and Singh 1996a). It was observed that succinic dehydrogenase activity in the nervous tissue of *Lymnaea acuminata* was increased in in-vivo treatment, whereas with in-vitro exposure, allicin caused no significant change in succinic dehydrogenase activity. The inhibition kinetics of these enzymes indicates that allicin caused an uncompetitive inhibition of AChE and a competitive inhibition of LDH and alkaline phosphatase. The increase in 24 hour toxicity of garlic bulbs harvested from the 2nd to the 11th month after sowing, against *Lymnaea acuminata*, was 48.33 times, whereas against *Indoplanorbis exustus* it was 24 times (Singh and Singh 1996b). Both piperonyl butoxide and MGK-264 enhanced the toxicity of *Azadirachta indica*, a powdered extract of *Allium sativum* bulbs and an oleoresin of *Zingiber officinale* rhizomes against the snails *Lymnaea acuminata* and *Indoplanorbis exustus* (Singh et al. 1998). The response of snails to the

synergised mixtures was both time and dose dependent. *Allium sativum* bulb powder and its binary combination with *Cedrus deodara* oil significantly reduced fecundity, egg viability and survival of the terrestrial snail *Achatina fulica* within 15 days (Rao and Singh 2000). Discontinuation of the treatments after day 30 did not lead to a recovery trend in the next 30 days. Day 0 sublethal treatment of all the molluscicides caused a maximum reduction in protein, amino acid, DNA, RNA and phospholipid levels and simultaneous increase in lipid peroxidation in the ovotestis of treated *A. fulica*. The binary treatment of *Cedrus deodara* oil and *Allium sativum* bulb powder was found to be toxic to *Achatina fulica* than single treatment (Rao and Singh 2002). This combination treatment was found to be effective than single treatment against AChE, LDH and AP in the nervous tissue of the snail (Rao et al. 2003).

It was observed that the combination of plant-derived molluscicide *Polianthes tuberosa*, *Trachyspermum ammi* and *Allium sativum* powder; *Azadirachta indica* oil; and oleoresin of *Zingiber officinale* and their active molluscicidal components, viz. tigogenin, hecogenin, azadirachtin, allicin, thymol and [6]-gingerol in combination with MGK-264 or piperonyl butoxide, caused a significant reduction in fecundity, hatchability and survival of young snails of *Lymnaea acuminata* (Singh and Singh 2000a). The plant-derived molluscicides *Azadirachta indica* oil, *Allium sativum* powder and oleoresin of *Zingiber officinale* rhizome and their active molluscicidal components, azadirachtin, allicin and [6]-gingerol, alone or in combination (1 + 5) with piperonyl butoxide (PB) or ENT 8184 (MGK-264), caused a significant reduction in the activity of acetylcholinesterase, lactic dehydrogenase, acid and alkaline phosphatases and sodium–potassium ATPase in the nervous tissue of *Lymnaea acuminata* (Singh and Singh 2000b). There was a significant increase in the activity of succinic dehydrogenase. In-vivo exposure for 24 hours to sublethal concentrations of azadirachtin, allicin and [6]-gingerol, singly and with PB or ENT 8184, significantly altered the dopamine and 5-hydroxytryptamine levels in the nervous tissue of *L. acuminata*. It was concluded that these active moieties singly or with PB or ENT 8184

adversely affect all known neurotransmission mechanisms in the snail, either separately or through a complex interaction between the different neurotransmitters.

Effects of sublethal treatment (20 and 60 % of LC₅₀ at 24 hours) of the plant-derived molluscicides *Annona squamosa* and *Lawsonia inermis* and their combinations with other herbal molluscicides, such as *Cedrus deodara*, *Azadirachta indica*, bulb powder of *Allium sativum* and *Polianthes tuberosa*, and oleoresin of *Zingiber officinale* and acetogenins extracted from the seeds of *A. squamosa* were toxic to the snail *Lymnaea acuminata* (Singh and Singh 2004). It was observed that the plant-derived molluscicides are singly and in binary combinations with other herbal molluscicides, and the extracted acetogenins caused a significant reduction in the fecundity, hatchability and survival of young snails.

Anthelmintic Activity

Garlic may be useful as an alternative treatment against nematode parasites in animals and humans (Ayaz et al. 2008). Freshly crushed garlic homogenate administered orally eight times was 78.03 % effective against the nematode *Aspicularis tetraptera* in naturally infected mice. Ivermectin was 91.24 % effective. Administration of raw garlic mixed with food daily for 5 days to a man infected with the hookworm, *Necator americanus*, and a young dog infected with *Ancylostoma caninum* elicited a significant reduction in the number of larvae of both species in faecal cultures made during the period of garlic ingestion (Bastidas 1969). Dead eggs were found in the faecal cultures. However there was no evidence of garlic effect on the output of eggs of both species. Garlic essential oil produced significant reduction in the frequency and the amplitude of the spontaneous muscular activity of whole fluke *Fasciola gigantica* at 1 and 3 mg/mL concentrations (Singh et al. 2009). It caused complete paralysis of the fluke after 15 minutes of administration of 3 mg/mL concentration. Similar to whole fluke, essential oil of *A. sativum* (3 mg/mL) also produced flaccid paralysis in the strip preparations of the flukes.

Ethanol extracts of six plant species including *Allium sativum* exhibited anthelmintic activity in-vitro against *Haemonchus contortus* from sheep (Ahmed et al. 2013).

Garlic/Drug Interaction Activity and Metabolising Enzymes

Garlic phytochemicals and garlic supplements can influence the pharmacokinetic and pharmacodynamic behaviour of concomitantly ingested drugs by various mechanisms including enzyme inhibition/activation (cytochrome P450, glutathione *S*-transferase, glucuronyl transferase), P-glycoprotein (Pgp) activation or inhibition, altered Pgp expression and membrane fluidity (influx, efflux, passive diffusion) and modulated drug solubility and uptake (Berginc and Kristl 2013). Garlic phytochemicals from aged garlic extract modified the activities of secretory and absorptive transporters in both the intestine and liver and competitively inhibited CYP3A4 enzyme. The increased activities of the most important intestinal efflux (P-glycoprotein – Pgp, multidrug resistance-associated protein 2 – MRP-2, breast cancer resistance protein – BCRP) and uptake (monocarboxylate transporter 1 – MCT1, organic anion-transporting polypeptide – OATP, peptide transporter 1 – PepT1) transporters were caused by changes in the electrophysiological membrane properties and by allosteric modifications.

Aged garlic extract (AGE) was found to enhance P-glycoprotein (Pgp) and multidrug resistance-associated protein 2-mediated effluxes through rat jejunum of marker substrates rhodamine 123 and 2,4-dinitrophenyl-*S*-glutathione, respectively (Berginc et al. 2009). In contrast rhodamine 123 efflux through the Caco-2 cell monolayers was not altered by aged garlic extract, whereas the efflux of 2,4-dinitrophenyl-*S*-glutathione increased significantly. So altered activity of the important transport proteins could significantly change the pharmacokinetic properties of conventional medicines taken concomitantly with aged garlic extract. Increased activities of secretory (Pgp, multidrug resistance-associated protein 2) and

absorptive (monocarboxylate transporter 1, organic anion-transporting polypeptide) transporters involved in drug absorption were observed in the rat small intestine and Caco-2 cell monolayers in the presence of AGE (Berginc et al. 2010c). Transport of drugs mediated by breast cancer resistance protein and H(+)-oligopeptide transporter 1 was activated in rat intestine but was inhibited through Caco-2 cells. Passive membrane permeability of tested compounds remained unaltered through the rat small intestine, while significant changes were observed with Caco-2 cell monolayers. Aged garlic extract significantly inhibited saquinavir efflux from rat hepatocytes, while the efflux of darunavir significantly increased (Berginc et al. 2010a). Garlic phytochemicals inducing the distribution changes of saquinavir and darunavir were most probably flavonoids and lipophilic organosulfur compounds, respectively. All tested phytochemicals (except *S*-allyl L-cysteine) and aged garlic extract inhibited CYP3A4 metabolism of both drugs and modulated hepatic distribution of the corresponding saquinavir and darunavir metabolites. The fractions of tested anti-HIV drugs absorbed could decrease significantly during self-medication with garlic supplements or ritonavir dose adjustments (Berginc et al. 2010b). Due to distinct saquinavir and darunavir preferences for binding sites on efflux transporters, the presence of other compounds (garlic phytochemicals, ritonavir), capable of influencing intestinal transporter-enzyme interplay, might lead to pharmacokinetic interactions during concomitant consumption of antiretrovirals and garlic supplements as observed in clinical studies and case reports with anti-HIV drugs.

Studies suggested that the effect of garlic oil on the hepatic drug-metabolising enzyme system was found to be dose dependent (Dalvi 1992). Adult, male Sprague–Dawley rats treated with a single dose of garlic oil (500 mg/kg i.p.) showed a significant depression of hepatic cytochrome P450, aminopyrine N-demethylase and aniline hydroxylase, while microsomal protein content, cytochrome b5, NADPH-cytochrome c reductase, benzphetamine N-demethylase and cytosolic glutathione S-transferase remained unaffected 24 hours following the treatment. In contrast, daily administration of garlic oil (50 mg/kg i.p. for 5 days) produced a significant

increase in hepatic cytochrome P450, aminopyrine N-demethylase and benzphetamine N-demethylase activities, but not in the rest of the aforementioned parameters of biotransformation reactions. Oral administration of diallyl sulfide (DAS), a garlic component, inhibited 1,2-dimethylhydrazine-induced colon and liver cancer in rats (Brady et al. 1988). The selective inhibition of activity of P450IIE1, an isoenzyme of cytochrome P450, and suppression of its level in microsomes may contribute to the reported chemoprotective effects of DAS. DAS also inhibited N-nitrosodimethylamine (NDMA) demethylase activity in-vitro. Further studies suggested that diallyl sulfide inhibited the metabolism of cytochrome P450 2E1 substrates by competitive inhibition mechanisms and by inactivating P450 2E1 via a suicide-inhibitory action of its putative metabolites diallyl sulfoxide and diallyl sulfone (Brady et al. 1991a). They also demonstrated a time- and dose-dependent decrease of hepatic microsomal P450IIE1 activity, induction of P450IIB1 and pentoxyresorufin dealkylase activity and moderate induction of ethoxyresorufin dealkylase activity by oral DAS treatment (Brady et al. 1991b). Treatment with putative metabolites of DAS, diallyl sulfoxide and diallyl sulfone, led to similar modulations in monooxygenase activities, but the decrease of P450IIE1 activity by the sulfone occurred more rapidly. When rats were subjected to a 48 hour fast and DAS treatment, the starvation-induced microsomal P450IIE1 level was decreased by DAS. Inhibition of hepatotoxicity due to exposure to P450IIE1 substrates, CCL₄ and NDMA, by DAS was observed under a variety of treatment schedules. Studies suggested that diallyl sulfone (DASO₂) selectively modulated cytochrome P450 isoenzymes in cultured rat primary hepatocytes and that the induction of P450 2B1/2 by DAS in rat liver may be mediated by its metabolite, DASO₂ (Pan et al. 1993a). They further demonstrated that the induction of P450 2B1/2 in rat liver by DAS was mainly due to transcriptional activation (Pan et al. 1993b). In the DAS-treated rats, P450 2B1/2 mRNA was also markedly induced in the stomach and duodenum. DAS treatment, however, did not change the levels of P450 2B1/2 mRNA in the lung and nasal mucosa.

Diallyl disulfide (DADS) enhanced intestinal epoxide hydrolase (EH) and cytochrome P450 (P450) 2B1/2 protein levels and the activities of pentoxy- and benzyl-oxyresorufin O-dealkylases, arylhydrocarbon hydroxylase, microsomal epoxide hydrolase, p-nitrophenol UDP-glucuronyl transferase and glutathione S-transferase and decreased N-nitrosodimethylamine demethylase activity in rats (Haber et al. 1995). In the liver, DADS produced similar effects and, in addition, increased cytochrome P450 1A1/2 protein level and phenoxazone-metabolising activities (ethoxy- and methoxyresorufin O-dealkylases) and p-hydroxybiphenyl UDP-glucuronyl transferase and decreased P450 2E1 level. Low doses of DAS were found to increase tissue activities of the phase II detoxification enzymes quinone reductase and glutathione transferase in the gastrointestinal tract of the rat and may afford protection against cancer of the gastrointestinal tract (Munday and Munday 1999).

Garlic oil and its organosulfur compounds, diallyl sulfide (DAS) and diallyl disulfide (DADS), modulated the drug-metabolising (cytochrome) and antioxidant enzyme activities in rats (Sheen et al. 1999). The action of garlic oil appeared to be independent of dietary lipid content. Oral administration of rats for 6 weeks with garlic oil and its three organosulfur compounds, diallyl sulfide (DAS), diallyl disulfide (DADS) and diallyl trisulfide (DATS), exhibited a modulatory effect on rat hepatic detoxification enzyme activity and protein and mRNA expression (Wu et al. 2002). Garlic oil and DAS significantly increased pentoxyresorufin O-dealkylase (PROD) activity is compared with that of the control rats. In contrast, N-nitrosodimethylamine demethylase activity in rats that received DADS and DATS was significantly lower than that in the control rats. To the phase II enzyme, garlic oil, DADS and DATS significantly increased the glutathione S-transferase (GST) activity towards ethacrynic acid. The protein contents of cytochrome P450 1A1, 2B1 and 3A1 were increased by garlic oil and each of three allyl sulfides, and the change among the allyl sulfides was in the order of DAS > DADS > DATS. The placental form of GST (PGST) level was also increased by garlic oil and the three allyl sulfides, but the increase among the allyl sulfides was DATS congruent with

DADS > DAS. P450 2E1, however, was suppressed by each garlic component. Changes in cytochrome P450 1A1, 2B1 and 3A1 and PGST mRNA levels by garlic components were similar to those noted in the protein levels. Gastric intubation of rats with a single dose of 200 mg/kg diallyl sulfide (DAS), diallyl disulfide (DADS) and allyl methyl sulfide (AMS) decreased hepatic CYP2E1 protein by 45 %, 25 % and 47 %, respectively (Davenport and Wargovich 2005). Daily treatment for 1, 4 and 8 weeks with 200 mg/kg DAS and AMS resulted in time-dependent increases in hepatic CYP1A1 and CYP1A2 protein levels to a maximum of 600 % and 50 % for DAS and 1,600 % and 240 % for AMS after 8 weeks. Dosing for 8 weeks with 200 mg/kg DAS, but not AMS or lower doses of DAS, induced bile duct obstruction and focal areas of necrosis. The results indicated that DAS and AMS may be beneficial in inhibiting chemically induced colon cancer, but that longer dosing with higher concentrations of DAS may elicit minor hepatic toxicity. Oral administration of garlic allyl sulfides 0.5 or 2 mmol/kg BW diallyl sulfide (DAS) or 0.5 mmol/kg BW diallyl disulfide (DADS) or diallyl trisulfide (DATS) to rats three times per week for 6 weeks differentially induced cytochrome CYP 2B1 and glutathione S-transferase expression, and this upregulation of these two biotransformation enzymes was tissue specific (Lii et al. 2006).

Chen et al. (2003) found that co-administration of garlic oil (GO) and fish oil (FO) modulated the antioxidant- and drug-metabolising capacity of rats and that the effect of both drug-metabolising enzymes was additive. Garlic oil dose dependently increased hepatic glutathione S-transferase (GST), glutathione reductase, superoxide dismutase (SOD) and ethoxyresorufin O-deethylase (EROD) activities, but decreased glutathione peroxidase and N-nitrosodimethylamine demethylase (NDMAD) activities. The high-FO group had greater SOD and EROD, NDMAD and GST activities than those fed on low or high maize (MO) oil. GO dose dependently enhanced the protein level of the Ya, Yb1 and Yc isoenzymes of GST and cytochrome P450 (CYP) 1A1 and 3A1, but GO suppressed CYP2E1 expression. Regardless of the dosage of GO, the high-FO diet increased CYP1A1,

CYP3A1 and CYP2E1 levels compared with the high- and low-MO diets. Accompanying the changes observed in immunoblots, CYP1A1 and CYP3A1 mRNA levels were increased by GO in a dose-dependent manner and also increased additively in combination with FO feeding. Earlier they found that dietary fat (corn oil) and garlic oil independently modulated cytochrome P450 2B1 and glutathione (GSH) S-transferase (PGST) expression at transcriptional and/or post-transcriptional stages in the rat (Chen et al. 2001).

Exposure of immortalised human hepatocytes (Fa2N-4 cells) to increasing concentrations of garlic extract led to progressive reduction in Fa2N-4 CYP2C9 activity (Ho et al. 2010). CYP2C9 mRNA expression also revealed a concentration-dependent reduction. Greater than 90 % reduction in CYP2C9 activity was observed following 4 days of exposure to 50 µg/mL garlic extract. In contrast, exposure to garlic extract had no effect on the CYP3A4 enzymatic activity or RNA transcript concentration in Fa2N-4. Garlic peroxidase possessed a pentacoordinated haeme group with a histidine as a proximal ligand (El Ichi et al. 2011). Garlic peroxidase exhibited a high affinity for hydrogen peroxide as well as various reducing co-substrates. In addition, high enzyme specificity was demonstrated. Also, garlic peroxidase showed a great potential for the application for drug metabolism as shown by its ability to react with 1-nitrohexane in the presence of sodium dithionite.

Administration of garlic and atorvastatin to dyslipidaemic rats augmented atorvastatin maximum observed plasma concentration, half-life, area under plasma concentration-time curve (AUC) and mean resident time (Reddy et al. 2012).

In a 12-week double-blind, randomised, placebo-controlled pilot study of 48 patients on warfarin therapy who completed the study, intake of garlic extract did not increase haemorrhage (Macan et al. 2006). The results suggested garlic extract to be relatively safe and to pose no serious haemorrhagic risk for closely monitored patients on warfarin oral anticoagulation therapy.

Pharmacokinetic Studies

After consumption of onions or garlic, the methylates of N-acetyl-S-(2-carboxypropyl)cysteine (1), N-acetyl-S-allylcysteine (2) and hexahydrohippuric acid (3) were detected in human urine (Jandke and Spiteller 1987). The compounds 1 and 2 were metabolites of peptides introduced with onions or garlic into the body. Allicin (allyl thiosulfinate) showed a remarkable first-pass effect and passed the isolated perfused rat liver unmetabolised only at high concentrations which caused considerable cell injuries (Egen-Schwind et al. 1992b). Diallyl disulfide and allyl mercaptan were identified as metabolites of allicin and could be determined in the perfusion medium as well as in the bile and the liver tissue. Ajoenes and vinylthiols were detected in the perfusion medium after liver passage, but no metabolites of them could be identified.

After oral administration of 27 mg 2-vinyl-4H-1,3-dithiin and 9 mg 3-vinyl-4H-1,2-dithiin to rats, both vinylthiols could be detected in the serum, kidney and fat tissue, over a period of 24 hours, whereas in the liver only 1,3-vinylthiol was found (Egen-Schwind et al. 1992a). Pharmacokinetic parameters ($t_{1/2}$, k_e , Cl_{tot} , AUC and V_d) were determined using compartment models, elucidating the different pharmacokinetic behaviour of both vinylthiols. 1,3-Vinylthiol appeared to be less lipophilic and was rapidly eliminated from the serum, kidney and fat tissue, whereas 1,2-vinylthiol was more lipophilic and showed a tendency to accumulate in fat tissue. Allicin, the precursor of the vinylthiols, was metabolised more rapidly in liver homogenate than the vinylthiols. After oral administration of doses (8 mg/kg) of garlic constituents (alliin, allicin and vinylthiols (2-vinyl-[4H]-1,3-dithiin and 3-vinyl-[4H]-1,2-dithiin)) in the form of an oil macerate of the ^{35}S -labelled substance to rats, there was no detectable difference in organ distribution between ^{35}S -allicin and the labelled vinylthiols (Lachmann et al. 1994). All that could be established from the urinary metabolite pattern was that unchanged ^{35}S -allicin and unchanged labelled vinylthiols were absent. The results revealed no differences in pharmacokinetic behaviour between ^{35}S -allicin and the labelled vinylthiols.

The total amount of *N*-Acetyl-*S*-allyl-L-cysteine (allylmercapturic acid, ALMA) found in the urine of volunteers who consumed two garlic tablets was 0.43 mg (de Rooij et al. 1996). In the urine of the three volunteers who consumed not only two garlic tablets but also additional fresh garlic, a significantly higher amount of ALMA was excreted in the urine, 1.4 mg. The elimination half-life of ALMA, estimated from urinary excretion rate versus time curves, was 6.0 hour. Ten glutathione (GSH) conjugates were identified in the bile collected from rats dosed with diallyl sulfide (DAS), namely, *S*-[3-(*S'*-allyl-*S'*-dioxomercapto)-2-hydroxypropyl]glutathione (M1, M2; diastereomers), *S*-[3-(*S'*-allyl-*S'*-dioxomercapto)-2-hydroxypropyl]-glutathione (M5), *S*-[2-(*S'*-allyl-*S'*-dioxomercapto)-1-(hydroxymethyl)ethyl]glutathione (M3, M4; diastereomers), *S*-[3-(*S'*-allylmercapto)-2-hydroxypropyl]glutathione (M6), *S*-(3-hydroxypropyl)-glutathione (M7), *S*-(2-carboxyethyl)glutathione (M8), allyl glutathionyl disulfide (M9) and *S*-allylglutathione (M10) (Jin and Baillie 1997). With the exception of M6, all of the above GSH conjugates were detected in the bile of rats treated with diallyl sulfone diallyl sulfone (DASO), while only M3, M4, M5, M7, M8 and M10 were found in the bile of rats treated with DASO₂.

Cycloalliin, an organosulfur compound found in garlic and onion, when administered intravenously at 50 mg/kg to rats, was rapidly eliminated from blood and excreted into urine, and its total recovery in urine was 97.8 % in 48 hours (Ichikawa et al. 2006). After oral administration, cycloalliin appeared rapidly in plasma. Orally administered cycloalliin was distributed in the heart, lung, liver, spleen and especially kidney. When administered orally at 50 mg/kg, cycloalliin was excreted into urine but not faeces. However, the total faecal excretion of (3*R*,5*S*)-5-methyl-1,4-thiazane-3-carboxylic acid was 67.3 % (value corrected for cycloalliin equivalents). In addition, no (3*R*,5*S*)-5-methyl-1,4-thiazane-3-carboxylic acid was detected in plasma (<0.1 µg/mL), and negligible amounts (1.0 %) were excreted into urine. In in-vitro experiments, cycloalliin was reduced to (3*R*,5*S*)-5-methyl-1,4-thiazane-3-carboxylic acid during anaerobic incubation with caecal contents of rats. The data indicated that the low bioavailability

(3.73 % and 9.65 % at 25 and 50 mg/kg, respectively) of cycloalliin was due mainly to reduction to (3*R*,5*S*)-5-methyl-1,4-thiazane-3-carboxylic acid by the intestinal flora and also poor absorption in the upper gastrointestinal tract.

Most of the administered allixin in mice disappeared within 2 hours, and the bioavailability of allixin in the serum was estimated to be 31 % by obtained area under the blood concentration-time curve (AUC) (Kodera et al. 2002b). Three allixin metabolites were identified having a hydroxylated pentyl group, namely, hydroxy-5-methoxy-6-methyl-2-(4-hydroxypentyl)-4H-pyran-4-one; 3-hydroxy-5-methoxy-6-methyl-2-(2-hydroxypentyl)-4H-pyran-4-one; and 3-hydroxy-5-methoxy-6-methyl-2-(1-hydroxy-pentyl)-4H-pyran-4-one.

Various components of garlic and aged garlic extract, including allicin, S-allylcysteine (SAC) and volatile metabolites of allicin, were found in breath, plasma and simulated gastric fluids (Rosen et al. 2000, 2001). Major volatile compounds such as diallyl disulfide (DADS) and diallyl sulfide (DAS) were not the major compounds found in the breath; rather, the major volatile was allyl methyl sulfide, which may have been formed from the action of glutathione on DADS and DAS or on other components containing the C₃H₅-S-moiety. Volatiles such as *p*-cymene and D-limonene were also detected in the breath especially after 1.5 hour garlic consumption. Data indicated that allicin is decomposed in stomach acid to release allyl sulfides, disulfides and other volatiles that were postulated to be metabolised by glutathione and/or S-adenosylmethionine to form allyl methyl sulfide (Rosen et al. 2000, 2001). SAC, a nonvolatile bioactive component of aged garlic preparations could be absorbed by the human body and could be determined in plasma.

Adverse Effects of Garlic

Inhalation and cutaneous absorption were reported to be common portals of entry of garlic volatiles (Buchan 1974). Habitual exposure to extremely small concentrations could cause nausea, vomiting (sudden and explosive), contact dermatitis, pharyngitis, lethargy and the tell-tale garlic breath.

Acute intoxications could also produce decerebrate central nervous system phenomena with convulsions. Adverse effects of garlic that had been reported with oral ingestion, inhalation and topical exposure included smelly breath, body odour, flatulence, oesophageal and abdominal pain, small intestinal obstruction, contact dermatitis, rhinitis, asthma, bleeding, myocardial infarction, urticaria, angioedema, anaphylaxis, skin blisters and ulcero-necrotic lesions (Morbidoni et al. 2001; Singh and Singh 2008). They asserted that the causality of garlic for specific adverse effects was established for smelly breath, body odour and allergic reactions; data regarding other adverse effects were primarily based on case reports. The frequency of adverse effects of garlic and whether they vary by particular preparations were yet to be established. Case reports have highlighted the possibility that garlic use may cause allergic reactions (allergic contact dermatitis, generalised urticaria, angioedema, pemphigus, anaphylaxis and photoallergy), alteration of platelet function and coagulation (with a possible risk of bleeding) and burns (when fresh garlic is applied on the skin, particularly under occlusive dressings) (Borrelli et al. 2007). Consumption of garlic by nursing mothers modifies their infant's behaviour during breast-feeding. Finally, garlic may enhance the pharmacological effect of anticoagulants (e.g. warfarin, fluindione) and reduce the efficacy of anti-AIDS drugs (i.e. saquinavir). Garlic appeared to have no effect on drug metabolism, but patients taking anticoagulants should be cautious (Tattelman 2005). One should be prudent to stop taking high dosages of garlic 7–10 days before surgery because garlic could prolong bleeding time.

Garlic Breath

Immediately after finely grated, raw garlic ingestion, two major odour compounds allyl mercaptan and diallyl disulfide were identified in human mouth breath (Minami et al. 1989). Allyl mercaptan was the major garlic-smelling compound in human mouth breath, and diallyl disulfide was secondary. Considerable compositional differences found in the analyses for the gas phase of garlic cloves, kept in oil, were likely

associated with the poor stability of allicin in a lipophilic environment; a marked increase in the amounts of 2-propene-1-thiol, acetic acid and ethanol was observed in the gas phase, whereas trisulfides were present in traces only (Laakso et al. 1989). The occurrence of 2-propene-1-thiol and diallyl disulfide, the two principal sulfur components in exhaled air, also may indicate a rapid degradation of most garlic volatile components probably caused by the enzymatically active human salivary or digestive system. Allyl methyl sulfide, diallyl sulfide, diallyl disulfide, *p*-cymene and D-limonene were found consistently in the breath of all human subjects after ingestion of garlic (Ruiz et al. 1994). Allyl thiol was detected occasionally. Hydrogen sulfide, a potential breath odour compound, was not efficiently trapped due to its low breakthrough volume in the adsorbent resins and thus was analysed by direct injection of breath samples using sulfur-sensitive flame photometric GC. Diallyl disulfide (DADS) was found with allyl mercaptan (AM) in human breath after ingestion of dry or fresh garlic (Cai et al. 1995). Excretion of selenium as dimethyl selenide was observed in humans only in response to acute oral doses of selenium. After ingestion of raw garlic, the concentrations of allyl methyl disulfide, diallyl sulfide, diallyl disulfide and diallyl trisulfide reached a maximum and declined to baseline values within the next 2–3 hours in the breath of a test person (Taucher et al. 1996). Concentrations of allyl methyl sulfide, dimethyl sulfide and acetone increased much more slowly and showed enhanced values even 30 hours after garlic consumption. The strong increase of the concentration of acetone might be indicative of enhanced metabolism of serum cholesterol, triglycerides and total lipids in the bloodstream. Low-molecular sulfur compounds (LMSC), namely, allyl mercaptan, methyl mercaptan and allyl methyl sulfide, were detected in significant amounts in human breath after garlic ingestion (Tamaki and Sonoki 1999). The quantities of these compounds arising from heat-treated garlic were smaller than those from raw garlic. These compounds had the tendency of decreasing with the passage of time. In contrast, almost no high-molecular sulfur compounds (HMSC) were detected in both raw- and heat-treated garlic. Raw garlic exhibited higher values of

volatile compounds, and the higher the values, the stronger the garlic flavour or malodour.

Adverse Garlic/Drug Interaction

Garlic supplements can impede HIV medication (Anonymous 2002; Berginc and Kristl 2013) and may affect intake of other drugs (James 2001; Berginc and Kristl 2013). In a study of healthy volunteers, garlic supplementation to saquinavir treatment was found to decrease the content of saquinavir in the plasma by about 50 % (Piscitelli et al. 2002). The authors reiterated that patients should use caution when combining garlic supplements with saquinavir as a sole protease inhibitor for AIDS therapy. The blood-thinning effects of warfarin were greatly enhanced in individuals taking garlic and could amplify the risk of bleeding problems (Sunter 1991). Two herbal supplements in particular, *ginkgo biloba* and garlic, had demonstrated effects on warfarin (Evans 2000).

Adverse Oxidising Activity in Canines

Five compounds, namely, *bis*-2-propenyl trisulfide (1), *bis*-2-propenyl tetrasulfide (2), *bis*-2-propenyl pentasulfide (3), *bis*-2-propenyl thiosulfonate (4) and *trans*-sulfuric acid allyl ester 3-allylsulfanyl-allyl ester (5), oxidising canine erythrocytes were isolated from an aqueous ethanol garlic extract (Hu et al. 2002). A mixture of compounds 1–3 and compounds 4 and 5 induced methaemoglobin formation in canine erythrocyte suspension in-vitro resulting in the oxidation of canine erythrocytes. The constituents of garlic had the potential to oxidise erythrocytes and haemoglobin, suggesting that foods containing quantities of garlic should be avoided for feeding dogs. Also *trans*-sulfurous acid allyl ester 3-allylsulfanyl-allyl-ester, 2-propene-1-sulfinothioic acid-S-methyl ester and 2-propene-1-sulfinothioic acid-S-(*E*)-1-propenyl ester isolated from aqueous ethanol garlic extract induced methaemoglobin formation in a canine erythrocyte suspension in-vitro resulting in the oxidation of canine erythrocytes (Yang et al. 2003).

Toxicity Studies

Animal studies found that swelling of the liver, hypertrophy of the spleen and adrenal glands and decrease of erythrocytes with various morphological changes were clearly observed in young rats after 3 and 8 days on the group with high-dosed raw garlic juice, but almost these changes were not observed at any time on extracted-aged garlic juice administration (Nakagawa et al. 1980). The growth of rats in the raw garlic juice-administered group was retarded. In oral chronic toxicity in Wistar rats, no toxic symptoms due to garlic extract even at a dose level of 2,000 mg/kg for five times a week during 6 months were found (Sumiyoshi et al. 1984). High dose of garlic extract did not inhibit the body weight gain, while the food consumption decreased slightly for the nutritional effects of it in both male and female rats. There were no significant differences in urinary, haematological and serological examinations compared to each groups. In the histopathological findings, no toxic signs were observed on any of the tissues and organs examined. In the acute toxicity test of garlic, the LD₅₀ values of garlic extract by per os (PO), intraperitoneal (IP) or subcutaneous (SC) administration was estimated over 30 mL/kg, respectively, in male and female of Wistar rats and ddY mice (Nakagawa et al. 1984). In 30 mL/kg of I.P. group, five of ten in male rats and one of ten in female rats were died within a day after administration; however, no specific signs due to garlic extract were observed in survivals for 7 days. Studies showed that garlic extract, 300 and 600 mg/kg/24 hour for 21 days, caused toxic effects affecting weight growth, biological parameters and histologic structures in female and male rats (Fehri et al. 1991).

Significant rise in urea and D-aspartate aminotransferase and inhibition of alkaline phosphatase in serum were observed in rats fed with garlic extract (2 mL/100 g body weight, intragastrically) for 10 days (Joseph et al. 1989). The liver showed histological changes. Garlic oil feeding (10 mg/100 g body wt, intragastrically) after 24 hour fasting was found lethal. The cause of death appeared to be acute pulmonary oedema. However, similar feeding of garlic oil was well tolerated by rats in the fed state. Also, 24 hour-fasted rats could tolerate this dose of garlic oil, provided they were

previously adapted to garlic oil feeding. A case of spontaneous spinal epidural haematoma causing paraplegia secondary to a qualitative platelet disorder from excessive garlic ingestion was reported by Rose et al. (1990). The case also demonstrated satisfactory recovery from thoracic spinal epidural haematoma in a nonagenarian. Administration of low doses of garlic (50 mg/kg) to rats either orally or intraperitoneally had little effect on the lung and liver tissues as compared to control animals (Alnaqeeb et al. 1996). In contrast, administration of high doses of garlic (500 mg/kg) resulted in profound changes in the lung and liver tissues of rats. Intraperitoneal administration of the high dose of garlic was more damaging to the lung and liver tissue of rats than oral administration. This was also confirmed by studies of Banerjee et al. (2001) and Rana et al. (2006). Administration of fresh garlic homogenates at low doses 250 mg/kg/day to rats significantly reduced thiobarbituric acid reactive substances (TBARS) and glutathione peroxidase. Both 500 and 1,000 mg/kg/day doses significantly reduced endogenous antioxidants (catalase and SOD) without altering TBARS. A 1,000 mg/kg/day dose of garlic caused marked histopathological and ultrastructural changes in both the liver and kidneys. The results indicated that garlic in low doses had the potential to enhance the endogenous antioxidant status, although at higher doses a reversal of these effects was observed. Rana et al. (2006) found that garlic at high dose (5 g/kg body weight/day) had the potential ability to induce liver damage, and low doses (0.1 or 0.25 g/kg body weight/day) were safe doses.

The low dose of garlic oil suppressed endotoxin-induced inducible nitric oxide synthase (iNOS) activity, ulceration and apoptosis in the intestinal mucosa of Wistar rats (Chiang et al. 2006). The high dose of garlic oil significantly lowered the peripheral level of nitrate/nitrite and endotoxin-induced iNOS activity in the rat intestinal mucosa but worsened intestinal mucosal damage accompanied by elevated peripheral proinflammatory cytokines. Diallyl trisulfide but not diallyl disulfide showed similar toxic effect as that of high-dose garlic oil. The results suggested the preventive effect and possible toxicity of garlic oil and its organosulfur compounds in

endotoxin-induced systemic inflammation and intestinal damage. Studies by Hamlaoui-Gasmi et al. (2012) showed that a high garlic dose induced liver toxicity and a pro-oxidative status characterised by increased malondialdehyde and decreased antioxidant enzyme activities as catalase, peroxidase and superoxide dismutase. Also, garlic increased intracellular H_2O_2 but decreased free iron and Ca^{2+} . Grape seed and skin extract alone or in co-treatment with garlic had the reverse effect and counteracted almost all garlic-induced deleterious impacts to near control levels. Studies in young (6-week-old) male C57BL/6 mice showed that diallyl disulfide (DADS) may have adverse effects on hippocampal neurogenesis and neurocognitive functions by modulating ERK (extracellular signal-regulated kinase) and BDNF (brain-derived neurotrophic factor)–CREB (cAMP response element-binding protein) signalling (Ji et al. 2013). The results suggested caution in consuming large amounts of garlic products particularly during the period of neural growth.

In a randomised, double blind, placebo-controlled, parallel group clinical trial of 58 newly diagnosed, smear-positive pulmonary tuberculosis patients (31 given garlic tablets, 27 placebo tablets), no significant difference was found between the two groups regarding age, sex, nationality, smoking, underlying diseases and opium usage. During 8 weeks of anti-TB (antituberculosis) treatment, 8 (13.0 %) patients developed drug-induced hepatotoxicity (DIH). Fifty percent of the patients who developed DIH were in the garlic group. Results indicated no significant difference between groups in developing DIH.

Studies indicated that garlic could affect beneficial probiotic *Bifidobacterium* species in a manner similar to that exhibited in pathogens (Booyens et al. 2014). The results highlight that caution should be taken especially when using raw garlic and probiotic bifidobacteria simultaneously as the viability of these bacteria could be reduced by allicin released upon the crushing of garlic cloves, thereby limiting the health benefits that the consumer anticipates to gain from probiotics.

Garlic Chemical Burn and Allergy

Garlic had been reported to be safe in low doses, but it could lacerate the stomach if taken in excessive amounts (Ayaz and Alpsoy 2007). A case of contact dermatitis to garlic was reported by Bleumink et al. (1972). Patch tests with a piece of garlic bulb and extracts of garlic were positive. The active substance proved to be readily soluble in water, alcohol and acetone. The allergenic material was found to be of low molecular weight, heat labile and present in the outer parts of the bulb. Garlic was found to be a type 4 allergen (Cronin 1987). Dilutions of garlic and of onion 50 % in *Arachis* oil were not irritants and seemed effective patch test materials for hand eczema of caterers.

Lybarger et al. (1982) reported that repeated exposure to garlic dust induced severe asthma in an atopic patient. Subsequently, the patient also developed marked adverse responses after ingestion of garlic. Immunological investigations carried out in an asymptomatic period revealed significant skin reactivity and bronchospasm after challenge with both garlic dust and extract. The results of a controlled oral challenge test to garlic dust were also positive. The patient's serum contained unusually high quantities of garlic-specific IgE. Inhalation of garlic dust can cause severe asthma (Armentia and Vega 1997).

Eight Chinese patients developed contact dermatitis after rubbing the cut end of a fresh garlic bulb onto the skin to treat fungal and other infections at the groin, neck, lower limb, hand or face (Lee and Lam 1991). Repeated open application tests with fresh garlic were all positive, and patch tests with garlic extract were all negative. The results confirmed that the contact dermatitis was due to irritation. The patients were treated successfully with topical fluorinated steroid. Añibarro et al. (1997) reported on 12 patients (all of them garlic workers) with occupational asthma induced by garlic dust. Garlic sensitisation was demonstrated by bronchial challenge test in seven patients (group 1) and ruled out in the remaining five. One nursing mother received severe burns to the breast from prolonged (2 days) application of a poultice of raw,

crushed garlic to treat a self-diagnosed *Candida* infection (Roberge et al. 1997). Friedman et al. (2006) reported three patients with self-inflicted garlic burns. Garlic application could result in local inflammation, but, if applied under a pressure bandage or poor wound care or a secondary infection, it could cause a severe dermal reaction and a deep chemical burn.

Raw garlic, when cut and placed on the tongue or lips, elicits painful burning and prickling sensations through unknown mechanisms (Macpherson et al. 2005). They showed that raw but not baked garlic activated TRPA1 and TRPV1, two temperature-activated ion channels that belong to the transient receptor potential (TRP) family. They further showed that allicin, an unstable component of fresh garlic, was the chemical responsible for TRPA1 and TRPV1 activation and was therefore likely to cause garlic's pungency.

Bagga et al. (2008) reported a case of chemical burn of oral mucosa caused by crushed garlic. To relieve toothache, the patient placed crushed garlic cloves in the buccal vestibule overnight and developed garlic burn injury manifesting as slough and ulceration in that region. Allergic contact cheilitis to garlic characterised by inflammation of the lips was reported by Ekeowa-Anderson et al. (2007).

Another case of garlic chemical burn was reported in a 23-year-old woman who developed chemical burn after applying crushed garlic on a wart on her right cheek and placing a tape over it (Filobos et al. 2012). Garlic was found to cause severe chemical burn in a 41-year-old man with chronic pruritus on the left shin following garlic applied under occlusion (Xu et al. 2014a).

Garlic-sensitive patients showed positive tests to garlic compounds diallyl disulfide, allylpropyldisulfide, allyl mercaptan and allicin (Papageorgiou et al. 1983). Guinea pigs sensitised to garlic extracts cross-reacted to diallyl disulfide and reacted to allicin, an oxidised derivative of diallyl disulfide present in garlic. Pérez-Pimiento et al. (1999) reported an IgE-mediated anaphylactic reaction to young garlic in a patient sensitised to pollen and dried fruit. Prick-

prick tests with young garlic and garlic were positive. Alliin lyase was found to be a major garlic allergen in a garlic-allergic group of patients in Taiwan (Kao et al. 2004). Skin tests showed that the purified protein elicited IgE-mediated hypersensitive responses in patients with garlic allergy. Skin tests showed that the purified protein elicited IgE-mediated hypersensitive responses in patients with garlic allergy. Garlic alliin lyase showed strong cross-reactivity with alliin lyases from other *Allium* species, namely, leek, shallot and onion. Ma and Yin (2012) reported a case of anaphylaxis induced by ingestion of raw rather than cooked garlic. IgE binding proteins could only be detected in raw garlic extract but not in cooked garlic as the allergens were heat labile.

In February 1989, three cases of botulism occurred in persons who consumed garlic bread made from a garlic-in-oil product and were reported by Morse et al. (1990). Testing of leftover garlic-in-oil showed it to have a pH of 5.7 and to contain high concentrations of *Clostridium botulinum* organism and toxin. This was the second episode of botulism associated with a low acid garlic-in-oil product which needs constant refrigeration. Gimenez et al. (1988) reported that garlic was not effective in reducing botulinum toxin production by *C. botulinum* type A. Ismaiel and Pierson (1990) reported that garlic oil (100 ppm) inhibited germination of *Clostridium botulinum* A, B and E in broth media but had no significant effect on outgrowth and toxin production.

Unpleasant taste (100 %), halitosis (90 %) and nausea (30 %) after using garlic mouthwash for 5 weeks were reported by 30 subjects after the end of the study (Groppo et al. 2007).

Traditional Medicinal Uses

Garlic is said to be a diaphoretic, diuretic, expectorant, febrifuge, stimulant, stomachic, tonic, anthelmintic, antiasthmatic, anticholesterolaemic, antiseptic, antispasmodic and cholagogue (Grieve 1971; Lust 1974; Launert 1981). Onion and garlic rich in several phytonutrients are recognised as important elements of the Mediterranean diet, but are also used in the treatment and prevention of a number of diseases,

including cancer, coronary heart disease, obesity, hypercholesterolaemia, diabetes type 2, hypertension, cataract, microbial infections and disturbances of the gastrointestinal tract (e.g. colic pain, flatulent colic and dyspepsia), because of their hypocholesterolaemic, hypolipidaemic, antihypertensive, antidiabetic, antibiotic, antithrombotic and antihyperhomocysteinaemia effects and to possess many other biological activities including antimicrobial, antioxidant, anticarcinogenic, antimutagenic, antiasthmatic, immunomodulatory and prebiotic activities (Kendler 1987; Augusti 1996; Bianchini and Vainio 2001; Lanzotti 2006; Corzo-Martínez et al. 2007). Fenugreek, garlic and onion are recommended in Persian folklore medicine as beneficial in the treatment of diabetes (Jelodar et al. 2005). Today, in many parts of the world, garlic is being used both as prophylaxis and for the cure of variety of diseases including acute and chronic infections like gastritis, dysentery, typhoid fever, cholera, tuberculosis, pneumonia, diabetes mellitus, heart disease and hypertension (Khataibeh et al. 2006). In the Errachidia province in southeastern Morocco, garlic and onion are among several plants used most frequently to treat hypertension (Tahraoui et al. 2007). Traditionally, garlic has been known to boost the immune system; aged garlic has more potent immunomodulatory effects than raw garlic (Chandrashekar and Venkatesh 2009). Garlic and onion have been used as medicinal agents for thousands of years (Ali et al. 2000b). Both garlic and onion had been shown to have applications as antimicrobial, antithrombotic, antitumour, hypolipidaemic, antiarthritic and hypoglycaemic agents. *Allium sativum* (garlic)-derived preparations are used alone or with amphotericin B in Asia to treat human systemic fungal infections and cryptococcal meningitis (Davis et al. 1994). Therapeutic properties of garlic have been recognised in the processing of garlic capsules, tablets and other formulations related to human health (Augusti 1996). Aged black garlic is a type of fermented garlic (*Allium sativum*) which has been used in Oriental countries for a long time because of the various biological properties of garlic derivatives (Lee et al. 2011).

According to Burkill (1966) in Peninsular Malaysia, garlic was administered internally for flatulence. It was used in a

tonic preparation with other herbs in *ubat jamu* after childbirth. Garlic was prescribed chiefly in herbal mixtures for treating intestinal ailments of various kinds, with *Tinospora* as vermifuge; with galangal and pepper for diarrhoea; with *Aloe* and pepper in a purge; with turmeric, *Nigella* seeds, cumin and coriander and *Massoia* for vomiting; with *Citrus hystrix* peels, *Nigella* seeds and cloves for stomach pains; and with *Cnesti*, *Artocarpus* and *Nigella* for chronic colonic obstruction. Garlic was also prescribed for improving appetite and for correcting effects of gluttony. Garlic was given with *Carum copticum* for coughs and was used as an ingredient in prescriptions for headaches, gouty pains, liver congestions, asthma and various feminine complaints.

According to Grieve (1971) garlic has been used as an antiseptic during the past two world wars. Garlic has been employed as a specific for leprosy and also smallpox. Garlic was used as an antiseptic in ointment and lotions to disperse hard swelling and in poultices for scrofulous sores. Garlic was also used to prevent anthrax in cattle. Syrup of garlic was found invaluable as medicine for asthma, hoarseness, cough, breathing difficulty and other pulmonary disorders. Garlic was also useful in chronic bronchitis, tuberculosis and dropsy. Garlic was crushed and mixed with lard to relieve whooping cough by rubbing on the chest and back. An infusion of bruised garlic bulb before and after every meal gave good effect in epilepsy. Garlic cloves pounded with honey taken 2–3 consecutive nights were good for rheumatism. Bruised garlic in boiled milk was taken as vermifuge. Garlic was also used as a digestion aid.

According to Stuart (2014), in the Philippines, garlic bulbs were used for hypertension, as a diuretic and eaten fresh or burned for coughs in children. Crushed garlic was rubbed on affected areas in arthritis, rheumatism and toothaches. Crushed cloves were applied to both temples as poultice for headache. Garlic is rubbed over ringworm with a relieving effect. In Mexico, fresh bulb is eaten as prevention for tuberculosis. In India, garlic juice diluted in water is applied externally to prevent hair from turning grey. In the Antilles, garlic juice is used as vermifuge. Juice of garlic bulb with common salt is

applied to bruises and sprains, also used for neuralgia and earache. Crushed garlic juice or cut clove crosswise was rubbed directly to areas of insect bites of scorpions, centipedes and the like to mitigate the pain (Chiej 1984; Stuart 2014).

According to Lu (2005) in traditional Chinese Medicine, garlic is good for cold abdominal pain, oedema, diarrhoea, dysentery and whooping cough. He reported that there had been fewer cases of pulmonary tuberculosis in Shandong province where people consumed more garlic than other provinces. As a result of these findings, garlic had been made into tablets and used with good results. Also Chinese people consumed large quantities of garlic in cases of malnutrition or oedema.

Other Uses

Garlic plant and bulb contain phytochemicals that exhibit pesticidal activities against plant pests (insects and nematodes) and diseases (bacterial and fungal). The growing plant is said to repel insects, rabbits and moles (Riotte 1978). The juice from the bulb is used as an insect repellent (Chiej 1984). Several tablespoons of chopped garlic and grated soap infused in boiling water, when cooled, are used as an insecticide (Allardice 1993). An extract of the plant is also used as a fungicide in blight and mould or fungal diseases of tomatoes and potatoes (Allardice 1993). A few cloves of garlic spread among stored fruit will delay fruit from rotting (Chiej 1984).

Garlic oil exhibited insecticidal activity against the eggs, larvae and adults of *Tribolium castaneum* and adults of *Sitophilus zeamais* (Ho et al. 1996). The eggs were the most susceptible stage, followed by adults, 10-day-old larvae and older larvae. *T. castaneum* adults were more susceptible to garlic oil than *S. zeamais* adults, with KD_{50} values of 1.32 mg/cm² and 7.65 mg/cm², respectively. When rice and wheat were treated with garlic oil, eggs that were laid in the media failed to produce F1 progeny at concentrations of >2,000 ppm in rice for *T. castaneum* and 5,000 ppm in wheat for *S. zeamais*. Methyl allyl disulfide and diallyl trisulfide, two major garlic compounds, exhibited contact toxicant, fumigant and feeding deterrent activity against stored product pests *Sitophilus zeamais* and *Tribolium castaneum* (Huang et al. 2000). Purified garlic leaf lectin (ASAL), a 12 kDa dimeric mannose-binding protein, was found to have detrimental effect on the growth and survival of two important homopteran insect pests, *Lypaphis erysimi*, commonly known as aphids, and *Dysdercus cingulatus* (red cotton bug) (Bandyopadhyay et al. 2001). Horseradish, anise and garlic oils showed the most potent insecticidal activities against larvae of *Lycoriella ing  nue* among the plant essential oils (Park et al. 2006). At 1.25   L/L, horseradish, anise and garlic oils caused 100, 93.3 and 13.3 % mortality. Garlic bulb extracts exhibited repellancy and mortality effects against *Tetranychus urticae* (Hincapie et

al. 2008). Extracts were obtained using as solvents CO₂ in supercritical conditions and had the lowest mean lethal concentration (LC₅₀), and the petroleum ether extract was the most repellent.

Studies by Yang et al. (2010) suggested that garlic essential oil combined with diatomaceous earth had a strong additive effect against adult rice weevils, *Sitophilus oryzae*, and red flour beetles, *Tribolium castaneum*. The activity of the combination treatment lasted longer than that of essential oil alone, and the survival of eggs or larvae to adult stage was significantly inhibited in the combined treatments against both species, compared with the use of essential oil alone. Diallyl trisulfide was found to be more potent than methyl allyl disulfide. The essential oil of *A. sativum* possessed contact toxicity against overwintering adults of *Cacopsylla chinensis* with an LC₅₀ value of 1.42 µg per adult (Zhao et al. 2013). The two main constituent compounds, diallyl trisulfide and diallyl disulfide, exhibited strong acute toxicity against the overwintering *C. chinensis*, with LC₅₀ values of 0.64 and 11.04 µg per adult, respectively. Synthetic fusion-protein containing domains of Bt Cry1Ac and *Allium sativum* lectin (ASAL) conferred enhanced (8-fold and 30-fold) insecticidal activity against major lepidopteran pests, *Pectinophora gossypiella* and *Helicoverpa armigera* (Tajne et al. 2014). Afolabi-Balogun et al. (2012) isolated and characterised a mannose-binding insecticidal lectin gene BLEC1 from garlic. The cloning and characterisation of BLEC1 would pave the way for its potential use in plant genetic engineering in the development of insect resistance plant. Studies showed that garlic essential oil, diallyl disulfide and diallyl trisulfide, had significant fumigant activity against the angoumois grain moth, *Sitotroga cerealella*, with 50 % lethal concentration values at 1.33, 0.99 and 1.02 µL/L air space, respectively; meanwhile, the three materials possessed high behavioural deterrent activities against adults in the Y-tube olfactometer (Yang et al. 2012). When applied to rice grains, these materials reduced adult longevity and inhibited oviposition, with ovipositional inhibition above 70 % at a concentration of 1.5 µL/25 g in either no-choice or two-choice tests. Garlic extracts

exhibited acaricidal activity against the two-spotted spider mite, *Tetranychus urticae* (Attia et al. 2012). Female mortality increased with garlic concentration, with LD₅₀ and LD₉₀ values of 7.49 and 13.5 mg/L, respectively. Reduced fecundity was observed at concentrations of 0.36 and 0.74 mg/L. Aqueous and methanol garlic extracts showed the highest insecticidal activity (mortality rate of 81 % and 64 %, respectively) against the larvae of *Spodoptera litura* (*S. litura*) at a concentration of 1,000 ppm (Meriga et al. 2012).

Antimicrobial activity in-vitro of garlic allicin was shown against the plant pathogenic bacteria *Agrobacterium tumefaciens*, *Erwinia carotovora*, *Pseudomonas syringae* pv. *maculicola*, *Pseudomonas syringae* pv. *phaseolicola*, *Pseudomonas syringae* pv. *tomato*, *Xanthomonas campestris* pv. *campestris*, the fungi *Alternaria brassisicola*, *Botrytis cinerea*, *Plectosphaerella cucumerina*, *Magnaporthe grisea* and the oomycete *Phytophthora infestans* (Curtis et al. 2004). Disease reduction in plants by allicin was shown for *Magnaporthe grisea*-infected rice, *Hyaloperonospora parasitica*-infected *Arabidopsis thaliana* and *Phytophthora infestans*-infected potato tubers. Significantly, the active principle was effective in reducing *P. infestans* spore germination in-vitro and disease in blighted tubers via the vapour phase (fumigation) as well as by direct application at the inoculation site. Horseradish ethanol extracts exhibited fungistatic activity against *Sclerotium rolfsii*, *Fusarium oxysporum* and *Fusarium culmorum*, while garlic extracts at the same concentration provided a good fungicidal activity against *Botrytis cinerea* and *S. rolfsii* (Tedeschi et al. 2011). Antifungal N-feruloyl amides N-feruloyltyrosine and N-feruloyltyramine, isolated from *A. sativum* roots, showed antifungal activity towards *Fusarium culmorum* (Fattorusso et al. 1999).

Furostanol saponins isolated from garlic bulbs exhibited antimicrobial activity towards two fungal species, the airborne pathogen *Botrytis cinerea* and the antagonistic fungus *Trichoderma harzianum* (Lanzotti et al. 2012). Three furostanol saponins ceposide A–ceposide C exhibited antifungal activity (Lanzotti 2012). Saponin ceposide B

showed a significant growth inhibition of all fungi *Botrytis cinerea*, *Trichoderma atroviride*, *Trichoderma harzianum*, *Mucor* sp., *Alternaria alternata* and *Phomopsis* sp. with the exception of *Fusarium oxysporum* f. sp. *lycopersici*, *Sclerotium cepivorum* and *Rhizoctonia solani*. Ceposide B was the only one capable of inhibiting the growth of *Aspergillus niger*. Ceposides A and C were effective in reducing the growth of all fungi with the exception of *A. niger*, *S. cepivorum* and *Fusarium oxysporum* f. sp. *lycopersici*. Seven compounds isolated from garlic showed significant antifungal activity against *Trichoderma harzianum*, and only five compounds were effective against *Botrytis cinerea* (Lanzotti 2012; Lanzotti et al. 2012). In general, the isolated compounds showed the following rank of antifungal activity: spirostanol saponin 34 > spirostanol saponin 33 = voghieroside C > voghieroside B = the two eugenol glycosides > voghieroside A. The most promising compound appeared to be voghieroside C that showed a significant growth inhibition of both fungi. The root exudates from 10- to 60-day-old plants of garlic inhibited the germination of 3 crops (lettuce, rape and radish) and mycelial growth of 6 pathogens (*Pythium helicoide*, *P. irregular*, *P. ultimum*, *P. violae*, *P. heterothal* and *P. sylvati*) (Yuan et al. 2012). The inhibitory effects of root exudates were highest from the 30- and 40-day-old garlic plants. However, the hypocotyl growth of test crops was stimulated.

Recent studies indicated the polysulfides present in garlic to be with activity against free living nematodes that damaged carrot and parsnip crops and root-knot nematodes that damaged carrot and tomato crops (Anwar et al. 2009). Allicin, from garlic, at 25 ppm for 5 minutes as a root-dip treatment was effective against the nematode, *Meloidogyne incognita* (Gupta and Sharma 1993). Allicin reduced egg hatching and killed nematode juveniles. An aqueous garlic extract, salicylaldehyde; a nonylphenol ethoxylate surfactant; and a formulation containing these constituents exhibited in-vitro nematicidal effects against the potato cyst nematode, *Globodera pallida* (Danquah et al. 2011). The formulation caused 100 % mortality at 75.0 $\mu\text{L/L}$ with an LC_{50} of 43.6 $\mu\text{L/L}$ after 24 hours exposure. Salicylaldehyde was the most

toxic constituent of the formulation with an LC50 of 6.5 $\mu\text{L/L}$ after 24 hours, while the garlic extract achieved 50 % J2 mortality at 983.0 $\mu\text{L/L}$, demonstrating that the formulation and salicylaldehyde are more toxic to *G. pallida* in-vitro than oxamyl but less toxic when compared with aldicarb.

N-terminal fusion of the *Allium sativum* leaf agglutinin (ASAL) with SUMO (small ubiquitin-related modifier) peptide, SUMO-ASAL, may be a preferred candidate insecticidal protein for the development of transgenic plants Upadhyay et al. (2010).

A formulation consisting of 2 mL of aqueous garlic extract and 25 ppm Zn^{2+} afforded 70 % inhibition efficiency in corrosion inhibition of carbon steel immersed in well water (Rajam et al. 2013). Polarisation study revealed that this formulation controlled the anodic reaction predominantly. FTIR spectra revealed that the protective film consisted of Fe^{2+} –allicin complex and $\text{Zn}(\text{OH})$. An excellent glue made from garlic juice when spread on glass, it enables a person to cut clean holes in the glass (Chiej 1984). Garlic juice is also used as a glue in mending glass and china (Uphof 1968).

Garlic is also steeped in mysticism and mythology. In Europe, garlic is used for protection or white magic; in central Europe, garlic is regarded as a powerful deterrent against demons, werewolves and vampires (McNally 1994). To ward off vampires garlic could be worn, hung in windows or rubbed on chimneys and keyholes. In Buddhism, in the *Shurangama Sutra* (Mahayana school), Buddha explained how the ‘Five Pungent Spices’, including garlic and onions, were forbidden (Ohlsson 1998). ‘If these five are eaten cooked, they increase one’s sexual desire; if they are eaten raw, they increase one’s anger’. In Taoism, during the Tang dynasty, people attending the altar in the temple, looking on the dead or newly born, eating the five pungent foods (chives, scallions, onions, garlic and ginger) were forbidden (Pregadio 2008). These prohibitions could extend for 7, 14 or 49 days. In connection with the malodour associated with garlic, Islam views eating garlic and subsequently going to the mosque as inappropriate

and should not approach the mosque (Izutsu 1983). The prophet Muhammad dislikes the scent of garlic. The followers of the Krishna sect of Hinduism abstain from eating garlic, onion and mushroom which are deemed to have negative properties (Narayanan 2007).

Comments

Etoh and Simon (2002) summarised the current classification of the *Allium sativum* species based on the morphological, isoenzyme and molecular markers into four informal subspecies: the rather diverse longicuspis group including most garlic from Central Asia; the subtropical group which developed under the climatic conditions of South, Southeast and East Asia; the ophioscorodon group from Central and East Europe; and the Mediterranean sativum group. The sativum group, probably derived from longicuspis forms in West Asia more than 3,000 years ago, has been grown in the Mediterranean area since ancient times (Etoh and Simon 2002). It has spread from there throughout the world during the last 500 years (Maaß and Klaas 1995). However, the classification of sativum taxon is still ambiguous. Maaß and Klaas (1995) added that the *pekinense* subgroup comes from the east of Asia. Ovesna et al. (2011) found a correlation between the genetic basis of garlic clones as identified by AFLP and cysteine sulfoxide content across 135 genotypes. 286 informative AFLP fragments grouped 135 accessions in eight clusters, and two clusters contained only *A. sativum* L. var. *ophioscorodon* clones; four clusters grouped together both non-bolting and semi-bolting clones, whereas the remaining two contained only non-bolting types. These AFLP markers efficiently differentiated var. *ophioscorodon* from var. *sativum* clones.

arracacia Hook.

Family

Apiaceae

Common/English Names

Arracacha (common), Peruvian Carrot, Peruvian Parsnip,
White Carrot

Vernacular Names

Aymara: Lakachu, Lecachu

Bolivia: Arracacha (Quechua, Spanish), Lacache (Aymará), Racacham (Quechua)

Brazil: Batata–Apio, Batata-Baroa, Batata-Cenoura, Batata-Fiusa, Batata-Jujuba, Batata-Salsa, Batata-Suiça, Batata-Tupinambá, Cenoura Amarel, Mandioquinha-Sals, Pastinaca (Portuguese); Batata-Tupinambá (Tupi)

Chile: Lacache (Aymará)

Columbia: Arocueche (Muzo), Arracacha (Quechua, Spanish), Gaud, Huahué (Paez-Coconuco), Pacucarrá (Chocó Indians), Yengó (Kamsá), Zanahoria (Spanish), Sacarracach

Cuba: Afío, Arracacha

Ecuador: Arracacha (Quechua, Spanish), Zanahoria, Zanahoria Blanca (Spanish)

French: Arracacha, Panème, Pomme De Terre-Céleri

Latin America: Arrecate, Arecate (Spanish)

Peru: Arracacha (Quechua, Spanish), Zanahoria Blanca, Zanahoria Del Pais, Zanahoria Morada (Spanish), Huisampilla, Oqqe, Racacha, Ricacha, Virraca (Quechua)

Puerto Rico: Apio

Spanish: Arracacha, Racacha, Zanahoria Blanca, Apio Criollo, Sonarca

Venezuela: Aricachi (Ayoman), Apio, Apio Criollo (Spanish), Kiu-Tits (Timote), Arrecate, Arecate

Origin/Distribution

Although the genus *Arracacia* is particularly diverse in Mexico, the wild species most closely resembling arracacha are known from Peru and Ecuador (Hermann 1997). Today, arracacha is produced mainly in four countries – Brazil, Colombia, Ecuador and Venezuela.

Agroecology

Arracacha production areas in the Andes range over 32° of latitude from 10°N (Mérida, Venezuela) to 22°S (southern Bolivia), with marketed production coming mostly from north of the equator (Hermann 1997). It adapts to a wide range of mesothermic and tropical frost-free, montane environments as well as day length regimes.

The plant grows west of the Andes at altitudes varying from 600 to 3,600 m, but optimally between 1,800 and 2,500 m elevation. In Columbia, it is mainly grown in elevations of 1,800–2,500 m, Brazil 1,000–2,000 m, Peru 1,200–3,200 m, Ecuador 1,500–300 m, Bolivia 1,000–3,500 m and Venezuela 1,200–3,200 m. The plant flourishes in areas with temperatures of 14–21 °C and mean annual rainfall of 1,000–1,200 mm, although it will grow in areas with 600 mm rainfall. Arracacha is intolerant of frost and abhors temperatures above 25 °C. It thrives in deep, well-drained, fertile sandy soils rich in organic matter and with soil pH 5–6. It performs well in volcanic soils.

Arracacha is frequently intercropped with maize, beans and coffee or rotated with banana and plantains.

Edible Plant Parts and Uses

Arracacha starchy root (Plate 1) is popularly eaten as a food item in South America and also in some Central American countries (Hodge 1954; National Research Council 1975; Popenoe et al. 1989; Hermann 1997; Noguera and de Delahaye 2000; Garcia et al. 2007). The roots are eaten boiled or as an ingredient in soups and stews, side dishes, in dumplings, gnocchi (a kind of pasta), pastries, as purees, roasted and fried in slices or strips, biscuits and coarse flour.

Plate 1 Tuberous arracacha root

The roots are used in stews comprised of meat (beef, chicken or pork) and vegetables (potatoes, yucca, peas, lima beans, plantains, oca, ulucuo, mashua, chopped onion, tomato) and cheese. The stews are called *cocido* (in Columbia, Venezuela), *sancocho* (in Columbia), *chupe* (In Peru) and *locro* (in Peru, Ecuador). Variations of this dish include *viudo de pescado* from the Magdalena valley (Tolima, Colombia), in which fish replaces meat and pork, and the *mondongo* from Antioquia, a stew with arracacha, potatoes, sausages and beef tripe as the characteristic ingredients. In modern Brazilian cuisine, a dish called *Soufflé de mandioquinha-salsa* is made from cooked, hot, mashed arracacha with butter and egg yolks. Rio de Janeiro has contrived *batata baroa em calda* (arracacha

compote), comprising blanched arracacha pieces being cooked in dissolved sugar. In Minas Gerais, Brazil, descendants of Italian immigrants use arracacha instead of potato in the well-known gnocchi dish. Another common dessert dish is *pastels* in Ecuador or *buñuelos de apio* in Venezuela, this recipe comprised cooked and mashed arracacha roots mixed with butter, eggs and sugar into ball-shaped fritters and fried in oil. In Costa Rica, arracacha is finely chopped and fried with minced meat and onions as a filler in *tortillas de maiz*. Arracacha is also used as a filling for *picadillos*, a traditional Costa Rican dish served on patron saint's day. In Puerto Rico arracacha is used in *alcapurrius*, a deep-fried fritter whose dough comprised a mixture of purees from arracacha, glutinous plantain and starchy yautía (*Xanthosoma sagittifolium*) stuffed with meat fillings. Soups and purées having arracacha as their main starchy ingredient are deliciously creamy and light food and provide light nourishment for the sick and infants. In its processing plant in San José de Rio Pardo, São Paulo state, Nestle-Brazil uses arracacha as an ingredient in both wet and dry formulae of instant soups and baby food. Arracacha chips have been available for many years in Quito supermarkets. Arracacha starch is easily digestible and palatable and was widely used for pastry in Colombia during the first half of the nineteenth century. Arracacha starch has been used for making *bocadillos* (cookies) and small spongy cakes called *bizcochuelos*.

The leaves are prepared in the same way as celery in raw or cooked salads, hence the name 'Creole celery' which is given to it in Venezuela. The blanched tender, young stems are used for salad or as cooked greens.

Botany

A stout, caulescent, herbaceous plant, 0.5–1.2 m high, with a short, cylindrical, comose rootstock (10 cm long, 10 cm across) with marked horizontal ring markings. At maturity, from the basal part of the rootstock, two types of roots are produced: long, fine, filamentous roots and a ringlike cluster of slender tuberous and fusiform lateral roots, resembling parsnip, with lustrous off-white skin and white (blanca), yellow (tamarilla) or purple (morada) core. Arising from nodes of the crown (upper part of the rootstock) are a number of cylindrical stems or cormels with close ringlike markings giving rise to aerial branching shoots bearing leaves and inflorescences. Leaves resemble parsley leaves and have 8–45 cm long petioles with weakly developed basal sheath. Leaves are broadly ovate, 1–3 cm long and broad, biternate or bipinnate, the leaflets ovate–lanceolate to ovate, 4–12 cm long, 1.5–6.5 cm wide, acuminate, mucronate–serrate and coarsely incised or lobed, squamulose or scaberulous. The inflorescences are terminal, composite umbels with involucre bractlets and bearing small, actinomorphic and epigynous, flowers on 2–4 mm pedicels. Male (staminate) and bisexual flowers are similar except that the male flowers lack functional female organs. Bisexual flowers have five purplish-maroon oval petals, five stamens and a bicarpellate inferior ovary, each carpel with one ovule. The styles (three or four) emerge from an epigynous disc which functions as a nectary. The styles are basally enlarged to form the more or less conical stylopodium. Fruit oblong one-seeded achene, 10 mm long by 2–3 mm across, constricted below apex and has prominent ribs.

Nutritive/Medicinal Properties

Composition of arracacha per 100 g edible portion was reported as energy 103–105 cal, moisture 73–75 %, protein 0.11–0.9 %, fat 0.2–0.36%, carbohydrates 24.7–28.70 %, fibre 0.75–0.95 %, ash 1.2–1.4 %, K 2.1–2.4 mg, Ca 29.2–34.2 mg, P 45–55 mg, Mg 62.1–64 mg, Fe 8–10 mg, thiamine 0.1 mg, niacin 4.15–4.45 mg, vitamin A 1.75–1.77 mg and ascorbic acid 22–24 mg (ACNF 2009).

Matsuguma et al. (2009) reported the chemical composition of arracacha roots (range of two varieties at two production sites) as moisture 69.9–74.5 %, ash 4.23–4.85 %, protein 4.18–6.11 %, total carbohydrate 77.5–82.2 %, starch 77.5–82.2 %, lipid 0.61–1.39 % and fibre 9.17–10.9 %; arracacha starch as moisture 6.86–10 %, ash 0.05–0.31 %, protein 0.14–0.26 %, total carbohydrate 99–99.4 %, starch 97.6–98.7 %, lipid 0.39–0.42 % and fibre 0 %; and arracacha bagasse as moisture 6.25–7.8 %, ash 1.44–1.83 %, protein 1.83–2.52 %, total carbohydrate 75.3–81.8 %, starch 67.6–69.2 %, lipid 0.3–0.73 % and fibre 14–20.1 %. Carboxyl content of arracacha starches were w/w (wet weight basis) native 0.18–0.21 % and modified 0.29–0.34 %; reducing power mg Cu/g starch were native 23.5–49.4 mg and modified 47.4–73.4 mg; swelling power of starch 14.5–21 times at 65 °C, 18.9–26.5 times at 75 °C and 35.4–56.9 times at 85 °C; solubility of starch 9.6–10.4 % at 65 °C, 16.9–30.1 % at 75 °C and 39.2–82.8 % at 85 °C (Matsuguma et al. 2009). The carboxyl content, the reducing power and the amount of the water liberated from the pastes after freeze-thawing were higher for the oxidised starches, and their pastes were clearer than those of the native starches of the two varieties from the two production areas. All the oxidised samples had lower pasting temperatures (from 57.2 to 61.9 °C) than their respective native counterparts (from 59.1 to 62.5 °C). In the thermal analysis, the temperatures of the pyrolysis were higher for the native than for the modified starches. The native starches in all the solvents had higher tendency to retrogradation (from 40 to 72 RVU) than the modified ones

(0.7–21 RVU). For the soups, they suggested that low viscosity starches should be preferred, but for the use as the gelling agent in the pie filling, a high viscosity would be desired for preventing the spilling during the transportation. Native starch was found to have 38.2–47.1 % paste clarity and modified starch 86–96.5 paste clarity. Higher amylose contents produced opaque pastes, and lower contents produced clear, transparent pastes. More opaque pastes like arracacha native starch would be desired for foods like puddings and ready-to-eat desserts. The modified starches, on the other hand, produced the transparent pastes and could be used on the pie fillings, for example.

Arracacha starch granules were irregular-shaped with granular sizes between 7 and 23 μm , amylose content of 4 %, amylopectin with average chain length of 22.6 and β -amylolysis limit of 56.6 %, B-type X-ray diffraction pattern, gelatinisation enthalpy of 17.6 J/g and peak temperature of the endothermic DSC (differential scanning calorimetry) transition was 60.1 °C (Santacruz et al. 2002). A decrease in pH from 6.5 to 4.0 resulted in a reduction of the elastic modulus for arracacha starch. Storage of arracacha starch gels at 4 °C showed that *A. xanthorrhiza* formed gels which were stable in elastic modulus and phase angle for 3 days of storage (Santacruz et al. 2003). Storage at freezing temperature (−20 °C) produced higher changes in elastic modulus than refrigeration conditions. Arracacha carrot starch presented round and irregular-shaped granules, low amylose content and B-type X-ray diffraction pattern (Rocha et al. 2011). Amylopectin of this starch contained a large proportion of long degree of polymerisation ($\text{DP} > 37$) and short ($\text{DP} 6\text{--}12$)-branched chains. Arracacha starch had structural characteristics that differed from those of cassava and potato starches. Annealing affected the semicrystalline structure of this starch, enhancing its crystallinity, mainly due to a better interaction between amylopectin chains. Pérez et al. (1999) reported arracacha starch granules to be spherical or truncated egg-shaped, ranging from 4 to 26 μm in diameter. The starch was similar in gross chemical composition and basic physical to cassava starch but differed in pasting properties, with arracacha starch showing lower breakdown and consistency

indices. The two starches also showed different water absorption and solubility patterns.

Arracacha flour formulation of 60 % flour was found to contain high levels of protein (10.07 %), carbohydrates (58.3 %), fat (10.07 %) and dietary fibre (8.53 %, resistant starch 2.3–2.38 %) as well as minerals P, Ca, Fe and Mg (García et al. 2007). Stability analysis during 90 days at room temperature showed that the low moisture content (5.75 %) and water activity maintained functional characteristics of high water absorption, solubility and starch swelling power. In-vitro digestibility was high (79.2 %) showing easy digestion as soup. The results suggested arracacha flour to be a good ingredient for soup-type products with high nutritional and energy properties.

Boiling at 99.5 °C for 20 minutes was found to be the best method to cook arracacha root due to a high retention of total phenolics (TP), total carotenoids (TC) and in-vitro antioxidant capacity (AC) in comparison to oven cooking at 200 °C for 45 minutes and microwave cooking at 800 W for 5 minutes (Pedreschi et al. 2011). During boiling, chlorogenic and caffeic acids and derivatives remained relatively stable. The drying temperature was negatively correlated to the residual content of TP and AC for the yellow and cream arracacha roots, but for the cream/purple arracacha variety, blanching preserved the TP and AC. Significant losses in chlorogenic and caffeic acids and derivatives were mainly observed during hot-air drying.

Chemical composition (g/100 g) of arracacha root chips was reported as: moisture 2.87–3.97, fat 17.38–23.91, ash 2.38–2.96, dietary fibre 6.38–8.26, raw protein 2.40–3.27, starch 30.51–40.40, total sugar 4.83–11.53 and reduced sugar 1.65–3.27 (Noguera and de Delahaye 2000). Results of the sensorial evaluation indicated that chips prepared in sunflower oil without blanching have the best overall quality. During storage, significant differences were found for texture. It was concluded that arracacha chips not blanched and fried in sunflower oil exhibited the highest nutritional quality, due to the lower fat content and superior sensorial rating.

Arracacha roots obtained from plants grown without the addition of poultry litter to the soil and bleached after harvest were the ones that best maintained their chemical characteristics, for a period of 5 months of storage at -18°C (De M Buso et al. 2014). Total titratable acidity, pH, β -1, 3-glucanase activity in roots were neither significantly influenced by the cultivation with poultry litter nor by the treatments for storage. The content of peroxidase was not influenced by the addition of poultry litter, while the content of soluble solids, phenolic compounds and the activity of catalase were not influenced by storage treatments. Carotenoid content was significantly influenced by the addition of poultry litter to the soil and by the postharvest treatment of arracacha roots; it was also influenced by the interaction postharvest treatment/months after harvest and by the interaction poultry litter addition/months after harvest. The highest carotenoid contents were found in roots of plants grown in soil with cover litter and with cover + incorporated litter, followed by a postharvest treatment with bleaching. Buds used for sprouting obtained from plants cultivated in soil with cover litter and treated with chitosan + lemongrass essential oil after harvest maintained their chemical quality for a period of 3 months of storage at 5°C .

Other Uses

The stump or crown of the roots is used as cattle feed. Fresh stem and leaves are used as animal fodder, while the dried leaves can be used to prepare meal used also as animal feed.

Studies by Medina et al. (2012) reported that arracacha native starch could be acetylated or oxidised to produce biodegradable films for packaging food such as meat and vegetables. Native starch films had lower water solubility and greater stability in acid and alkaline conditions.

Comments

Arracacha is vegetatively propagated using offsets (*colinos*) or shoots produced on the crown of the main rootstock (*cepa*).

Turkish: Kerevic

Vietnamese: Củ

Welsh: Seleriac

Origin/Distribution

Celeriac originated probably in the middle of the sixteenth century in Italy. It is mainly cultivated in Central and Eastern Europe and the Netherlands.

Agroecology

Celeriac is adapted to a temperate climatic regime with monthly mean temperatures of 15–21 °C; the roots is hardy to about –12 °C and can be left in the ground over winter to be harvested as required. The crop thrives best in a moist, rich, friable soil with pH of 5.2–8.3 in open, full sun position. It requires abundant moisture in the growing season; otherwise, the root will be small and tough.

Edible Plant Parts and Uses

Celeriac is a versatile vegetable and can be used both cooked and raw in salads. It is often used as a flavouring in soups, stews and casseroles, but can also be mashed or baked. Mashed celeriac is best when combined with another root vegetable like potatoes to create a smoother mash consistency. One classic dish is celeriac remoulade, where the vegetable is grated or cut into small pieces and served with a mustard mayonnaise. It is also used raw in salads, grated and often tossed with creamy salad dressings. Celeriac combines well with meats such as duck, pork and lamb and herbs such as bay leaves and thyme. Celeriac is also processed for canning, freezing and dehydration. The leaves can also be used as flavouring in soups or eaten raw but have a very strong flavour. The leaves can be dried for flavouring salt. The seed or its essential oil is also used as flavouring agents.

Botany

A deciduous, erect, herbaceous biennial growing to 1 m high by 0.5 m wide with a crown of rosulate celery like pinnate leaves with rhombic leaflets and hollow stalks (Plate 1). The edible portion is the swollen, knobby, rounded to odd shape, 7–12 cm across that is derived from the hypocotyl and part of the tap root and stem beneath the soil surface (Plates 2 and 3). The flesh is creamy white and firm. The flowers are creamy white, 2–3 mm diameter, produced in dense compound umbels. The seeds are broad ovoid to globose, 1.5–2 mm long and wide.

Plate 3 Odd-shaped, grotesque celeriac

Nutritive/Medicinal Properties

Proximate nutrient composition of celeriac per 100 g edible portion (USDA, ARS 2014) was reported as water 88 g, energy kcal 42 (176 kj), protein 1.5 g, total fat 0.3 g, ash 1 g, carbohydrate 9.2 g, total dietary fibre 1.8 g, total sugars 1.6 g, Ca 43 mg, Fe 0.7 mg, Mg 20 mg, P 115 mg, K 300 mg, Na 100 mg, Zn 0.33 mg, Cu 0.07 mg, Mn 0.158 mg, Se 0.7 µg, vitamin C 8 mg, thiamine 0.05 mg, riboflavin 0.06 mg, niacin 0.7 mg, pantothenic acid 0.352 mg, vitamin B 6 0.165 mg, total folate 8 µg, choline 9 mg, vitamin E (α-tocopherol) 0.36 mg, vitamin K (phylloquinone) 41 µg, total saturated fatty acids 0.079 g, 14:0 (myristic acid) 0.002 g, 16:0 (palmitic acid) 0.069 g, 18:0 (stearic acid) 0.006 g, total monounsaturated fatty acids 0.058 g, 16:1 undifferentiated (palmitoleic acid) 0.002 g, 18:1 undifferentiated (oleic acid) 0.065 g, total polyunsaturated fatty acids 0.148 g, 18:2 undifferentiated (linoleic acid) 0.148 g and lutein + zeaxanthin 1 µg. Celeriac had been reported to contain 2.4 mg/100 g apigenin and 0.18 mg/100 g quercetin (Lugasi and Hovari et al. 2000).

Two polyacetylenes – falcarinol and falcarindiol – were identified in Polish celeriac varieties (Jablonska-Rys 2007). The largest amount of falcarinol was found in Makar and Jablkowy celeriac variety, 25.34 and 22.37 mg/100 g dry mass, respectively. Odrzanski and Luna varieties contained the highest amount of falcarindiol 10.13 and 12.55 mg/100 g of dry mass, respectively. Bioactive polyacetylene compounds had been considered to contribute substantially to the beneficial properties of Apiaceae plants including celeriac (Roman et al. 2011). Heterogeneous and tissue-specific occurrence of total and individual polyacetylenes in celeriac roots was shown in Raman maps.

Root and petiole tissues of celery and celeriac accessions were shown to contain linear furanocoumarins (LFCs) when infected with the root fungus *Fusarium oxysporum* f. sp. *apii*. LFC levels were low (<5 ppm) in young celery and celeriac roots 7 weeks postinoculation, but levels as high as 50 ppm

were detected in severely rotted celery root and crown tissues of mature 5270R plants (Heath-Pagliuso et al. 1992). The amounts of furocoumarins varied within the batches of celeriac, the sum of the phototoxic furocoumarins being 2.1–4.5 mg/kg (on a fresh weight basis) (Järvenpää et al. 1997). However, the yields obtained by supercritical fluid extraction (SFE) were in agreement with those from Soxhlet extraction. Peroutka et al. (2007) found celeriac to contain only linear furanocoumarins, namely, bergapten (70–3,150 µg/100 g FW), xanthotoxin (40–2,200 µg/g FW), isopimpinellin (140–1,260 µg/100 g FW) and psoralen (10–1,050 µg/100 g FW). Studies by Schulzova et al. (2008) found in all analysed celeriac samples the presence of linear furanocoumarins psoralen, bergapten, xanthotoxin and isopimpinellin; none of angular furanocoumarins (angelicin, sphondin, isobergapten) or linear trioxsalen was detected. The total furanocoumarins content was relatively low; the average levels of furanocoumarins determined in hardy fresh celeriac roots were 8.8 mg/kg, ranging from 1.7 to 23.5 mg/kg. Content of targeted toxicants was relatively low and obviously does not present health risk for consumers. Schulzová et al. (2012) reported that the average contents of furanocoumarins (psoralen, bergapten, xanthotoxin and isopimpinellin) for all 3 years in Polish celeriac varieties Albin and Kompakt were 2.6 mg/kg and 10.2 mg/kg, respectively. In all crop years, higher levels were found in the variety Kompakt.

Studies by Radziejewska-Kubzdela et al. (2014) found that modified atmosphere packaging of shredded celeriac not subjected to washing or soaking pretreatment made it possible to obtain a product with good sensory and microbiological quality and the highest content of phenolic compounds. The applied pretreatment consisting of washing or soaking of shredded celeriac in water resulted in decreases in 8-methoxypsoralen content by approximately 50 and 70 %, respectively, and phenolic content by 30 % compared with samples that were not subjected to pretreatment. During storage of shredded celeriac, a further significant reduction in phenolic compounds and an approximately 2.5-fold increase in the total content of furanocoumarins were found. The level of

furanocoumarins recorded in the tested product posed no health hazard.

Kaiser et al. (2013) identified and quantified 14 phenolic compounds in celeriac (mg/100 g DM): caffeoyl hexose A (6.5 mg), ferulic acid derivative (2.7 mg), caffeoyl hexose B (1.2 mg), quinic acid derivative 10.1 mg, caffeoyl hexose C (tr), caffeic acid derivative 59.4 mg, apiin 180.7 mg, diosmetin-apiosylglucoside/chrysoeriol-apiosylglucoside A (tr), diosmetin-apiosylglucoside/chrysoeriol-apiosylglucoside B (74.7 mg), malonylapiin A (13.4 mg), diosmetin-acetylapiosylglucoside/chrysoeriol-apiosylglucoside A (6 mg), malonylapiin B (21 mg), diosmetin-malonylapiosylglucoside/chrysoeriol-malonylapiosylglucoside (7.7 mg) and total phenolics 386 mg. Individual phenolic compounds were differently affected upon heat treatment. The contents of the main phenolic compound apiin decreased upon heat treatment, whereas the levels of the minor compounds malonylapiin A and B increased. Thermal treatment strongly affected peroxidase and polyphenol oxidase activities of celeriac; enzyme activities decreased with increasing temperature and heating time. Only by extended steam and water blanching at 100 °C, respectively, complete inactivation of peroxidase and polyphenol oxidase was achieved. The obtained celeriac products were characterised by their bright white colour. Consequently, blanching was recommended as the initial operation in the processing of celeriac into novel pasty products.

In carrots, celeriac, scorzoneras and horseradish caffeic acid was found to dominate after hydrolysis (Stöhr and Herrmann 1975). The contents of phenolic acids in the roots were much smaller than in the corresponding leaves. A mannitol–mannose 1-oxidoreductase was isolated from celeriac root tips (Stoop and Pharr 1992). This enzyme catalysed the NAD-dependent oxidation of mannitol to mannose, not mannitol to fructose. The enzyme was strongly inhibited by NADH and sensitive to alterations of NAD/NADH ratio.

Aliphatic C(17)-polyacetylenes of the falcarinol type, which occur in common food plants of the Apiaceae family

such as carrot, celeriac, parsnip and parsley, had demonstrated interesting bioactivities including antibacterial, antimycobacterial and antifungal activity as well as anti-inflammatory antiplatelet-aggregatory, neuritogenic and serotonergic effects (Christensen 2011). In addition, the cytotoxicity of falcarinol-type polyacetylenes towards human cancer cells, bioavailability and their potential anticancer effect in-vivo indicated that these compounds may contribute to the health effects of certain vegetables and hence could be important nutraceuticals. Their possible health-promoting effects and recent patents on bioactivity of falcarinol-type polyacetylenes and inventions were also reviewed.

Antioxidant Activity

Upon thermal treatment, the antioxidant capacities (TEAC assay) and the total phenolic contents (TPC) of celeriac remained virtually unchanged (Kaiser et al. 2013). The TPC in unheated celeriac determined amounted to 123.4 mg GAE/100 g DM. The antioxidant capacities of heated samples determined by the FRAP assay were even higher than those of the unheated control. Steam blanching of celeriac resulted in an increase in the antioxidant capacities, while upon water blanching, the values decreased with increasing blanching time.

Anticancer Activity

Zidorn et al. (2005) tested polyacetylenes isolated from celery against leukaemia, lymphoma and myeloma cell lines. All four polyacetylenes showed at least moderate toxicity to all cell lines, with falcarinol proving to be the most active compound with a pronounced cytotoxicity against acute lymphoblastic leukaemia cell line CEM-C7H2, with an IC_{50} of 3.5 μ mol/colorectal cancer cells appeared to be less susceptible than other cell lines in their study. Studies by Kang et al. (2011) found that even if present at low levels in apiaceous vegetables, imperatorin, trioxsalen and isopimpinellin may contribute significantly to cytochrome P450 1A2 (CYP1A2) inhibition and potentially decreased procarcinogen activation.

Moreover, the in-vivo effect of isopimpinellin on CYP1A2 may be longer lasting compared to reversible inhibitors.

The polyacetylene falcarinol had been shown to be protective against chemically induced colon cancer development in rats; it was found to have a biphasic effect upon CaCo-2 cells, with pro-proliferative effects at low doses and antiproliferative (apoptosis-inducing) effects at high doses (Young et al. 2007). In another study, Young et al. (2008) reported on the biphasic responses of bioactive polyacetylenes, falcarinol and falcarindiol, present in carrots, celery, celeriac and other umbelliferous vegetables, on the stress responses in primary myotube cultures. Preincubation with low concentrations of both polyacetylenes prior to H₂O₂ exposure induced a cytoprotective effect, whereas higher concentrations had adverse effects. Earlier, Hansen et al. (2003) similarly reported biphasic activity of falcarinol in primary mammary epithelial cells, exerting stimulatory effects between 0.01 and 0.05 µg/ml and inhibitory effects between 1 and 10 µg/ml.

Anti-inflammatory Activity

Ethyl acetate extracts of celeriac-containing polyacetylenes inhibited proinflammatory cyclooxygenases (Cox-1 and Cox-2) at IC₅₀ concentrations of 0.26 and 0.06 mg/mL, respectively (Metzger et al. 2013). Supercritical fluid extraction of dried celeriac root offered potential as an industrial scale enrichment process of anti-inflammatory polyacetylenes. The dried feed stock contained 4.5x's the amount of polyacetylenes compared to purple carrots. Optimal extraction conditions were low temperature (40 °C), high pressure (500 bar) and high ethanol co-solvent (20 % w/w). Pressure was more important for extraction of falcarinol and falcarindiol than temperature. Under optimal extraction conditions, 1.7 % of the starting dry weight or 47 % of the total lipids were extracted, and up to 43 % of falcarindiol was obtained compared to exhaustive ethyl acetate extraction.

Antisteoporotic Activity

Mühlbauer et al. (2003) found that feeding rats 1 g/day of celeriac and 24 other items tested out of a total of 53 exhibited a protective effect against osteoporosis by significantly inhibiting bone resorption.

Immunomodulatory Activity

In a study of Apiaceous vegetables, at non-cytotoxic concentration, its related coumarins and flavonoids exhibited three types of immunomodulation including type 1 of phytohaemagglutinin (PHA), ConA and quercetin (increased lymphocyte activation and IFN- γ (interferon- γ) secretion); type 2 of isopimpinellin (enhanced lymphocyte activation) and type 3 of rutin, bergapten and xanthotoxin (elevated IFN- γ secretion) (Cherng et al. 2008). The augmentation of lymphocyte proliferation was closely correlated to an increase in the number of lymphocyte cells including CD8⁺ T cells and activated peripheral blood mononuclear cells, whereas elevation of IFN- γ secretion was due to the activated CD8⁺ T cells.

Allergy Problem

Occupational dermatitis from celeriac had been reported by Agathos (1980). The birch pollen allergen (Bet v 1)-homologous food allergen Api G1 was isolated and cloned from celeriac (Hoffmann-Sommergruber et al. 1996). Immunoblotting with sera from 22 patients with a positive double-blind placebo-controlled food challenge (DBPCFC) to celeriac confirmed the presence of known allergenic structures (Lüttkopf et al. 2000). The major allergen Api g 1 (16 kDa) was recognised by IgE from 13 of 22 patients (59 %). Another major allergen was CCD determined by IgE reactivity in 12 of 22 patients (55 %). Celery profilin, Api g 4, was recognised by IgE from 5 of 22 patients (23 %). Inhibition experiments with a purified carbohydrate moiety clearly showed that the IgE epitope mannose-xylose-fucose-glycan (Man α 1-6[Xyl β 1-2]Man β 1-4GlcNAc β 1-4[Fuc α 1-3]GlcNAc) or a closely related structure was present in

celeriac extract and was important in patients with clinical allergy to celery.

Bohle et al. (2003) found that humoral as well as cellular reactivity to the major celery/celeriac allergen Api g 1 was predominantly based on cross-reactivity with the major birch pollen allergen. The activation of Bet v 1-specific Th2 cells by Api g 1 may have consequences for birch pollen-allergic individuals. The nonoccupational sensitisation resulting from both direct and systemic contact with Apiaceae root vegetables (celeriac, parsnip and carrot) was apparently not caused by falcarinol (Paulsen et al. 2014). Twenty-four subjects with a positive double-blind, placebo-controlled food challenge result to celeriac, 20 atopic control subjects with birch pollen allergy who tolerated celeriac and 20 non-atopic subjects were enrolled in a study by Bauermeister et al. (2009). Component-resolved diagnosis allowed an increase in diagnostic sensitivity from 67 % to 88 % compared with extract-based diagnosis. Sensitisation to Api g 5 was attributable to its glycan moieties but did not interfere with diagnostic specificity. Husband et al. (2011) found the combination of high pressure and thermal processing to be an effective method to reduce the allergenicity of both apple and celeriac.

Other Uses

The growing plant has been reported to have insect repellent property; it repels the cabbage white butterfly so it is a good companion for tomatoes, *Allium* and *Brassica* vegetables (Riotte 1998).

Comments

Celeriac is readily propagated from seeds.

Origin/Distribution

The cultivated carrot is domesticated from the wild carrot *Daucus carota* that is native to Europe and southwestern Asia. The domestic carrot has been selectively bred for its greatly enlarged and more palatable, less woody textured edible taproot. Asia Minor (eastern Turkey) and the inner Asiatic regions were identified by Vavilov (1926) as the centres of origin of cultivated carrot with Central Asia (Kazakhstan, Kyrgyzstan, Tajikistan, Turkmenistan, Uzbekistan) as the basic centre of Asiatic kinds of cultivated carrots. The cultivated carrot is thought to originate from Afghanistan before the 900s, as this area is described as the primary centre of greatest carrot diversity (Mackevic 1929), Turkey being proposed as a secondary centre of origin (Banga 1963). On the basis of historical data, the first domesticated carrot roots were purple and yellow and recorded in Central Asia, Asia Minor, then in Western Europe and finally in England between the eleventh and fifteenth centuries (Banga 1963). Orange carrots were only documented in the fifteenth and sixteenth centuries in Europe suggesting that orange carotenoid accumulation may have resulted from a secondary domestication event (Banga 1957). White- and orange-coloured carrots were first described in Western Europe in the early seventeenth century (Banga 1963). Concomitantly, the Asiatic carrot was developed from the Afghan type, and a red type appeared in China and India around the eighteenth century (Laufer 1919; Shinohara 1984).

Analysis of allelic diversity of single nucleotide polymorphism (SNPs) data and in conjunction with historical data suggested an origin of domesticated carrot in Central Asia (Iorizzo et al. 2013). Among the wild carrots, those from Central Asia were genetically most similar to cultivated accessions. Furthermore, they found that wild carrots from North America were most closely related to European wild accessions.

Agroecology

Carrots are mostly cultivated as a cool season, temperate biennial crop with optimal growth between 15 and 18 °C, with a minimum of 7 °C and a maximum of 23 °C. Carrots can be grown in the tropics at high altitudes above 1,200 m or during the cool winter months in the subtropics. Production of the enlarged hypocotyl occurs most significantly when cool nights slow the plant respiration, allowing for an accumulation of carbohydrates. High soil temperatures, in excess of 25 °C, induce slow growth rates, fibrous roots and low carotene. Vernalisation of the plant at temperatures below 10 °C for several weeks initiates flower development and reduces carbohydrate accumulation in the hypocotyls.

Carrots flourish in well-drained, deep, friable, fertile soils. Muck and sandy loams are highly desired for carrot production. Optimum pH is 6.0–6.5. A regular supply of water is essential to obtain smooth and uniform roots.

Edible Plant Parts and Uses

Carrots are grown primarily for fresh consumption as julienne in salads, hors d'oeuvres, and as snacks and meal accompaniments. They are used in the preparation of soups, stews, stir fries, sauces, juices, curries and pies, and tender roots may be pickled. Grated carrots are used in carrot cakes, as well as carrot puddings, in jams and preserves with fruits. Carrot juice is also widely marketed, especially as a nutritious health drink, either stand-alone or blended with fruits and other vegetables such as celery. Carrots are puréed and used as baby food; dehydrated to make chips, flakes and powder; and thinly sliced and deep-fried, like potato chips.

Carotene is extracted from the root and used to colour margarines and is added to hen feed to modify egg yolk colour. Essential oil extracted from the seed is used for flavouring. Concentrated carrot protein containing 15.4 % (w/w) carrot antifreeze protein was found to have strong anti-recrystallisation ability and textural properties for potential uses in the food industry (Zhang et al. 2007, 2008). The application of carrot concentrated protein in frozen dough was proved to be a promising improver/additive for frozen dough fermentation.

Carrot leaves are also edible as leaf vegetable but are only occasionally eaten by humans.

Botany

Annual or biennial erect herb up to 50 cm tall at the mature vegetative stage and up to 120 cm tall when flowering, with hispid, branched stems; taproot swollen, fleshy, straight, conical to cylindrical, 5–50 cm long and 2–5 cm in diameter at top, orange (most common), reddish violet, yellow or white (Plates 2, 3, 4, 5, 6 and 7). Leaves rosulate at base of the plant, triangular–ovate in outline, 22 cm long by 20 cm wide, cauline leaves, 26–30 cm long by 14–20 cm wide, alternating on flowering stems, 2–3 pinnate; exstipulate; petiole long, sheathed at base, petiole and rachis hispid; segments divided into oblong–lanceolate or linear–acute ultimate lobes, lacy in appearance (Plate 1). Upper cauline leaves are smaller and less divided. Inflorescence a terminal, compound umbel (Plate 2) with numerous unequal rays, subglobose when in fruit; involucrel foliaceous bracts 7–13, pinnatipartite or pinnatisect, with linear lobes. Flowers mainly bisexual, but male flowers also present, often one – few dark purple sterile flowers present in the centre of the umbel, 2 mm across, 5-merous; pedicel 0.5–1.5 cm long; calyx with small teeth or absent; petals free, suborbicular–ovate, white, sometimes yellow or pinkish; stamens five, free, twice as long as petals; ovary inferior, subglobose to oblong, bristly hairy, 2-celled, styles 2. Fruit an oblong–ovoid to oblong–ellipsoid schizocarp 2–4 mm long, at maturity splitting into two 1-seeded mericarps, primary ridges ciliate, secondary ridges with hooked spines.

Nutritive/Medicinal Properties

Root Nutrients/Phytochemicals

The proximate nutrient composition per 100 g edible portion of raw carrot was reported as: water 88.29 g; energy 41 kcal (173 kJ); protein 0.93 g; total lipid 0.24 g; ash 0.97 g; carbohydrate 9.58 g; total dietary fibre 2.8 g; total sugars 4.74 g; sucrose 3.59 g; glucose 0.59 g; fructose 0.55 g; starch 1.43 g; minerals, Ca 33 mg, Fe 0.30 mg, Mg 12 mg, P 35 mg, K 320 mg, Na 69 mg, Zn 0.24 mg, Cu 0.045 mg, Mn 0.143 mg, F 3.2 mg and Se 0.1 µg; vitamins, vitamin C 5.9 mg, thiamine 0.066 mg, riboflavin 0.058 mg, niacin 0.983 mg, pantothenic acid 0.273 mg, vitamin B6 0.138 mg, total folate 19 µg, total choline 8.8 mg, betaine 0.4 mg, vitamin A 16706 IU, vitamin A 835 µg RAE, vitamin K (phylloquinone) 13.2 µg, vitamin E (α-tocopherol) 0.66 mg, β-tocopherol 0.01 mg, β-carotene 8,285 µg, α-carotene 3,477 µg, lycopene 1 µg and lutein +zeaxanthin 256 µg; total saturated fatty acids 0.037 g; 16:0 (palmitic acid) 0.035 g; 18:0 (stearic acid) 0.002 g; total monounsaturated fatty acids 0.014 g; 16:1 undifferentiated (palmitoleic acid) 0.002 g; 18:1 undifferentiated (oleic acid) 0.012 g; total polyunsaturated fatty acids 0.117 g; 18:2 undifferentiated (linoleic acid) 0.115 g; 18:3 undifferentiated (linolenic acid) 0.002 g; and amino acids, tryptophan 0.012 g, threonine 0.191 g, isoleucine 0.077 g, leucine 0.102 g, lysine 0.101 g, methionine 0.020 g, cystine 0.083 g, phenylalanine 0.061 g, tyrosine 0.043 g, valine 0.069 g, arginine 0.091 g, histidine 0.040 g, alanine 0.113 g, aspartic acid 0.190 g, glutamic acid 0.366 g, glycine 0.047 g, proline 0.054 g and serine 0.054 g (USDA, ARS 2014). The following minor carbohydrates were found in carrot: *scyllo*-inositol (1.5–5.8 mg/g DW), sedoheptulose (D-*altro*-2-heptulose) (1.4–24.6 mg/g DW), *myo*-inositol (2.2–9.8 mg/g) and mannitol (traces 1.3 mg/g) (Soria et al. 2009). Lipids extracted from carrot roots were found to contain phosphatidylethanolamine and phosphatidylcholine occurring as eight and seven molecular species, respectively (Gregor 1977).

Phan and Hsu (1973) found that concomitant with the elongation and the thickening of carrot root, there was an active synthesis of sugars, mainly sucrose, and carotenes, mainly β -carotene. The amounts of both groups peaked at the end of the third month after seeding and then plateaued. Roots contained 452.87 meq/100 g fw total phenols, 2.17 meq/100 g fw amino acids, 1.528 meq/100 g fw titratable acidity and 9.222 meq/100 g fw total acidity. Organic and amino acids increased slowly with age from rather low levels. In the 150 g FW root development stage, pyruvic acid (45.3 %) was most abundant, followed by isocitric (29.2 %) and malic (13.1 %) acids; other organic acids present were succinic (7.1 %), oxaloacetic (7.1 %), fumaric (1.7 %), citric (1.5 %) and glyoxylic (0.1 %). Phenolic compounds, abundant in the very young root, decreased rapidly during the first 3 months, then remained more or less constant up to harvest date. Carrots were found to contain malic, citric, succinic, fumaric, quinic and tartaric acids (Ruhl and Herrmann 1985). Depending on variety, growing stage and other factors, the total amount of organic acids in carrots is about 2,000–3,000 mg/kg (Vilisek 2013). After harvest isocitric and malic acids represent about 90–95 % of the total acids. The total content of isocitric and malic acids is approximately 1,000 mg/kg and 80 mg/kg, respectively. Tartaric acid (18–55 mg/kg), succinic acid (22–130 mg/kg), fumaric acid (5–8 mg/kg), quinic acid (42–60 mg/kg) and oxalic acids (100 mg/kg) were found in smaller quantities as were other acids in lower amounts. Nilsson (1987) found that sowing date had no influence on the concentration of sucrose, phosphorus, potassium, calcium and magnesium in carrot root dry matter up to 137 days from sowing. Carotene decreased only after the last sowing. Sucrose concentration of the roots increased throughout the periods studied irrespective of the time of sowing. The longer the growing period, the higher was the sucrose concentration. The concentration of hexoses decreased from the first harvest at 70 days to reach a constant level at about 130 days from sowing. Suojala (2000) found that the latter the harvest of carrots, the higher the content of soluble sugars, especially sucrose, tended to be. Total sugar and sucrose contents at the beginning of the harvest period were higher in the colder year than in the

warmer year. The general pattern of increasing hexose and decreasing sucrose contents during storage was observed.

Carrot roots were reported to contain carotin and hydrocarotin (Husemann (1861). Six carotenes α -carotene, β -carotene, γ -carotene, ζ -carotene, β -zeacarotene and lycopene were detected in dark orange carrots (Simon and Wolff 1987). β -carotene accounted for 44–79 % of total carotenes, while β -, α - and ζ -carotenes comprised 94–97 % of total carotenes. Total carotene ranged from 63 to 548 ppm across lines and location/years. Carrots and other horticultural crops as a source of provitamin A carotenes provide a relatively inexpensive and readily sustainable approach to alleviate world vitamin A deficiency (Simon 1990).

Four major carotenoids were detected from coloured cultivars (yellow, purple or orange): lutein, α -carotene, β -carotene and its isomer 13*cis* β -carotene (Nicolle et al. 2004b). Yellow and purple varieties contained only lutein and β -carotene, whereas no carotenoids could be detected in white cultivars. The predominant carotenoid in all samples was β -carotene accounting for 43–71 % of the total carotenoids and α -carotene accounting for 17–22 % of total carotenoids. Lutein represented 29–41 % of the total carotenoids in yellow and purple carrots but a smaller portion (0.4–2.7 %) in other cultivars. Carotenoid levels in purple and yellow carrots varied from 469 to 605 $\mu\text{g}/100\text{ g}$, whereas ten times more carotenoids were found in orange carrots. The dark orange cultivar contained the highest amount of carotenoids, especially β -carotene (17 mg/100 g), whereas the purple cultivar was the poorest in β -carotene (0.32 mg/100 g) together with white cultivars. One yellow, one purple and one dark orange cultivars contained more than 600 $\mu\text{g}/100\text{ g}$ of fresh weight vitamin E, while three others (one white cultivar and two orange cultivars) contained very low amount of α -tocopherol; their content was twofold lower than values given by food composition table. Vitamin C content varied from 1.44 to 5.75 mg/100 g in all 20 carrot varieties. The ascorbic acid content was much greater in the dark orange (four times), yellow (3.7 times) or white (3.4 times) cultivars than in orange carrots. Mean mineral content (mg/100 g fw) in all 20 cultivars was

579 mg K, Na 26.6 mg, Mg 12.1 mg, Ca 35.1 mg, Fe 0.79 mg and Zn 0.25 mg. According to Arscott and Tanumihardjo (2010), carrot varieties have undergone phenotypic recurrent selection (biofortification) to improve the profile of compounds such as augmenting provitamin content by >40 %. The most novel carrot produced to date is an orange–purple–red variety that not only contains provitamin A activity as α - and β -carotene but also contains anthocyanins and the nonprovitamin A carotenoid lycopene, of which both are potent antioxidants. Also, carrot contained phenolic constituents with a single aromatic ring (phenolic acids), mainly chlorogenic acid as potent antioxidants. Biofortified carrots of many colours not only provide vitamin A but may contribute to optimal health and utilise as a functional food.

Four major carotenoids were identified in five different coloured carrots (Surles et al. 2004). High β -carotene orange carrots were found to contain the greatest concentration of total carotenoids. Except for the white, all the carrots are a significant source of bioavailable carotenoids. Sensory evaluation showed the high β -carotene orange and white carrots to be favoured over the yellow, red, and purple carrots in both blind and non-blind treatments.

Total carotenoids (sum of lutein, lycopene, α -carotene and β -carotene) in $\mu\text{g/g}$ DW was highest in dark orange carrot (1334.7 μg), followed by typical orange (816.3 μg), red (610 μg), purple orange (334.2 μg) and purple yellow (9,771 μg); yellow (52 μg) and white carrots (17.6 μg) contained small amounts of carotenoids (Sun et al. 2009). α - and β -carotenes were highest in dark orange followed by typical orange, more or less same in the others. Lutein content was higher in purple–yellow (26.6 μg) followed by yellow (19.8 μg), white (14.2 μg), purple–orange (9.04 μg), dark orange (5.53 μg) and orange (3.61 μg) carrot and lowest in red carrot (1.68 μg). Lycopene in red carrot (419.4 μg) was higher than the rest, dark orange (7.76 μg), orange (5.09 μg), purple orange (2.20 μg), yellow (0.32 μg) and white (0.35 μg). Most abundant carotenoid was β -carotene in dark orange (939.7 μg), followed by typical orange (579.3 μg), purple orange (239.5 μg), purple yellow (127.9 μg), yellow (30.1 μg) and white (2.81 μg). α -

carotene was highest in dark orange (381.9 µg), typical orange (228.3 µg), purple orange (83.7 µg), purple yellow (18.9 µg), yellow (1.86 µg), red (1.74 µg) and white (0.46 µg).

Carotenoid content in six carrot cultivars ranged from 60 to 134 mg/kg (Matejkocá and Petriková 2010). Significantly higher levels of carotenoids were found in late and moderately late cultivars in comparison to early ones. Vitamin C content in these cultivars ranged from 54 to 132 mg/kg. Significantly higher contents of vitamin C were also found in the late cultivars. Thirty-day storage resulted in a significant reduction average of 47 % in vitamin C content. There was also a reduction in the carotenoid content, but to a lesser extent, on average of 11 %. Carrots, being one of the highest dietary sources of β -carotene and naturally high in the (all-*E*)- β -carotene isomer, were reported to have higher bioavailability, provitamin A activity and antioxidant capacity compared to *Z* (*cis*) isomers (Imsic et al. 2010). Storing carrots at either 4 °C to simulate long-term storage or 20 °C to simulate marketing practices resulted in increases in (all-*E*)- β -carotene of 20.3 % after 3 days at 4 °C and 34.4 % after 14 days at 20 °C, respectively. The levels of *Z* isomers in raw carrots were low with (13*Z*)- β -carotene and (9*Z*)- β -carotene accounting for less than 1.8 % of the total β -carotene present. Levels of (9*Z*)- β -carotene decreased during storage at either temperature, whereas storage at 4 °C resulted in a 109 % increase in (13*Z*)- β -carotene after 56 days. Cooking significantly increased the levels of (13*Z*)- β -carotene and (9*Z*)- β -carotene and resulted in the production of (15*Z*)- β -carotene, which was absent in raw carrots. Storage at 4 °C for 15 days or more prior to cooking reduced the susceptibility of (all-*E*)- β -carotene to thermal isomerisation during cooking, resulting in lower levels of all three *Z*- β -carotene isomers being generated, while storage at 20 °C for up to 21 days resulted in significantly higher levels of (all-*E*)- β -carotene before and after cooking but had no effect on *Z*-isomer production during cooking. They concluded from their study that, for the greatest health benefit, fresh carrots could be stored for up to 21 days at 20 °C or at 4 °C for up to 56 days without significant reduction in (all-*E*)- β -carotene and should be consumed raw or boiled for less than 15 minutes to limit *Z*- β -carotene isomer formation. When no

additional B or Ca was supplied to carrot plants, an increase in the accumulation of α - and β -carotenes (33–50 %), vitamin C (45–70 %) and total phenolic acids was observed (Singh et al. 2012b). High calcium levels decreased the lycopene content in ‘Nutri-Red’ carrots. High levels of micronutrients production lead to an increase in carrot antioxidant properties.

Six novel pyranoanthocyanins were identified in black carrot (*Daucus carota* L. subsp. *sativus* var. *atrorubens*) juice (Schwarz et al. 2004). The two major compounds, namely, the vinylcatechol adducts of cyanidin 3-*O*-(6-*O*-feruloyl- β -D-glucopyranosyl)-(1 $\rightarrow$ 6)-[β -D-xylopyranosyl-(1 $\rightarrow$ 2)]- β -D-galactopyranoside and cyanidin 3-*O*-[β -D-xylopyranosyl-(1 $\rightarrow$ 2)]- β -D-galactopyranoside, respectively, were isolated. The four remaining pigments were characterised as the vinylphenol and vinylguaiacol adducts of cyanidin 3-*O*-[β -D-xylopyranosyl-(1 $\rightarrow$ 2)]- β -D-galactopyranoside, the vinylguaiacol adduct of cyanidin 3-*O*-(6-*O*-feruloyl- β -D-glucopyranosyl)-(1 $\rightarrow$ 6)-[β -D-xylopyranosyl-(1 $\rightarrow$ 2)]- β -D-galactopyranoside and the vinylcatechol adduct of cyanidin 3-*O*-(6-*O*-sinapoyl- β -D-glucopyranosyl)-(1 $\rightarrow$ 6)-[β -D-xylopyranosyl-(1 $\rightarrow$ 2)]- β -D-galactopyranoside. These compounds were formed during storage of the juice through the direct reaction of either caffeic, ferulic or coumaric acid with the respective genuine anthocyanins.

Three cyanidin glycosides have been identified in the black carrot: the known cyanidin 3-lathyroside and two new pigments, a cyanidin 3-xylosylglucosylgalactoside and its feruloyl derivative (Harborne 1976). Feruloyl and sinapyl derivatives of cyanidin 3-glucosylgalactoside occurred exceptionally in the stem of one subspecies, *maritimus*. Anthocyanins found in black carrots (*Daucus carota* subsp. *sativus* var. *atrorubens*) included cyanidin glycosides, peonidin glycosides and pelargonidin glycosides (Kammerer et al. 2003). Total anthocyanin amounts ranged from 45.4 to 17.4 g/kg dry matter in 15 black carrot cultivars (Kammerer et al. 2004b). Cyanidin 3-xylosyl(glucosyl)galactosides acylated with sinapic acid, ferulic acid and coumaric acid were detected as major anthocyanins in black carrot (*Daucus carota* subsp. *sativus* var. *atrorubens*) cultivars Antonina, Beta Sweet, Deep

Purple and Purple Haze (Montilla et al. 2011). The anthocyanins detected included cyanidin 3-xylosylgalactoside, cyanidin 3-xylosyl (sinapoylglucosyl)galactoside, cyanidin 3-xylosyl(feruloylglucosyl)galactoside, cyanidin 3-xylosyl(*p*-coumaroylglucosyl)galactoside, cyanidin 3-xylosyl(caffeoylglucosyl)galactoside and cyanidin 3-xylosyl(*p*-hydroxybenzoylglucosyl)galactoside. Sucrose was predominant in all cultivars ranging from 39.5 % (cv. Afghan Purple) to 93.4 % (cv. Syria). Fructose (3.1–26.4 %) and glucose (3.5–34.2 %) were found in considerable smaller amounts with glucose. Unclarified black carrot juice, a rich source of anthocyanins, contained cyanidin 3-galactoside-xyloside-glucoside-ferulic acid as the major anthocyanin, followed by cyanidin 3-galactoside-xyloside-glucoside-coumaric acid and cyanidin 3-galactoside-xyloside-glucoside (Türkyılmaz et al. 2012). After depectinisation, two more anthocyanins (cyanidin 3-galactoside-xyloside and cyanidin 3-galactoside-xyloside-glucoside-sinapic acid) were also identified. These results indicated that depectinisation and bentonite treatment had positive effect on the colour of black carrot juice, while gelatin–kieselsool treatment and pasteurisation had negative effect.

The anthocyanins found in seven coloured carrots were Cy-3-(2"-xylose-6-glucose-galactoside) (Cy3XGG), Cy-3-(2"-xylose-galactoside) (Cy3XG), Cy-3-(2"-xylose-6"-sinapoyl-glucose-galactoside) (Cy3XSGG), Cy-3-(2"-xylose-6"-feruloyl-glucose-galactoside) (Cy3XFGG) and Cy-3-(2"-xylose-6"-(4-coumaroyl) glucose-galactoside) (Cy3XCGG) (Sun et al. 2009). Cy3XSGG content in purple–orange carrot was higher than that in purple–yellow carrot. Cy3XG, Cy3XFGG and Cy3XCGG contents in purple–yellow carrots were higher than those in purple–orange carrots. Cy3XFGG and Cy3XG were highest in purple–orange carrot, and Cy3XSGG was highest in purple–yellow carrot. Total anthocyanin content in purple–yellow carrot was 17.3 $\mu\text{mol/g dw}$ and 17.9 $\mu\text{mol/g}$ in purple–orange carrot. Raman spectroscopy revealed detailed information regarding the relative content and distribution of carotenoids, α -, β -carotene, lutein and lycopene in carrot root (Baranska et al. 2006). The level of β -carotene was heterogeneous across root sections of

orange, yellow, red and purple roots and in the secondary phloem increased gradually from periderm towards the core, but declined fast in cells close to the vascular cambium. α -carotene/lutein was deposited in younger cells with a higher rate than β -carotene, while lycopene in red carrots accumulated throughout the whole secondary phloem at the same level.

White carrot contained the highest content of volatiles, followed by orange, purple and yellow (Alasalvar et al. 2001). In total, 11, 16, 10 and 9 phenolic compounds were determined for the first time in orange, purple, yellow and white carrots, respectively, and the total concentration of all phenolic acids was the highest in purple carrots. Of these, chlorogenic acid was the most predominant phenolic compound in all carrot varieties. Differences in the relative sweetness, contents of vitamin C and α -carotene and β -carotene and certain flavour characteristics were observed among the coloured carrot varieties examined. Purple carrots contained 2.2 and 2.3 times more α - and β -carotenes (trace in yellow; not detected in white) than orange carrots, respectively. As regards to polyphenolic content, carrot was found to contain mainly hydroxycinnamic acid derivatives, namely, neochlorogenic acid (3'-caffeoylquinic acid), chlorogenic acid (5'-caffeoylquinic acid), 3'-*p*-coumaroylquinic acid, 3'-feruloylquinic acid, 3'4'-dicaffeoylquinic acid, 5'-feruloylquinic acid, 5'-*p*-coumaroylquinic acid, 4'-feruloylquinic acid, 3'5'-dicaffeoylquinic acid, 3'4'-diferuloylquinic acid and 3'5'-diferuloylquinic acid (Alasalvar et al. 2001). Phenolic acids were extracted from black carrot roots (*Daucus carota* subsp. *sativus* var. *atrorubens*) and black carrot juice concentrate (Kammerer et al. 2004a). Most of the compounds detected were identified as depsides composed of *p*-coumaric, caffeic and ferulic acids. Additionally, three hydroxybenzoic acid derivatives and one quercetin glycoside were detected. 5-*O*-Caffeoylquinic acid (chlorogenic acid) represented the predominant compound amounting to 657 mg/kg in the roots and 5,815 mg/kg in the concentrate. The specific fragmentation patterns of mono- and dihydroxycinnamoylquinic acids allowed the distinction of

several stereoisomers. The presence of 4-*O*-caffeoylquinic acid and several further hydroxycinnamic acid esters, together with compounds not belonging to the depside type, was also found. Lako et al. (2007) found raw carrots to contain per 100 g: 16 mg GAE total polyphenols, <1 mg myricetin, <1 mg quercetin, traces of fisetin, traces of morin, traces of isorhamnetin, 4.4 mg α -carotene, 14 mg β -carotene and a total antioxidant capacity (TAC) of 2 mg TEAC/100 g. Carrot was found to contain 37.5 mg/kg luteolin (Miean and Mohaned 2001); <1.4 mg/kg luteolin, myricetin <1 mg/kg (Hertog et al. 1992), 3.1–14.3 mg/kg fw (Tsanova-Savova and Ribarova 2013); flavonol kaempferol 15.3 μ g/g wet weight (Arai et al. 2000); 0.6 mg/100 g Fw ascorbic acid; total flavonoids 0.7 mg QE/100 g FW, flavonols quercetin 21 μ g/100 g FW and kaempferol 72 μ g/100 g FW and hydrophilic antioxidant capacity 276 μ M TE/100 g FW in ORAC assay (Kevers et al. 2007). From the extracts of Ri T-DNA-transformed carrot roots, six flavonoids were isolated and identified: three flavonols (quercetin, kaempferol, rutin or quercetin 3-rutinoside) and three flavones (apigenin, chrysin and luteolin) (Rhlid et al. 1993). Three flavonols (quercetin, kaempferol, rutin or quercetin 3-rutinoside) and two flavones (apigenin, luteolin) were identified in carrot root exudates (Poulin et al. 1993). Flavonols like quercetin and kaempferol had been reported to have stimulatory effects on the hyphal growth of *Gigaspora margarita*, a vesicular–arbuscular mycorrhizal fungus. Domestically prepared carrot juice contained per ml juice 235 μ g/ml caffeic acid, 194 μ g/ml chlorogenic acid, 17.3 μ g/ml quercetin and two dihydrochalcones: 219 μ g/ml phloretin and 54.3 μ g/ml phloridzin (Przybylska et al. 2007). In the case of carrot roots, the transgenic material (2,979 μ g/g dw) was richer in phytochemicals than the normal roots (643 μ g/g dw). Transgenic carrot roots contained 712 μ g/g dw chlorogenic acid, 1,241 μ g/g dw 4-hydroxybenzoic acid and 1,019 μ g/g dw unknown phenol, while normal roots contained 373 μ g/g dw chlorogenic acid and 270 μ g/g dw 4-hydroxybenzoic acid. Rakcejeva et al. (2012) reported the following chemical composition of five hybrid carrots cultivated in Latvia: moisture content 86.95–90.15 %, soluble solids 6.10–10.3 °Brix, firmness 81.28–103.98 N, carotenoid

60.21–79.47 mg/100 g DM and total phenolic content 272.21–539.76 mg GAE/100 g DM. All hybrids contained gallic acid, caffeic acid, chlorogenic acid and catechin, and some hybrids also contained vanillin, ferulic acid and epicatechin.

Twenty-three volatile compounds were identified in the raw carrot (Heatherbell et al. 1971). Of these, diethyl ether, acetaldehyde, acetone, propanal, methanol, ethanol and β -phellandrene had not been previously reported in raw carrots. Acetaldehyde, sabinene, myrcene and terpinolene were considered important character-impact compounds in raw carrot aroma. Differences in volatile composition between canned, freeze-dried and raw carrot were found to be mainly quantitative rather than qualitative. Ethanethiol, dimethyl sulfide and dimethyl-substituted styrene compounds formed with canning. Canning resulted in an approximate 50 % loss of ‘higher boiling’ compounds; however, it produced an increase in ‘lower boiling’ compounds, particularly methanol, which increased from 0.05 to 60 ppm. Freeze-drying resulted in an approximate 75 % loss of total volatile content. Ethanethiol, dimethyl sulfide, acetaldehyde, octanal, 2-decenal and possibly dimethyl-substituted styrene compounds were deemed important in canned carrot flavour. Volatile terpenoids found in carrot roots included: α -pinene, β -pinene, myrcene, α -phellandrene, α -terpinene, limonene, γ -terpinene, terpinolene, bornyl acetate, β -caryophyllene, *E*- γ -bisabolene (Senalik and Simon 1986). Most carrot volatiles, in particular terpenoids (sabinene, β -pinene, β -myrcene, limonene, *trans*-caryophyllene, α -humulene, β -bisabolene and α -farnesene) decreased by at least 50 % within 60 seconds of blanching (Shamaila et al. 1996). Ratings on quality attributes of colour, texture, raw carrot aroma, sweetness, flavour and overall impression decreased with blanching time, while cooked carrot aroma increased. There were correlations between blanching times, flavour volatiles and sensory attributes. A total of 35 different volatile compounds were identified in carrots (Alasalvar et al. 1999). Of these, *trans*-ocimene, 2,5-dimethyl styrene, camphor, borneol, α -santalene, α -selinene, γ -elemene and α -zingiberene in raw carrots and propanol in stored carrots were identified for the first time. Major volatile compounds identified in raw carrots were α -pinene, sabinene,

myrcene, limonene, γ -terpinene, terpinolene, β -caryophyllene and γ -bisabolene. Mono- and sesquiterpenes accounted for about 97 % of the total volatiles identified. Carrot volatiles did not change appreciably during the 28-day storage period at 5, 25 and 35 °C, except propanol that showed exponential increases at higher temperatures. No propanol was detected in fresh raw carrots. Cooking resulted in 88.6, 93.0 and 95.5 % loss in total volatiles after cooking times of 10, 20 and 30 minutes, respectively.

Terpenoid volatiles, such as α -pinene, sabinene, β -myrcene, limonene, γ -terpinene, terpinolene, *trans*-caryophyllene and β -bisabolene, and several furan derivatives were found to contribute to aroma in dehydrated carrot root samples (Soria et al. 2008).

The orange carrot genotypes were characterised by having significantly higher intensities in carrot flavour and aroma, while the reverse was true for the yellow genotypes (Kreutzmann et al. 2008b). The purple genotype was characterised by having significantly higher intensity in sickly sweet flavour and nutty flavour, and the red genotype was characterised by having significantly higher intensities in green aroma and flavour, bitterness and burning aftertaste. It was concluded that the isolated terpenes did correlate to the harsh flavour attributes. Thirty volatiles were found in the head space extract and 25 were identified, and monoterpenes and sesquiterpenes accounted for 99 % of total volatile mass. Major monoterpenes were α -pinene, sabinene, β -pinene, β -myrcene, γ -terpinene, terpinolene and limonene. Major sesquiterpenes were β -caryophyllene, α -humulene and (*E*)- γ -bisabolene. Also detected were estragole (*p*-allylanisole) and α -chamigrene which were not reported before. Other volatiles identified included α -thujene, camphene, α -phellandrene, β -phellandrene, (*Z*)- β -ocimene, (*E*)- β -ocimene, *p*-cymene, (*E,E*)-2,4-heptadienal, camphor, (*Z*)- β -farnesene, γ -cadinene, β -bisabolene, cuparene, γ -elemene, caryophyllene oxide and (–)-caryophyllene oxide.

Thirty-six volatile compounds were identified in the headspace; monoterpenes and sesquiterpenes accounted for about 98 % of the total volatile mass in all carrot cultivars

(Kjeldsen et al. 2001). Loss of carrot volatiles during concentration of headspace samples under a stream of nitrogen was detected; losses among major monoterpenes in the concentrated samples varied from 16 % for *p*-cymene to >40 % for α -pinene as compared to non-concentrated samples. Losses among high-boiling sesquiterpenes varied from not detectable (β -caryophyllene, α -humulene and caryophyllene oxide) to approximately 7 % for (*E*)- γ -bisabolene and (*Z*)- γ -bisabolene. A total of 52 compounds were quantified, of which mono- and sesquiterpenes accounted for approximately 99 % of the total volatile mass (Kjeldsen et al. 2003).

Phenylpropanoids constituted the second class of compounds, whereas the third class contained the fatty acid derivative octanal. Major volatile compounds were (–)- α -pinene, β -myrcene, (–)-limonene, (+)-limonene, (+)-sabinene, γ -terpinene, *p*-cymene, terpinolene, β -caryophyllene, α -humulene and (*E*)- γ -bisabolene and (*Z*)- γ -bisabolene. All volatiles had been previously isolated with exception of (+)-cuparene, thymohydroquinone dimethyl ether, a caryophyllene oxide isomer and 3-oxo- β -ionone. Other volatiles included (+)- α -pinene, eugenol, elemicin, myristicin, (–)-caryophyllene oxide, (*Z*)- γ -bisabolene, α -zingiberene, (*E*)- γ -bisabolene, (+)-borneol, santalene, (+)- α -terpinyl acetate, (*E,E*)- α -farnesene, (+)-valencene, (*E*)- β -farnesene, α -humulene, (*Z*)- β -farnesene, (+)-aromadendrene, thymol methyl ether, β -caryophyllene, (+)-bornyl acetate, (*E*)- α -bergamotene, (–)-camphor, (–)- α -copaene, 6-methyl-5-hepten-2-one, (*E*)- β -ocimene, (–)- β -phellandrene, α -terpinene, (–)- α -phellandrene, (–)-thujene, (–)-camphene, (–)- β -pinene, (+)- β -pinene, 4 unknown sesquiterpenes, two unknown compounds and an unknown monoterpene. A considerable increase in the concentration of mono- and sesquiterpenes was observed during refrigerated storage, whereas the concentration of terpenoids was around the same level during frozen storage. The major volatiles together with (+)- α -pinene, (–)- β -pinene, (+)- β -pinene, 6-methyl-5-hepten-2-one, (–)- β -bisabolene, β -ionone, and myristicin had an odour sensation, which included notes of ‘carrot top’, ‘terpene-like’, ‘green’, ‘earthy’, ‘fruity’, ‘citrus like’, ‘spicy’, ‘woody’ and ‘sweet’.

Yahyaa et al. (2013) found the volatile norisoprenoids farnesylacetone, α -ionone, and β -ionone accumulated in Nairobi, Rothild and Purple Haze carrot cultivars but not in Yellowstone and Creme de Lite in a pattern reflecting their carotenoid content. A cDNA encoding a protein with carotenoid cleavage dioxygenase activity, DcCCD1, was identified in carrot and may have a role in carrot flavour biosynthesis. Aroma extract dilution analysis (AEDA) found linden ether with the highest flavour dilution (FD) factor among cooked carrot volatiles (Buttery and Takeoka 2013). Others with tenfold lower FD factors were β -ionone, eugenol, β -damascenone, (*E*)-2-nonenal, octanal (+myrcene) and heptanal. Compounds showing the highest odour activity values included β -damascenone, (*E*)-2-nonenal, (*E,E*)-2,4-decadienal, β -ionone, octanal, (*E*)-2-decenal, eugenol and *p*-vinylguaiacol.

Constituents identified in carrot root essential oil: α -farnesene (17.07 %), caryophyllene (10.91 %), 2-formylmethyl-4, 6, 6-trimethyl-bicyclo [3. 3. 1] hept-3-ene (4.15 %), 1, 2, 3, 4-tetrahydro-6,7-dimethyl-naphthalene (2.83 %), 1-methyl-4-(5-methyl-1-methylene-4-hexenyl)-(*S*)-cyclohexene (1.62 %), 1, 1, 4, 8-tetramethyl-*cis*, *cis*, *cis*-4, 7, 10-cycloundecatriene (1.12 %), 1-octadecene (0.64 %), 1-methyl-4-(1-methylethyl) -1, 4-cyclohexadiene (0.14 %), 1-methyl-4-(1-methylethylidene)-cyclohexene (0.88 %), acetic acid, 1, 7, 7-trimethyl-bicyclo [2. 2. 1] hept-2-yl ester (0.50 %), 1, 2, 3, 4, 4a, 5, 6, 8 a-octahydro-7-methyl-4-methylene-1-(1-methylethyl)-(1 α , 4a β , 8a α)-naphthalene (0.14 %), 2, 6-dimethyl-6-(4-methyl-3-pentenyl)-bicyclo [3. 1. 1] hept-2-ene (0.57 %), 7, 11-dimethyl-3-methylene-(*E*) -1, 6, 10-dodecatriene (0.58 %), 1, 2, 3, 5, 6, 8a-hexahydro-4, 7-dimethyl-1-(1-methylethyl)-(1*S-cis*)naphthalene (0.15 %), germacrene D (0.55 %), 5-(1, 5-dimethyl-4-hexenyl)-2-methyl-[*s*-(*R**, *S**)] -1, 3-cyclohexadiene (0.26 %), caryophyllene oxide (0.605), α,α , 4-trimethyl-benzene methanol (0.11 %), 1, 2, 3, 5, 6, 7, 8, 8a-octahydro-1, 4-dimethyl-7-(1-methylethenyl)-[1*S* -(1 α , 7 α , 8 a β)]-azulene (0.11 %), α -bisabolol (0.27 %), 1, 2-diethyl-3, 4-dimethyl-benzene (0.22 %), 1, 2, 4-metheno-1H-cyclobuta[b]cyclo (32.29 %), 1, 9-heptadecadiene-4, 6-diyne-3-ol (0.17 %), 6*Z*-2,

5, 5, 10-tetramethyl-undeca-2, 6, 9-trien-8-one (0.21 %), tricyclo[3. 3. 2. 0(3, 7)]decane (0.25 %), 6-bromo 1-hexene (0.11 %), 1, 2, 3, 4-tetrahydro-1, 1,6-trimethyl-naphthalene (1.01 %), 1, 2, 3, 4-tetrahydro-5, 7-dimethyl-naphthalene (0.17 %), α -methyl-($\pm$) -2-naphthalene methanol (0.60 %), (*Z*, *E*) -2, 9-heptadecadiene-4, 6-diyn-8-ol (0.26 %), 3-nonen-5-one (0.38 %), bromo-cyclohexane (0.12 %) and 1H-imidazol-2-amine (0.17 %) (Wu et al. 2006).

Carrots contained a wide array of phytochemicals such as carotenoids, phenolics, phenolics, polyacetylenes, isocoumarins, sesquiterpenes and α -tocopherol (Metzger et al. 2008; Metzger and Barnes 2009). Of the 13 coloured carrot varieties, Deep Purple carrot had the highest concentration of total polyacetylenes, α -tocopherol and total phenolics and also contain anthocyanins. Commercial fresh market and baby orange carrots both had high concentrations of provitamin A carotenoids. The bioactive fraction of purple carrot extract was found to be rich in the polyacetylene compounds falcarindiol, falcarindiol 3-acetate and falcarinol.

A compound falcarindiol with the structure *cis*-heptadeca-1,9-diene-4,6-diyn-3,8-diol was isolated from root tissue extracts of *Daucus carota* (Garrod et al. 1978). Lund (1992) found that the previously reported compound falcarindiol 3-monoacetate consisted of a mixture of the 3-acetate and its allylic isomer, 1-acetoxy-heptadeca-2,9-diene-4,6-diyn-8-ol. A new phenylpropanoid, epilaserine oxide, was isolated along with six known compounds, laserine, 2-epilaserine, panaxynol, ginsenoyne K, (8 *E*)-1,8-heptadecadiene-4,6-diyn-3,10-diol and vaginatin (Yang et al. 2008). Polyacetylenes falcarindiol (FaDOH), falcarindiol 3-acetate (FaDOAc) and falcarinol (FaOH) were detected in carrot root extracts using high-performance liquid chromatography coupled with diode array detection (Christensen and Kreutzmann 2007; Purup et al. 2009). The average recovery rates were 99.2, 96.8 and 99.7 % for FaDOH, FaDOAc and FaOH, respectively. The amounts of polyacetylenes falcarinol, falcarindiol and falcarindiol 3-acetate in carrots varied significantly due to external factors (harvesting times, localities) and between stored and fresh samples (Kjellenberg et al. 2010). Kjellenberg et al. (2012)

found the falcarinol/total polyacetylene ratio was positively correlated with the root size, the amount of sucrose and the sucrose/total soluble sugar ratio among both fresh and stored samples. Root size was inversely correlated with the amounts of falcarindiol and falcarindiol 3-acetate, especially among stored samples. Stored carrots exhibited an inverse correlation between polyacetylenes and the amount of soluble sugar. At a falcarinol content at harvest below approximately 200 mg/kg dry weight, the amounts of all polyacetylenes increased during storage, but above that level the amounts of all polyacetylenes instead decreased. Pferschy-Wenzig et al. (2009) found the content of falcarinol [(Z)-heptadeca-1,9-diene-4,6-diyn-3-ol] ranged from 0.70 to 4.06 mg/100 g fresh weight in carrot roots of 27 different carrot genotypes.

The carrot phytoalexin, 6-methoxymellein, accumulated in carrot suspension culture when it was incubated with a partial hydrolysate of carrot cells obtained by pectinase or trypsin treatment (Kurosaki et al. 1984). Cultured carrot cells incubated with the phytoalexin formed three different metabolites: among them, two which accumulated in the medium, were identified as the β -glucoside of 6-methoxymellein and 6-hydroxymellein. Marinelli et al. (1990) isolated 6-methoxymellein, and 6-hydroxymellein, its presumed biosynthetic precursor, from carrot root slices infected with *Sclerotium rolfsii* and *Fusarium solani*. Elicitation of both 6-methoxymellein and 6-hydroxymellein synthesis was achieved also in carrot cell suspension cultures by direct addition of pectinolytic enzymes such as *Aspergillus niger* pectinase highly purified *Fusarium moniliforme* endopolygalacturonase. Talcott and Howard (1999) reported that 6-hydroxymellein was preferentially detected inside the cells, while 6-methoxymellein was always found in the culture medium. Small-diameter carrot roots accumulated greater amounts of 6-methoxymellein in periderm tissue compared to large roots. De Girolamo et al. (2004) found that processing carrots into a puree resulted in 10–25 % greater extraction of 6-methoxymellein than grinding fresh carrot samples, whereas steam-cooked and thermally processed purees had 15 % greater extraction than unheated purees. 6-methoxymellein was found in 78 % of fresh and conventionally processed

carrot products samples with levels ranging from 0.02 to 76 µg/g. They found that the levels of 6-methoxymellein in blanched carrots obtained by boiling water or steam treatment were reduced by 69 or 33 %, respectively, as compared to fresh carrots. No decrease in 6-methoxymellein levels was observed after maceration with pectinolytic enzyme preparations. A reduction of 6-methoxymellein by 85 or 94 % was obtained after the entire cycle of carrot juice processing, depending on the blanching procedure used.

A bitter principle identified as 3-methyl-6-methoxy-8-hydroxy-3, 4-dihydroisocoumarin was isolated from carrots (Dodson et al. 1956; Sondheimer 1957a, b). The concentrations of 3-methyl-6-methoxy-8-hydroxy-3,4-dihydroisocoumarin (MMHD) formed in carrot roots inoculated with certain fungi or treated with indole-3-acetic acid, 2,4-dichlorophenoxyacetic acid or 2,4,5-trichlorophenoxyacetic acid (2,4,5-T) were related to the amount of ethylene produced by the root tissue (Chalutz et al. 1969). The formation of dihydroisocoumarins, chromones (eugenin) and scopoletin was induced in carrot roots by storage in the presence of low concentrations of ethylene and by inoculation with various fungi (Coxon et al. 1973). Ethylene applied exogenously in concentrations above 0.3 ppm induced the formation of MMHD in carrot root discs. Continued production of MMHD required the continued presence of ethylene. Lafuent et al. (1989) found the rate of 8-hydroxy-3-methyl-6-methoxy-3, 4-dihydroisocoumarin. Formation increased with increasing ethylene concentrations (0.5–50 ppm) and with increasing temperatures (0–15 °C). No isocoumarin was detected in intact carrots stored in air. Exposure of carrots to 0.1 ppm ethylene at 5 °C for 30 days resulted in little isocoumarin formation, whereas 0.5 ppm for 14 days induced over 20 mg/100 g peel, which could be easily detected sensorially. The isocoumarin contents of water stressed and unstressed whole carrots held for 30 days at 5 °C under 0.5 ppm ethylene were similar. Sliced carrots held under the same conditions showed a marked increase in isocoumarin levels, reaching 120 mg/100 g peel. Sarkar and Phan (1975) demonstrated that biosynthesis of 8-hydroxy-6-methoxy-3-methyl-3,4-dihydroisocoumarin (also called isocoumarin) and

5-hydroxy-7-methoxy-2-methylchromone (eugenin) in carrot root tissues treated with ethylene must proceed via the acetate pathway. Seljåsen et al. (2001) found ethylene treatment of carrots caused an increase in 6-methoxymellein and the conversion of higher amounts of sucrose to fructose and glucose compared to control carrots stored in air. This corresponded to higher sensory scores for bitterness and terpene flavour and a lower score for sweetness. Principal component analysis showed a more expressed bitter taste, earthy flavour, green flavour, terpene flavour and aftertaste in the ethylene-treated carrots. Correlations were found between the sweet taste and the content of sucrose ($r = 0.91$), and between the contents of various terpenes (particularly γ -terpinene, limonene and caryophyllene) and terpene flavour, green flavour, aftertaste and bitter taste ($r \geq 0.72$). In the air-stored carrots, these off-flavours seemed to be masked by a high sucrose content. Carrot root concentrations of α - and β -pinene, myrcene, α - and γ -terpinene, limonene, *p*-cymene, terpinolene, caryophyllene, bornyl acetate, and 2-nonenal varied depending on the carrot line (Holley et al. 2000). Lines with the highest °Brix to terpinolene ratios indicating a higher degrees of sweetness (and lower bitterness).

The following bitter compounds were isolated from cold-stored carrots and commercial carrot puree: 3-methyl-6-methoxy-8-hydroxy-3,4-dihydroisocoumarin (6-methoxymellein), 5-hydroxy-7-methoxy-2-methylchromone (eugenin), 2,4,5-trimethoxybenzaldehyde (gazarin), (*Z*)-heptadeca-1,9-diene-4,6-diin-3,8-diol (falcarindiol), (*Z*)-heptadeca-1,9-diene-4,6-diin-3-ol (falcarinol) and (*Z*)-3-acetoxy-heptadeca-1,9-diene-4,6-diin-8-ol (falcarindiol 3-acetate) (Czepa and Hofmann 2003). Due to the low concentrations of <0.1 mg/kg and the high taste thresholds found for eugenin and gazarin, these compounds could be unequivocally excluded as important contributors to the bitter taste of carrots. Also based on the ratio of the concentration to the bitter detection threshold, it was clearly demonstrated that neither in fresh and stored carrots nor in commercial carrot puree did 6-methoxymellein contribute to the bitter off-taste. Contrariwise, the concentrations of falcarindiol in stored

carrots and, even more pronounced, in carrot puree were found to be 9- and 13-fold above its low bitter detection concentration of 0.04 mmol/kg, thus demonstrating that this acetylenic diol significantly contributed to the bitter taste of the carrot products investigated. According to Czepa and Hofmann (2004), the isocoumarin 6-methoxymellein was not a key player imparting the bitter taste in carrots but bisacetylenic oxylipins (*Z*)-heptadeca-1,9-dien-4,6-diyn-3-ol; (*Z*)-3-acetoxy-heptadeca-1,9-dien-4,6-diyn-8-ol and (*Z*)-heptadeca-1,9-dien-4,6-diyn-3,8-diol (falcarindiol) contributed mainly to the off-taste. Besides the known bitter compounds, 6-methoxymellein, falcarindiol, falcarinol and falcarindiol 3-acetate, the following bitter new compounds were identified in carrots with low bitter recognition thresholds between 8 and 47 $\mu\text{mol/L}$: vaginatin; isovaginatin; 2-epilaserine oxide; laserine oxide; laserine; 2-epilaserine; 6,8-*O*-ditigloyl-6 ss ,8 α ,11-trihydroxygermacra-1(10) *E*,4 *E*-diene; 6-*O*-angeloyl-, 8-*O*-tigloyl- 6 ss ,8 α ,11-trihydroxygermacra-1(10) *E*,4 *E*-diene; as well as 8-*O*-angeloyl-tovarol and α -angeloyloxy-latifolone (Schmiech et al. 2008). Besides the previously reported falcarinol, falcarindiol and falcarindiol 3-acetate, nine additional bisacetylenes were identified, among which six derivatives were reported for the first time in literature and three compounds were previously not identified in carrots (Schmiech et al. 2009). Potential bitter compounds like polyacetylenes, isocoumarins and phenolic acids were quantified in the peel and the corresponding peeled carrot of eight carrot genotypes ('Bolero', 'Mello Yello', 'Nairobi', 'Tornado', 'Purple Haze', 'Line 1', 'Line 2' and 'Line 3') representing extremes in sensory-perceived odour, flavour and taste (Kreutzmann et al. 2008a). Falcarindiol and a di-caffeic acid derivative were highly related to bitterness in contrast to falcarinol and other potential bitter compounds. Falcarindiol and the di-caffeic acid derivative were primarily present in the peel, whereas falcarinol was almost evenly distributed in the root. Investigation of bitterness revealed that high sugar content to some extent could mask the bitter perception of carrots.

Four sesquiterpenes daucane esters, 2 α -acetyloxy-4 β -hydroxy-6 α -*p*-hydroxybenzoyloxy-dauc-8-ene, 2 α -acetyloxy-

4 β -hydroxy-6 α -angeloyloxy-10 β - hydroxybenzoyloxy-dauc-8-ene, 2 α -acetyloxy-4 β -hydroxy-6 α -angeloyloxy-10 β -cinnamoyloxy-dauc-8-ene and fercomin; falcarindiol; ferulenol; and sitosterol glucoside were isolated from wild carrot roots (Ahmed et al. 2005).

The amount of wax extracted from the periderm of carrot root was 53.2 mg/kg of chloroform extractable material, equivalent to 74 % weight of chloroform extract or 29 $\mu\text{g}/\text{cm}^2$ was/surface area (Espelie et al. 1980). The composition of carrot wax comprised 2.8 % hydrocarbon, 0.7 % wax ester, 34 % fatty alcohol, 50 % fatty acids and 13 % unknown component. The total amount of even-chain components of suberin-associated hydrocarbons was 47 %. The proportion of even-chain alkanes from carrot leaf wax was 15 %. Fatty alcohols and/or fatty acids combined total for carrots were 6.5 %.

Rhamnogalacturonan II, a small complex pectic polysaccharide, was obtained by enzymatic liquefaction from carrot juice (Doco et al. 1997). Rhamnogalacturonan II contained the diagnostic sugars, apiose, 2-*O*-methyl-L-fucose, 2-*O*-methyl-D -xylose, aceric acid, 3-deoxy-D-manno-octulosonic acid (Kdo) and 3-deoxy-D-lyxo-heptulosonic acid (Dha). An alcohol-insoluble residue from carrot root was found to contain partially non-methyl esterified polysaccharides (Needs et al. 1998). Digestion with driselase gave small amounts of acidic oligosaccharides, and alkaline hydrolysis gave more acidic 1,4-linked oligogalacturonic acids as products. These components appeared to contain non-methyl galacturonoyl esters, and the predominant component was shown to be a monomethyl-esterified, singly acetylated tetragalacturonic acid. The majority of the polymer fractions obtained from carrot root cell walls comprised pectic polysaccharides, with varying quantities of neutral sugars (arabinose and galactose) (Kang et al. 2008). Hemicellulosic polymers were generally found only in the strong alkali extracts (4 M KOH). *p*-OH-benzoic acid was the predominant phenolic ester, and *p*-OH-benzaldehyde was also detected in the fractions at much lower levels. *p*-OH-benzoic acid was

associated predominantly with the branched pectic polysaccharides, in contrast to the *p*-OH-benzaldehyde.

Sturm et al. (1995) found that the genes for isoenzymes I and II of soluble acid β -fructofuranosidase (sI, sII) were mainly expressed in roots, sI predominating in primary roots and sII in developing taproots. Developing taproots contained only transcripts for sII and for sucrose synthase (ss). The expression of the gene for cell wall β -fructofuranosidase (cw β F) was development specific but not organ specific; high transcript levels were only found in plants with primary roots, with about equal amounts in leaf lamina, petioles and roots. Oligogalacturonate hydrolase was isolated from carrot roots (Stratilová et al. 2005). Its molecular mass, isoelectric point, glycosylation as well as cleavage of pectate from the nonreducing end corresponded to an exopolygalacturonase. The affinity of this enzyme to the substrates increased with the increasing degree of polymerisation, and the difference was observed only in the maximal ratio of catalysis of oligomeric and polymeric substrates.

Pectin methylesterase isolated from black carrot showed very high activity in a broad pH range of 6.5–8.5, with the optimum pH occurring at 7.5 (Ünal and Bellur 2009).

A 36 kDa antifreeze protein, localised in the apoplast, was isolated from the taproot of cold-acclimated carrot plants (Smallwood et al. 1999). This protein inhibited the recrystallisation of ice and exhibited thermal–hysteresis activity. The polypeptide behaved as a monomer in solution and was N-glycosylated. Meyer et al. (1999) isolated a encoding an antifreeze protein (AFP) from carrot. The carrot AFP was highly similar to the polygalacturonase inhibitor protein (PGIP) family of apoplastic plant leucine-rich repeat (LRR) proteins.

Cell Tissue/Suspension Culture

Phytochemicals

Phosphatidylcholine, phosphatidylethanolamine, phosphatidylinositol and triacylglycerol were the main lipid

components detected in carrot suspension culture cells (Kleinig and Kopp 1978). Oleosomes (lipid droplets) isolated from carrot suspension culture cells were found to contain mainly of triacylglycerols (>97 %), free fatty acids about 1 %, phospholipid >0.05 % and very little protein (1–2 %) (Kleinig et al. 1978). The fatty acid pattern (%) of oleosomal triacylglycerols and total polar lipids, respectively, comprised: 14:0 (1.7 %, 0.7 %), 16:0 (24.1 %, 25.1 %), 16:1 (0 %, trace), 18:0 (12.9 %, 8.1 %), 18:1 (1.2 %, 0.3 %), 18:2 (53.6 %, 59.2 %) and 18:3 (6.4 %, 6.4 %). The fatty acid pattern of triacylglycerols was very similar to that of polar cellular membrane lipids. The major fatty acids detected at five embryo stages following induction of embryogenesis in carrot cultures were C16:0, C18:0, C18:1, C 18:2 and C18:3 (Warren and Fowler 1979). Quantitative rather than qualitative changes in fatty acid content were observed, although globular embryos had some fatty acids of long (C20 and above) chain length not observed in earlier (small meristematic cell stage, large vacuolated cell stage) or later embryo (heart and torpedo) stages. Embryogenic carrot cultured cells were shown to synthesise putrescine from exogenously supplied [(14)^C]arginine at twice the rate of control non-embryogenic cells (Montague et al. 1979). The activity of arginine decarboxylase, an important enzyme in the synthesis of putrescine, was found to be elevated by as much as twofold in embryogenic cells. A nitrogen-containing tertiary base was isolated from carrot seeds (Gambhir et al. 1979). Soluble esterases were identified in carrot, four carboxylesterases and two arylesterases (Carino and Montgomery 1968). Acetyl, propionyl and n-butyryl esters of phenol, sodium 2-naphthol-6-sulfonate and glycerol and n-hexyl ester of sodium 2-naphthol-6-sulfonate were hydrolyzed by carrot esterases. Carrot esterases showed maximal activity with phenyl esters, while the esters of sodium 2-naphthol-6-sulfonate and triglycerides were hydrolyzed at slower rates. Polyphenol oxidase was purified from carrot cell cultures (Söderhäll and Söderhäll 1989). N-acetyl glutamate kinase (NAGK) was purified and characterised from *Daucus carota* suspension cultures (Lohmeier-Vogel et al. 2005). Carrot NAGK was shown to have a subunit molecular weight of 31 kDa and form

a hexamer. Reduction of acetophenone by carrot hairy root cultures afforded (*S*)-phenylethanol in high yield (96 %) and excellent enantiomeric excess (*ee* > or = 98 %) (Caron et al. 2005). Aromatic ketones, keto esters and a simple aliphatic ketone were reduced with good stereoselectivity (*ee* = 62–98 %) and moderate to high chemical yields (25–90 %).

The product of gitoxigenin transformation by *Daucus carota* cell suspension culture was isolated from culture filtrates and identified as 5 β -hydroxygitoxigenin (Veliky et al. 1980). Four anthocyanins were found in the carrot cell culture: cyanidin 3-glucogalactoside, cyanidin-3,5-digalactoside, cyanidin 3-glucoside and cyanidin 3-galactoside (Hemingson and Collins 1982). Cyanidin 3-(sinapoylxylosylglucosylgalactoside) was identified as a major anthocyanin in carrot cell tissue culture (Harborne et al. 1983). Microsomal preparations from carrot cell suspension cultures catalysed the formation of *trans*-5-*O*-caffeoyl-D-quinic acid (chlorogenic acid) from *trans*-5-*O*-(4-coumaroyl)-D-quinic acid, and *trans*-5-*O*-(4-coumaroyl) shikimate was converted to about the same extent to *trans*-5-*O*-caffeoylshikimate (Kühnl et al. 1987). *trans*-4-*O*-(4-coumaroyl)-D-quinic acid, *trans*-3-*O*-(4-coumaroyl)-D-quinic acid, *trans*-4-coumarate and *cis*-5-*O*-(4-coumaroyl)-D-quinic acid did not act as substrates. They found that the biosynthesis of the predominant caffeic acid conjugates in carrot cells occurred via the corresponding 4-coumaric acid esters. Thus, in this system, 5-*O*-(4-coumaroyl)-D-quinic acid could be seen as the final intermediate in the chlorogenic acid pathway.

A trypsin inhibitor with a molecular weight of about 12,800 was purified from embryogenic carrot cells (Carlberg et al. 1987). The protease inhibitor was heat stable and inhibited trypsin but had no activity towards chymotrypsin or subtilisin. An autocatalytic protein-glycosylating glycosyltransferase enzyme (40,000 Da) was purified from carrot cell suspension (Quentmeier et al. 1987). Dark-grown carrot tissue cultures were found to contain both protein components of the NADP/thioredoxin system—NADP—thioredoxin reductase and the thioredoxin characteristic of heterotrophic systems, thioredoxin H (Johnson et al. 1987).

Thioredoxin H a 12-kdalton (kDa) acidic protein was capable of activating chloroplast NADP–malate dehydrogenase more effectively than fructose-1,6-bisphosphatase. NADP–thioredoxin reductase was partially purified and found to be an arsenite-sensitive enzyme composed of two 34-kDa subunits. Protein preparations from cell suspension cultures of an Afghan carrot containing the enzymes 1-*O*-hydroxycinnamoyl- β -glucose–cyanidin 3-*O*-(2''-*O*-xylosyl-6''-*O*-glucosylgalactoside) 6'-*O*-hydroxycinnamoyltransferases catalysed the formation of acylated anthocyanins from a cyanidin triglycoside isolated from the carrot cultures using 1-*O*-sinapoyl-, 1-*O*-feruloyl- and 1-*O*-(*p*-coumaroyl)- β -glucose as acyl donors (Gläßgen and Seitz 1992). Thuleau et al. (1993) found solubilised proteins from carrot cell membrane-bound calcium channel blockers and form calcium-permeable ion channels. Their results suggested that the 75-kDa Ca^{2+} channel blocker-binding protein from carrot cells played a role in channel sensitivity to Ca^{2+} channel inhibitors and may constitute one of the components of Ca^{2+} channels in higher plants. A soluble phosphatidylinositol 4-kinase (PI 4-kinase) was found in carrot suspension culture cells (Okpodu et al. 1990). The enzyme was found to have a molecular weight of 83,000 (Okpodu et al. 1995). The isolated lipid kinase phosphorylated phosphatidylinositol but not lysophosphatidylinositol or phosphatidylinositol.

A highly enantioselective preparation (92–99 % enantiomeric excess, 100 % conversion) of various 4-aryl-2-hydroxy but-3-enoic carboxylic acid esters from the corresponding 4-phenyl-2-keto but-3-enoic acid esters was found to be mediated by carrot plant cell cultures under mild and environmentally benign conditions in aqueous medium (Baskar et al. 2004). *Agrobacterium rhizogenes*-induced hairy root cultures of *Daucus carota* showed a considerable amount of *p*-hydroxybenzoic acid accumulation both in cytosol and in the cell wall (Sircar et al. 2007). This phenolic acid finds application in food, pharmaceutical and polymer industries. Studies by Sircar and Mitra (2009) suggested that *p*-hydroxybenzaldehyde might be the immediate precursor in *p*-hydroxybenzoic acid biosynthesis. In-vitro conversion of *p*-

coumaric acid to *p*-hydroxybenzoic acid with *p*-hydroxybenzaldehyde as intermediate using cell-free extract provided an unequivocal support for CoA-independent and non-beta-oxidative route of *p*-hydroxybenzoic acid biosynthesis in carrot hairy roots.

Six anthocyanins were isolated from cell suspension cultures of an Afghan carrot cultivar. The structures of these compounds were elucidated as cyanidin 3-*O*-lathyrósíde, cyanidin 3-*O*-(2''-*O*- β -D-xylopyranosyl-6''-*O*- β -D-glucopyranosyl- β -D-galactopyranoside) and the latter acylated with 4-coumaroyl, feruloyl, 4-hydroxybenzoyl and sinapoyl (Gläßgen et al. 1992). The major anthocyanins accumulated by an Afghan cultivar of *Daucus carota* were cyanidin 3-(xylosylglucosylgalactosides) acylated with sinapic or ferulic acid (Rose et al. 1996). They detected two enzymatic glycosylation reactions in the protein preparations from carrot cell suspension cultures. The first reaction was a galactosyl transfer catalysed by UDP-galactose–cyanidin galactosyltransferase (CGT) resulting in cyanidin 3-galactoside. The putative second reaction involved the formation of cyanidin 3-(xylosylgalactoside) catalysed by UDP-xylose–cyanidin 3-galactoside xylosyltransferase (CGXT). In both cases, a molecular mass of 52 kDa was determined, indicating that the native protein was a monomer of 52 kDa. Feeding 15 cinnamic and benzoic acids to anthocyanin-producing wild carrot cell cultures one at a time afforded 17 anthocyanins differing only in the acyl group (Baker et al. 1999). The extra two were anthocyanins acylated with 4-chlorobenzoic acid and 4-trifluoromethyl-benzoic acid. They found that the majority of acids used by carrot cell cultures to acylate anthocyanins were mediated via the 1- β -D-glucose ester pathway.

Studies indicated the presence of cyanidin 3-lathyrósíde [cyanidin 3-*O*{ β -D-xylopyranosyl (1→2) β -D-galactopyranoside}] (90 %) and cyanidin 3- β -D-glucopyranoside (10 %) in carrot callus cultures, whereas only cyanidin 3-lathyrósíde (0.05 %) was found in the explant carrot (Narayan and Venkataraman 2000). The main anthocyanins detected in cultivars of black carrot (*Daucus carota* L. subsp. *sativus* var.

atrorubens) Antonina and Purple Haze were found to be five cyanidin-based anthocyanins: cyanidin 3-xylosylglucosylgalactoside, cyanidin 3-xylosylgalactoside and the sinapic, ferulic and coumaric acids derivative of cyanidin 3-xylosylglucosylgalactoside (Algarra et al. 2014). The anthocyanins present in the black carrots were essentially acylated, and their levels were found to correspond to 25 % and 50 % of the total phenolic content for the Purple Haze and Antonina cultivars, respectively.

Total lipids constituted approx. 0.2 % of fresh weight in carrot callus and suspension culture but approx. 0.5 % in heart- and torpedo-shaped embryoids (Dutta and Appelqvist 1989). Petroselinic acid (*cis*-6–8:1), accounting for approx. 70 % of carrot seed oil, was not present in callus, suspension culture (0 time) and globular embryoids. Petroselinic acid first occurred in the heart-shaped embryoids and reached a maximum level of 1.4 % in the triacylglycerols of torpedo-shaped embryoids. The major fatty acids invariably in all kinds of tissues were linoleic (18:2) and palmitic (16:0) acids, and the minor ones were stearic (18:0), oleic (*cis*-9–18:1), vaccenic (*cis*-11–18:1) and linolenic (18:3) acid. Different cultural conditions could not boost petroselinic acid accumulation but did increase triacylglycerol content in total lipids in embryoids with a maximum level of approx. 17 mg triacylglycerols per g fresh weight. Abscissic acid, sorbitol and their combination gave the maximum level of total lipids per g fresh weight; approx. 75 % of the lipids were triacylglycerols.

Flower/Fruit/Seed Phytochemicals

From the fruits the following compounds were isolated: two guaiane-type sesquiterpene glycosides, 11-*O*-acetyl-torilolone 8-*O*-β-D-glucopyranoside and 1β-hydroxytorilolone 11-*O*-β-D-glucopyranoside (Fu et al. 2010a); two new guaiane-type sesquiterpenoids containing an interesting epoxy unit, daucuside and daucusol (Fu et al. 2010c); a new guaiane-type sesquiterpene glycoside, torilolone 8-*O*-β-D-glucopyranoside (1), together with a known analogue compound, torilolone 11-*O*-β-D-glucopyranoside (Fu et al. 2010b) and a new sesquiterpene named as daucucarotol with the structure

(1 α ,5 α ,8 α ,10 β)-decahydro-6 α -hydroxy-8 α ,8 α ,6 β -trimethyl-1,8-naphthalene-dimethanol (Fu et al. 2009). Two new sesquiterpenes, 11-(acetyloxy) torilolone (**1**) and 1 β -hydroxytorilolone (**2**), were isolated from carrot fruit (Yi et al. 2009).

A new flavone glycoside, apigenin 7-*O*- β -D-galactopyranosyl-(1 $\rightarrow$ 4)-*O*- β -D-mannopyranoside, and apigenin 4'-*O*- β -D-glucoside and kaempferol 3-*O*- β -D-glucoside were isolated from carrot seeds (Gupta and Niranjana 1982). 2,4,5-trimethoxybenzaldehyde, oleic acid, trans-ascarone and geraniol were isolated from carrot seeds (Momin et al. 2003). Daucic acid, carotol and daucol were isolated from carrot seed oil (Ashraf et al. 1977). Studies by Lichtenthaler et al. (2003) found (–)-daucic acid to have d-lyxo-CONFIGURATION rather than the previously assigned D-xylo stereochemistry. Configurational identity in the pyranoid rings of (–)-daucic acid and 3-deoxy-D-manno-octulosonate (KDO), together with available biosynthetic evidence on chelidonic acid, a leaf closing factor, suggested a joint, KDO 8-phosphate 8-P-based pathway, for their biosynthesis in plants.

Constituents identified in carrot flower essential oil included: (1*R*)- α pinene (12.64 %), caryophyllene (9.62 %), β -myrcene (9.15 %), 3,7-dimethyl-1,3,7-octatriene (7.15 %), (+)-*epi-bicyclosesquiphellandrene* (6.19 %), limonene (5.15 %), 3-carene (3.66 %), camphene (2.79 %), γ -elemene (2.71 %), 1,1,4,8-tetramethyl-*cis,cis,cis*-4,7,10-cycloundecatriene (2.17 %), 7,11-dimethyl-3-methylene-(*E*)-1,6,10-dodecatriene (1.15 %), 4-methylene-1-(1-methylethyl-cyclohexene) (1.13 %), 1-methyl-4-(1-methylethylidene)-cyclohexene (1.01 %), 2,6,6-trimethyl ($\pm$)-bicyclo[3.1.1]hept-2-ene (0.47 %), (+)-4-carene (0.10 %), 1-methyl-3-(1-methylethyl) benzene (0.11 %), 1-methyl-4-(1-methylethyl)-1,4-cyclohexadiene (0.65 %), 2-methyl-6-methylene-oct-3,7-dien-2-ol (0.16 %), 4-methyl-1-(1-methylethyl)-3-cyclohexen-1-ol (0.29 %), α,α , 4-trimethyl-3-cyclohexene-1-methanol (0.35 %), acetic acid, 1, 7, 7-trimethyl-bicyclo [2. 2. 1] hept-2-yl ester (0.13 %), 4-(2-butenyl)-1, 2-dimethyl-(*E*)-benzene (0.08 %), 1, 3, 5-trimethyl-2-(1-methylethenyl)-benzene (0.11 %), 3, 7, 7-trimethyl-bicyclo [4-1. 0] hept-2-ene (0.16 %), 1, 5, 5-

trimethyl-6-methylene-cyclohexene (0.15 %), copaene (0.26 %), 1a, 2, 3, 5, 6, 7, 7a, 7b-octahydro-1, 1, 7, 7a-tetramethyl-[1aR-(1a α , 7 α , 7a α , 7b α)]-1H-cyclopropa[α]naphthalene (0.25 %), 1, 2, 3, 4, 4a, 5, 6, 8a-octahydro-7-methyl-4-methylene-1-(1-methylethyl)-(1 α , 4a β , 8a α)-naphthalene (0.44 %), octahydro-3,8,8-trimethyl-6-methylene-[3R-(3 α , 3a β , 7 β , 8a α)]-1H-3a,7-methanoazulene (0.22 %), 1H-benzocycloheptene-2, 4 a, 5, 6, 7, 8, 9, 9a-octahydro-3, 5, 5-trimethyl-9-methylene-(4 a*S-cis*) (0.36 %), 6-dimethyl-6-(4-methyl-3-pentenyl)-bicyclo [3. 1. 1] hept-2-ene (0.25 %), 1, 2, 3, 5, 6, 8 a-hexahydro-4, 7-dimethyl-1-(1-methylethyl)-(1*S-cis*)-naphthalene (0.52 %), 3, 7-dimethyl-(*Z*)-1, 3, 6-octatriene (2.11 %), 4, 11, 11-trimethyl-8-methylene-[1*R*-(1*R**, 4*Z*, 9*S**)]-bicyclo[7- 2.0]undec-4-ene (0.39 %), carotol (16.39 %), decahydro-4a-methyl-8-methylene-2-(1-methylethyl)-[1*R*-(1 α , 2 β , 4a β , 8a α)]-1-naphthalenol (0.17 %), τ -muurolol (0.53 %), 1, 2, 4-trimethoxy-5-(1-propenyl)-(Z)-benzene (0.34 %), α -cadinol (0.68 %), 2, 7, 7-trimethyl-bicyclo[3. 1. 1] hept-2-en-6-one (0.12 %), α -bisabolol (0.49 %), 1, 2, 3, 4, 4a, 5, 6, 8a-octahydro-4a, 8-dimethyl-2-(1-methylethenyl)-[2*R*-(2 α , 4a α , 8a β)]-naphthalene/-selinene (2.05 %), 3, 7, 11-trimethyl-(*Z*, *E*)-2, 6, 10-dodecatrien-1-ol (0.03 %), (*E*, *E*)-7, 11, 15-trimethyl-3-methylene-hexadeca-1, 6, 10, 14-tetraene (0.10 %), 1, 2, 3, 4-tetrahydro-5, 6-dimethyl-naphthalene (0.42 %), 1, 2, 3, 4-tetrahydro-6,7-dimethyl-naphthalene (0.24 %), 1, 2, 3, 4-tetrahydro-5, 7-dimethyl-naphthalene (1.61 %), phytol (0.33 %), 1-(2-butenyl)-2,3-dimethyl-benzene (0.27 %), heneicosane (0.10 %), 3,3,6-trimethyl-1,5-heptadien-4-one (0.18 %), pentacosane (0.15 %), heptacosane (0.28 %) and nonacosane (0.14 %) (Wu et al. 2006).

Daucus carota poly(A)-binding proteins, DcPAB, was found to be differentially expressed under different conditions suggesting a potently unique role in the development of carrot somatic embryo (Lin et al. 2003). 4-hydroxybenzyl alcohol (4HBA) accumulated in carrot flowers and immature and mature fruits, but not in vegetative tissues (Kobayashi et al. 2003). The concentration of 4HBA was highest after flowering, when the zygote developed into the early globular-stage embryo. 4HBA accumulation then decreased with seed development. Exogenous application of 4HBA to immature

carrot fruits inhibited seed formation. Many 4HBA-treated seeds did not include a mature embryo. D, L-IDITOL, kaempferol 3-O-B-glucoside, laserine and a mixture of stigmasterol and sitosterol were isolated from carrot flower (Akgul et al. 2009). The main components in the Sardinian essential oil of flowering and mature carrot umbels with seeds were β -bisabolene (17.6–51.0 %) and 11- α -(H)-himachal-4-en-1- β -ol (9.0–21.6 %); instead, the oils from Portuguese samples were predominantly composed of geranyl acetate (5.2–65.0 %) and α -pinene (3.5–37.9 %) (Maxia et al. 2009). Supercritical extracts contain lower amounts of monoterpenes and higher amounts of sesquiterpene hydrocarbons. The main components of the essential oil of carrot flowering and mature umbels with seeds from Sejnane were eudesm-7(11)-en-4-ol (8.2–8.5 %), carotol (3.5–5.2 %), sabinene (12.0–14.5 %), α -selinene (7.4–8.6) and 11- α -(H)-himachal-4-en-1- β -ol (12.7–17.4 %), whereas the oils from Tunis were predominantly composed of elemicin (31.5–35.3 %) and carotol (48.0–55.7 %) (Marzouki et al. 2010). Thirty-six compounds were identified in carrot seed essential oils, with a predominance of sesquiterpene hydrocarbons in most samples (22.63–89.93 % of the total oil composition) (Rokbeni et al. 2013). The main volatile compounds identified were β -bisabolene (mean content of 39.33 %), sabinene (8.53 %), geranyl acetate (7.12 %) and elemicin (6.26 %). Carrot umbel essential oil yield varied from 0.7 to 1.8 % (v/w) during umbel ontogeny (Verma et al. 2014). Thirty-four constituents, forming 94.5–97.9 % of the total compositions, were identified. The essential oil composition was characterised by high proportions of monoterpenoids (35.9–81.3 %) and sesquiterpenoids (15.1–62.0 %). Major constituents of the essential oils were carotol (10.2–58.5 %), α -pinene (21.2–41.2 %), myrcene (6.4–14.1 %), limonene (4.4–12.7 %) and sabinene (0.2–5.3 %).

The sesquiterpenoid monoethylenic tertiary alcohol carotol isolated from carrot essential oil was found to have the structure Δ^2 -3,10-dimethyl-6-isopropylbicyclo-(0,3,5)-decen-6-ol (Chiurdoglu and Descamps 1960). A sesquiterpene ether, carota-1,4- β -oxide, was isolated from the essential oil of carrot seeds (Dhillon et al. 1989). A new daucane-type sesquiterpene

alcohol, *trans*-dauc-8-en-4 β -ol, plus five known sesquiterpene compounds, *trans*-dauca-8,11-diene, dauca-5,8-diene, acora-4,9-diene, acora-4,10-diene, (*E*)- β -10,11-dihydro-10, 11-epoxyfarnesene and (*E*)-methylisoeugenol, was isolated and characterised from carrot seed oil (Mazzoni et al. 1999). Carrot seed oil was found to be the source of the carotane sesquiterpenes carotol, daucol and β -caryophyllene (Jasicka-Misiak et al. 2004).

Soluble beta-fructofuranosidase with an intracellular location and an isoelectric point of 3.8 (isoenzyme I) was purified and characterised from dry carrot seeds and seedlings (Unger et al. 1992). The purified protein, which was N-glycosylated with high-mannose-containing and high-xylose-containing complex glycans, was eluted as a monomeric polypeptide with a molecular mass of 68,000. The enzyme hydrolyzed sucrose with a K_m of 5 mM and a broad pH optimum around 5.0. Carboxylesterase activity was detected in carrot seed and seedling (Melati et al. 1996).

The major oleosin proteins of 15 and 19 kDa and the major storage albumins of 20 and 28 kDa were purified to homogeneity from carrot seeds (Ross and Murphy 1993). Similar-sized proteins in total protein and oil body fractions were observed from non-embryogenic and embryogenic carrot suspension cultures and from carrot somatic embryos. The carrot cultures in-vitro did not accumulate the high levels of octadecenoic fatty acids found in seeds but rather accumulated an oil which was high in linoleic acid and whose fatty acid profile resembled that of the membrane lipids. Non-embryogenic carrot cell cultures accumulated very little starch, whereas high levels were found in embryogenic cell cultures. Starch levels declined to low levels during somatic embryo development to the torpedo stage. In the early stage of carrot seed development, triacylglycerols comprised approximately 43 % of linoleic acid and almost equal proportions of myristic, palmitic, petroselinic, oleic and linolenic acids (Dutta and Appelqvist 1991). Petroselinic acid content increased rapidly up to about 3 weeks after pollination and levelling to approximately 75 %. Linoleic acid was the major component in total polar lipids at both early and mature seed stage,

approximately 39 % and 32 %, respectively. Linolenic acid decreased from about 27 % at early to about 3 % at mature stage with concomitant increase in oleic and petroselinic acids. In roots, both triacylglycerols and total polar lipids had linoleic acid as the major fatty acid, 75 % and 69 %, respectively. No petroselinic acid was found in leaves before flowering. However, a very small amount of petroselinic acid was found besides the predominant linoleic and linolenic acids in the triacylglycerol fraction in leaf lipids of plants carrying maturing seed. Seed coats had 45 % petroselinic acid in triacylglycerol but only 1.8 % in total polar lipids. Somatic embryos initiated from developing seeds of domestic carrot failed to accumulate any detectable amount of petroselinic acid in the lipids. Carrot seed was found to contain crotonic acid (*E*)-2-butenic acid (Jasicka-Misiak et al. 2005).

Storage proteins were isolated from dry carrot achenes (Dodeman et al. 1998). These proteins consisted of glycoproteins, the most abundant of which displayed a molecular mass (*M*(r)) of 58,000, albumins of *M*(r) 42,000 comprising at least one beta-1,3-glucanase and two globulins of *M*(r) 90,000 and 50,000–55,000 respectively, the second being an oligomer composed of three subunits of *M*(r) 13,000, 20,000 and 30,000. None of these storage proteins identified in the endosperm were detected in zygotic embryos. In contrast, two novel proteins were isolated from zygotic embryos, namely, a globulin family of *M*(r) 50,000 and pI 6.3–6.8, which was named ‘daucin’, and a late embryogenesis abundant (LEA) protein family of *M*(r) 25,000 named ‘RAB25’. Since the latter proteins were apparently absent in the endosperm, the results suggested that the maturation of carrot zygotic embryos required its own specific set of storage and LEA proteins.

Leaf/Stem Phytochemicals

The following flavonoids were isolated from carrot leaves: luteolin 7- β -D-glucoside, luteolin 4'- β -D-glucoside, luteolin 7- β -D-glucuronide, apigenin 7- β -D-glucoside, apigenin 7-rutinoside, chrysoeriol 7- β -D-glucoside and luteolin 7-rutinoside (Teubert et al. 1977). In *Daucus carota* leaf, the 7-

and 4'-sulfates of luteolin were found; the two characters were polymorphic and appeared to be present more frequently in north temperate than in south temperate populations (Harborne and King 1976). In carrot leaf and root tissues, monoterpenes were biosynthesised exclusively via the 1-deoxy-D-xylulose/2-C-methyl-D-erythritol-4-phosphate (DOXP/MEP) pathway, whereas sesquiterpenes were generated by the classical mevalonic acid pathway as well as by the DOXP/MEP route (Hampel et al. 2005). The experiments demonstrated independent de novo biosynthesis of terpenoids in carrot roots and in carrot leaves. Flavonoid (chlorogenic acid (CA), luteolin 7-*O*-(6''-*O*-malonyl)- β -D-glucopyranoside (L7MG) and luteolin 7-glucoside (L7G)) concentrations were highest in the tissues of new alternate leaves of the reproductive shoot or in new carrot spring foliage (Brooks and Feeny 2004). Chlorogenic acid concentrations in leaf tissues increased throughout the growing season. Leaf-surface amounts of CA, L7G and L7MG were highest at the point in the life cycle when plants were differentiating or bolting.

Constituents identified in carrot leaf and stem essential oil included: caryophyllene (17.24 %), (+)-*epi*-bicyclosesquiphellandrene (10.14 %), phytol (6.35 %), (1*R*)- α -pinene (5.69 %), d-limonene (4.98 %), 3, 7-dimethyl-1, 3, 7-octatriene (4.85 %), 1-methyl-4-(1-methylethylidene)-cyclohexene (3.65 %), 3, 7-dimethyl-(*Z*)-1, 3, 6-octatriene (3.25 %), 1, 1, 4, 8-tetramethyl-*cis*, *cis*, *cis*-4, 7, 10-cycloundecatriene (2.47 %), 1-methyl-4-(1-methylethyl) -1, 4-cyclohexadiene (1.81 %), 1,2,4-trimethoxy-5-(1-propenyl)-(Z)-benzene (1.67 %), hexacosane (1.20 %), caryophyllene oxide (1.09 %), camphene (0.43 %), 4-methyl-1-(1-methylethyl)-bicyclo[3. 1. 0] hex-2-ene (0.19 %), β -pinene (0.53 %), β -myrcene (0.53 %), 1-methyl-3-(1-methylethyl)-benzene (0.47 %), 4-methyl-1-(1-methylethyl) -(*R*)-3-cyclohexen-1-ol (0.10 %), α,α , 4-trimethyl-3-cyclohexene-1-methanol (0.11 %), acetic acid, 1, 7, 7-trimethyl-bicyclo[2. 2. 1] hept-2-yl ester (0.24 %), 2, 5, 5-trimethylcyclohex-2-enone (0.12 %), 1-(2-butenyl) -2, 3-dimethyl-benzene (0.1 %), 4-ethenyl-4-methyl-3-(1-methylethenyl) -1-(1-methylethyl) -(3*R-trans*) -cyclohexene (0.47 %), 1-(2, 6, 6-trimethyl-1, 3-cyclohexadien-1-yl) -2-buten-1-one (0.20 %), 4-methyl-8-

quinolinol (0.24 %), copaene (0.36 %), 1a, 2, 3, 5, 6, 7, 7 a, 7b-octahydro-1, 1, 7, 7a-tetramethyl-[1aR -(1a α , 7 α , 7a α , 7b α)] -1H -cyclopropa[a] naphthalene (0.88 %), 1-methyl-2-(1-methylethyl)-benzene (0.20 %), octahydro-7-methyl-3-methylene-4-(1-methylethyl) -, [3aS -(3a α , 3b β , 4 β , 7 α , 7 aS*)] -1H-cyclopenta[1, 3] cyclopropa[1, 2] benzene (0.28 %), 7, 11-dimethyl-3-methylene-(Z) -1, 6, 10-dodecatriene (0.16 %), germacrene D (0.13 %), α -farnesene (0.92 %), γ -elemene (0.63 %), 1-methyl-4-(5-methyl-1-methylene-4-hexenyl)-(S)-cyclohexene (1.26 %), 2, 3, 4, 7, 8, 8a-hexahydro-3, 6, 8, 8-tetramethyl-[3R-(3 α , 3a β , 7 β , 8a α)] -1H -3a, 7-methanoazulene (0.21 %), 1, 2, 3, 4, 4a, 5, 6, 8 a-octahydro-7-methyl-4-methylene-1-(1-methylethyl) -(1 α , 4a β , 8a α)-naphthalene (0.09 %), 1, 2, 3, 5, 6, 8a-hexahydro-4, 7-dimethyl-1-(1-methylethyl) -(1S-cis)-naphthalene (0.46 %), 1, 3-bis(1-methylethyl) -1, 3-cyclopentadiene (0.38 %), 4-methylene-1-methyl-2-(2-methyl-1-propen-1-yl) -1-vinyl-cycloheptane (0.06 %), epizonarene (0.20 %) τ -muurolol (0.56 %), α -cadinol (0.77 %), 1-methyl-6-methylenebicyclo[3. 2. 0]heptane (0.13 %), α -bisabolol (1.66 %), 1-{2-[3-methyl-3-(5-methyl-furan-2-yl) -butyl] -oxiran-2-yl}-ethanone (0.12 %), 9-octadecyne (0.63 %), N -(3, 4-dichlorophenyl) -2-methyl-2-propenamide (0.42 %), 2, 6, 11, 15-tetramethyl-hexadeca-2, 6, 8, 10 %), geranyl tiglate (0.14 %), 1, 2, 3, 4-tetrahydro-5, 7-dimethyl-naphthalene (0.14 %), hexadecahydro-fluoranthene (0.18 %), 1-(2-butenyl)-2, 3-dimethyl-benzene (0.42 %), 1-(1-naphthyl)ethanol (0.12 %), docosane (0.11 %), 1-cyclohexyl-3-methyl-butane-1, 1-dicarbonitrile (0.41 %), tricosane (0.21 %), 3, 3, 6-trimethyl-1, 5-heptadien-4-one (0.42 %), tetracosane (0.28 %), pentacosane (0.12 %), heptacosane (0.11 %) and nonacosane (0.80 %) (Wu et al. 2006).

Two furocoumarins, 8-methoxypsoralen and 5-methoxypsoralen, were detected in all parts of fresh carrot plants (Ceska et al. 1985) including fruits (Ceska et al. 1986). Carbonic anhydrases were purified and characterised from leaves and roots of mature *Daucus carota* cv. nantes (Demir et al. 1997). Each enzyme molecule was a hexamer having M_r 137,800 and the subunit M_r was 22,800. A dimer carbonic

anhydrase with M_r of 45,700 was also detected. The amount of this dimer was higher in leaves than in roots.

Antioxidant Activity

The antioxidant activity of processed (blanched and dehydrated) and raw purple carrots as measured by DPPH (1, 1-diphenyl-2-picrylhydrazyl) EC_{50} value ranged from 7.80 to 30.23 mg sample/mg DPPH (Uyan et al. 2004). Studies by Zhang and Hamauzu (2004) suggested that phenolics could play an important role in antioxidant properties in carrots, and other hydroxycinnamic derivatives such as dicaffeoylquinic acids in the extracts may exert some strong antioxidant activities along with chlorogenic acid, the major hydroxycinnamic acid, representing from 42.2 % to 61.8 % of total phenolic compounds detected. The phenolic contents in different tissues decreased in the following order: peel > phloem > xylem. Although carrot peel accounted for only 11.0 % of the amount of the carrot fresh weight, it could provide 54.1 % of the amount of total phenolics in 100 g fresh weight of carrots, while the phloem tissue provides 39.5 %, and the xylem tissue provides only 6.4 %. All phenolic extracts had stronger radical scavenging ability than pure chlorogenic acid, vitamin C and β -carotene.

Ravindra and Narayan (2003) found that the anthocyanin obtained from carrot callus culture exhibited an antioxidation activity stronger than malvidin, peonidin and alpha-tocopherol and weaker than delphinidin at pH 2, 4 and 7 by the linolenic acid auto-oxidation system. Studies by Zhang and Hamauzu (2004) suggested that phenolics could play an important role in the antioxidant properties in carrots, and other hydroxycinnamic derivatives such as dicaffeoylquinic acids in the extracts may exert some strong antioxidant activities along with chlorogenic acid, the major hydroxycinnamic acid, representing from 42.2 to 61.8 % of the total phenolic compounds detected. The phenolic contents in different tissues decreased in the following order: peel > phloem > xylem. Although carrot peel accounted for only 11.0 % of the amount of the carrot fresh weight, it could provide 54.1 % of the

amount of total phenolics in 100 g fresh weight of carrots, while the phloem tissue provides 39.5 %, and the xylem tissue provides only 6.4 %. All phenolic extracts had stronger radical scavenging ability than pure chlorogenic acid, vitamin C and β -carotene. Nicolle et al. (2004b) found that the amount of total phenolic acids varied widely in the 20 coloured carrot cultivars, ranging from 3.3 to 16.9 mg of GAE/g of dry weight (gallic acid equivalent). Among fresh material, low levels of phenolics were found in white cultivars (3.3–3.4 mg GAE/g of dry weight), in yellow (4.3–4.4 mg GAE/g dry weight) and in orange cultivars (from 3.3 to 6.0 mg GAE/g dry weight), whereas purple cultivars contained higher amounts of phenolics (9.6 and 16.9 mg GAE/g dry weight). In terms of antioxidant activities against peroxy radical ($\text{ROO}^\bullet$)-generated AAPH [2,2'-azo-bis(2-amidinopropane)dihydrochloride sulfate], the dark orange cultivars had the highest ORAC (oxygen radical absorption capacity) values. Most of the orange cultivars had ORAC values that fell in the average (8.9 μmol Trolox equivalent/gram fresh weight), whereas the white cultivars had the lowest ORAC values. No significant difference between yellow, purple and most of the orange lines was observed. The highest content of carotenoids (mg/100 g Fw) was found in orange cultivars: 'Kazan F_1 ' 17.1 mg β -carotene, 28 mg carotenes and 1.5 mg xanthophylls; 'Afro F_1 ' 16.7 mg β -carotene, 27.4 mg carotenes and 1.1 mg xanthophylls; 'Salsa F_1 ' 13.9 mg β -carotene, 22.8 mg carotenes and 1.3 mg xanthophylls; and 'Korund F_1 ' 13 mg β -carotene, 19.7 mg carotenes and 1.8 mg xanthophylls (Mech-Nowak et al. 2012). The lowest carotenoids were found in white and yellow cultivars: 'White Satin F_1 ' 0.1 mg β -carotene, 0.1 mg carotenes and 0.4 mg xanthophylls and 'Yellowstone F_1 ' 0.5 mg β -carotene, 0.5 mg carotenes and 2.2 mg xanthophylls, while 'Deep Purple F_1 ' purple rooted with a yellow core had slightly higher carotenoids 0.9 mg β -carotene, 1.3 mg carotenes and 2.2 mg xanthophylls. DPPH antioxidant activity did not correspond with total carotenoid contents with the exception of 'Kazan F_1 '. Despite having low-carotenoid content, 'Deep Purple F_1 ' had highest antioxidant capacity

indicating that other compounds tocopherol, unsaturated fatty acids and polyphenols including anthocyanins may be responsible for its antioxidant capacity. No relevant differences were not found in total antioxidant capacity (DPPH) between tested 'Nante', 'Bolero', 'Champion' and 'Maestro' carrot hybrids as 22.33 % DPPH, 22.16 % DPPH and 22.84 % DPPH, respectively, but different antioxidant capacity was detected in carrot hybrids 'Forto' and 'Berlikum', as 24.28 % DPPH and 23.12 % DPPH, respectively (Rakcejeva et al. 2012).

Studies showed that the highest values for quality characteristics, such as antioxidant capacity and total pectin, total phenolic and total carotenoid contents of carrot juice, were obtained with the combined electrical applications (electroplasmolysis + microwave) (Rayman and Baysal 2011). As a result of electroplasmolysis, a 9.7 % increase in juice yield was obtained. In addition, 100 % pectin methylesterase inactivation was found with the microwave heating application. In addition, these quality characteristics were protected better in the group of combined applications of the electrical methods (electroplasmolysis + microwave) during storage. Compared with fresh carrot juice, blanching and enzyme liquefaction could result in the increase of the total polyphenol content (TPC) and the antioxidant activity in scavenging DPPH free radicals (DPPH) and Fe(2+)-chelating capacity (FC), whereas pasteurisation could result in the decrease of the TPC and the antioxidant activity in DPPH and FC (Ma et al. 2013). In contrast, blanching, enzyme liquefaction and pasteurisation showed little influence on the antioxidant activity in lipid peroxidation protection. Polyphenols still retained high antioxidant activity after the processes, with potential health benefits for consumers.

Of the following coloured carrots, orange, white, yellow, red, solid-coloured purple and purple with an orange core, the higher α -carotene content in the orange cultivar and the purple cultivar with an orange core resulted in a higher antioxidative capacity (Grassmann et al. 2007). Also, the lycopene content in the red cultivar was higher in 2004 than in 2003, which again led to an increased antioxidative capacity. In the case of

phenolics, higher values were found for the purple-coloured cultivars in 2004, which only in the case of the purple cultivar with an orange core, however, led to a higher antioxidative capacity.

In seven coloured carrots, anthocyanins were the major antioxidants in purple–yellow and purple–orange carrots, and chlorogenic acid was a major antioxidant in all carrots (Sun et al. 2009). Chlorogenic acid, caffeic acid, *p*-hydroxybenzoic acid, ferulic acid and other cinnamic acid isomers predominated in carrots of different colours. Carotenoids did not contribute to total antioxidant capacity, but correlated with antioxidant capacity of hydrophobic extracts. Both the DPPH (2,2'-diphenyl-1-picrylhydrazyl) and ABTS (2,2'-azinobis(3-ethylbenzothiazoline-6-sulfonic acid) assays showed that the hydrophilic extract had higher antioxidant capacity than the hydrophobic extract. Purple–yellow carrots had the highest antioxidant capacity, followed by purple–orange carrots, and the other carrots did not significantly differ. The antioxidant capacity of purple–yellow carrots was >90 times higher than that of the hydrophobic extracts in both ABTS and DPPH assays. Purple carrots had higher antioxidant capacity values due to their anthocyanin content (Metzger and Barnes 2009). Deep Purple carrot had the highest concentration of total polyacetylenes, total α -tocopherol and total phenolics. The reducing capacity expressed in Trolox equivalents units of two black carrot cultivar extracts from Cuevas Bajas, Spain, was determined to be 86.4 and 182.0 $\mu\text{M TE}/100\text{ g fw}$ and the radical scavenging ability to be 17.6 and 240.0 $\mu\text{M TE}/100\text{ g fw}$ (Algarra et al. 2014). The antioxidant features of the black carrot extracts were shown to be significantly higher than those of orange carrots. Pectinase enzyme-assisted processing significantly improved the antioxidant composition of black carrot juice (Khandare et al. 2011). There was an overall increase of 33 % in juice yield, 27 % in total phenolics and 46 % in total flavonoids. The total anthocyanin content in black carrot juice was almost doubled. The in-vitro total antioxidant activity in black carrot juice extracted through enzyme-assisted processing was 30.0 and 62.0 $\mu\text{mol TE}/\text{mL}$ in ferric reducing antioxidant power (FRAP) and cupric-reducing antioxidant capacity (CUPRAC) assays, respectively.

Purple carrot cultivars possessed on average 9 times more phenolics in mg/100 g FW (245.7 mg total phenols (Folin–Ciocalteu), 311.5 mg total phenols (UV/Vis), 95 mg phenylpropanoids, 51.6 mg flavonols) and high in anthocyanins (64.9 mg/100 g FW) than roots of other colours and exhibited the highest radical scavenging activity (RSA) 51.5 % (Leja et al. 2013). Red carrot cultivars contained 31 mg total phenols (Folin–Ciocalteu), 40.4 mg total phenols (UV/Vis), 9.6 mg phenylpropanoids, 6.5 mg flavonols and 0.5 mg anthocyanins and had an RSA of 9.3 %. The orange, white and yellow exhibited lower RSA, on average, at 6 % level. Orange carrot cultivars contained 29.3 mg total phenols (Folin–Ciocalteu), 39.6 mg total phenols (UV/Vis), 9.5 mg phenylpropanoids, 6.5 mg flavonols and 0.5 mg anthocyanins and had an RSA of 6.6 %. Yellow carrot cultivars contained 21.5 mg total phenols (Folin–Ciocalteu), 35.3 mg total phenols (UV/Vis), 9.5 mg phenylpropanoids, 6.5 mg flavonols and 0.5 mg anthocyanins and had an RSA of 6.0 %. White carrot cultivars contained 186 mg total phenols (Folin–Ciocalteu), 24.2 mg total phenols (UV/Vis), 5.4 mg phenylpropanoids, 3.5 mg flavonols and 0.2 mg anthocyanins and had an RSA of 6.0 %. Carrots of Asian origin belonging to Eastern gene pool were more often purple or red and richer in phenolics and had higher antiradical activity than those from the Western gene pool with mainly orange roots.

Intense wounding (23.5 cm²/g) of carrots induced approximately 2.5- and 12.4-fold increase in soluble phenolics and antioxidant capacity, respectively, after 4 days compared to whole carrots (Surjadinata and Cisneros-Zevallos 2012). Wounding induced the synthesis of mainly chlorogenic acid (5-CQA) and 3,5-dicaffeoylquinic acid. A higher proportion of 5-CQA in the phenolic mixture was responsible for an increasing specific antioxidant capacity (809 and 1,619 µg Trolox/mg phenolics for whole carrots and shreds, respectively, for Choctaw cultivar). Wounded carrots can be promoted as an inexpensive rich source of phenolic antioxidants for the regular diet. Carrot oil (extracted from the umbels) exhibited antioxidant activity in-vitro using 1,1-diphenyl-2-picryl hydrazyl free radical scavenging assay

(DPPH), ferrous ion chelating assay (FIC) and the ferric reducing antioxidant power assay (FRAP) (Shebaby et al. 2013). The FRAP value was 164 $\mu\text{mol FeSO}_4/\text{g}$, and the IC_{50} values for DPPH and FIC assays were 2.1 mg/ml and 0.43 mg/ml, respectively.

Studies by Chatatikun and Chiabchalard (2013) demonstrated that ethanolic extracts of baby carrot and carrot had a high amount of phenolic and flavonoid compounds and had high antioxidant activities as measured by DPPH and ABTS. Baby carrots had higher antioxidant activities than carrots, and the ethanolic extracts of carrot and baby carrot showed higher antioxidant activities than petroleum extracts. Fractions with high phenolic or flavonoid contents also had high antioxidant activities when they were assayed by DPPH and ABTS.

Ethanolic extracts of baby carrots (33.0 mg VCEAC/g dry plant material) and carrots (27.5 mg VCEAC/g dry plant material) had significantly higher DPPH antioxidant activities as compared to those found in petroleum extracts. Ethanolic extracts from baby carrots and carrots had antioxidant activities of 42.2 and 34.5 mg VCEAC/g dry plant material, respectively. Ethanolic extracts of baby carrots and carrots showed high scavenging activities with $\text{IC}_{50} = 830 \mu\text{g/ml}$ and $837.5 \mu\text{g/ml}$, respectively. Antioxidant activities of petroleum extract from baby carrots and carrots were 14.7 and 4.2 mg VCEAC (vitamin C equivalent antioxidant capacity)/g dry plant material, respectively. Ethanolic extracts of baby carrot and carrot had a total phenolic content of 35.9 and 30.7 mg GAE/g dry plant material, respectively. Ethanolic extracts from baby carrots and carrots had total flavonoid contents of 35.3 and 20.4 mg QE/g dry plant material, respectively, while petroleum extracts from baby carrot and carrot had total flavonoid content of 17.7 and 3.7 mg. The results suggested that baby carrots had higher flavonoid contents than carrots and the ethanolic extracts had higher flavonoid contents than the petroleum extracts.

Although the dichloromethane flower extract showed potent DPPH scavenging activity (32.57 %), the isolated

compounds D, L-iditol, kaempferol 3-*O*-B-glucoside, laserine and a mixture of stigmasterol and sitosterol showed weaker activity; kaempferol 3-*O*-B-glucoside showed higher 9.2 % activity than the other compounds (Akgul et al. 2009).

Anti-inflammatory Activity

Volatile oil of carrot seeds at 50 and 100 mg/kg resulted in 60 and 70 % inhibition of carrageenan-induced rat paw oedema, respectively (Porchezian et al. 2000). Carrot seed extract at doses of 200 and 400 mg/kg significantly inhibited carrageenan-, histamine- and serotonin-induced paw oedema as well as formaldehyde-induced arthritis in rats (Vasudevan et al. 2006).

2,4,5-trimethoxybenzaldehyde (1), oleic acid (2), *trans*-asarone (3) and geraniol (4) isolated from carrot seeds were found to be cyclooxygenase inhibitors (Momin et al. 2003). All four compounds exhibited 3.32, 45.32, 46.15 and 3.15 % of prostaglandin H endoperoxide synthase-I (COX-I) inhibitory activity and 52.69, 68.41, 64.39 and 0 % prostaglandin H endoperoxide synthase-II (COX-II) inhibitory activity at 100 mg/ml, respectively. Compound 1 showed selectivity towards COX-II enzyme inhibition at 100 µg/mL. The inhibition of COX-II enzymes by compounds 1 at 100 µg/mL was significant when compared to aspirin, ibuprofen, naproxen and Celebrex at concentrations studied.

A bioactive chromatographic fraction of purple carrot extract attenuated lipopolysaccharide (LPS) inflammatory response (Metzger et al. 2008; Metzger and Barnes 2009). There was a dose-dependent reduction in nitric oxide production and mRNA of proinflammatory cytokines (IL-6, IL-1β, TNF-α) and iNOS in macrophage cells. Protein secretions of IL-6 and TNF-α were reduced 77 and 66 % in porcine aortic endothelial cells treated with 6.6 and 13.3 µg/mL of the LH-20 fraction, respectively. Polyacetylene compounds falcarindiol, falcarindiol 3-acetate and falcarinol isolated from the bioactive fraction reduced nitric oxide production in macrophage cells by as much as 65 % without cytotoxicity. The results suggested that polyacetylenes, not

anthocyanins, in purple carrots were responsible for anti-inflammatory activity. Only seven coloured carrot varieties had inhibitory activity ($IC_{25} = 257\text{--}1,321\text{ }\mu\text{g/mL}$) in macrophage cells. Carrot aqueous extract exhibited anti-inflammatory effect on acetic acid-induced experimental colitis in rats (Patil et al. 2012a). Seven days pretreatment with carrot aqueous extract (200 and 400 mg/kg, p.o.) significantly decreased stool consistency, macroscopic score and colitis-elevated colon weight, colon width, colon weight to length ratio, spleen weight, ulcer area, ulcer index, colonic myeloperoxidase and nitric oxide. Carrot extract significantly attenuated histological alterations associated with acetic acid-induced ulcerative colitis.

Cardiovascular Protective Activity

Administration of carrot extract ameliorated the adverse effects of isoproterenol-induced myocardial infarction in rats and maintained cardiac tonicity (Muralidharan et al. 2008). Isoproterenol-elevated serum aspartate transaminase and alanine transaminase, lactate dehydrogenase, lipid peroxidase levels and elevated lipid peroxidation in heart homogenate were decreased by carrot extract. The decreased total protein and lactate dehydrogenase levels in the heart homogenate were restored to near normal levels by carrot extract. The levels of Na^+K^+ ATPase and Mg^{2+} ATPase were decreased and that of Ca^{2+} ATPase was increased in carrot-treated group significantly. Potter et al. (2011) found that adults drinking carrot juice may protect the cardiovascular system by increasing total antioxidant status and by decreasing lipid peroxidation independent of any of the cardiovascular risk markers measured. Drinking carrot juice did not affect the plasma cholesterol, triglycerides, Apo A, Apo B, LDL, HDL, body fat percentage, insulin, leptin, interleukin-1a or C-reactive protein. Drinking carrot juice decreased systolic pressure, but did not influence diastolic pressure. Drinking carrot juice significantly increased the plasma total antioxidant capacity and decreased plasma malondialdehyde production.

Hepatoprotective Activity

Carrot extract exhibited hepatoprotective activity against carbon tetrachloride (CCl₄)-induced hepatocellular injury in mice (Bishayee et al. 1995). The elevated serum enzyme levels (viz., serum glutamate oxaloacetate transaminase (SGOT), serum glutamate pyruvate transaminase (SGPT), lactate dehydrogenase, alkaline phosphatase (ALP), sorbitol and glutamate dehydrogenase) by CCl₄ induction were significantly lowered due to pretreatment with carrot extract. The extract also decreased the elevated serum bilirubin and urea content due to CCl₄ administration. Increased activities of hepatic 5'-nucleotidase, acid phosphatase, acid ribonuclease and decreased levels of succinic dehydrogenase, glucose 6-phosphatase and cytochrome P450 produced by CCl₄ were reversed by the extract in a dose-responsive manner. On another study, oral administration of carrot extract (25 mL/kg/day) for 30 days produced significant hepatoprotection against lindane (20 mg/kg/day)-induced hepatotoxicity in rats (Balasubramaniam et al. 1998). The elevated levels of serum enzymes, namely, aspartate transaminase, alanine transaminase and alkaline phosphatase and the levels of thiobarbituric acid reactive substances, cholesterol, triglycerides and LDL cholesterol in lindane administered rats were observed to be decreased significantly in the lindane + carrot extract group. The carrot extract also restored the depressed antioxidants and HDL cholesterol levels to near normal. Singh et al. (2012b) reported that methanol carrot seed extract protected the liver against oxidative stress induced in rats by thioacetamide. Carrot seed-treated rats showed a significant decrease in SGPT, SGOT and ALP levels and lipid peroxidation compared to the thioacetamide group. Carrot seed extract-treated group recorded increases in antioxidant enzymes, superoxide dismutase (SOD), catalase (CAT), glutathione reductase (GRD), glutathione peroxidase (GPX) and glutathione S-transferase (GST).

Gastroprotective Activity

Administration of carrot juice at the dose of 200 and 400 mg/kg to rats significantly decreased gastric volume, free acidity, total acidity and ulcer index, while it increased the pH and the mucus content as compared with control (Nayeem et al. 2010). Carrot juice at a dose of 400 mg/kg produced 60.45, 56.80 and 43.51 % significant inhibition when gastric ulceration were induced by pylorus ligation, aspirin and ethanol, respectively. The results indicated that carrot juice possessed gastroprotective property and the results supported traditional uses of the roots of this plant in the treatment of gastric ulcer and acidity.

Anticancer Activity

In-Vitro Studies

Among all the compounds isolated from carrot roots, phloretin and quercetin were the most effective in decreasing the viability of human colon cancer cell lines (HT29 and LoVo cells) (Przybylska et al. 2007). In the case of HT29 cells, the IC₅₀ for phloretin was determined as 400 µmol/L and 260 µmol/L after 5 hour and 24 hour incubation, respectively, whereas for LoVo cells the IC₅₀ was determined as 380 µmol/L and 170 µmol/L after 5 hour and 24 hour incubation, respectively. The addition of chlorogenic acid (present in both carrot juice and roots) and caffeic acid (present in carrot juice) to the cell culture medium reduced the viability of both cell lines in a significant manner. Caffeic acid was significantly more effective, decreasing survival of HT29 cells to 62.06 % and 25.07 % at 500 µmol/L and 1,000 µmol/L, respectively. LoVo cells were less sensitive to caffeic acid, the highest concentration (1,000 µmol/L) decreasing viability to 68.27 % after 24 hours. Chlorogenic acid had less effect on the viability of both cancer cell lines. A nonpolar active phenylpropanoid component from carrot, 2-epilaserine, exhibited significant cytotoxicity against HL-60 cancer cells (Yang et al. 2008). Carrot oil (extracted from the umbels) exhibited anticancer activity against human colon (HT-29, Caco-2) and breast (MCF-7, MDA-MB-231) cancer cell lines (Shebawy et al. 2013). It exerted a significant increase in cell death and

decrease in cell proliferation in a time- and dose-dependent manner.

The sesquiterpene daucucarotol, isolated from the fruit, displayed weak cytotoxic activity against human gastric cancer cell lines BGC-823 with inhibition of 13.3 %, but showed less cytotoxicity against AGS (Fu et al. 2009). Daucuside (1) and daucusol (2) were isolated from the fruits and were also evaluated for the cytotoxic effects against two human gastric cancer cell lines BGC-823 and AGS (Fu et al. 2010c).

Treatment of leukaemia cell lines with carrot juice extract induced apoptosis and inhibited progression through the cell cycle (Zaini et al. 2011). Lymphoid cell lines were affected to a greater extent than were myeloid cell lines, and normal haematopoietic stem cells were less sensitive than most cell lines. The study showed that extracts from carrots could induce apoptosis and cause cell cycle arrest in leukaemia cell lines. Carrots had been reported to contain beneficial agents, such as β -carotene and polyacetylenes, which could be effective in the treatment of leukaemia.

A hormesis effect was seen for isolated carrot polyacetylenes (falcarinol and falcarindiol) when added to Caco-2 cancer cells in concentrations ranging from 1 ng/mL to 20 μ g/mL (Purup et al. 2009). The relative inhibitory potency was falcarinol > falcarindiol. No hormesis effect was observed when adding the polyacetylenes to human intestinal epithelial cells of normal origin (FHs 74 Int.). Combinations of falcarinol and falcarindiol added to normal and cancer cells showed a synergistic response for the inhibition of cell growth. Extracts of carrots, containing different amounts of falcarinol, falcarindiol and falcarindiol 3-acetate had significant inhibitory effects on both normal and cancer cell proliferation. In cancer cells, the extract containing the highest concentration of falcarinol tended to have the highest growth inhibitory effect, in accordance with a higher potency of falcarinol than falcarindiol. In another study, treatment of all three human lymphoid leukaemia cell lines with the fraction from carrot extracts which contained polyacetylenes (falcarinol, falcarindiol and falcarindiol 3-acetate) and carotenoids (β -carotene and lutein) was significantly more cytotoxic than the

four other fractions (Zaini et al. 2012). Treatments with purified polyacetylenes also induced apoptosis in a dose- and time-responsive manner. Moreover, falcarinol and falcarindiol 3-acetate isolated from carrot were more cytotoxic than falcarindiol. In contrast, the carotenoids showed no significant effect on either apoptosis or cell proliferation in any of the cells investigated. Ethanol extracts of lyophilised black carrot calli and black carrot harvested from fields were assayed for anticancer activity in-vitro on various human cancer cell lines including MCF-7, SK-BR-3 and MDA-MB-231 (human breast adenocarcinomas); HT-29 (human colon adenocarcinoma); PC-3 (human prostate adenocarcinoma); and Neuro-2A (*Mus musculus* neuroblastoma) cancer cell lines (Sevimli-Gur et al. 2013). The highest cytotoxic activity was achieved against Neuro-2A cell lines exhibiting viability of 38–46 % at 6.25 µg/ml concentration for all calli and natural extracts. A significantly high IC₅₀ value of 170.13 µg/ml was attained in normal cell line Vero indicating that its potential as an ideal candidate for the treatment of brain cancer without causing negative effects to normal healthy cells.

Animal Studies

The petroleum ether extract of carrot seeds administered intraperitoneally at doses of 3 mg and 10 mg/kg body weight/day for 7 days showed antitumour activity, inhibiting the growth of Ehrlich ascites tumour in mice (Majumder and Gupta 1998). Kobaek-Larsen et al. (2005) found that the dietary treatments of a standard rat feed Altromin supplemented with either carrot containing 35 µg/g falcarinol or maize starch supplemented with 35 µg falcarinol/g purified from carrots delayed or retarded the development of large aberrant crypt foci and azoxymethane (AOM)-induced colon preneoplastic tumours in male BDIX rats. Zeinab et al. (2011) reported that topical treatment of carrot umbel oil extract exhibited remarkable antitumour activity against 7,12-dimethyl benz(a)anthracene (DMBA)-induced skin cancer compared with non-treated mice. Carrot oil delayed tumour appearance and inhibited tumour incidence and yield.

Survey/Clinical Studies

In a food and supplement use in a population-based case-control study of breast cancer risk conducted in Maine, Massachusetts, New Hampshire and Wisconsin in 1988–1991, Longnecker et al. (1997) found that eating carrots or spinach more than twice weekly, compared with no intake, was associated with an odds ratio of 0.56 (95 % confidence interval 0.34–0.91). Estimated intake of preformed vitamin A from all evaluated foods and supplements showed no trend or monotonic decrease in risk across categories of intake. These data did not allow them to distinguish among several potential explanations for the protective association observed between intake of carrots and spinach and risk of breast cancer. The findings were, however, consistent with a diet rich in these foods having a modest protective effect. In a randomised crossover trial of 22 healthy young men on a low-carotenoid diet, consumption of carrot juice led to a marked increase of β -carotene and α -carotene in faeces and faecal water, as did lycopene after consumption of tomato juice (Schnäbele et al. 2008). Faecal water showed high dose-dependent cytotoxic and antiproliferative effects on colon adenocarcinoma cells (HT29). These effects were not markedly changed by carrot and tomato juice consumption. Neither bile acid concentrations nor activities of the bacterial enzymes beta-glucosidase and beta-glucuronidase in faecal water changed after carrot and tomato juice consumption. Faecal water pH decreased only after carrot juice consumption. Short-chain fatty acids (SCFA) were probably not responsible for this effect, as SCFA concentrations and profiles did not change significantly. In summary, the 2-week intervention with carotenoid-rich juices led only to minor changes in investigated luminal biomarkers relevant to colon carcinogenesis. Based on evidence that higher plasma carotenoid concentrations may be protective in relation to breast cancer recurrence, Butalla et al. (2012) conducted a study on carrot juice intervention of 69 overweight breast cancer survivors. They found daily intake of fresh carrot juice to be a simple and effective approach to increasing plasma total carotenoids and in turn reducing oxidative stress, but not

inflammatory markers, in women previously treated for breast cancer.

Antihypercholesterolemic Activity

A 3-week diet supplementation with carrot (15 % dry matter) caused a significant decrease of liver cholesterol and liver triglycerides in cholesterol-fed rats (Nicolle et al. 2003). Faecal total steroid excretion increased by 30 % upon feeding the carrot diet as compared to the control. The secretion of bile acids was maintained, whereas the cholesterol apparent absorption was reduced in rats fed with carrot diet. Carrot consumption also improved the antioxidant status. It significantly decreased the urinary excretion of thiobarbituric acid reactive substances (TBARS), reduced the TBARS levels in heart, increased the vitamin E plasmatic level and tended to increase the ferric reducing ability of plasma (FRAP) as compared to the controls. The carrot diet provided carotenoid antioxidants: 5.1 mg β -carotene, 1.6 mg α -carotene and 0.25 mg lutein per 100 g diet. β -carotene was also detected in the liver and heart. They also found that although vitamin E was not affected by carrot diet, vitamin E–triglycerides ratio was significantly higher in animals fed with carrot diets. The carrot diet induced an increase of vitamin E in the heart in both cholesterol-free and cholesterol-supplemented mice suggesting a higher protection of this tissue (Nicolle et al. 2004a).

In a randomised, double-blind, placebo-controlled trial of 16 obese males, A 4-week intervention of dried purple carrot (118.5 mg/day of anthocyanins and 259.2 mg/day of phenolic acids) resulted in no statistically significant changes in body mass, body composition, appetite, dietary intake, low density lipoprotein, total cholesterol, blood pressure or C-reactive protein in these obese participants (Wright et al. 2013). However, high density lipoprotein cholesterol was lower in the intervention group. Aspartate aminotransferase and alanine aminotransferase did not change, indicating that the intervention was safe.

Antithrombotic Activity

The different carrot varieties demonstrated a variable effect on thrombosis in-vitro and in-vivo (Yamamoto et al. 2008). In particular, a variety designated SAKATA-0421 exerted an antithrombotic effect in-vivo independent from heat treatment of the filtrate at 100 °C for 10 minutes. After oral intake, the particular heat-resistant variety (SAKATA-0421) showed antithrombotic effect in-vivo possibly due to antiplatelet reactivity and/or spontaneous thrombolytic activity. There was no significant correlation between antithrombotic activity and the levels of polyphenolics and any other biochemical parameter, including antioxidant activity, α -carotene and β -carotene, alpha-tocopherol and ascorbic acid.

Hypotensive Activity

Intravenous administration of two coumarin glycosides coded as DC-2 and DC-3 from carrot caused a dose-dependent (1–10 mg/kg) fall in arterial blood pressure in normotensive anaesthetised rats (Gilani et al. 2000). In in-vitro studies, both compounds caused a dose-dependent (10–200 μ g/ml) inhibitory effect on spontaneously beating guinea pig atria as well as on the K^+ -induced contractions of rabbit aorta at similar concentrations. These results indicated that DC-2 and DC-3 may be acting through a blockade of calcium channels, and this effect may be responsible for the blood pressure-lowering effect of the compounds observed in the in-vivo studies.

Wound Healing Activity

Animals treated with topical ethanolic extract of *Daucus carota* cream formulation (1 %, 2 % and 4 % w/w) showed significant decrease in wound area, epithelisation period and scar width, whereas rate of wound contraction significantly increased as compared to control group animals in excision wound model (Patil et al. 2012b). In incision wound model there was significant increase in tensile strength, hydroxyproline content and protein content of animals treated with topical carrot root cream formulation (2 % and 4 % w/w,

respectively). When applied topically, the cream did not show any sign and symptoms of skin irritation.

Cognitive Function Enhancement Activity

A quaternary base chloride, isolated from a water-soluble fraction of an alcoholic extract of carrot seeds, exhibited procholinergic activity (Gambhir et al. 1966a, b). It was found to inhibit brain cholinesterase activity thereby elevating the brain acetylcholine levels via increased synthesis of acetylcholine, which would in turn prove beneficial in cognitive dysfunctions. Ethanol carrot seed extract (200, 400 mg/kg, p.o.) exerted significant improvement in memory scores of young mice in the elevated plus maze test and aged mice using the passive avoidance apparatus (Vasudevan and Parle 2006). Further, carrot seed extract reversed the amnesia induced by diazepam. The extract (200, 400 mg/kg, p.o.) reduced significantly the brain acetylcholinesterase activity and cholesterol levels in young and aged mice. The results indicated that carrot seed extract may prove to be a useful remedy for the management of cognitive dysfunctions on account of its multifarious beneficial effects such as memory-improving property, cholesterol-lowering property and anticholinesterase activity. In another study, administration of carrot seed ethanol extract (200 and 400 mg/kg, p.o.) elicited significant improvement in memory of young and aged rats in the elevated plus maze, Hebb-Williams maze and hexagonal swimming pool tests (Mani et al. 2010). Carrot seed extract also reversed the amnesia induced by scopolamine (0.4 mg/kg, i.p.) and diazepam (1 mg/kg, i.p.).

Anticataract/Anti-macular Degenerative Activity

In normotensive rabbits topical application of carrot seed extract at the concentration of 0.3, 0.6 and 1.2 % resulted in mean IOP (intraocular pressure) reduction of 19.33, 23.20 and 25.61 %, respectively, from baseline (Agarwal et al. 2008). In water-loaded rabbits, maximum mean IOP reduction with 0.6 % carrot extract was 29.39 %, which was comparable to

pilocarpine. In steroid pretreated rabbits, maximum mean IOP reduction was 30.27 % from baseline, which was significantly higher than pilocarpine. A human intervention study showed that consumption of carrot juice containing high concentrations of the provitamin A carotenoid β -carotene resulted in slightly, non-significantly increased plasma retinol concentrations and significantly increased (almost double, from 1.2 to 2.0 ng/mL) plasma concentrations of all-*trans*-retinoic acid (Rühl et al. 2008). In contrast, consumption of tomato juice and spinach powder resulted in no significant alteration in concentrations of plasma retinol and vitamin A metabolite and all-*trans*-retinoic acid. Yoon et al. (2013) found that pretreatment with extract of carotenoid-overexpressing transgenic carrot enhanced antioxidant and protective activities on degenerative diseases of the eye. The carrot extract reduced cell death in a retinal ganglion cell line, RGC-5 cells, exposed to 1-buthionine-(*R,S*)-sulfoximine and L-glutamic acid.

In a randomised, blinded, 3×3 crossover intervention study of four women and five men aged 23–28 years, consumption of yellow carrots rich in lutein significantly increased serum lutein concentrations and did not result in the decrease in β -carotene concentrations that accompanies administration of lutein supplements (Molldrem et al. 2004). Lutein from the yellow carrot treatment was 65 % as bioavailable as that from the lutein supplement treatment. Increasing lutein intake from foods could increase the density of macular pigment of the human retina and decrease the risk of developing macular degeneration.

Antinociceptive Activity

Carrot seed extract at doses of 200 and 400 mg/kg significantly attenuated the writhing responses induced by an intraperitoneal injection of acetic acid and late phase of pain response induced by a subplantar injection of formalin in mice (Vasudevan et al. 2006).

Immunomodulatory Activity

In a blinded, randomised, crossover study of healthy men, supplementation of a low-carotenoid diet with tomato or carrot resulted in relatively fast responses in plasma carotenoid concentrations which were not accompanied by concomitant changes in immune functions (Watzl et al. 2003). For IL-2, NK cell cytotoxicity and lymphocyte proliferation, maximum responses were observed during depletion periods. The highest production rate was measured only for TNF-alpha at the end of the first intervention period. Juice intervention did not modulate the secretion of IL-4. The study showed that increased plasma carotenoid concentrations after vegetable juice consumption were accompanied by a time-delayed modulation of immune functions in healthy men consuming a low-carotenoid diet.

Zhang et al. (2010) transformed the gene of UreB (urease B) an effective and common immunogen of all strains of *Helicobacter pylori* into carrot by *Agrobacterium*-mediated transformation, and the regenerated carrot plants demonstrated that the expressed UreB protein accounted for 25 µg/g roots was effective to induce immune response in mice. The results suggested that the UreB transgenic carrot could be potentially used as an edible vaccine for controlling *H. pylori*.

Spasmolytic Activity

The tertiary base isolated from carrot seeds was found to have papaverine-like nonspecific smooth muscle relaxant and spasmolytic activity, but its activity was found to be about one tenth of that of papaverine (Gambhir et al. 1979).

Renoprotective Activity

Oral daily administration 14 days prior and 14 days after the induction of renal ischaemia/(I/R) in rats with petroleum ether carrot extract, fractional methanol carrot extract and direct methanol carrot all at 250 and 500 mg/kg dosage significantly reduced the levels of serum creatinine, uric acid and urea compared to disease control (Afzal et al. 2013). The findings demonstrated that postconditioning with carrot root extract significantly improved kidney function in I/R rats.

Vitamin A/Carotenoid/Anthocyanin Availability Activity

Studies showed that a 4-week supplemental feeding with twice the amount of α -carotene isolated from carrots was as effective as β -carotene in maintaining the vitamin A status of Mongolian gerbils (*Meriones unguiculatus*) (Tanumihardjo and Howe 2005). Conversion factors were approximately 5.5 μg α -carotene or approximately 2.8 μg β -carotene to 1 μg retinol. Feeding studies in Mongolian gerbils (*Meriones unguiculatus*) showed that red carrot maintained vitamin A status, but constituent β -carotene may interfere with hepatic lycopene bioavailability (Mills et al. 2007). Another study found that liver stores of β -carotene or vitamin A in the gerbils did not differ between orange and purple carrot diets when equal amounts of β -carotene from each of the diets were consumed (Dosti et al. 2006). Both the orange and purple carrot diet resulted in higher liver vitamin A compared with the supplement. High β -carotene carrots resulted in more than twofold higher β -carotene and 1.1 times greater vitamin A liver stores compared with typical orange carrots. The results suggested that high β -carotene carrots may be an alternative source of vitamin A to typical carrots in areas of vitamin A deficiency. Second, phenolics including anthocyanins and phenolic acids in purple carrot do not interfere with the bioavailability of β -carotene from purple carrots.

In a study of eight healthy females aged 23–36 years old, daily consumption of processed carrots and spinach over a 4-week period produced an increase in plasma β -carotene concentration that averaged three times that associated with the consumption of the same amount of β -carotene from these vegetables in the raw form (Rock et al. 1998). The results suggested that isomerisation of β -carotene by heat treatment did not negate the enhanced β -carotene uptake associated with consuming commercially processed vegetables compared with raw vegetables. The results of two crossover studies in humans showed lycopene and β -carotene to be bioavailable from red carrots, and lycopene absorption appeared to be affected by carrot fibre (Horvitz et al. 2004). It was found that the

lycopene in the red carrot was about 44 % as bioavailable as that from tomato paste. Red carrots provide an alternative to tomato paste as a good dietary source of lycopene and also provide bioavailable β -carotene. Administration of orange carrot (OC) and purple carrot (PC) smoothies to female subjects at breakfast did not affect the absorption of β -carotene postprandially (first 24 hours) (Arscott et al. 2010). Peak plasma concentrations of OC and PC treatments did not differ.

In a clinical feeding study using purple carrots as the anthocyanin source, plasma and urine responses were found to be lower for acylated versus nonacylated anthocyanins from raw carrots (463 μmol of anthocyanins: 400 μmol acylated, 63 μmol nonacylated), 250 g cooked (357 μmol of anthocyanins: 308.5 μmol acylated, 48.5 μmol nonacylated) and 500 g cooked (714 μmol of anthocyanins: 617 μmol acylated, 97 μmol nonacylated) purple carrots (Kurilich et al. 2005). Four of the five carrot anthocyanins were found intact in plasma by 30 minutes after carrot consumption and peaked between 1.5 and 2.5 hours. Acylation of anthocyanins resulted in an 11–14-fold decrease in anthocyanin recovery in urine and an eight to tenfold decrease in anthocyanin recovery in plasma. Cooking increased the recovery of nonacylated anthocyanins but not acylated anthocyanins.

Antimicrobial Activity

Sesquiterpenes daucane esters, 2 α -acetyloxy-4 β -hydroxy-6 α -*p*-hydroxybenzoyloxy-dauc-8-ene, 2 α -acetyloxy-4 β -hydroxy-6 α -angeloyloxy-10 β -hydroxybenzoyloxy-dauc-8-ene and fercomin, and ferulenol, from wild carrot roots, exhibited low antibacterial activities against 4 Gram-positive (*Staphylococcus aureus*, *Streptomyces scabies*, *Bacillus subtilis*, *Bacillus cereus*) and two Gram-negative species (*Pseudomonas aeruginosa*, *Escherichia coli*) as well as antifungal against *Fusarium oxysporum* and *Aspergillus niger* (Ahmed et al. 2005). The essential oil obtained from carrot aerial parts at the end of the flowering stage inhibited in-vitro growth of human enteropathogen *Campylobacter jejuni*, *Campylobacter coli* and *Campylobacter lari* strains tested, including one multidrug-resistant *C. jejuni* strain (Rossi et al.

2007). Compounds that were responsible for the antibacterial activity were identified as (*E*)-methyloisoeugenol and elemicin.

The strongest antifungal activity was observed for the main constituent of carrot seed oil, carotol, which inhibited the radial growth of *Alternaria alternata* (Jasicka-Misiak et al. 2004). Supercritical extracts contain lower amounts of monoterpenes and higher amounts of sesquiterpene hydrocarbons. Antifungal activities of the Sardinian carrot umbel oils were the highest, particularly for dermatophytes and *Cryptococcus neoformans*, with MIC values of 0.16–0.64 $\mu\text{L/mL}$ (Maxia et al. 2009). Carrot essential oils exhibited antimicrobial activity against *Escherichia coli*, *Staphylococcus aureus* and clinical strains of *Candida albicans* and *C. tropicalis* 1011 RM; the MIC values obtained were all $>2.5\%$ (v/v) (Marzouki et al. 2010). Tunisian carrot seed essential oils exhibited interesting antibacterial and antifungal activities against one Gram-positive (*Staphylococcus aureus*) and two Gram-negative bacteria (*Escherichia coli* and *Salmonella typhimurium*), as well as against a pathogenic yeast (*Candida albicans*) (Rokbeni et al. 2013).

Agglutinating Activity

An extract of *D. carota* induced agglutination of most serotypes of *Streptococcus mutans* but not of *Streptococcus salivarius* or *Streptococcus mitis* (Bratthall 1978). When added to a suspension of mixed bacteria, a piece of *D. carota* may selectively sorb *S. mutans*, while *S. salivarius* and *S. mitis* were affected to a minor degree.

Carrot cell cultures were found to secrete a lectin, with the molecular weight of 58,000, which could strongly enhance the activation of carrot prophenoloxidase by CaCl_2 (Söderhäll et al. 1990). The purified protein did also show haemagglutinating activity towards rat as well as rabbit erythrocytes, and this activity was inhibited by N-acetylglucosamine or fetuin.

Analgesic Activity

Writhing induced by acetic acid in mice was inhibited by 50 and 69 % at 50 and 100 mg carrot seed volatile oil/kg, respectively, indicating analgesic activity (Porchezian et al. 2000).

Larvicidal Activity

Amyris balsamifera, *Daucus carota* and *Pogostemon cablin* essential oils showed 100 % larvicidal activity against *Culex pipiens pallens* (Park and Park 2012). Among the tested oils, the larvicidal activity of *D. carota* oil was the strongest followed by *P. cablin* and *A. balsamifera*. Carotol from carrot, showed >90 % mortality against *C. pipiens pallens* at 0.1 mg/mL. In acute toxicity testing of the water flea, *Daphnia magna*, *P. cablin* oil was the most toxic followed by *A. balsamifera* and *D. carota*. Among the isolated compounds, carotol was the most toxic to water fleas.

Abortifacient/Antifertility Activity

Alcoholic carrot seed extracts were found to possess extremely weak oestrogenic activity (Sharma et al. 1976). The extract significantly inhibited the uterotrophic effect of 17 β -oestradiol in the 3-day antioestrogenic assay. Oral administration of the extract from days 4 to 6 post-coitum in doses of 80 and 120 mg/mouse effectively inhibited implantation. However, oral administration on days 8–10 post-coitum did not affect pregnancy. The administration of carrot seed alcoholic extract at a lower dose showed anti-implantational activity, whereas higher doses caused foetus resorption (Bhatnagar 1995). The main effect of the extract appeared to be an abortifacient activity. At higher dose levels the extract demonstrated an oestrogenic nature with a prolonged estrous phase, whereas lower doses showed an antioestrogenic nature and an increase in the percentage duration of the dioestrous phase of the oestrous cycle. The petroleum ether extract and fraction 5 (fatty acids) of carrot seeds arrested the normal oestrous cycle of adult mouse and reduced the weight of ovaries significantly (Majumder et al. 1997). The cholesterol and ascorbic acid content in ovaries were significantly elevated by both

treatment with extract and fraction 5 (fatty acids) of carrot seeds. The significant inhibition of $\Delta^5,3\text{-}\beta$ -hydroxy steroid dehydrogenase and glucose 6-phosphate dehydrogenase, the two key enzymes involved in ovarian steroidogenesis, was also observed in mouse ovaries after 15 days of treatment. Results suggested that the fraction 5 (fatty acids) present in carrot seeds acted as an antisteroidogenic agent.

Adverse Intake Effect

A case of carotinaemia in a patient with excessive β -carotene food intake (approximately 1 kg per day carrots), diabetes mellitus and physiological amenorrhea was reported (Mikkelsen et al. 2009). The patient developed yellow discolouration in the palms and the soles of her feet. Blood samples showed a significantly increased level of serum β -carotene, but normal vitamin A value and liver enzymes. The status of physiological amenorrhoea and dysregulated diabetes mellitus may have deteriorated the yellow discolouration of the skin. A case of excessive carrot ingestion (6–7 lb of carrots per week to facilitate dieting) by a 48-year-old male was reported by Sansone and Sansone (2012). He suffered abdominal discomfort and had yellow/orange skin discolouration and was diagnosed with constipation, hypercarotinaemia and possible vitamin A toxicity. Following the cessation of excessive carrot ingestion, his liver enzymes normalised within 1 month.

Allergy Issues

Carrot allergen, a 16-kDa protein, was identified as a major IgE-binding component and designated Dau c 1 (Hoffmann-Sommergruber et al. 1999). Cross-inhibition assays verified the existence of common B-cell epitopes present on Dau c 1, Api g 1 as well as on Bet v 1. Dau c 1 was reported as a major allergen of carrot displaying IgE cross-reactivity with the homologous major birch pollen allergen Bet v 1 (Marković-Housley et al. 2009). The structure of Dau c 1 was similar to those of the major allergens from celery, Api g 1, and birch pollen, Bet v 1. It was found that the majority of carrot-allergic

patients had Bet v 1 cross-reactive IgE antibodies, whereas others had Dau c 1-specific IgE antibodies which did not recognise Bet v 1. Up to 25 % of food allergic subjects in central Europe suffer from carrot allergy and two isoforms of the major carrot allergen Dau c 1 had been described: Dau c 1.01, comprising five variants (Dau c 1.0101–Dau c 1.0105) and Dau c 1.02 (Wangorsch et al. 2012). Dau c PRP-like protein was identified as a new allergenic isoform, Dau c 1.03, in carrot roots. 68 % of carrot-allergic patients were sensitised to rDau c 1.03. The IgE reactivity of rDau c 1.03 is strongly correlated with reactivity to rDau c 1.0104, but not to rDau c 1.0201. The IgE reactivity of rDau c 1.03 is strongly correlated with reactivity to rDau c 1.0104, but not to rDau c 1.0201. They asserted that the epitope diversity of different Dau c 1 isoforms should be considered for component-resolved diagnosis and gene silencing of carrot allergens.

Traditional Medicinal Uses

The carrot plant is reported to be anthelmintic, carminative, deobstruent, diuretic, galactagogue, ophthalmic and stimulant (Grieve 1971; Lust 1974; Launert 1981; Chiej 1984; Duke and Ayensu 1985). Carrot is used in the traditional medicine for the treatment of gastric disorders, viz., acidity and gastric ulcer (Nayeem et al. 2010), and carrot acts as a diuretic, soothes the digestive tract and stimulates the uterus (Bown 1995). Plant infusion is used in the treatment of various complaints including digestive disorders and kidney and bladder diseases and in the treatment of dropsy (Grieve 1971; Bown 1995). Grated carrot has been used to treat threadworm infection (Chevallier 1996). Carrot leaf infusion has been used to counter cystitis and kidney stone formation (Chevallier 1996). Carrot seeds are diuretic (Duke and Ayensu 1985), carminative, emmenagogue and anthelmintic (Grieve 1971; Duke and Ayensu 1985). Carrot seed infusion is used in the treatment of oedema, flatulent indigestion and menstrual problems (Bown 1995).

Other Uses

Certain varieties of carrots have been used as feed for horses and dairy cattle. Studies by Aimaretti et al. (2012) demonstrated that bioethanol can be obtained from carrot discards by enzymatic hydrolysis prior to compressing and filtering to obtain carrot must. In this way, fermentable sugars extracted increased 3.5 times, and the production of 77.5 L of ethanol for each ton of discarded carrots was achieved. This process yielded bagasse as by-product, which could be used for animal feed.

An essential oil obtained from the seed is used in perfumery and as a food flavouring (Uphof 1968; Bown 1995). The oil has also been used cosmetically in antiwrinkle creams (Bown 1995). Water extracts from the carrot seed exhibit plant growth inhibitory properties against cress, cucumber, onion and carrot in a dose-dependent manner (Jasicka-Misiak et al. 2005). The low molecular active component was identified as crotonic acid 9(*E*)-2-butenic acid. The determined strong herbicidal properties of crotonic acid and its availability after release to soil combined with its high level in seeds suggested that it might be considered as an allelopathic and autotoxic factor in the seeds. In Ethiopia fruits are used against tapeworm.

Studies showed that carrot waste materials, namely, carrot stem powder and carrot leaves powder, could be used as a potential adsorbent for the removal of methylene blue and malachite green dyes from aqueous solution (Kushwaha et al. 2011). Yadav et al. (2007) reported the use of carrot and baker's yeast for the bio-reduction of prochiral ketones by carrot dehydrogenase enzymes to synthesise a wide range of chiral secondary alcohols of biological importance. Carrots were used to reduce cyclic amino ketones in high yields and enantiomeric excesses (Lacheretz et al. 2009). This cheap, eco-compatible and efficient reducing reagent allows the easy access to precursors of biologically active products.

Falcarindiol isolated from carrot root showed antifungal activity towards plant pathogens, *Mycocentrospora acerina*

and *Cladosporium cladosporioides* (Garrod et al. 1978). The ED₅₀ for inhibition of germination of chlamydospores of *M. acerina* was 31.8 µg/ml.

Comments

Daucus carota is a complex and variable species. On the basis of morphological (leaf and root) traits, two main categories of domesticated carrots were reported (Small 1978):

Var. *sativus* refers to carrots originating from the West and exhibiting orange, yellow or sometimes white roots and highly indented, nonpubescent, yellow-green foliage.

Var. *atrorubens* refers to carrots originating from the East, exhibiting yellow, reddish-purple to purple-black, rarely yellowish-orange storage roots and poorly indented, grey-green, pubescent foliage.

Many intermediate variants exist between these two types. Wild carrots proved to be separable into two overlapping comprehensive groups, which were informally labelled subspecies aggregate *gingidium* and subspecies aggregate *carota* (the latter assemblage also encompassing the cultigens).

Pastinaca sativa

T. K. Lim¹✉

(1) Canberra, Aust Capital Terr, Australia

Scientific Name

Pastinaca sativa L.

Synonyms

Anethum pastinaca Wibel (illeg.), *Elaphoboscum sativum* (L.) Rupr., *Peucedanum pastinaca* (L.) Benth. Hook. f., *Peucedanum sativum* (L.) Benth. Hook. f., *Selinum pastinaca* (L.) Crantz.

Family

Apiaceae

Common/English Name

Parsnip

Vernacular Names

Afrikaans: Witwortel

Albanian: Pastinakë

Arabic: Gazar Abiad

Armenian: Varot

Austrian: Pastinake

Belarusian: Pasternak Pasjany

Belgium: Pastenaak

Brazil: Chirivia

Bulgarian: Paštárnak, Pshturnak

Catalan: Pastenage, Xirivia

Chinese: Bai Sun, Mei Guo Fang Feng, Ou Fang Feng

Croatian: Pastrnjak

Czech: Pastinák, Pastinák Lucni Setý, Pastinák Setý

Danish: Almindelig Pastinak, Pastinak

Dutch: Gewone Pastinaak, Pastinaak

Eastonian: Aed-Moorputk, Moorputk, Pastinaak

Esperanto: Pastinako

Finnish: Palsternakka, Ruokapasternakka

French: Pastenague, Panais, Patennais

Gaelic: Cuirdín Bán, Meacan Bán

Galician: Cherouvea

Georgian: Dzirtetre, Pasternaki

German: Echte Pastinake, Gemeiner Pastinak, Gemüse-Pastinak, Hammelmöhre, Moorwurzel, Pastinake, Pastinak

Greek: Elaphovoskon

Hungarian: Kerti Pasztinák, Paszternák, Pasztinák

Icelandic: Nípa

India: Gujur (Hindu)

Italian: Carota Rossa, Pastinacá

Japanese: Paasunitpu

Kazakh: Pasternak Posevnoj

Kirghiz: Pasternak

Korea: Bangphung

Latvian: Pastinaki, Pastinaks

Lithuanian: Paprastasis, Pastarnokas, Pastarnokai

Macedonian: Običen Paškanat

Malaysia: Parsnip

Maltese: Pastinakka

Nepali: Gujar

Niuean: Pāsinipi

Norwegian: Pastinakk

Polish: Pasternak Zwyczajny

Portuguese: Chirivia, Pastinaca, Pastinaga

Romanian: Păstârnac, Păstirnac, Păstirnac Commun

Russia: Pasternak Posevnoj

Wyllt

Yiddish: Pasternak

Yugoslavia: Pastinak, Navadni Rebrinek

Zulu: Ipasinipu

Origin/Distribution

Wild distribution of parsnip occurs in Europe to Caucasus, Anatolia, Lebanon and Western Siberia. Parsnip has naturalised in many temperate areas and can be found in disturbed open areas, such as along railway embankments, roadsides, trails, riverbanks, ditches, beaches, sloughs, forest clearings, abandoned mine sites, quarries and other waste areas, gardens, meadows, swampy lowlands and grassy area. Parsnip is cultivated in the temperate region worldwide and in the cooler highlands above 900 m in the tropics and subtropics. It is mainly grown in home gardens and for specialty markets.

Agroecology

A cool temperate climate is required by parsnip. It prefers full or partial sun, moist to mesic conditions and fertile loamy soil. The plant also tolerates other types of soil.

Edible Plant Parts and Uses

Parsnip can be eaten raw, cooked, boiled, fried or roasted (Grieve 1971; Launert 1981; Facciola 1990). The roots are sweeter than carrots. The root is delicious baked; it can also be used in soups, stews, salads, casseroles, pies and puddings and dried for seasoning soups and processed for canning. Parsnip is also used for making jam, marmalade preserve and sweet flour for cakes. Parsnip is eaten with salt fish and boiled eggs during Lent. Roasted parsnip is considered an important ingredient in Christmas dinner and is featured in the traditional Sunday roast.

Parsnip is also used for making beer and wine in Britain and Ireland. In Ireland, cottagers make a beer by boiling the roots with water and hops and afterwards fermenting the liquor. In the north of Ireland, they have been often brewed with malt instead of hops and fermented with yeast, the result being a pleasant drink. Parsnip wine, when properly made, is esteemed by many people; the quality has been said to approach the famed Malmsey of Madeira.

Leaves and young shoots are cooked with other greens as a vegetable or added to soups. The seed is used as a condiment and has similar taste as dill.

Botany

A robust, biennial or short-lived monocarpic herb 1–1.6 m high. Root yellowish white, up to 30×10 cm, stout fleshy, broad proximally and tapering distally (Plate 1) becoming fibrous and tough with age. The stems are erect, glabrous to sparsely hairy, angular and furrowed. The basal and lower cauline leaves are oddly pinnate, oblong ovate in outline $20\text{--}30 \times 10\text{--}16$ cm with nine sessile leaflets, ovate–oblong, lobed, 5–8 long by 2.4–4 cm wide, obtuse, base obliquely subcordate, the terminal segment cuneate. Petioles subterete, basal sheathes 3–4 cm long. Upper cauline leaves gradually reduced in size and sessile. Flowers greenish yellow, pedicellate, in compound umbels 4–9 cm across, umbellets 15–30, consisting of 12–40 flowers. Terminal (primary) umbels with fertile bisexual flowers with oblong hypanthia towards the outside and staminate flowers towards the centre. Lateral umbels (secondary and tertiary) with more staminate flowers and less bisexual flowers. Flower, 4–5 mm, with five yellowish-green petals, a greenish-yellow nectar pad and insignificant, reduced sepals. Stamens 5, carpel 1 with bilocular ovary. Fruit a glabrous schizocarp, $5\text{--}6 \times 4\text{--}6$ mm, dorsally flattened and ribbed, splitting into two mericarp, each with one, pale brown, oval or globose, narrowly winged seed.

Plate 1 Parsnip roots

Nutritive/Medicinal Properties

Root Nutrient/Phytochemicals

The nutrient composition of parsnip was reported as water 79.53 g, energy 75 kcal (314 kJ), protein 1.20 g, total lipid (fat) 0.30 g, ash 0.98 g, carbohydrate 17.99 g, total dietary fibre 4.9 g, total sugars 4.80 g, calcium 36 mg, iron 0.59 mg, magnesium 29 mg, phosphorus 71 mg, potassium 375 mg, sodium 10 mg, zinc 0.59 mg, copper 0.120 mg, manganese 0.560 mg, selenium 1.8 µg, vitamin C, 17.0 mg, thiamine 0.090 mg, riboflavin 0.050 mg, niacin 0.700 mg, pantothenic acid 0.600 mg, vitamin B6 0.090 mg, total folate 67 µg, vitamin E (α -tocopherol) 1.49 mg, vitamin K (phylloquinone) 22.5 µg, total saturated fatty acids 0.050 g, 14:0 (myristic) 0.003 g, 16:0 (palmitic) 0.030 g, 18:0 (stearic) 0.014 g, total monounsaturated fatty acids 0.112 g, 16:1 undifferentiated (palmitoleic) 0.003 g, 18:1 undifferentiated (oleic) 0.102 g, total polyunsaturated fatty acids 0.047 g, 18:2 undifferentiated (linoleic) 0.041 g and 18:3 undifferentiated (linolenic) 0.003 g (USDA-ARS 2014). Vacuolar membranes of parsnip, parsley and carrot roots contained a high level of unsaturated fatty acids (up to 78 % of total fatty acids) (Makarenko et al. 2007). In parsnip linoleic acid (53.5 %) predominated, followed by high level of hexadienoic acid (C16:2 ω 6) (8 %), followed by α -linolenic acid (4.4–7.3 %) in parsley and parsnip. Palmitic acid predominated among the saturate fatty acids. Parsnip also contained the flavonol quercetin 1 mg (Lugasi and Hovari 2000).

Five furanocoumarins, imperatorin, bergapten, isopimpinellin, xanthotoxin and sphondin, were identified and quantified in the intact seeds of wild and cultivated parsnip (Berenbaum et al. 1984). Fruits were found to contain the following furanocoumarin: psoralen, xanthotoxin, bergapten, angelicin, imperatorin, isobergapten and isopimpinellin (Berenbaum et al. 1991). Five biologically active furanocoumarins (psoralen, bergapten, xanthotoxin, trioxsalen and angelicin) were found in celery and parsnips (Lombaert et al. 2001). Of 110 parsnips samples, 109 (99 %) contained

quantifiable levels of furanocoumarins. The mean level of total furanocoumarins in the positive parsnip samples was 15.1 µg/g; the maximum level detected was 145 µg/g. Xanthotoxin and bergapten were the most commonly detected furanocoumarins in both celery (68 % and 63 %) and parsnips (97 % and 96 %).

Four linear furanocoumarins (psoralen, xanthotoxin, isopimpinellin and bergapten) were identified on the surfaces of callus cells of *Pastinaca sativa* in the concentration range of 0.055–1.1 µg total/g fresh weight (Zobel and Brown 1993). Shake cultures produced up to two orders of magnitude more furanocoumarins than callus cells, and extrusion was accelerated, but the concentrations of particular exported furanocoumarins varied, again pointing to selective extrusion. Parsnip tissues cultured in-vitro were found to produce furanocoumarins psoralen, bergapten, xanthotoxin, isopimpinellin and umbelliferone (Ekiert and Gomolka 2000a), bergapten, xanthotoxin, isopimpinellin and sphondin (Ekiert and Gomolka 2000b). Total content of coumarins ranged from 115.7 to 408.5 mg/100 g of the dry weight; isopimpinellin predominated quantitatively (maximum content of 238.9 mg/100 g) followed by psoralen (maximum content of 108.8 mg/100 g). Imperatorin was not detected in callus tissues although it dominated in the analysed fruits of the studied plant (200.0 mg/100 g). Ostertag et al. (2002) found that furocoumarin concentrations (sum of five furocoumarins: angelicin, isopimpinellin, 5-methoxypsoralen, 8-methoxypsoralen and psoralen) in freshly harvested parsnips was generally lower than 2.5 mg/kg, and storage of parsnips in any form investigated at –18 °C over up to 50 days did not lead to a marked increase in furocoumarin levels. In contrast, storage of whole parsnips, but not of cubes or homogenate, at +4 °C resulted in a marked biphasic increase of furocoumarin concentrations after 7 and 38 days of storage up to levels of about 40 mg/kg. A dramatic increase in furocoumarin concentrations up to 566 mg/kg was observed when whole parsnips obtained from the market were kept at room temperature over 53 days, resulting in a visible microbial (mould) infection.

Parsnip roots inoculated with several non-pathogenic fungi afforded a 20-fold increase in the phytoalexin, xanthotoxin; other furanocoumarins detected included bergapten, isopimpinellin, angelicin, psoralen and imperatorin (Johnson et al. 1973). Ceska et al. (1986) found that furocoumarin contents in spoiled and diseased parsnip roots were increased 25-fold over normal levels. Mixed crystals of furocoumarins such as angelicin, psoralen, 5-methoxypsoralen and 8-methoxypsoralen could be detected on the surfaces of the parsnip roots. Parsnip roots infected with *Fusarium sporotrichioides* accumulated high levels of fungitoxic furanocoumarins mainly xanthotoxin and angelicin (Desjardins et al. 1989). Copper chloride and fungal (*Bipolaris sorokiniana* and *Alternaria* spp.)-treated root slices of parsnip were found to produce the following furanocoumarins xanthotoxin, isopimpinellin, angelicin, bergapten, sphondin, pimpinellin and isobergapten (Al-Barwani and Eltayeb 2004). However, isoimperatorin earlier reported to be a constituent of parsnip root was not detected. Xanthotoxin angelicin and psoralen were the major phytoalexins induced in parsnip roots by the fungus *Bipolaris sorokiniana*. Treatment with however copper chloride resulted in the accumulation of xanthotoxin and isopimpinellin as the major induced compounds, while psoralen was not detected. Induction of parsnip roots with copper chloride resulted in a 20 to 29-fold increase in the amounts of xanthotoxin.

Polyacetylenes, falcarinol and falcarindiol were isolated from parsnip root nonpolar extract (Zidorn et al. 2005). Parsnip contained the highest amount of falcarinol and falcarindiol, followed by carrot and fennel. Polyacetylenes, i.e. falcarinol, falcarindiol and falcarindiol-3-acetate, were found in parsnip (Kramer et al. 2011). Distribution of total polyacetylenes as well as individual compounds was confirmed in parsnip roots using nondestructive Raman analysis (Roam et al. 2011). Blanching (95 °C) had the greatest influence on the retention of polyacetylenes in sous vide (90 °C 10 minutes) processed parsnip discs resulting in significant decreases of 24.5 and 24 % of falcarinol and falcarindiol, respectively (Rawson et al. 2010). Subsequent anaerobic storage of sous vide processed samples resulted in a

significant decrease in falcarinol contents but elicited no change in falcarindiol content. Falcarinol contents in water immersion (WI, 70 °C for 2 minutes) processed samples were significantly higher than in sous vide samples. Falcarindiol was particularly susceptible to aerobic storage following WI processing with losses of up to 70 % occurring after 5 days storage. When thermally treated, falcarinol-type polyacetylene underwent degradation such as oxidation and dehydrogenation forming oxidised form of falcarinol-type molecules, in this case falcarindione, dehydrofalcarinol and dehydrofalcarinone. Thermal processing impacted significantly on colour of parsnip samples compared to minimally processed in both sous vide and WI processed samples resulting in parsnip discs becoming darker, yellower and browner following processing and storage. Absolute configuration of falcarinol (9Z-heptadeca-1,9-diene-4,6-diyn-3-ol) from *Pastinaca sativa* was found to have a 3R absolute configuration (i.e. (3R, 9Z)-heptadeca-1,9-diene-4,6-diyn-3-ol) (Corell et al. 2013). Aliphatic C (17)-polyacetylenes of the falcarinol type, found in common food plants of the Apiaceae family such as carrot, celeriac, parsnip and parsley, had demonstrated interesting bioactivities including antibacterial, antimycobacterial and antifungal activity as well as anti-inflammatory, antiplatelet, antiaggregatory, neuritogenic and serotonergic effects (Christensen 2011).

The essential oil from the fully grown root was found to be rich in myristicin and terpinolene (together 80–88 %), forming the major components in the essential oil from fresh parsnip roots (Kubeczka and Stahl 1975). Minor components included mono- and sesquiterpene hydrocarbons such as (*E*)- β -farnesene, β -bisabolene, β -sesquiphellandrene and γ -palmitolactone. The composition of essential oils in parsnip roots changed with plant developmental stages; at the seedling stage (0–18 days), the primary oil ducts between the pericycle cells contained mainly sesquiterpene hydrocarbon *trans*- β -farnesene (34.9 %), with smaller amounts of myristicin (14.4 %) and terpinolene (3.1 %); as the roots thicken during the secondary stage (23–30 days), the sesquiterpene content decreases, whereas the myristicin and terpinolene contents increased; and at the adult stage (38–160 days) with the

development of secondary oil ducts, the level of sesquiterpene declined to 1.5 %, while that of myristicin and terpinolene increased to 62.6 and 25.5 %, respectively (Stahl-Biskup and Wichtmann 1991). The essential oil from the fully grown parsnip root was found to be rich in myristicin and terpinolene and contained minor amounts of (*E*)- β -farnesene, β -bisabolene, β -sesquiphellandrene and γ -palmitolactone (Lawrence 2002).

The coumarins *p*-coumaric acid and umbelliferone were found to be the precursors of furanocoumarins bergapten, imperatorin, isopimpinellin and xanthotoxin in parsnip (Brown 1970). Two α -hydroxyisopropylidihydrofuranocoumarin appeared to be natural intermediates in the biosynthesis of linear and angular furanocoumarins (Steck 1969). Angelicin synthase, alternative name Cytochrome P450 CYP71AJ4, was isolated from *P. sativa* and found to be involved in angular furanocoumarin biosynthesis (Larbat et al. 2009). It converted (+)-columbianetin to angelicin and produced hydroxycolumbianetin as a by-product. The reaction mechanism was initiated by the elimination of syn-C-3'-hydrogen from C-3'. It exhibited no activity with demethylsuberosin, (+)-marmesin, 5-hydroxymarmesin, psoralen, bergaptol, xanthotoxol, bergapten, xanthotoxin, isopimpinellin, cinnamic acid, 4-coumaric acid, 2-coumaric acid, ferulic acid, coumarin, herniarin, scopoletin or umbelliferone.

Parsnip was found to contain minute amounts (8 ng/g) of the steroid 5 α -androst-16-en-3-one, known as a boar pheromone which contributed to its characteristic fragrance (Claus and Hoppen (1979).

Finely powdered suberin from six root crops including *Pastinaca sativa* was fractionated into phenolic (<10 %) and aliphatic (13–35 %) fractions (Kolattukudy et al. 1975). The aliphatic fractions consisted mainly of ω -hydroxy acids (29–43 %), dicarboxylic acids (16–27 %), fatty acids (4–18 %) and fatty alcohols (3–6 %). Among the fatty acids, very long chain acids (>C₂₀) were the dominant components in all six plants. Among the alcohol fraction, C₁₈, C₂₀, C₂₂ and C₂₄ saturated

primary alcohols were the major components. C₁₆ and C₁₈ dicarboxylic acids were the major dicarboxylic acids of the suberin of all six plants, and in all cases octadec-9-ene-1, 18-dioic acid was the major component except in rutabaga. The composition of the ω -hydroxy acid fraction was quite similar to that of the dicarboxylic acids; 18-hydroxy-octadec-9-enoic acid was the major component in all plants except rutabaga.

The amount of wax extracted from the periderm of parsnip storage organ was very small 49 mg/kg of chloroform-extractable material, equivalent to 49% weight of chloroform extract or 17 $\mu\text{g}/\text{cm}^2$ was/ surface area (Espelie et al. 1980). The composition of parsnip wax comprised 50 % hydrocarbon, 1.1 % wax ester, 9 % fatty alcohol, 25 % fatty acids and 15 % unknown component. The hydrocarbons from the suberin layer had a broader chain-length distribution, a predominance of shorter carbon chains and a higher proportion of even-numbered carbon chains than the leaf alkanes from the same plant. Parsnip suberin alkanes had 33 % even-chain homologs. The proportion of alkanes shorter in chain length than C₂₉ was 34 % for the suberin wax of parsnip. Chain-length distributions of the fatty alcohols, fatty acids, ω -hydroxy acids and dicarboxylic acids in the polar fraction of the CHCl₃ extract of parsnip storage organ were 0.07 %, 1.11 %, 0 % and 0 % respectively. In parsnip, the major free and esterified fatty acids comprised a higher proportion of longer-chain components, where C₂₂ and C₂₄ comprised slightly more than 15 % each of the free fatty acid fraction but 2 % or less of the esterified acids.

Fruit/Bud/Aerial Parts Phytochemicals

Furanocoumarin compounds reported from the roots, stems, leaves, buds, flowers, fruits or seeds of wild parsnip included: angelicin (angular), apterin (angular), bergapten (linear), imperatorin (linear), isobergapten (angular), isoimperatorin (linear), isopimpinellin (linear), pimpinellin (angular), psoralen (linear), sphondin (angular), xanthotoxin (linear) and xanthotoxol (linear) (Pathak et al. 1962; Berenbaum 1985; Berenbaum and Zangerl 1986). There is considerable variation

in the toxicity and photoactivity of these different furanocoumarin compounds (Berenbaum et al. 1991). The linear furanocoumarins were reported to be highly toxic to diverse herbivores and pathogens, but the angular types were generally less reactive (Scott et al. 1976) and may possess additional (deterrent), complementary or synergistic effects (Berenbaum and Feeny 1981; Berenbaum 1985).

The composition of essential oils from different parts of fresh plants of *Pastinaca sativa* revealed the existence of four chemotypes: plants with high and low amount of myristicin and plants with and without acetic acid esters of aliphatic C8 and C10 alcohols in the fruit oil (Stahl and Kubeczka 1978, 1979). Terpene hydrocarbons *cis*- β -ocimene, *trans*- β -ocimene, terpinolene and *trans*- β -farnesene were identified besides γ -palmitolactone, in the essential oil of the aerial parts (Kubeczka and Stahl 1977). Additional minor amounts of several mono- and sesquiterpene hydrocarbons, myristicin and an unknown diterpene alcohol were also detected.

Light and nutrient availability jointly affected the concentration of four of the six furanocoumarins in parsnip aerial parts (with exception of sphondin and angelicin) (Zangerl and Berenbaum 1987). UV radiation increased the level of all six except imperatorin and sphondin and also influenced the relative amounts of furanocoumarins. Furanocoumarins being UV phototoxic to many organisms, including insects, the response of parsnip plants to UV radiation may affect their resistance to herbivores.

Metabolites (mean values in $\mu\text{g}/\text{mg}$ dry weight) detected in intact wild parsnip foliage and damaged (24 hours previously) foliage were determined, respectively, as follows: fatty acids, C16:0 (palmitic acid) (1.03, 1.19), C16:3 (hexadecatrienoic acid) (1.54, 1.24), C18:0 (stearic acid) (0.85, 0.62) and C18:1 (oleic acid) (4.50, 3.97); sugars, glucose (6.19, 3.04), fructose (5.59, 3.00), myoinositol (3.75, 3.49), sorbitol (0.52, 0.38) and sucrose (1.34, 1.47); soluble protein (244, 307); ascorbic acid (5.12, 5.10); terpenes, *cis*-ocimene (1.68, 1.69), *trans*-ocimene (2.43, 2.42) and farnesene (4.32, 2.88); furanocoumarins, imperatorin (0.07, 0.10), bergapten (0.32, 0.41), psoralen (0.15, 0.15), isopimpinellin (0.15, 0.16), xanthotoxin (1.01, 1.44) and

sphondin (0.06, 0.10); palmitolactone (1.26,1.01); and myristicin (1.60, 1.31) (Zangerl and Berenbaum 1998). Significant damage-induced changes in foliage chemistry were observed for 7 of the 22 compounds quantified.

Highest relative furanocoumarin content (per cent dry weight) was found in parsnip buds, ripe seeds and flowers; in contrast furanocoumarin content was lowest in roots and stems (Berenbaum 1981). Leaves of rosette plants generally contained more furanocoumarins than did leaves of flowering plants; as leaves senesced, furanocoumarin concentrations declined, concomitant with increases in the stem and ripe seeds. Seeds at all stages of maturity were remarkably uniform in furanocoumarin content. Xanthotoxin was the principal furanocoumarin in parsnip at all times during the season except during late May and early June when bergapten predominated. Xanthotoxin, bergapten and imperatorin were present at all stages of growth; two minor components, sphondin and angelicin, were present in the reproductive parts of some flowering plants. Allocation of nitrogen within the plant was significantly correlated with allocation of furanocoumarins. This relationship was especially prominent in late stages of development in flowering plants, when nitrogen, along with furanocoumarins, was transferred from senescent leaves to seeds.

Across all umbel orders (primary, secondary and tertiary) and male and female floral stages, the range of mean relative furanocoumarin proportions in the flowers for angelicin was <0.01–0.1 %, imperatorin 20.9–53.3 %, bergapten 9.8–15.4 %, isopimpinellin 8.1–21.2 %, xanthotoxin 23.4–51.9 %, sphondin 1.1–2.4 % and psoralen <0.1–5.3 % (Nitao 1988). Defloration of the primary umbel at either the bud or female flower stage failed to alter total furanocoumarin concentration in the seeds; the range of mean relative proportions in the seeds were for angelicin 1.0–1.7 %, imperatorin 27.2–33.0 %, bergapten 18.7–22.3 %, isopimpinellin 10.7–19.8 %, xanthotoxin 29.8–38.0 % and sphondin 1.0–1.8 %. No psoralen was detected in the seeds.

The characteristics of the floral fragrances of flowers, buds and leaves of Apiaceous plants including *Pastinaca sativa*

were found to originate in differences in the proportions of the monoterpene hydrocarbons, among which α -pinene, β -pinene, *cis*- β -ocimene, *trans*- β -ocimene, limonene, sabinene and myrcene dominated (Borg-Karlson et al. 1993). Volatile compounds including aliphatic hydrocarbons, terpenoids, aromatic compounds and nitrogenous compounds were found. The terpenoid, linalool, a known marker pheromone in solitary bees was also detected. *Heracleum sibiricum* and *P. sativa* had very similar fragrances.

The concentration of the furanocoumarins psoralen, xanthotoxin and bergapten on the leaf surfaces of *Pastinaca sativa* was 0.12 $\mu\text{g/g}$ (25 % of total) (Zobel et al. 1990). Eight coumarins found occurring with psoralen, xanthotoxin and bergapten on leaf surfaces were identified as the simple coumarins scopoletin, scoparone and osthol; the linear furanocoumarins imperatorin and phellopterin; the angular furanocoumarins angelicin and pimpinellin; and the pyranocoumarin seselin (Zobel et al. 1990).

Mono- and sesquiterpenes were abundant in buds but absent from female flowers and green fruits (Zangerl et al. 1997). The aliphatic esters octyl acetate and octyl butyrate were found as the only essential oil components found exclusively within tissues consumed by the webworm, *Depressaria pastinacella*; both esters were found to be produced only in reproductive tissues. Furanocoumarins, which were found in all organs, were present at low concentration in buds, at intermediate concentrations in female flowers and at highest concentrations in fruits. Among the primary metabolites, developmental shifts were, for the most part, quantitative. Soluble protein and fatty acid content declined with development. A qualitative change in fatty acid composition was observed in that linolenic acid in buds was replaced by petroselinic acid in fruits.

In a study of resistance of parsnip chemotypes to parsnip webworm, *Depressaria pastinacella*, 22 metabolites were detected in the buds, flower and young fruits (Zangerl and Berenbaum 2004). Parsnip webworm had been found to feed exclusively on the buds, flowers and green fruits. The chemotypes differed significantly for 14 of the 22 constituents,

including 4 nutrients. The secondary metabolites found included furanocoumarins (imperatorin, bergapten, xanthotoxin, sphondin, psoralen and isopimpinellin), the coumarin osthol (not present in bud), terpenes (*cis*- and *trans*-ocimene, caryophyllene, bergamotene, cubebene and farnesene), the phenylpropanoid myristicin (not present in fruit) and three fatty acid derivatives (palmitolactone, octyl acetate and octyl butyrate). The primary metabolites found included: soluble protein, sugars (fructose, glucose, sorbitol, myoinositol), phytic acid and saturated and unsaturated C18 fatty acids. Constituents that distinguished resistant individuals from susceptible ones were high levels of osthol, octyl butyrate and fatty acids in developing fruit, as well as high levels of linear furanocoumarins in buds and high bud caryophyllene combined with low bud protein. Conversely, susceptibility was associated with overall average chemical composition and with high levels of bergamotene, cubebene, myristicin and palmitolactone in buds and high protein in both buds and fruit. Significant heritabilities were found for unsaturated C18 fatty acids in both buds and developing fruits; stearic acid in developing fruits, fructose and sorbitol in buds; fructose in fruits, myoinositol in fruits; and bergapten and psoralen in fruits.

Furanocoumarins bergapten and imperatorin were isolated from the fruits (Soine et al. 1956). Flavonoids were detected in the fruit (Maksyutina and Kolesnikov 1962). From the fruits of *P. sativa*, subsp. *sylvestris*, the bergapten, imperatorin, isopimpinellin and xanthotoxin were isolated; their contents were found to be higher than in the fruits of other varieties of *Pastinaca* gathered in the same season. Sphondin was also identified (Stein and Posocco 1984). Surface concentrations of linear furanocoumarins (psoralens) varied between traces and 40 µg/g of the mature parsnip fruits or seeds, amounting to 0.38–43 % of the total. In the whole, fruits concentrations were very high in *Pastinaca sativa* reaching levels of milligrams per gram fresh weight of fruits (Zobel and Brown 1991). The chemical content (µg/mg dry fruit) of octyl esters and furanocoumarins in mature wild parsnip fruits were: octyl acetate 1.56 µg, octyl butyrate 4.28 µg, bergapten 1.85 µg, imperatorin 3.72 µg, sphondin 0.31 µg and xanthotoxin 4.02

μg (Carroll et al. 2000). From the essential oil of fruits, the aliphatic esters butyl butyrate, hexyl butyrate and decyl butyrate and decyl acetate and the free alcohols hexanol-(1) and decanol-(1) were identified besides octenol-(1), the acetic, butyric and caproic acid esters, respectively, several terpene hydrocarbons and myristicin (Kubeczka and Stahl 1977).

The coumarin osthole was detected in the seed (Maksyutina 1967). Three flavonoid glycosides, hyperin, rutin and pastenoside, were isolated from the seeds (Maksyutina and Litvinenko 1966). Structure of pastenoside was elucidated as isorhamnetin 3-β-D-glucopyranoside 4'-α-L-rhamnopyranoside. Enzymatic hydrolysis of pastenoside yielded the monoglycoside deglucopastenoside, with the structure, isorhamnetin 4'-α-L-rhamnopyranoside.

Furanocoumarins imperatorin, bergapten, isopimpinellin, xanthotoxin and sphondin were found to be restricted to the vittae or oil tubes within the ripe seeds of wild parsnip; the furanocoumarin content and composition of these organs varied with their location (Berenbaum and Zangerl 1986). Eighteen components were characterised in parsnip seed essential oil representing 95 % of the oil with octyl butyrate (79.5 %) and octyl hexanoate (5.3 %), as the major constituents (Kurkcuoglu et al. 2006). Other components were: hexyl butyrate (3.3 %) phenylethyl butyrate (2.2 %), octanol (1.4 %), decyl butyrate (1.3 %), decanal (0.6 %), octanal (0.3 %), octyl acetate (0.3 %), (Z)-β-ocimene (0.2 %), butyl butyrate (0.1 %), α-zingiberene (0.1 %), β-sesquiphellandrene (0.1 %), *ar-curcumene* (0.1 %), benzyl butyrate (0.1 %), (*e*)-nerolidol (0.1 %), phenylethyl hexanoate (0.1 %) and decanol (<0.1 %).

Anticancer Activity

Studies demonstrated that isopimpinellin and imperatorin could effectively inhibit DMBA (7,12-dimethylbenz[a]anthracene) and benzo[a]pyrene (B[a]P) skin tumour initiation when given orally and have little or no systemic toxicity in mice at relatively high doses (Kleiner et al. 2002). Orally administered isopimpinellin and imperatorin significantly inhibited B [a] P-DNA adduct formation by 37 %

and 26 %, respectively. Imperatorin also blocked DMBA-DNA adduct formation by 43 %. Isopimpinellin significantly reduced the mean number of papillomas per mouse by 49, 73 and 78 % compared to corn oil controls at 30, 70 and 150 mg/kg body wt, respectively. Orally administered isopimpinellin also significantly reduced the percentage of mice with papillomas at the highest dose tested (150 mg/kg). Of the polyacetylenes isolated, falcarinol proved to be the most active compound with a pronounced toxicity against acute lymphoblastic leukaemia cell line CEM-C7H2, with an IC_{50} of 3.5 μ mol/L (Zidorn et al. 2005). *P. sativa* ethanol extract exhibited varying degree of apoptotic activity in-vitro against ML-1 human acute myeloblastic leukaemia, J-45.01 human acute T cell leukaemia, EOL human eosinophilic leukaemia, HL-60 human Caucasian promyelocytic leukaemia, 1301 human T cell leukaemia lymphoblast, C-8166 human T cell leukaemia, U-266B1 human myeloma, WICL human Caucasian normal B cell and H-9 human T cell lines (Bogucka-Kocka et al. 2008).

Antimicrobial Activity

Angelicin and its derivatives showed antifungal activity against *Candida albicans*, *Cryptococcus neoformans*, *Saccharomyces cerevisiae* and *Aspergillus niger* in-vitro (Sardari et al. 1999). The furanocoumarins extracted from parsnip demonstrated antifungal activity against *Trichophyton mentagrophytes* var. *granulosum*, *T. tonsurans*, *T. mentagrophytes*, *T. mentagrophytes* var. *interdigitale*, *T. mentagrophytes* var. *asteroides* and *Microsporum gypseum* (Wolski et al. 2000).

Hyperpigmentation Activity

Pathak et al. (1962) reported the use of furocoumarin (psoralens), namely, psoralen, 8-methoxypsoralen (xanthotoxin) and 5-methoxypsoralen (bergapten), in the treatment of vitiligo and as a means of increasing pigmentation after exposure to UV.

Allergy and Toxicity Issues

Parsnip root was found to contain three photoactive, mutagenic and photocarcinogenic psoralens, psoralen, xanthotoxin (8-methoxypsoralen) and bergapten (5-methoxypsoralen), in a total concentration of about 40 ppm, and these were reported not to be destroyed by normal cooking procedures (boiling or microwave) (Ivie et al. 1981). Studies showed that dried healthy parsnip root tissue fed to male Swiss Webster mice for 30 days caused no significant histopathological changes in the oesophagus and forestomach (Mongeau et al. 1994). In the liver, the highest level (but neither of the two lower levels) of dried diseased parsnip root tissue led to swelling of the cytoplasm in cells surrounding the central vein of hepatic lobules, with consequent compression of the peripheral cells. Using [3H]thymidine radioautography, a dose-related increase in cell labelling with the level of diseased parsnip root tissue was demonstrated in the liver. Beattie et al (2007) reported that threshold erythema during high-dose UVA1 therapy of volunteers with skin types I and II was unaffected by ingestion of a 200 g portion of parsnip containing psoralen.

Occupational dermatitis from organically grown parsnip was reported by Aberer (1992). Lutchman et al. (1999) reported 11 patients who had been involved in harvesting parsnips for week in a local farm presented themselves in Ipswich Hospital, Suffolk, with phytophotodermatitis characterised by painful erythematous rash on their forearms and hands. It was suggested to be related to photosensitising furocoumarins in parsnip. A new case of systemic contact dermatitis caused by celeriac, parsnip and carrot in a patient was reported by Paulsen et al. (2013).

Traditional Medicinal Uses

It has been used in folk medicine for kidney disorders, jaundice and other maladies (Grieve 1971; Foster and Duke 1998). The root and leaves are diuretic. A tea made from parsnip root has been employed in the treatment of women's complaints, and a strong decoction has been used for

intermittent fever. A poultice of the roots has been applied externally to inflammations and sores and to treat psoriasis and vitiligo. Oils extracted from parsnip seeds have been used to treat intermittent fever.

Other Uses

Roots and shoots serve as good animal feed especially for pigs and dairy cattle. The leafy shoots and roots are used to a domestic insect spray to control aphids and red spider mites. Parsnips are not only a valuable item of human food, but equal, if not superior to carrots for fattening pigs, making the flesh white and being preferred by pigs to carrots. Washed and sliced and given with bran, horses eat them readily and thrive on them. In Brittany and the Channel Islands, they are largely given to cattle and pigs, and milch cows fed on them in winter are said to give as much and as good milk and yield butter as well flavoured as when feeding on grass in May and June grieve.

Furanocoumarins found in parsnip had been shown to be toxic or repellent to insects (Berenbaum 1978, 1981; Berenbaum et al. 1991; Carroll and Berenbaum 2002; Cianfroga et al. 2002) and associated with resistance to a specialist insect herbivore *Depressaria pastinacella* (Berenbaum et al. 1986). Berenbaum et al. (1991) found that individually, none of the other furanocoumarins (bergapten, angelicin, imperatorin, isobergapten, isopimpinellin, psoralen) present in parsnip seeds was as toxic as the photosensitiser xanthotoxin against *Heliothis zea*. Nevertheless, the natural mixture of compounds was toxicologically more effective both in the presence and absence of UV light than was an equimolar amount of xanthotoxin. The difference in toxicity diminished with increasing light levels. Octyl butyrate, a known deterrent to webworm, *Depressaria pastinacella*, was found to be highly correlated with furanocoumarin content in parsnip and differed significantly among normal and parthenocarpic fruit, suggesting that webworms may be able to avoid furanocoumarins by virtue of their behavioural response to octyl butyrate (Cianfroga et al. 2002). The aliphatic esters octyl acetate and octyl butyrate, found only in parsnip reproductive tissues (Zangerl et al. 1997), were found to be feeding deterrents, while octyl acetate also served as an olfactory attractant and octyl butyrate an olfactory repellent of

parsnip by the webworm, *Depressaria pastinacella* (Carroll and Berenbaum 2002).

Comments

Parsnip is cultivated as a root vegetable and forage plant mainly in temperate regions worldwide, sometimes in the tropics and subtropics. It was an important vegetable and fodder plant in Western and Central Europe from the Middle Ages to the eighteenth century but had been largely replaced by potato and carrot.

Origin/Distribution

Giant taro is native to tropical Asia – probably originated from India, Sri Lanka and Southeast Asia and spread to other Asian tropical countries and Oceania.

Agroecology

Giant taro is found in Sri Lanka, India, the Philippines and Malaysia where it grows in the forest understorey in openings, roadside ditches, margins of wet fields and along streams or cultivated at low and medium, 0–600 m altitudes. It has been reported to adapt best to areas with 1,700 mm rainfall uniformly distributed throughout the year (Kay 1973). It prefers moist, but well-drained soil that is rich in organic humus and will grow in medium to heavy soils and limestone soils that are well drained as it abhors water-logged conditions. It is moderately salt tolerant as it is found growing on many atolls in the South Pacific. Giant taro can tolerate shallow flooding. It is the most drought tolerant of all the edible aroids. It is a little more cold hardy than many of its relatives, tolerating temperatures down to 10 °C, but freezing temperatures damage the leaves but the trunk sprouts new ones (Kay 1973).

Edible Plant Parts and Uses

Swollen stems tubers and leaves of giant taro are edible. The underground corms and cormels are also used for food after thorough cooking, particularly in times of scarcity. The swollen stem tubers, corms and cormels are starchy and fibrous but are poisonous if eaten raw because it contains raphide oxalic acid crystals, causing the mouth and throat to swell, sometimes fatally. They require prolonged boiling or roasting before serving or processing as a food. They are cut into pieces and boiled in water and again in broth or coconut milk and is also fried in coconut or kenari (*Aleurites moluccana*) oil or curries and stews. In Papua New Guinea, the young leaves are cooked in coconut milk and eaten. The leaves may be eaten cooked (e.g. fried with onions, garlic, chilli, etc.). Giant taro is a source of easily digestible, white starch or flour.

Botany

Giant taro is a coarse, erect perennial monoecious, rhizomatous plant growing up to 5 m high with massive leaves borne on green succulent stout petioles 0.6–1.8 m long at the tipoff stems of larger plants (Plates 1, 2 and 3). The petioles emerge from a stout upright, elongated, erect, woody stem, 1–1.2 m long and 25 cm diameter (Plate 2), arising from a basal corm. The leaves are very large, glossy medium green, broadly sagittate, 0.9–1.8 m long by 0.6–1.2 m wide, with the margins slightly undulate; the apex pointed, and the base deeply cordate and prominent lateral venation. Inflorescences are relatively large and usually appear in clusters (2 to several) and are subtended by cataphylls. The upper part of the spathe is yellowish and membranous and forms an incomplete hood around the spadix and is deciduous or marcescent. The spadix has four parts, a lower pistillate zone, a sterile zone and the staminate zone top by a large sterile appendix. Pistillate zone conic–cylindrical, 1–2 cm by 1.5 cm across, female flowers are naked, globose, pale green ovaries and with button-like sessile three to five lobed, yellow stigma. The ovules are few and orthotropous. Sterile interstice slightly shorter or equal to female zone, whitish. Staminate zone cylindrical, 3–7 cm long by 2 cm across, whitish, male flowers consist of 5–9 merous rhomboid–hexagonal synandria. Fruiting spathe oblong–ellipsoid, 8 cm long, green. Fruits are several seeded ellipsoid or ovoid, green ripening to scarlet fleshy berries (Plate 4).

Nutritive/Medicinal Properties

Stem/Corm/Cormel:

Nutrients/Phytochemicals

The food nutrient value of the edible portion of the raw giant taro stem tubers had been reported as per 100 g edible portion: energy 100 cal (412 kJ), water 70 g, protein 2.2 g, fat 0.1 g, available carbohydrate 23 g, dietary fibre 1.9 g, Na 30 mg, K 267 mg, Ca 38 mg, Mg 52 mg, Fe 0.8 mg, Zn 1.6 mg, thiamine 0.02 mg, riboflavin 0.02 mg, niacin traces, vitamin C 17 mg and vitamin E 2 mg (Dignan et al. 1994). Kay (1973) reported the food value of the edible portion of the raw stem tubers of giant taro as energy 293–599 kJ/100 g, water 63–81 %, crude protein 0.6–3.3 %, fat 0.1–0.2 %, carbohydrate 17–27 %, ash 1.1–1.3 %, calcium 46–153 mg/100 g, iron 0.5–1 mg/100 g, phosphorus 45–72 mg/100 g, niacin 0.4 mg/100 g, riboflavin 0.02–0.03 mg/100 g, thiamine 0.09–0.1 mg/100 g and ascorbic acid trace. Much of the calcium is in calcium oxalate crystals.

Alocasia macrorrhiza tubers were found to contain on a weight-to-weight basis 60.5 % neutral lipids, 19.0 % glycolipids and 20.5 % phospholipids, while the total extractable lipids accounted for 0.6 % of the dry weight (Opute and Osagie 1978). Additionally, the presence of tri- and tetragalactosyl diglycerides was confirmed. The predominant fatty acid in each lipid class was linoleic acid with palmitic, oleic and linolenic acids being the other ones. A high degree of unsaturation (66 %), similar for most tuber lipids, was established for the component fatty acids of *Alocasia*. Ferredoxin isoproteins (Fd A and Fd B) were isolated from *Alocasia macrorrhiza* (Wada et al. 1992). They consisted of single polypeptide chains of 97 and 98 residues, respectively, and both Fds had a molecular mass of 10,800 Da. There was an 88 % identity between the sequences of the isoproteins (Fd A and Fd B).

Tubers were found to contain sterols: cholesterol, β -sitosterol, stigmasterol, campesterol and fucosterol (Osagie 1977). Tubers contain a heat-labile amylase enzyme (Shivaraj

et al. 1979), trypsin/chymotrypsin inhibitors (Sumanthi and Pattabiraman 1977; Hammer et al. 1989; Peng et al. 1993; Argall et al. 1994; Mathews et al. 1996) and a lectin AML (Zhu et al. 2006). A new ceramide alomacrorrhiza A was isolated from the ethanolic extract of the root and its structure elucidated as (2S,3S,4R)-2 N-[(2'R)-2'-hydroxy-hexacosanoyl]-tetradecane-1,3,4-triol (Nguyen et al. 2004). Five new indole alkaloids, alocasins A–E, together with known hyrtiosin B and hyrtiosulawesin were isolated from *Alocasia macrorrhiza* rhizome (Zhu et al. 2012).

Major compounds identified in the ethanol extract of *A. indica* corm included: β -hydroxyque brachamine (1.9 % area), gibb-3ene-1,10-dicarboxylic acid,2,4 α -dihydroxy-1-methyl-8-methylene,14 α -lactone,10methyl ester (3.8 %), 4,4-dithiobis butanoic acid (2.6 %), 5-(*p*-aminophenyl)-4-(*O*-tolyl)-2 thiazolamine (8.4 %), 3H-1,4-benzodiazepine-2-amine,7-chloro-N-methyl-5-phenyl,4-oxide (4.7 %), 10, 12, 14 nonacosatriynoic acid (15.3 %), androst-4-en-11-ol-3,17-dione,9-thiocyanato (16 %), estra-1,3,5(10)-trien-17-one,3-hydroxy-6-methoxy,*O*-methyloxime (29.5 %), 17 α -ethynyl-17 β -hydroxy-6- β -methoxy-3 α , 5 cyclo-5 α -androstan-19-oic acid (tr), 1H indole,3 benzyl -2-phenyl (tr) and 1H indole, 5 methyl-2,3-diphenyl (tr) (Pal et al. 2014a).

Alocasia indica starch, an almost white powder, was found to a mean grain diameter of 4.77 μ m, ash value 3.2 %, swelling factor of 10.63, viscosity (5 % w/v) of 8.16 and pH 8.1 and 9.4–9.8 % loss on drying (Lodha and Nemade 2012). *A. indica* starch in 10 % w/w tablet formulation was found to possess disintegrating property and could be useful in conventional tablet formulation. The disintegration time for tablet formulations prepared using 10 % w/w isolated starch was less (109 seconds) than that of the tablet formulations prepared using maize starch as a disintegrant (129 seconds).

Other Plant Parts: Phytochemicals

The plant was reported to contain oxalic acid (Srivastava and Krishnan 1959). Calcium oxalate crystals occur in the form of raphides, which are highly abundant in aroids (Araceae) such

as taro (*Colocasia esculenta*), swamp taro (*Cyrtosperma chamissonis*) and elephant ear taro (*Alocasia macrorrhiza*) and yams (*Dioscorea esculenta*) (Loy et al. 1992; Crowther 2009). Loy et al. (1992) noted that the size, cross-section and termination shape of raphides produced by different species varied so as to be “seemingly distinctive ... to genus”. Raphide of *A. macrorrhiza* was described as elongate with pointed ends and square in cross-section. Four types of raphides were reported to be produced by higher plants based on sectional and termination shape and crystallographic characteristics, and giant taro was found to have type 4 raphides, twinned crystals with H-shaped cross-sections (because of middle groove) and asymmetrical ends sharp at one end and wedge shaped or blunt at the other end (Crowther 2009).

Young leaves contained the cyanogenic glycosides triglochinin (*O*-[β -D—glucopyranosyl]-1-cyano-1-hydroxy-2-methylcarboxy-carboxy- Δ -1,2(*E*)- Δ -3,4(*Z*)-butadiene) and isotriglochinin (*O*-[β -D—glucopyranosyl]-1-cyano-1-hydroxy-2-methylcarboxy-carboxy- Δ -1,2(*E*)- Δ -3,4(*Z*)-butadiene) (Nahrstedt 1975). Beta-glucosidases isolated from *Alocasia macrorrhiza* were found to be highly specific for the hydrolysis of the cyanogenic glucoside triglochinin endogenous to this plant (Hösel and Nahrstedt 1975). The main fractions possessed molecular weights of approximately 310,000 and 105,000, comprising subunits of molecular weight 55,000–60,000. The hexameric beta-glucosidase was shown to dissociate in dimers without any alteration of activity (Hösel and Klewitz 1977). They suggested it was possible that the different beta-glucosidases splitting triglochinin arose during purification from the hexameric form which occurred in the plant. The hydroalcoholic leaf extract of *Alocasia indica* was reported to contain flavonoids, cyanogenic glycosides, citric acid, ascorbic acid and polyphenolic compounds (Mulla et al. 2009a).

The spadix was reported to contain 16 free amino acids, appreciable amounts of citric and malic acids, ascorbic acid and traces of succinic acid and also glucose, fructose and sucrose (Joshi and Pandit 1956). A class of arabinogalactan

proteins, β -lectins was isolated from the leaves and seeds (Clarke et al. 1978).

Antioxidant Activity

The hydroalcoholic leaf extract at 1,000 $\mu\text{g/mL}$ showed maximum scavenging of superoxide radical (87.17) by riboflavin-NBT system, followed by scavenging of stable radical 1,1-diphenyl-2-picryl hydrazyl (DPPH) radical (83.48 %), nitric oxide radical (74.09 %) and hydroxyl radical (60.96 %) at the same concentration (Mulla et al. 2009b). However, the extract showed only moderate activity by iron chelation (68.26 %). The ethanolic leaf extract also showed remarkable antioxidant activity in-vitro antioxidant models of screening like scavenging of 1, 1-diphenyl-2-picryl hydrazyl (DPPH) radical, nitric oxide radical, superoxide anion radical and hydroxyl radical comparable to the standard reference drug ascorbic acid (Mulla et al. 2010a). The hexane, benzene, toluene, chloroform, diethyl ether, ethyl acetate and water fraction of *Alocasia macrorrhiza* plant parts exhibited DPPH antioxidant activity with IC_{50} values in the following order, roots > rhizome > leaves (Mandal et al. 2010). Maximum antioxidant activity was observed in diethyl ether extracts. The IC_{50} values were comparable with those of quercetin and ascorbic acid as standards. The methanol rhizome extract showed a dose-dependent moderate DPPH radical scavenging activity, and the maximum scavenging activity of 38.42 % was found at 500 $\mu\text{g/mL}$. The IC_{50} value of the extract was 693.0 $\mu\text{g/mL}$ (Rahman et al. 2012). The extract exhibited mild reducing power activities compared to ascorbic acid. In DPPH radical scavenging assay, the ethanol tuber extract exhibited strong radical scavenging activity with the 50 % inhibitory concentration value of 42.66 $\mu\text{g/mL}$ (Islam et al. 2013). Total phenolic content was found to be 542.26 mg gallic acid equivalent per 100 g of dried tuber extract, whereas flavonoid content was found to be 4.30 mg quercetin equivalent/g of dried tuber extract. In reducing power assay, the tuber extract showed strong reducing power in a concentration-dependent manner.

Antihyperglycaemic Activity

The methanol extract of *A. macrorrhizos* rhizome administered to alloxan-induced hyperglycaemic mice at 500 mg/kg produced a significant decrease in the blood glucose level (55.49 %) at 8 hours of treatment when compared with the control and was comparable with the reference drug, metformin (Rahman et al. 2012). Studies showed that streptozotocin-induced diabetic rats administered with graded doses (200 mg and 400 mg/kg) of *A. indica* leaf extract for 3 weeks elicited significant increase in body weight and decrease in blood glucose level and serum lipid profiles (cholesterol and triglyceride) in test extract-treated animals compared to diabetic control group (Patil et al. 2012).

Anticancer Activity

Aqueous extract of *A. macrorrhiza* exhibited inhibitory effect of 29.38 % against murine sarcoma S180 in mice and inhibitory effect of 51.72 % against transplantable human gastroadenitis (SGC-7901) in nude mice (Ke et al. 1999). No antitumour effect was shown against Ehrlich ascites carcinoma in mice. *A. macrorrhiza* root ethyl acetate extract exhibited antitumour effects in-vitro against human lung adenocarcinoma A549, murine melanoma B16 and human gastric adenocarcinoma BGC-823 cancer cell lines with IC₅₀ values of 94.6, 541.9 and 629.5 µg/mL, respectively, and acetone extract against A549 and B16 cancer cell lines with IC₅₀ values of 40.9 and 438.0 µg/m, respectively (Zhao 2008).

Indole alkaloids, isolated from the rhizome, hyrtiosulawesin and alocasins A, D and E, showed mild antiproliferative activity in-vitro against human throat cancer (Hep-2) and human hepatocarcinoma (Hep-G2) cell lines, while compounds hyrtiosulawesin and alocasin B showed weak antiproliferative activity against human nasopharyngeal carcinoma epithelial (CNE) cell line (Zhu et al. 2012). *Alocasia macrorrhiza* tuber aqueous extract exhibited proliferation inhibition and apoptosis effects on human hepatocellular carcinoma cells in-vitro and inhibited hepatoma

growth in-vivo (Fang et al. 2012). The mechanism of its action was suggested to be associated with the inhibition of DNA synthesis, cell cycle (G(0)/G(1)) arrest, apoptosis induction through upregulation the mRNA and protein expressions of PPAR γ , Rb, Bax and capase-3 genes and downregulation of the expressions of cyclin D1 and Bcl-2 genes.

Cytotoxicity Activity

The methanol rhizome extract showed mild cytotoxicity with a LC₅₀ value of 188.14 μ g/mL as compared to vincristine sulfate, which served as the positive control with a LC₅₀ value of 11.32 μ g/mL in the brine shrimp lethality assay (Rahman et al. 2012). The petroleum ether and carbon tetrachloride-soluble fractions of the tuber methanol extract showed potent cytotoxicity activity with LC₅₀ of 0.58 μ g/mL and 0.50 μ g.mL, respectively, in the brine shrimp *Artemia salina* lethality assay (Hoque et al. 2012).

Laxative and Diuretic Activities

The ethanolic leaf extract at 100, 200 and 400 mg/kg concentrations produced significant laxative, diuretic and natriuretic activity in rats (Mubeen et al. 2012).

Anti-inflammatory Activity

Oral administration of the ethanol dried rhizome extract to rats at doses of 300 and 600 mg/kg of body weight exerted a significant anti-inflammatory activity against carrageenan-induced paw oedema in rats which was comparable to the standard drug aspirin at the dose of 150 mg/kg of body weight (Rahman et al. 2011). The ethanolic leaf extract and gels produced dose-dependent activity in the carrageenan-induced paw oedema, formalin-induced paw oedema, arachidonic acid-induced ear oedema and xylene-induced ear oedema assays (Mulla et al. 2010a).

Analgesic Activity

The ethanolic leaf extract and gels produced dose-dependent antinociceptive activity when evaluated by the acetic acid-induced writhing response, hot-plate method and tail-flick method in albino rats (Mulla et al. 2010a). The ethanol dried rhizome extract showed significant writhing inhibition in acetic acid-induced writhing in mice at the oral dose of 300 and 600 mg/kg of body weight comparable to the standard drug diclofenac sodium at the dose of 25 mg/kg of body weight (Rahman et al. 2011).

Antimicrobial Activity

Bhatt and Saxena (1980) reported the seed extract exhibited antifungal activity in-vitro. Alocasin, an antifungal protein isolated from the rhizomes of the giant taro, reduced the activity of HIV-1 reverse transcriptase (Wang and Ng 2003). Alocasin displayed antifungal activity against the fungus *Botrytis cinerea*. It exhibited weak haemagglutinating activity, only at a concentration of 1 mg/mL. The petroleum ether, chloroform, acetone, ethanol and water leaf extracts at 5 and 10 mg/mL doses showed significant in-vitro antibacterial and antifungal activity against bacteria *Bacillus subtilis*, *Staphylococcus aureus*, *Klebsiella pneumonia*, *Escherichia coli*, and fungi *Aspergillus niger*, *Candida albicans* and *Saccharomyces cerevisiae* (Mulla et al. 2010b). The ethanol extract was found to possess comparatively more potent antimicrobial activity with lower MIC (minimum inhibitory concentration) against the tested microorganisms. The methanol tuber extract and chloroform-soluble fraction showed growth inhibitory activity in-vitro against *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Shigella boydii* and *Vibrio parahaemolyticus* (Hoque et al. 2012). The chloroform fraction also inhibited growth of *Bacillus subtilis*, *Sarcina lutea*, *Escherichia coli*, *Shigella dysenteriae* and *Vibrio mimicus*.

Hepatoprotective Activity

Oral administration of hydroalcoholic extract of *A. indica* (250 and 500 mg/kg) effectively inhibited CCl₄ and paracetamol-

induced changes in the serum marker enzymes, cholesterol, serum protein and albumin in a dose-dependent manner as compared to the normal and the standard drug silymarin-treated groups (Mulla et al. 2009a). Hepatic steatosis, fatty infiltration, hydropic degeneration and necrosis observed in CCl₄ and paracetamol-treated groups were completely absent in histology of the liver sections of the animals treated with the extracts. *Alocasia macrorrhiza* leaf juice was found to possess hepatoprotective and antioxidative efficacy when tested in-vitro using rat liver slice model (Patil et al. 2011). *A. macrorrhiza* leaf extract decreased significantly the leakage of aminotransferase (AST), alanine aminotransferase (ALT) and alkaline phosphatase (ALP) into the surrounding incubation medium and prevented the depletion of total glutathione contents and build-up of TBARS induced by CCl₄ and Tylenol. Ethanolic extract of the corm also showed potent hepatoprotective activity against CCl₄-induced hepatotoxicity in male albino Wistar rats (Pal et al. 2014a). The elevation in malondialdehyde (MDA) level in CCl₄-treated animal which indicated lipid peroxidation in liver tissue was significantly reversed by the extract. In CCl₄-treated group, there was a decrease in glutathione (GSH) level by 30.04 % compared to control group. Treatment with the ethanol corm extract at 200 mg/kg/day enhanced the GSH level by 55.46 %. CCl₄ induced severe necrotic changes and substantial changes in liver which were ameliorated by the extract. Corm ethanol extract also exhibited antioxidant activity which was higher than the aqueous corm extract. For the ethanol corm extract, the IC₅₀ values for DPPH radical scavenging was 1.31 mg/mL, hydroxyl radical scavenging 3.90 µg/mL, nitric oxide radical scavenging 13.97 mg/mL and super oxide radical scavenging 5.73 µg/mL. For the aqueous corm extract, IC₅₀ values for DPPH radical scavenging was 3.32 mg/mL, hydroxyl radical scavenging 3.71 µg/mL, nitric oxide radical scavenging 19.95 mg/mL and super oxide radical scavenging 8.13 µg/mL. Both extract showed the presence of various phytochemical compounds, e.g. alkaloids, flavonoids, glycosides, saponin, tannins as well as superoxide dismutase (SOD) and catalase

(CAT) enzyme activity. Ethanolic extract showed higher phenolic and flavonoid content than aqueous extract.

Intraperitoneal administration of the ethanolic extract of *A. indica* corm for 15 days significantly ameliorated the hepatotoxic effects induced by alcohol in rats (Pal et al. 2014b). The extract significantly and dose dependently reduced the marked elevation of liver biomarkers such as serum ALT, AST, γ -glutamyl transpeptidase (γ -GT) and total bilirubin levels. It also improved antioxidant status (MDA, nitric oxide and GSH) and preserved hepatic cell architecture. Simultaneous supplementation with the extract significantly restored hepatic CAT and SOD activity levels towards normal.

Antidiarrheal Activity

The aqueous and ethanol leaf extracts exhibited significant in-vitro antidiarrhoeal activity compared to the standard drug ciprofloxacin (10 μ g/mL) as evaluated against *Escherichia coli*, *Salmonella typhimurium*, *Shigella flexneri* and *Staphylococcus aureus* by agar well diffusion method (Mulla et al. 2011). The aqueous and ethanol leaf extracts showed significant and dose-dependent antidiarrhoeal activity in-vivo comparable to that of the reference drug loperamide (10 mg/kg) against recinoleic acid-induced diarrhoea and magnesium sulfate-induced diarrhoea. The ethanol tuber extract significantly enhanced the latent period and decreased defecation in both castor oil- and magnesium sulfate-induced diarrhoea (Islam et al. 2013). The extract also lessened gastrointestinal motility in mice. Potential antibacterial activity was exhibited by the extract against all the tested bacterial strains in disc diffusion assay. The 50 % lethal concentration against brine shrimp nauplii was 81.09 μ g/mL.

Haemagglutinating Activity

Alocasin exhibited weak haemagglutinating activity, only at a concentration of 1 mg/mL (Wang and Ng 2003).

Immunomodulatory Activity

Alocasia macrorrhiza lectin exhibited mitogenic activity on human peripheral blood lymphocytes at 50 µg/mL (Kamboj et al. 1995). The lectins were T-cell mitogens, and did not induce any appreciable DNA synthesis in B-enriched lymphocytes. The mitogenic response was shown to be inhibited by asialofetuin in a concentration-dependent manner.

Antiprotozoal Activity

The aqueous and ethanol leaf extracts exhibited significant in-vitro antiprotozoal activity against both protozoa *Entamoeba histolytica* and *Giardia intestinalis* compared to the standard amoebicidal and giardicidal drugs, metronidazole and emetine (Mulla et al. 2011).

Thrombolytic Activity

The methanol extract of *A. indica* tuber and petroleum ether and carbon tetrachloride-soluble fractions showed moderate clot lysis activity ranging from 45.61 to 20.51 % (Hoque et al. 2012). They showed significantly membrane stability activity and significantly protected lysis of human erythrocyte membrane induced by hypotonic solution and heat-induced haemolysis, as compared to the standard acetyl salicylic acid.

Antimalarial Activity

Alocasia macrorrhiza leaf extract (60–300 ppm) exhibited larvicidal activity against the first to fourth instar larvae of the *Anopheles stephensi*, the malarial vector, and caused pupal mortality of *A. stephensi* (Durga Devi and Murugan 2013). The LC₅₀ and LC₉₀ values were represented as follows: LC₅₀ value of I instar was 126.55 ppm, II instar was 143.19 ppm, III instar was 165.10 ppm, and IV instar was 186.13 ppm. The LC₉₀ value of I instar was 278.81 ppm, II instar was 327.47 ppm, III instar was 380.01 ppm, and IV instar was 421.04 ppm. The LC₅₀ value of pupae was 205.68 ppm, and the LC₉₀ value of pupae was 456.92 ppm.

Anthelmintic Activity

The hydroalcoholic leaf extract and its petroleum ether and ethyl acetate fractions were found to paralyse (vermifuge) and kill the test earthworm, *Pheretima posthuma* (vermicidal) (Mulla et al. 2010c). The 50 mg/mL dose was more effective as compared to the standard reference, piperazine citrate.

Antihyperlipidaemic Activity

The hydroalcoholic extract of *Alocasia macrorrhizos* leaves at the dose of 250 and 500 mg/kg in rats fed a cholesterol-rich high-fat diet for 45 days significantly reduced triglyceride and VLDL-C levels; however, it increased LDL-C, and hence may not be suitable as a lipid-lowering agent (Ramya et al. 2012).

Protease Inhibitory Activity

Trypsin/chymotrypsin inhibitors were isolated from *Alocasia macrorrhizos*. A trypsin/chymotrypsin inhibitor with molecular weight of about 3,200 was isolated from the tubers (Sumathi and Pattabiraman 1977). The inhibitor acted on bovine trypsin, human trypsin and bovine chymotrypsin. It had no action on human chymotrypsin, subtilisin BPN, pronase, *Aspergillus oryzae* protease and human and porcine pepsins. The trypsin inhibitors isolated from giant taro, taro and giant swamp taro had molecular weight of 35,000–38,000 and was similar to the Kutniz family inhibitor (Hammer et al. 1989). The trypsin/chymotrypsin inhibitor in giant taro occurred as a dimer of two identical monomers each with slight polymorphism and could be an attractive candidate for conferring insect resistance in transgenic plants (Argall et al. 1994). It was found to have 184 amino acid sequence with molecular mass of 19,774 Da for the Met-24, Glu-50 form. Giant taro trypsin/chymotrypsin inhibitor was found to be more related to taro (*Colocasia esculenta*) than to that of giant swamp taro (*Cyrtosperma chamissonis*) (Peng et al. 1993). A full-length cDNA encoding the 206 amino acid open reading frame of a trypsin/chymotrypsin inhibitor abundant in the corms of giant taro (*Alocasia macrorrhiza*) was isolated

(Mathews et al. 1996). The cDNA of *Alocasia macrorrhiza* lectin (AML) was cloned and found to have an amino acid length of 280 amino acids with relative molecular weight of 29.7 kD (Zhu et al. 2006). It exhibited similarity to other mannose-binding lectins and similar proteins from Araceae family. Two typical B-lectin domains and three mannose-binding motifs were found in the sequence of AML. They concluded that this newly cloned AML cDNA encoded for a mannose-binding lectin.

Miscellaneous Activity

Nayak et al. (2002) found that *Alocasia macrorrhiza* tuber protein in its pure or crude form could be used for the rapid isolation of two of the prominent alpha2-globulins, haptoglobin and alpha2-macroglobulin from human serum.

Toxicity Issues

Several cultivars of *A. macrorrhiza* had been reported to be cyanogenic; young leaves had been found to contain up to 0.018 % of hydrogen cyanide, but cyanogenic glycoside was not reported to be present in the corms or stems (Kay 1973). A case of poisoning due to ingestion of a giant taro root tuber was reported by Chan et al. (1995). The patient developed neurological (severe pain and numbness in the perioral area and throat) and gastrointestinal (nausea, vomiting, abdominal pain) symptoms immediately after eating the root tuber. The neurotoxin was reported to be similar to sapotoxin that found in *Alocasia odora*. Twenty-seven cases of *A. macrorrhiza* poisoning were reported in 12 females and 15 males from age 1.5 to 68 years by Lin et al. (1998). One patient had eye contact, another skin contact. In the 25 cases that consumed the plant leaf or tuber either raw or cooked, the primary symptom was injected sore throat, and the secondary symptom was numbness of the oral cavity. Some patients had salivation, dysphonia, abdominal pain, ulcers of the oral cavity, difficulty in swallowing, thoracodynia, chest tightness and swollen lips. The authors believed that the presence of sapotoxin alone was not sufficient to explain the injected swollen and ulcerative

lesions and that presence of calcium oxalate in the whole plant could be responsible for inflammation of the oral cavity and mucous membranes. Tang et al. (2006) reported a case of crystalline keratopathy in the cornea caused by *Alocasia macrorrhiza* based on the observation of needle-like crystals in the corneal stroma following injury to the eye. The condition resolved in 3 months with the disappearance of the crystals confirmed by follow-up confocal microscopy.

In-vivo studies showed that oral administration of *A. macrorrhiza* extract in a dose of 144.6 mg/kg/day for 20 days impacted on the hepatorenal function in mice (Helal et al. 2008). RBCs and Hb were significantly decreased after treatment period. Total protein, albumin and globulin were significantly decreased, while, aminotransferase (AST), alanine aminotransferase (ALT), lactate dehydrogenase (LDH), gamma-glutamyl transferase (GGT), urea, creatinine and total lipid and cholesterol were significantly increased after treatment and recovery period of 10 days. Histological changes in treated sections of the liver showed evidence of cellular degeneration, and necrosis and in kidney sections, tubular necrosis, glomerular shrinkage and atrophied glomerular tuft of capillaries were prominent. Mallory-stained sections in liver showed increased collagen fibres around congested central veins, blood sinusoids and portal areas. The changes which were observed after treatment disappeared after a recovery period of 20 days.

Traditional Medicinal Uses

Giant taro had been used in folkloric medicine in India, Bangladesh, Southeast Asia and Papua New Guinea (Burkill 1966; Nadkarni and Nadkarni 1982; Chopra et al. 1986; Arief Haryana 2006; Khare 2007; Stuart 2013). In Malaysia, the application of the acrid juice had been reported to give instant relief to stings of the giant nettle (*Laportea*). Sap from the petioles were used to treat cough. In Java, the chopped-up roots and leaves may be used as an application for pains in the joints and as rubefacient. In Papua New Guinea, young leaves and sap are used externally to treat headache. In India, the tuber/corm is used in the treatment of scorpion stings, disease

of the abdomen and spleen and gout and rheumatism and as mild laxative, as diuretic and as anti-inflammatory agent; the leaf is traditionally used as astringent, styptic and antitumour agent, root and leaf as rubefacient and leaf and stem as a bath for skin disorders itch and burns. A poultice of fresh leaves is applied to relieve pain from varicose veins and improve blood circulation, steam oiled leaves are applied for painful joints, and toasted and powdered leaves are used to hasten wound healing. In Indonesia, the tuber is used for treatment of influenza, fever, headache, diarrhoea, malaria, typhoid, rheumatism, pulmonary tuberculosis and tuberculous lymphadenopathy, abscesses, ringworms and venomous bites of snakes, insects and dogs. In Bangladesh, the plant is employed in the treatment of diabetes; stem juice applied to prevent oedema, pain and bleeding from cuts and wounds. Whole plant is used as a therapy for pus in the ears, jaundice and constipation. In the Philippines, the petioles are ground together, placed in a piece of cloth with live coals and used as an application to alleviate toothache. Giant taro is widely used in China for treating joint disorders, flu complication, headache, bleeding haemorrhoids, pulmonary tuberculosis, chronic bronchitis and appendicitis and is used as an anti-inflammatory (Ke et al. 1999). In Hawaii, the tuber is employed for the treatment of severe burns and acute abdominal pains (Kaaikamanu and Akina 1922). In India, the tuber is traditionally used in the treatment of abdomen- and spleen-related disorder (Pal et al. 2014a).

Other Uses

Giant taro is widely planted as ornamental foliage plants in various landscape scenarios in gardens, parks and around buildings, hotels and resorts.

Crude *A. macrorrhiza* lectin (AML) was found to be toxic to larvae of cabbage butterfly (*Pieris rapae*), Asiatic corn borer (*Ostrinia furnacalis*) and tobacco cutworm (*Spodoptera litura*), acting mainly as stomach poison (Pan et al. 2007b). They also reported that four types of crude lectin extracted from *A. macrorrhiza* exhibited toxic effects on four insect cell lines, namely, Sf-9 from *Spodoptera frugiperda*, Se301 from *Spodoptera exigua*, Hi5 from *Trichoplusia ni* and Hz from *Heliothis zea*; the relative cell death rates observed at 2 % crude extract were 91.40 %, 91.62 %, 97.13 % and 82.30 % respectively, after 24-hours treatment (Pan et al. 2007a). They also found that AML decreased the activities of amylase and protease of soybean aphid (*Aphis craccivora*), by binding and inhibiting these digestive enzymes of aphids, leading to nutrient deficiency, weakening the aphids and eventually leading to aphid mortality (Pan et al. 2010).

Studies showed that boiled leaves of the Giant taro could be a complete replacement for soybean meal in the diets of Mong Cai pig sows with only a slight increase in time to re-mating (from 7.2 to 12.7 days) and a reduction of 3.5 % in litter weight at weaning and providing threefold increase in economic benefits (Duyet 2010). The plant was formerly cultivated as pig feed in Brazil (Kay 1973). It has also been investigated as a potential raw material for the production of alcohol.

Comments

Alocasia macrorrhiza can be distinguished from *A. odora*; the latter has peltate leaves and proportionately much shorter spadix appendix (Boyce 2008). Further, *Alocasia macrorrhizos* never produce stolons from the base of the stems.

Giant taro is propagated from suckers, but shoot tips with a narrow part of the stem and rolled up young leaves, or sections of stem having two or three buds are also frequently employed.

Origin/Distribution

The species is native to tropical Asia. It grows wild in Sri Lanka, the Philippines, Malaysia, Indonesia and other Southeast Asian countries. It is also found in India, southern China, New Guinea, Northern Australia and Polynesia.

Agroecology

The plant is a tropical crop and requires an average temperature of 25–35 °C during its growth period. In its native range, it occurs in almost all imaginable secondary conditions, either secondary forest, coastal monsoon forests and thickets or highly disturbed areas and in dappled shade or fully exposed areas, from sea level to 700 m altitude. It prefers evenly distributed rainfall between 1,000 and 1,500 mm per annum, although the plant can be grown with rainfall as low as 650 mm provided irrigation facilities are available. Warm humid conditions favour leaf growth, and dry conditions favour the development of the corms.

Elephant yam prefers friable, deep loamy non-alkaline soil. It is hardy in tropical areas when planted in rich, well-drained soil in a sheltered, humid position. It does best in partial shade. It succumbs to waterlogging and heavy clayey soil; hence, good drainage is essential.

Edible Plant Parts and Uses

Tubers eaten after thorough cooking in *sayur* or as a titbit, sliced, baked or boiled especially in Indonesia (Ochse and Bakhuizen van den Brink 1980). Very young shoots still in the bud are used as vegetables in Indonesia. Leaves are also used as a tobacco substitute. Young petioles of young unexpanded leaves are edible when thoroughly cooked and considered a delicacy in the Philippines (Burkill 1966; Stuart 2014). In Malaysia, the indigenous Sakai eat the tubers after pounding and prolonged cooking. Starch from the tuber is used as food for diabetic persons, and the petiole is soaked in water and cooked in Vietnam (Tanaka and Nguyen 2007). The tuber may be used as a source of starch and alcohol and have been used to prepare a flour for bread-making. In India, the corm is prepared in curries, fried or used as pickles and chutney, while the above-ground parts are also eaten as green vegetable (Wikipedia 2014).

Studies found that Chinese noodles made from a blend of wheat flour and 3 % konjac glucomannan (KGM) were relatively desirable in textural properties and scored best in sensory evaluation, indicating the potential for improving textural defect of noodles prepared from low-protein wheat flour by using KGM (Zhou et al. 2013).

Botany

Stout herbaceous plant grows annually from a perennial subterranean corm to a height of 1.5 m (Plate 1). Corm is depressed-globose, to about 30 cm in diameter, about 20 cm high, dark brown, with distinct annular root scars (Plate 4). The pustular surface of the stem is attractively blotched with paler shades of green (Plate 2). Leaf usually solitary divided into three major segments, which is further subdivided into oval or elliptic lobes about 6 cm long, leaf stalk up to 1 m or more, background colour pale to dark green with large and small pale blotches and numerous tiny dark dots (Plate 3). Inflorescence: flowers small, yellowish crowded into a stout column (spadix), male above and female below; the column is crowned by a reddish-brown bladderlike appendage, and the whole inflorescence is subtended by a large red brown bract (Plate 5). Fruit red, obovoid berry crowded on the spadix, 1.5 cm diameter, two to three seeded.

Nutritive/Medicinal Properties

The tuber of *Amorphophallus paeoniifolius* had been reported to have the following food value per 100 g edible portion (Brand-Millet et al. 1993): energy 70 kJ, moisture 79 g, nitrogen 0.24 g, protein 1.5 g, fat 0.3 g, ash 1.1 g, available carbohydrate 0 g, total dietary fibre 4.2 g, Ca 85 mg, Mg 33 mg, Fe 2.3 mg, Cu 0.1 mg, Na 3 mg, Zn 0.9 mg, niacin (derived from tryptophan or protein) 0.3 mg, niacin equivalents 0.3 mg and vitamin C 6 mg.

Analysis conducted in Indonesia reported that Suweg tuber flour had high content of dietary fibre (13.71 %) and protein (7.20 %) but had low fat content (0.28 %) (Faridah 2005). Suweg tuber had low glycaemic index (GI) of 42 with low starch in-vitro digestibility (61.75 %); hence, Suweg is categorised as a food product with low GI (<55).

The following compounds betulinic acid, triacontane, lupeol, stigmasterol, β -sitosterol and its palmitate were isolated from the plant (Chawla and Chibber 1976). Glucose, galactose (larger amount), rhamnose and xylose were also found as free sugars. The corm was reported to contain alkaloids, steroids, fats, fixed oil, flavonoids, tannins, proteins and carbohydrates (De et al. 2010b; Dey and Ghosh 2010b). The flavonoid content of the methanol and hydroalcoholic extracts of *A. paeoniifolius* corms were found to be 46.33 and 36.88 mg/g rutin, respectively (Nataraj et al. 2009a). Similarly total phenolic content of the extracts (ME and AE) were found to be 12.67 and 6.25 mg/g catechol equivalent, respectively. The triterpenoid amblyone was isolated from *Amorphophallus campanulatus* tuberous root (Khan et al. 2008). A water-soluble polysaccharide isolated from the aqueous extract of *Amorphophallus campanulatus* corm was found to contain D-galactose, D-glucose, 4-O-acetyl-D-methyl galacturonate and L-arabinose in a molar ratio of 2:1:1:1 (Das et al. 2009a). A polysaccharide konjac glucomannan with molecular weight of 115×10^6 daltons and moisture uptake of was found to consist of mannose and glucose units in the ratio of 1:0.13 (Nguyen et al. 2009, 2010). Water-soluble O-carboxymethyl glucomannan

derivatives (*O*-CMG) with different degrees of substitution were synthesised successfully by reaction of a konjac glucomannan (isolated from the tubers of *Amorphophallus paeoniifolius*, one of the most abundant *Amorphophallus* species in Vietnam forest) directly with monochloroacetic acid (Nguyen et al. 2011).

Resistant starch III was prepared from elephant foot yam starch using pullulanase enzyme (Reddy et al. 2014). The enzymatic and retrogradation process increased the yield of resistant starch III from starch with a concomitant increase in its water absorption capacity and water solubility index. A decrease in swelling power was observed due to the hydrolysis and thermal process. The reduced pasting properties and hardness of resistant starch III were associated with the disintegration of starch granules due to the thermal process.

Antioxidant Activity

The methanolic and aqueous extracts of *Amorphophallus campanulatus* corm exhibited antioxidant activity in different in-vitro models, namely, 1, 1-diphenyl-2-picryl hydrazyl (DPPH) method, nitric oxide method and reducing power methods (Sahu et al. 2009). The extracts showed good dose-dependant free radical scavenging property in all the models. IC₅₀ values for water and methanolic extract were found to be 59.91 and 99.40 µg/mL in DPPH method and 77.02 and 70.20 µg/mL in nitric oxide method. In reducing power method, the aqueous extract showed more reducing power compared to the methanolic extract.

Hepatoprotective Activity

Amorphophallus campanulatus corm exhibited potent hepatoprotective action against carbon tetrachloride-induced hepatic damage in rats (Jain et al. 2009). The ethanolic extract exhibited more potent hepatoprotective effects than the aqueous extract. The study suggested that possible mechanism of this hepatoprotective activity may be due to free radical scavenging potential caused by the presence of flavonoids in the extracts.

In-vitro and in-vivo studies revealed that the methanolic extract of *A. campanulatus* corm (ACME) had higher antioxidant and radical scavenging activity than the n-hexane extract which may be attributed to its higher phenolic and flavonoid content (Ansil et al. 2011). Methanolic extract of *A. campanulatus* (AMCE) corm significantly reversed the elevation of serum alanine transaminase (ALT) and aspartate transaminase (AST), alkaline phosphatase (ALP), lactate dehydrogenase (LDH) and tissue malondialdehyde levels induced by thioacetamide oxidative stress in male Wistar rats (Ansil et al. 2011, 2012). Hepatic and renal reduced glutathione (GSH), glutathione-S-transferase (GST), glutathione reductase (GR), glutathione peroxidase (GPx) and catalase levels were remarkably increased by the treatment with the extract. Quantification of histopathological changes also supported the dose-dependent curative effects of ACME.

Pretreatment of the rats with methanol and aqueous extracts of *A. paeoniifolius* corms prior to paracetamol administration caused a significant reduction in the values of serum glutamic oxaloacetic transaminase (GOT), glutamic pyruvic transaminase (GPT), ALP and bilirubin almost comparable to the standard hepatoprotective agents silymarin and Liv-52 (Hurkadale et al. 2012). The hepatoprotective was confirmed by histopathological examination of the liver tissue of control and treated animals. In a recent study, administration of ethanolic extract of *A. campanulatus* at 250 and 500 mg/kg body wt significantly normalised the values of SOD, CAT, GSH and TBARS in rats with hepatotoxicity induced by ethanol (Datta 2013). The elevated serum enzymatic levels of AST, ALT, ALP and total protein were significantly restored towards normal by pretreatment with ethanolic extract of *A. campanulatus*. Histopathological studies also confirmed the hepatoprotective nature of the extracts by normalising the hepatocellular architecture in the extract-treated groups when compared to the only ethanol-administered group.

Quercetin isolated from *A. paeoniifolius* corm ethyl acetate fraction was found to have hepatoprotective effect on CCl₄-induced hepatotoxicity in rats (Sharstry et al. 2010). The

extract reduced the CCl₄ elevated SGPT, SGOT and bilirubin enzymes levels, increased protein levels and attenuated the damaged hepatocytes towards normal architecture. The results were further supported by histopathology of isolated rat liver.

Anticancer/Cytotoxicity Activity

Amorphophallus paeoniifolius corm extract exhibited antiproliferative activity using *Allium cepa* root tip cell assay and Hep-2 cells (Angayarkanni et al. 2007). The corm petroleum ether and ethanol extracts showed low mitotic index 0.34 but high cytolytic index 75 % and 80 %, respectively. Of seven extracts tested, only petroleum ether and ethanol extracts displayed dose-dependent antiproliferative activity on Hep-2 cells. The terpenoid amblyone isolated from *A. campanulatus* exhibited moderate cytotoxicity against brine shrimp nauplii (Khan et al. 2008). In the cytotoxicity determination, LC₅₀ of the compound against brine shrimp nauplii was 13.25 µg/mL. The ethanol extract of *A. paeoniifolius* corm exhibited antioxidant and antitumour activity against 7,12-dimethylbenz(a)anthracene (DMBA)-induced mammary tumour in rats (Jagadheesh et al. 2010). The extract contained 8.8 g/100 g quercetin equivalent of flavonoids and exhibited significant antioxidant in scavenging DPPH and ABTS radicals in comparison to quercetin.

The subfractions of *A. campanulatus* tuber methanolic extract (ACME) viz. petroleum ether fraction (PEF), chloroform fraction (CHF), ethyl acetate fraction (EAF) and methanolic fraction (MEF) the subfractions of *A. campanulatus* tuber methanolic extract (ACME) viz. petroleum ether fraction (PEF), chloroform fraction (CHF), ethyl acetate fraction (EAF) and methanolic fraction (MEF) significantly inhibited the proliferation of colon cancer cell line, HCT-15 in a dose-dependent manner (Ansil et al. 2014). In addition, the extracts were found to induce apoptosis results suggested that, among the sub fractions of ACME, CHF had potent cytotoxic and apoptotic activity. *Amorphophallus campanulatus* tuber methanolic extract (ACME) exerted significant chemopreventive effect on 1, 2-dimethylhydrazine

(DMH)-induced colon carcinogenesis in rats (Ansil et al. 2013). Supplementation of ACME significantly improved colonic MDA (malondialdehyde) and reduced glutathione levels and the activities of antioxidant enzymes in DMH-intoxicated rats. ACME administration also significantly suppressed the formation and multiplicity of aberrant crypt foci.

Antimicrobial Activity

The terpenoid amblyone isolated from *A. campanulatus* exhibited good antibacterial activity against four Gram-positive bacteria (*Bacillus subtilis*, *Bacillus megaterium*, *Staphylococcus aureus* and *Streptococcus pyogenes*) and six Gram-negative bacteria (*Escherichia coli*, *Shigella dysenteriae*, *Shigella sonnei*, *Shigella flexneri*, *Pseudomonas aeruginosa* and *Salmonella typhi*) but insignificant antifungal activity against *Aspergillus flavus*, *Aspergillus niger*, *Rhizopus oryzae* and *Candida albicans* (Khan et al. 2008). The MIC values against the bacteria ranged from 8 to 64 µg/mL. The ability of mannans, especially konjac glucomannans, to prevent specific pathogens including *Escherichia coli* from adhering to the gut or bladder mucosa was highlighted by Tester and Al-Ghazzewi (2013).

Amorphophallus campanulatus leaf extract at levels greater than 4.5 mg/mL of 20 g/100 mL extract completely inhibited aflatoxin production by *Aspergillus flavus*, and suppression in growth was also well pronounced (81 % at 8.0 mg/mL) (Prasad et al. 1994). The comparative efficacy of the corm extract was lower. Calcium oxalate, an important constituent of the leaf, completely checked the growth and toxin biosynthesis at 0.4 mg/mL concentration.

Anti-inflammatory Activity

Methanol extract of *A. paeoniifolius* corm exhibited marked anti-inflammatory in carrageenan-induced paw oedema in rats, while the chloroform extract exhibited milder activity (De et al. 2010a). The methanol extract also exhibited antihistaminic effect in guinea pigs.

Antihyperglycemic Activity

The methanol extract of *A. campanulatus*, when administered to mice at doses of 50, 100, 200 and 400 mg per kg body weight, dose dependently reduced blood glucose levels in glucose-loaded mice, by 28.8, 29.1, 35.3, and 37.4 %, respectively (Rahaman et al. 2014). A standard antihyperglycaemic drug, glibenclamide, when administered at a dose of 10 mg per kg body weight, reduced blood glucose level by 40.7 %. Thus, the extract, at the highest dose tested, showed a near equivalent antihyperglycaemic potency to that of glibenclamide.

CNS-Depressant Activity

The petroleum ether extracts of *Amorphophallus paeoniifolius* corm at the dose levels of 100, 300 and 1,000 mg/kg body weight administered intraperitoneally into Swiss albino mice exhibited significant reduction in locomotor activity and in grip of the rotating rod, in a dose-dependent manner (Das et al. 2009b). The petroleum ether extract of *A. paeoniifolius* was found to have CNS depressant activity (Dey et al. 2011). A significant synergistic effect of the petroleum ether extract with diazepam was found, whereas there was little synergistic effect with phenobarbitone.

Analgesic/Antinociceptive Activity

The methanol extract of *A. campanulatus* corm when administered to mice at doses of 50, 100, 200 and 400 mg per kg body weight reduced the number of abdominal constrictions induced by intraperitoneal administration of acetic acid in mice by 30.4, 33.3, 42.4, and 45.5 %, respectively (Rahaman et al. 2014). In contrast, a standard antinociceptive drug, aspirin, when administered to mice at doses of 200 and 400 mg per kg body weight reduced the number of abdominal constrictions by 27.3 and 36.4 %, respectively, demonstrating that the extract, even at the lowest dose, was more potent than the lower dose of aspirin. The methanol extract of *A. campanulatus* tuber, given orally at the

doses of 250 and 500 mg/kg, showed significant analgesic activity in mice (Shilpi et al. 2005). Intraperitoneal administration of the methanol corm extract of *A. paeoniifolius* (250–500 mg/kg body weight) in mice exerted analgesic activity in the tail flick and acetic acid-induced writhing response tests in a dose-dependent manner (Dey and Ghosh 2010a). The plant was suggested to have compounds that inhibited cyclooxygenase enzyme or acted on central opioid receptors.

Anxiolytic Activity

The petroleum ether extract of *Amorphophallus paeoniifolius* corm showed potent anxiolytic activity at a dose-dependent manner in mice in the elevated plus maze and open field test (Saha et al. 2013). The extract however failed to show any significant anxiolytic activity in light and dark test.

Tyrosinase Activity

Tyrosinase and laccase activities were detected in *Amorphophallus campanulatus* corm (Paranjpe et al. 2003). Tyrosinase was found to be the predominant enzyme exhibiting mono- and di-phenolase activities, specificity for L-DOPA as substrate, optimum pH being 6.0, optimum temperature at 40 °C and Km at 1.05 mM. Three isoforms of tyrosinase were detected with apparent molecular mass approximately 127, 31 and 27 kDa, respectively. Tyrosinase was detected in the intercellular spaces of the plant tissue but not in the cytosolic region. Laccase showed substrate specificity for *p*-phenylenediamine (*p*-PD), Km at 2.7 mM, optimum pH being 5.0 and was inactivated above 40 °C. Tyrosinase from *Amorphophallus campanulatus* was immobilised on eggshell membrane using glutaraldehyde (Tembe et al. 2008). Studies on effect of pH showed retention of more than 90 % activity over a pH range 5.0–6.5. Membrane bound enzyme exhibited consistent activity in the temperature range 20–45 °C. Shelf life of immobilised tyrosinase system was found to be more than 6 months when stored in phosphate buffer at 4 °C.

Enzyme Inhibitory Activity

Amorphophallus campanulatus tubers exhibited antiprotease activity (Prathibha et al. 1995). When tubers were processed by pressure cooking, a partial retention of inhibition was observed in the case of trypsin inhibitor in *Amorphophallus*.

Immunomodulatory Activity

A water-soluble polysaccharide isolated from the aqueous extract of *Amorphophallus campanulatus* corm showed splenocyte activation (Das et al. 2009a). The methanol extract of *A. campanulatus* corm exhibited immunomodulatory activity by causing a significant decrease in charcoal clearance, spleen index and delayed-type hypersensitivity (DTH) response to sheep red blood cell (RBC) in sensitised mice (Tripathi et al. 2010).

Antidiarrhoeal Activity

Administration of the ethanolic extract of the *A. paeoniifolius* leaves, at the doses of 100, 200 and 400 mg/kg, significantly reduced the total number of faeces as well as diarrhoeic faeces in a dose-dependent manner in Swiss albino rats with castor oil-induced diarrhoea (Purwal et al. 2011).

Gastrotherapeutic Activity

The glucomannans including konjac glucomannans could be candidates for use as possible therapeutic tools for the treatment of a range of physiological disorders such as diverticulitis, Crohn's disease or ulcerative colitis (Tester and Al-Ghazzewi 2013).

Anticonvulsant Activity

Petroleum ether extracts of *A. paeoniifolius* showed dose-dependent anticonvulsant activity regarding onset of convulsion induced by isoniazid in mice (De et al. 2012)

Anthelmintic Activity

The methanol extract of *A. paeoniifolius* corm exhibited significant anthelmintic activity against *Pheretima posthuma* and *Tubifex tubifex* at highest concentration of 100 mg/mL (Dey and Ghosh 2010a). The extracts were found not only to paralyse (vermifuge) but also to kill the earthworms (vermicide). The chloroform, methanol extracts (containing tannins) and crude tannins showed very good anthelmintic activity against *Pheretima posthuma* (Ramalingam et al. 2010). Paralysis and death times were very close to the standard drug Albendazole.

Traditional Medicinal Uses

In Indian traditional medicine, the tubers are used as appetiser, aphrodisiac, expectorant, irritant and anti-catarrhal and for liver complaints, tumours, inflammation, haemorrhoids, vomiting, cough, bronchitis, asthma,, piles, abdominal pains, dyspepsia and acute rheumatism and for treating spleen enlargement (Chopra et al. 1986; Khare 2007) . The corm is deemed as carminative, restorative, stomachic and tonic. It is dried and used in the treatment of piles and dysentery. In Sri Lanka the corm is used for dropsy, urinary diseases, dyspepsia, toothache, rheumatism, boils, fistula, colitis, haemorrhoids, diuretic, piles, elephantiasis and glandular swellings. The tuber is widely used in South India as folk medicine to treat acute rheumatism, tumours, lung swelling, asthma, vomiting and abdominal pain (Angayarkanni et al. 2007). Traditionally, *Amorphophallus campanulatus* tuber is used for the treatment of enlarged spleen, rheumatism and tumour in India (Tripathi et al. 2010). *Amorphophallus paeoniifolius* was one of seven plant species that was found to be most important and frequently used by traditional healers in Palakkad district of Kerala, India, for dermatological infections/diseases and gastrointestinal disorders (Yabesh et al. 2014). Leaves were the most frequently used plant parts, and most of the medicines were prepared in the form of paste and administrated orally. In the Philippines, tubers (corms) are

used for treatment of boils and haemorrhoids and poultices
used as antirheumatic (Stuart 2014).

Other Uses

The tubers are sliced, sun-dried, pounded to a meal, boiled and fed to pigs, while the older petioles are boiled and used as pig food in the Philippines (Burkill 1966).

Comments

The fresh inflorescence emits an odour reminiscent of rotting meat which attracts pollinating carrion flies and beetles.

Origin/Distribution

C. esculenta is native to tropical Asia (Govaerts 2014). Taro appears to have originated in India and spread eastwards to Burma and China and southwards to Indonesia. Subsequently, it was taken to Japan, Melanesia, Polynesia and Hawaii; in historical times, it spread to Egypt and the eastern Mediterranean, thence to Africa, to the Guinea coast and to the Caribbean. It has been actively cultivated throughout tropical and subtropical regions. Today, it is grown throughout the West Indies and in West and North Africa. In Asia, it is widely planted in south and central China and is grown to a lesser extent in India. It is now a staple food in many islands of the Pacific including Papua New Guinea.

Isozyme studies of 1,427 cultivars and wild taro forms from Oceania and Asia conducted by Lebot and Aradhya (1991) indicated that the majority of Indonesian cultivars were different from the Philippines. Taro cultivars in Oceania were suggested to have a narrow genetic base introduced from Indonesia which was found to have the greatest taro diversity. AFLP analysis confirmed the isozyme results, and two distinct gene pools were found, one in Southeast Asia and the other in the Pacific (Lebot et al. 2004).

Agroecology

C. esculenta can be found growing naturalised or native mainly in moist forests and wet areas in riparian habitats, riverbanks, along streams, marshes and canals or cultivated near farmhouses, in water fields or as under-planting in coconut groves (Ibrahim et al. 1983; Safo-Kantaka 2004; Acevedo-Rodríguez and Strong 2005; Langeland et al. 2008). It can also be found in secondary forests, roadsides and disturbed areas near to abandoned crop fields (Wagner et al. 1999; Acevedo-Rodríguez and Strong 2005). Taro thrives in hot, humid conditions, with daily average temperatures of 21–27 °C with an annual rainfall of 250 mm to 1,750 mm evenly distributed during the growing period. It grows from sea level to 2,400 m elevation. It is primarily adapted to a moist environment. It can be grown under submerged or flooded conditions or on artificial elevations in swamps, as well as by dry cultivation in areas with high rainfall. It tolerates a wide range of soil types but does best on deep, well-drained, friable loams, particularly alluvial loams, with a high water table and a pH range of 5.5–6.5. It does best in partial shade but tolerates full sun with adequate water supply.

Edible Plant Parts and Uses

In China, caudices, corms and cormels are boiled, or cooked, with meat or seafood (Hu 2005). Sapal is a traditional fermented food in Papua New Guinea made by mixing cooked, grated taro corm with coconut cream and allowing it to ferment at ambient temperature (Gubag et al. 1996). The fermentation was primarily due to heterofermentative lactic acid bacteria predominantly *Leuconostoc mesenteroides* or *Leuconostoc paramesenteroides*. Achu is a thick porridge obtained by cooking and pounding taro corms and cormels in a mortar (Njintang and Mbofung 2006). Taro corm is a staple food in tropical Africa; in Cameroon, it is widely known for its famous dish achu (Ejoh et al. 1996). The corms are eaten boiled, fried or roasted as a side dish or are used for making fufu in Africa. The corm is also sliced and fried into taro chips. In Indonesia, the corm is sliced and pieces fried in coconut oil or roasted and eaten mixed with aren palm sugar syrup or without (Ochse and Bakhuizen van den Brink 1980). Thin corm slices are also deep-fried to make kripik. The boiled or steamed corms are also eaten sprinkled with grated coconut. The steamed or roasted corm is pounded and boiled with rice with added salt.

In Hawaii and parts of Polynesia, the corms are cooked and pounded into a paste that is allowed to ferment to produce 'poi'. A steamed pudding is made from grated taro and coconut. In addition to poi, taro is used in baby food, chips, taro bread (Moy and Nip 1983 and taro sorbet (Hong and Nip 1990). Results indicated that precooked taro flour can replace as locust bean gum (LBG), carboxymethylcellulose (CMC) and carrageenan gum (CG) successfully in tropical fruit (guava, pineapple and passion fruit) sorbet manufacturing without noticeable change in functional properties. In Hawaii, some of the taro food products available include poi, a product of steamed kalo which has been peeled and pounded into a thick paste (*pa'i ai*) and mixed with water until the desired consistency is achieved; poi in the bag, poi in the jar (baby food), dehydrated poi, deep-fried taro chips (snack) and taro

baskets or nests (a restaurant dish), taro bread or rolls, taro pancakes, tropical fruit–taro flakes, taro cookies, ice cream sorbets, extruded products, baked goods or pancakes, patties made from kalo and soy products instead of beef (taro burgers) and *Kūlolo* (a sweet pudding made from baked or steamed grated kalo and coconut cream) (Greenwell 1947; Nip 1979a, b; Nip 1980; Moy et al. 1980; Moy and Nip 1983; Hong and Nip 1990; Nip et al. 1994; Abbott 1992; Hollyer et al. 2000). In other countries, other forms of taro such as taro flakes (Taiwan), frozen taro chunks (China), dried taro chips (Fiji and Western Samoa) and frozen taro cake (Taiwan) are also available (Nip 1980). Taro is also made into baby food-type products, taro flour, taro meal or grits, canned taro, extruded products (rice, noodles and macaroni), fermented alcoholic beverage and gum replacer. Noodles can be prepared using 50 % taro flour and remaining equal proportions of rice and pigeon pea flours (Kaushal and Sharma 2013). The rehydration weight of noodles decreased with the increase in drying temperature.

Small-scale production of drum-dried tropical fruit (guava, papaya, mango, pineapple) – taro flakes – were reported by Nip (1979a, b). Taste of the tropical fruit–taro flakes was acceptable upon storage at 38 °C for 24 weeks. Studies by Moy et al. (1980) showed that taro flour could be extruded successfully into rice, noodle or macaroni by proper adjustment of initial dough temperature and moisture content. Protein enrichment (incorporation of mung bean flour or soy protein) improved to a limited extent the overall quality of extruded taro samples. Snap-type cookie formulations with taro flour as one of the major ingredients was developed by first modifying the taro flour and wheat flour ratios, followed by modification of the taro flour, wheat flour, sugar and shortening ratios (Nip et al. 1994). A drop-type chocolate chip cookie formulation was developed by replacing 51 % of the wheat flour with taro flour in a commercial formulation. Both cookie formulations developed were found to be highly acceptable. Three kinds of taro paste were prepared with taro–water–sugar ratios of 1:0.33:1.4, 1:0.33:0.8 and 1:0.33:0.2 (Lai et al. 1998). Results indicated that the paste with the highest sucrose concentration had the least hard texture. The declining

effect of sugar on hardness development and water mobility of the low-concentration system was fructose > glucose > lactose > sucrose. Taro paste with 10 g/kg sodium stearoyl lactylate showed a larger endothermic peak for amylose–emulsifier complex but a smaller peak for retrogradation than did those with 10 g/kg MG or those without emulsifier. Studies by Emmanuel et al. (2010) suggested that acceptable bread could be produced from the addition of unblanched taro flour to wheat flour at 10 % level. This would significantly reduce the cost of production of bread and other allied products. Studies showed that flour mixtures made from taro and nixtamalised maize flour produced puffed extruded snacks with good consumer acceptance (Rodríguez-Miranda et al. 2011). Taro corm mucilages exhibit unique rheological properties with considerable potential as a food thickener and stabiliser (Njintang et al. 2014).

Taro petioles are cooked and eaten in China (Xu et al. 2001; Hu 2005) and in Myanmar (Mathew and Naing 2005); petioles and leaves are eaten in Nepal (Pandey et al. 2000) and in Vietnam where the petioles are soaked in salt water first to prevent itching in handling (Tanaka and Nguyen 2007). Zuiki, a stalk of taro, is a traditional vegetable in Japan; raw zuiki is often boiled and vinegared to eat (Terasawa et al. 2007). Leaves are also consumed in sauces and stews, purees or soups (Ferrerres et al. 2012; Gonçalves et al. 2013).

Taro leaves and leaf stalks are used as a leafy vegetable and potherb for soups and sauces or as relish. They are especially popular in parts of West Africa, northeastern India, Oceania, Hawaii and the Caribbean region. In Indonesia, the petioles are cut into small pieces and cooked as sayur; the leaves are also cooked and eaten as *bobotok*, *getjok* or *loto* (Ochse and Bakhuizen van den Brink 1980). The leaves are also used to wrap salted fish which is steamed with grated coconut, lombok and salt. The lateral sprouts are also relished and are called *solor* or *seler*. In Western Cameroon, the leaves are used as a major ingredient in sauce preparations, among which black soup is the most popular, and the flowers are also used as a major ingredient in the preparation of *achu soup* (Ejoh et al. 1996). Zuiki, a stalk of taro (*Colocasia esculenta*),

is a traditional vegetable in Japan. In Hawaii, the leaves are canned for local sale. Taro inflorescences are used as cooked or fried food in some parts of the Solomon Islands, Papua New Guinea and Vanuatu.

Some of the common, popular and nutritious dishes cooked with taro plant parts in the Pacific are *taro salad*, *baseisei* (Fijian style): taro stalks, lemon juice, thin coconut cream, chopped spring onion and chopped chilli; *taro with seafood*: peeled taro root, cut into cubes, shellfish or small fresh fish, coconut cream, water, chopped onion, butter, margarine or oil and taro leaves; *taro leaves in coconut cream*, *palusami* (Samoan style): coconut, taro leaves, chopped onions, banana leaves and breadfruit leaves; *taro*: chicken, taro, chopped onion, chopped green leaves (e.g. taro leaves, pumpkin leaves, sweet potato leaves), tomatoes, coconut cream, water and lemon juice; *taro in coconut cream*: taro roots, thick coconut cream, chopped onion and chopped spring onions; *taro leaf soup*: young taro leaves, wafer, butter, margarine or oil, chopped onion, milk, flour, salt and pepper; and *grated taro pudding* (Tuvalu style): taro, banana leaves, coconut cream and toddy syrup (South Pacific Commission 1992).

Botany

A glabrous, acaulescent, mainly diploid, herbaceous, perennial plant, 50–150 cm high (Plate 1), with a massive, fleshy, starchy modified subterranean stem (corm) at the base. The corms vary greatly in size and are round, elongate and cylindrical, up to 35 cm long and 15 cm across (Plates 2, 3, 4, 5 and 9), often surrounded by a small number of secondary corms or cormlets called cormels (Plates 9, 10 and 11). The corm consists of the skin, cortex and core; the skin is rough and fibrous or covered with concentric rings of leaf scars and scales. The cortex and core can be white, light yellow, dark yellow, orange to pink and purple. The root system is adventitious and fibrous and white. At the apex of the corm is a whorl of petioles bearing large leaves with blades pointing obliquely downwards, 23–55 cm × 12–38 cm, cordate-hastate, sub-coriaceous, green above, glaucous below, the apex obtuse, acute or shortly acuminate, the base peltate-cordate and the margins more or less wavy (Plates 1 and 6); petioles are robust, uniformly light or dark green, with dark streaks of violet, erect, to 100 cm long, inserted 3–7 cm from base of blade and invaginate on lower 1/3 and sheathing at the petiole base (Plates 7 and 8). Inflorescences are axillary, ascending and solitary on stout peduncles nearly as long as the petiole, comprising a cylindrical, fleshy spathe, up to 40 cm long; the tube is green; the blade is lanceolate, not much wider than the tube, yellow to orange, deciduous or withering; the spathe surrounds a spadix yellow, much shorter than the spathe; the sterile flower zone and the distal appendage are shorter than the fertile male and female zones. Flowers are naked. Green pistillate flowers are located at the base of the spadix, and white sterile flowers are near its apex. Pistillate flowers have unilocular ellipsoid or obovoid ovaries, each with a single sessile, capitate stigma. Sterile flowers lack a stigma and style complex and are slightly taller than fertile pistillate flowers. Staminate flowers consist of 2–6 sessile linear anthers fused to form a synandrium. Berries are thin walled, green, ellipsoid and 3–5 mm in diameter containing a few ovoid, ridged, pale-yellow, small, albuminous seeds, 1.2–1.5 mm × 0.7–1 mm.

Nutritive/Medicinal Properties

Corm and Cormel Nutrients/Phytochemicals

Food value of raw, taro corms (*Colocasia esculenta*) per 100 g edible portion excluding 14 % ends and skins was reported as follows (USDA-ARS 2014): water 70.64 g, energy 112 kcal (469 kJ), protein 1.50 g, total lipid (fat) 0.20 g, ash 1.20 g and carbohydrate 26.46 g; total dietary fibre 4.1 g and total sugars 0.40 g; minerals, calcium 43 mg, iron 0.55 mg, magnesium 33 mg, phosphorus 84 mg, potassium 591 mg, sodium 11 mg, zinc 0.23 mg, copper 0.172 mg, manganese 0.383 mg and Se 0.7 µg; vitamins, vitamin C (total ascorbic acid) 4.5 mg, thiamine 0.095 mg, riboflavin 0.025 mg, niacin 0.600 mg, pantothenic acid 0.303 mg, vitamin B6 0.283 mg, folate (total) 22 µg, choline (total) 17.3 mg, vitamin A 76 IU, β-carotene 35 µg, β-cryptoxanthin 20 µg, vitamin E (α-tocopherol) 2.38 mg and vitamin K (phylloquinone) 1.0 µg; phytosterols 19 mg; lipids, fatty acids (total saturated) 0.041 g, 16:0 (palmitic acid) 0.035 g and 18:0 (stearic acid) 0.006 g; fatty acids (total monounsaturated) 0.016 g, 18:1 undifferentiated (oleic acid) 0.016 g; fatty acids (total polyunsaturated) 0.083 g, 18:2 undifferentiated (linoleic acid) 0.058 g and 18:3 undifferentiated (linolenic acid) 0.025 g; and amino acids, tryptophan 0.023 g, threonine 0.069 g, isoleucine 0.054 g, leucine 0.111 g, lysine 0.067 g, methionine 0.020 g, cystine 0.032 g, phenylalanine 0.082 g, tyrosine 0.055 g, valine 0.082 g, arginine 0.103 g, histidine 0.034 g, alanine 0.073 g, aspartic acid 0.192 g, glutamic acid 0.174 g, proline 0.060 g and serine 0.092 g. Taro corm was found to contain the following phytosterols (mg/100 g): total sterol 23.55 mg, cholesterol 0.64 mg, campesterol 2.02 mg, stigmasterol 6.62 mg and β-sitosterol 14.27 mg (Osagie 1977).

Nutrient and oxalate composition of air-dried corms of six American Samoa taro varieties: crude protein 2.9–5.0 %, crude fat 0.31–0.64 %, ash 1.97–3.29 %, carbohydrate 92.3–94.47 %, gross energy 3.32–4.40 kcal/g, thiamine 14–188 mg/100 g, minerals (µg/g) N 5,300–7,100 µg, P 1,200–2,520 µg, K 10,100–17,600 µg, Ca 580–840 µg, Mg 920–1270 µg, Na 84–

397 µg, Mn 2.6–5.8 µg, Fe 48–78 µg, Cu 5.3–9.3 µg, Zn 24–41 µg, B 7.9–9.6 µg, Mo 0.3–0.6 µg and total oxalate 1.76–3.52 mg/g (Nip et al. 1989). The nonnutritive fibre components were total fibre 6.04–7.38 %, acid detergent fibre 2.54–3.72 %, neutral detergent fibre 3.75–5.64 %, cellulose 1.62–2.27 %, lignin 0.85–1.48 % and pectin 1.58–2.73 %.

Proximate nutrient composition (fresh weight basis) of taro corms reported by Onwueme (1994) was moisture 63–85 %, carbohydrates (mainly starch) 13–29 %, protein 1.4–3 %, fat 0.16–0.36 %, crude fibre 0.6–1.18 %, ash 0.6–1.3 %, vitamin C 7–9 mg/100 g, thiamine 0.18 mg/100 g, riboflavin 0.04 mg and niacin 0.9 mg/100 g. Proximate nutrient per 100 g edible portion of taro corms reported by Lambert (1982) was moisture 77.5 %, energy 85 cal, carbohydrates 19 g, protein 2.5 g, fat 0.2 g, fibre 0.4 g, Ca 32 mg, P 64 mg, Na 7 mg, K 524 mg, Fe 0.8 mg, vitamin A trace IU, vitamin C 10 mg, thiamine 0.18 mg, riboflavin 0.04 mg and niacin 0.9 mg. Proximate nutrient composition of taro corms grown along the Lake Victoria Basin in Tanzania and Uganda (pooled values g/100 g DM) was moisture content C 68.7 %, ash 2.69 g, crude protein 3.8 g, crude fibre 1.34 g, fat 0.44 g, carbohydrates 23.03 and minerals (mg/100 g DM) K 715.39 mg, P 134.30 mg, Cu 0.19 mg, Fe 3.48 mg, Zn 4.32 mg, Mn 3.68 mg, Ca 68.67 mg, Mg 83.67 mg and Na 13.18 mg (Ndabikunze et al. 2011).

Taro corms (three taro accessions) contained the following carotenoids: lutein 2.3–3.4 %, 13-*cis*-β-carotenene 0.1–0.7 %, all-*trans*-β-carotene 0.502.7 % and 9-*cis*-β-carotene 0.2–0.5 % (Champagne et al. 2010). Minimum and maximum values for the carotenoids in taro corm in terms of µg/100 g fresh weight were determined as xanthophylls lutein tr (trace)–11.4 µg, zeaxanthin n.d. (not determined) to tr; 13-*cis*-β-carotenene tr–46.7 µg; all-*trans*-β-carotene tr–146.1 µg; 9-*cis*-β-carotene tr–18 µg; acyclic carotenes phytoene n.d. to tr; neorosporene n.d.; and vitamin A tr–17 µg RAE/100g FW. The concentrations of 15 elements (Al, Ca, Cl, Mg, Mn, Br, Co, Cr, Cs, Fe, K, Na, Rb, Sc, Zn) and NO₃⁻, SO₄²⁻, H₂PO₄⁻, Cl⁻, malate and oxalate were analysed in taro from Japan and China (Kobayashi et al. 2011). The mean concentrations of H₂PO₄⁻,

Co, Cr and Na significantly differed between taro grown in Japan and that grown in China.

Taro quality estimated by near-infrared reflectance spectroscopy (NIRS) showed high variance in cross-validation (r^2_{cv}) for starch (0.89), sugars (0.90), proteins (0.89) and minerals (0.90) but poor response for amylose (0.44) and cellulose (0.61) (Lebot et al. 2011). It was found that NIRS could be used to predict starch, sugar, protein and mineral contents in taro corms with reasonably high confidence.

Colocasia esculenta corms were found to contain Na (1521.34), K (4276.04), Mg (415.07), Ca (132.43), Fe (8.66), P (72.21), Zn (2.63), Mn (0.13) and Cu (0.78) (mg/100 g) (Njoku and Ohia 2007). The mean values of the proximate composition of *Xanthosoma sagittifolium* (white flesh), *X. sagittifolium* (red flesh) and *Colocasia esculenta* cormels evaluated were crude protein 2.98–5.50 g/100 g, total fat 0.28–0.97 g/100 g, ash 1.56–2.98 g/100 g, starch 12.2–36.0 g/100 g and crude fibre 1.11–3.00 g/100 g (Sefa-Dedeh and Kofi-Agyir 2004). Potassium was the most abundant mineral (763–1451 µg/100 g) with appreciable amounts noted for zinc (17–51.1 µg/100 g), magnesium (46.7–85.0 µg/100 g) and phosphorus (41.6–63.1 µg/100 g). Oxalate compositions of the fresh samples were in the range of 254–381 µg/100 g for the *X. sagittifolium* (red flesh), 302–323 µg/100 g for the *X. sagittifolium* (white flesh) and 328–460 µg/100 g for the *Colocasia esculenta*. No significant differences were found between the oven-dried and solar-dried samples (Njoku and Ohia 2007). However, drum drying reduced the oxalate levels by approximately 50 % to average levels ranging from 99.9 to 191 µg/100 g.

Corm composition (based on 50 g available carbohydrate) of dasheen (*C. esculenta* var. *esculenta*) was determined as 0.4 g protein, 0.3 g fat, 52.1 g, total carbohydrate and 2.2 g fibre and for eddoes (*C. esculenta* var. *antiquorum*) 4.9 protein, 0.7 g fat, 53.3 g, total carbohydrate and 3.4 g fibre (Ramdath et al. 2004).

Nutrient composition (mean and range expressed in %DM) of taro corms of 66 parent cultivars was determined by

Champagne et al. (2013) as starch 79.34, 64.60–88.20 %; sugars 4.07, 0.90–17.30 %; proteins 5.40, 2.30–9.20 %; minerals 3.93, 1.47–8.13 %; and cellulose 3.26, 1.40–7.30 %. The major and total carotenoids content (mean and range expressed in mg/g DM) found in 79 parent taro cultivars was lutein 0.16 mg, 0–1.21 mg; zeaxanthin 0mg, 0–0.14 mg; unidentified *cis* isomer of β -carotene 0.03 mg, 0–0.17 mg; 13-*cis*- β -carotene 0.37 mg, 0–2.72 mg; all-*trans*- β -carotene 0.53 mg, 0–4.77 mg; 9-*cis*- β -carotene 0.28 mg, n.d.–1.79 mg; and total carotenoids 1.47 mg, 0.09–9.77 mg.

Protein, fat, fibre, total ash and utilisable carbohydrates, respectively, in taro were found to be 6.43, 0.47, 2.63, 4.82 and 85.65 %, while the gross energy was 372.55 Kcal/100 g (Adane et al. 2013). The contents of the micronutrients, namely, Fe, Zn, Mg, Ca, Na, P and Mn were 5.86, 43.08, 7.24, 45.23, 13.81, 7.77 and 3.61 mg/100 g, respectively. Phytate for the raw product was 115.43, while oxalate and tannin were 243.06 and 47.69 mg/100 g, respectively. The protein content was lower by 9.37 % and 8.46 %, respectively, in the boiled and fermented products. The crude fat content was significantly different from the crude fat content of the boiled product which was 0.87 %. Fermentation resulted in a lower level of fibre which was 6.44 % and phytates of about 84.75 %. Boiling of taro resulted in a higher value of oxalate (70.9 %).

The fat, sugar, starch and crude protein content in fresh taro cormels varied from 0.08 to 0.98, 0.2 to 1.5, 7.5 to 24.8 and 1.0 to 2.8 %, respectively (Sen et al. 2005). Cormels provide 166–519 kJ of energy/100 g fresh weight. Moreover, cormels were a good source of minerals including potassium, calcium, phosphorus and iron; a moderate source of zinc and copper; and an inadequate source of manganese. The contents of the trypsin inhibitor, total oxalate, soluble oxalate and calcium oxalate varied from 52 to 1,020 Trypsin Inhibitory Unit (TIU)/g, 8–130, 4–89 and 4–93 mg/100 g, respectively.

Proximate nutrient composition of raw taro was determined as moisture 6.54 %, crude ash 2.44 %, crude fibre 3.01 %, crude protein 7.79 %, crude fat 0.65 %, carbohydrate 86.11 % and minerals (mg/100 g) Ca 55 mg, Fe 2.95 mg and

Zn 1.67 mg (Alcantara et al. 2013). Proximate nutrient composition of taro powder was determined as moisture 6.21 %, crude ash 2.78 %, crude fibre 3.10 %, crude protein 8.07 %, crude fat 0.45 %, carbohydrate 85.60 % and minerals (mg/100 g) Ca 64.84 mg, Fe 4.06 mg and Zn 1.84 mg. Proximate nutrient composition of taro noodles was determined as moisture 3.10 %, crude ash 1.39 %, crude fibre 1.24 %, crude protein 3.23 %, crude fat 0.19 %, carbohydrate 59.92 % and minerals (mg/100 g) Ca 32.41 mg, Fe 2.84 mg and Zn 1.29 mg. Proximate nutrient composition of taro cookies was determined as moisture 1.07 %, crude ash 0.24 %, crude fibre 0.27 %, crude protein 0.69 %, crude fat 0.13 %, carbohydrate 36.69 % and minerals (mg/100 g) Ca 13.90 mg, Fe 3.47 mg and Zn 0.87 mg.

Mean values obtained for *Colocasia esculenta* var. *antiquorum* and *Xanthosoma sagittifolium* in g/kg dry weight were crude protein 37.5–73.6, total fat 0.9–8.7, ash 28.7–77.7, crude fibre 4.3–42.0, total sugars 5.9–42.5 and starch 509.1–705.7 (Agbor-Egbe and Rickard 1990). The main sugars identified were fructose, glucose, sucrose and maltose. The amino acids with the highest concentrations were aspartic acid, glutamic acid and arginine. A significant reduction in starch content (to 39.8–47.4 g/kg) and increase in total sugar content (to 8.0–11.6 g/kg) occurred during the storage of cormels for 2 weeks under tropical ambient conditions (24–29 °C; 86–98 % RH). No significant differences between fresh and stored cormels were found in crude protein and amino acid contents.

Studies showed that taro contained 63.6–72.4 % moisture and upland-cultivated taro corms retained a higher moisture content compared to paddy taro (Huang et al. 2007). Taro corms also contained 21.1–26.2 % starch and 1.75–2.57 % crude protein and provided total energy in the range of 97.1–118.3 kcal/100 g fresh taro. Taro corms had reasonably high contents of potassium and magnesium, whose ranges were 2,251–4,143 and 118–219 mg/100 g dry matter, respectively. Upland-cultivated taro tended to have higher mineral content than paddy taro. Taro corms are moderately good sources of water-soluble vitamins, such as thiamine, riboflavin and ascorbic acid, compared to other tropical roots. A higher

soluble sugar content in upland-cultivated taro corms was found than in paddy taro. The cultivar Mein contained higher soluble fibre levels than two other cultivars. Total oxalate and phytic acid levels of taro corms were in the range of 234–411 and 139–169 mg/100 g dry matter, respectively, which included 60–75 % of water-soluble oxalate. Essential amino acid contents of taro proteins from both paddy and upland cultivation were fairly similar to the FAO reference pattern, except for the contents of sulfur-containing amino acids, tryptophan and histidine.

When compared with uncooked taro corms, the ash and crude fibre contents of taro accessions significantly decreased after cooking (Lewu et al. 2009). The moisture content, crude protein, crude lipid, carbohydrate and caloric contents increased with cooking in all the accessions, except UFCe1 and UFCe5 where the crude lipid content was reduced. The results indicated that cooking enhanced the carbohydrate, energy and protein contents of the tubers. They further showed that the tubers could be used for allergic infants, old people and invalids since the fibre contents were still appreciably high despite the slight reduction after cooking the tubers. The change in taro corm boiling time led to a significant reduction in the moisture, reducing sugars, total sugars, crude fat, crude fibre, total phenolic compound contents and iodine affinity of starch, whereas the total carbohydrate content, water absorption capacity, water solubility index, paste clarity and foam capacity increased significantly (Amon et al. 2014).

Studies showed that irrespective of the cooking medium (water, tamarind solution, lemon solution or steam), the hardness, soluble proteins and resistant starch significantly decreased during cooking, while absorbance at 280 and 450 nm, iodine index, degree of cell separation and soluble sugars significantly increased (Aboubakar et al. 2009). A significant correlation was observed between the hardness and the iodine value, resistant starch, soluble sugars and degree of cell separation, suggesting multiple mechanisms involved in the softening of taro corms during cooking. It was observed that steam cooking of the slices induced the highest softening, while boiling in water induced the lowest softening of the

corms. However, cooking in tamarind and lemon solutions induced a bitter and acid taste to the corms. While no consistent change was observed during steaming, significant reduction was observed in the oxalate content during boiling probably due to leaching in boiling solutions and acid hydrolysis.

Taro Starch

Taro corm starch contained 28 % amylose (Amin 1955). Periodate oxidation, methylation and hydrolysis revealed a chain length of 490 glucose units for amylose and 22 units for amylopectin. The results were similar to potato starch. The mean particle sizes of the taro (Ishikawa-wase and Takenokoimo) starches were 1.4 μm and 2.0 μm , respectively (Sugimoto et al. 1986). The susceptibilities of the taro (Ishikawa-wase and Takenokoimo) starch granules to hog pancreatin were similar to that of normal maize starch granules. Hollows were observed on the surface of taro (Ishikawa-wase and Takenokoimo) starch, after an attack by pancreatin. The initiation temperatures for gelatinisation were 62 °C for Ishikawa-wase and 73 °C for Takenokoimo. The onset temperatures were 65 °C for Ishikawa-wase and 76 °C for Takenokoimo. The amylose contents of isoamylase-debranched starches were 13.5 % for Ishikawa-wase and 10.8 % for Takenokoimo. On X-ray diffractometry, the taro (Ishikawa-wase and Takenokoimo) starches showed A-type patterns. Taro starch was found more susceptible to pancreatin hydrolysis than other tuber and root starches (Sugimoto et al. 1979). Starch granules in the slices of taro seed corms, mother corms, cormels, secondary cormels and third cormels were found to be polygonal in shape and showed similar sizes and shapes during development (Sugimoto et al. 1987). The initiation temperature for gelatinisation of starch granules, as judged on photopastography, tended to be lower in the later stages of development than in the earlier stages. The amylose content of starch granules changed in the following increasing order: mother corm < cormel. On X-ray diffractometry, starch granules prepared from corms and cormels grown under a high environmental temperature showed A-type patterns; however,

those prepared from corms and cormels grown under a lower environmental temperature showed Ca-type ones.

Starch granule size was found to vary considerably among the ten different taro accessions, C-9 starch having the largest average granule size (5.19 μm) while the lowest was recorded for C-46 (2.96 μm) (Moorthy et al. 1992). The total amylose content varied between 14 and 19 % with C-9 starch having the highest value. Soluble amylose content ranged from 4 to 11 %. C-9 starch had the highest peak viscosity, almost twice as much as the others. The swelling volumes ranged from 25.0 to 60.0 mL/g with C-266 starch having the highest swelling volume.

Starch contents of the flours prepared from taro corms of Bun-long, dasheen, Hawaii Red (Lehua), Hawaii White and Niu'e varieties varied from 73 to 76 % (Jane et al. 1992). Starch yields of the flours varied from 51 to 58 %. Nitrogen contents varied from 0.33 to 1.35 % and from 0.014 to 0.025 % in the flours and starches, respectively. Taro starches had irregular, polygonal shapes and small granular sizes. Among the five varieties, Bun-long had the smallest average diameter (2.6 μm) and largest (3.76 μm) in dasheen starch. Amylose contents varied from 18 to 22 %. Molecular sizes of the taro amyloses ranged from degree of polymerisation (DP) 150–550. Branch chain lengths of the taro amylopectin varied from DP 16.8 to 18.4 and from DP 37.2 to 40.5 for short and long branches, respectively. All five starch varieties gave an A-type X-ray diffraction pattern. The taro starches contained 0.23–0.52 % lipid and 0.017–0.025 % phosphorus. The onset gelatinisation temperatures of the taro flours varied from 72 to 79 °C, whereas those of the taro starches ranged from 69 to 74 °C. Retrogradations of the starches and the flours, as measured by their enthalpy changes, appeared to be more severe than that of corn starch. Taro starch pastes had significantly higher viscosities than their flour counterparts.

Significantly smaller sizes (0.05–0.08 μm) of starch granules were observed for *Colocasia esculenta* than for the *X. sagittifolium* (red-flesh and white-flesh) varieties (Sefa-Dedeh and Kofi-Agyir 2002). Significant differences in raphide sizes were observed among the varieties, with the *C. esculenta*

having more pronounced needlelike structures. *C. esculenta* showed lower hot paste viscosity but higher thermal stability than the *Xanthosoma* species. Peak viscosity was highest in the *X. sagittifolium* (red-flesh) variety, while the white-flesh variety showed the least tendency to retrogradation. *Xanthosoma sagittifolium* and *Colocasia esculenta* starches were white in colour and had granule sizes varying significantly in length (6.47–13.63 μm) and width (5.36–8.45 μm), while amylose content ranged from 11.55 to 33.77 % (Falade and Okafor 2013). Peak, breakdown and final viscosities, pasting temperature (84.53–88.75 $^{\circ}\text{C}$) and time (4.55–4.97 minutes) varied significantly among cultivars. Also, water absorption capacity (21–36 %), pH (4.8–5.3), gelling point (60.5–69.5 $^{\circ}\text{C}$), foam capacity (4.46–18.28 %), bulk density (0.14–1.15 g/mL) and swelling power (2.31–10.09) varied significantly among the cultivars. Average yield of the starches varied significantly from 10.03 to 18.61 %.

Starch yields prepared from the flours of six taro varieties varied between 66.5 % for cv. KW2 and 86.6 % for cv. RIE (Aboubakar et al. 2008). The protein content varied from 2.9 % for cv. KW1 to 4.9 % for cv. CN in the flours. Taro starch had irregular, polygonal shapes and small granular sizes. The amylose contents varied from 14.7 to 30.85 %. The taro starch contained 0.2–0.6 % lipids and 2 % ash. The onset gelatinisation temperatures of the taro flours varied from 55.2 to 65.49 $^{\circ}\text{C}$, whereas those of the starches are between 48.08 for KW2 and 64.37 $^{\circ}\text{C}$ for KW1. Retrogradation of the starches and the flours appeared to vary significantly between the varieties. The water absorption capacity varied from 240 to 470 % and from 60 to 250 % for the flours and starches samples, respectively. Taro flours had higher solubility index than their starch counterparts. Among the varieties, RIN and CE starches had the highest solubility, whereas KW1 starch had the lowest.

Studies showed that the amylose content of the starch isolated from *Xanthosoma sagittifolium* was higher than those shown by *Colocasia esculenta* and *Manihot esculenta* starches (Pérez et al. 2005). The phosphorous content was higher in *Xanthosoma sagittifolium* than in *Colocasia esculenta* or the

commercial *Manihot esculenta* starches. The gelatinisation profile range was wider in *Manihot esculenta* C. than taro and tannia. *C. esculenta* flour showed higher crude fat, total, soluble, insoluble dietary fibre and mineral (P, Ca, Fe, and Zn) contents, whereas *X. sagittifolium* flour showed higher starch, ash and reducing sugar content (Pérez et al. 2007). *X. sagittifolium* flour showed higher titratable acidity and relative density values, being darker and more yellowish than its counterpart. *X. sagittifolium* flour showed higher gelatinisation temperature than *C. esculenta* flour. Parameters such as viscosity during the holding time (95 °C for 30 minutes), viscosity at 50 °C, setback, and consistency were lower in *C. esculenta* flour than in *X. sagittifolium* flour. The viscosity peak and breakdown indices were higher in *C. esculenta* flour than in the *X. sagittifolium*. Taro starches gave higher potassium and phosphorus but lower calcium levels than the cassava and corn starches (Mweta et al. 2010). The shape of the starch granules varied from spherical to polygonal with taro starches displaying smaller-sized granules than cassava and corn starches. Taro starches exhibited amylopectin molecules of higher molecular weights but amylose molecules of lower molecular weights than cassava and corn starches. Taro starches exhibited lower water absorption capacity and swelling power, paste clarity and viscosity but higher solubility, gelatinisation temperatures and retrogradation tendencies than cassava and corn starches.

At 95 °C, heat-moisture-treated, oxidised and acetylated taro starches were more soluble, while cross-linked starch was less soluble as compared to raw starch (Alam and Hasnain 2009). Heat-moisture-treated and chemically modified starches had lower swelling power (at 95 °C) than that of isolated starch. Swelling power and solubility were found to be a function of pH, and it was observed that all these modified starches had greater swelling capacity and solubility at pH 2.0 and 10.0. of taro starch (in dry basis) was 81 %, and this starch had low amylose content (2.5 %) (Agama-Acevedo et al. 2011). Taro starch granules showed a mixture of shapes with sizes between 1 and 5 µm and presented an A-type XRD pattern with a crystallinity level of 38.26 %. Solubility and water retention capacity did not change in the temperature

range of 50–70 °C, and thereafter, they increased as temperature increased too. Taro starch showed high peak viscosity due to its high amylopectin content. The peak temperature of gelatinisation of taro starch was 80.6 °C with an enthalpy value of 10.6 J/g, with low retrogradation rate due to its low amylose content. Weight-average molar mass (M_w) and gyration radius (R_z) of taro starch were 1.21×10^9 g/mol and 424 nm, respectively. Taro tuber could be an alternative for starch isolation with functional and physicochemical characteristics for food and nonfood applications.

Results of studies found that taro starches from corms planted in summer had the largest granule size, a low uniformity of gelatinisation and a high tendency to swell and collapse when heated in water and showed an elasticity during gelatinisation that was higher than that of starches planted in the other seasons (Lu et al. 2008). In addition to the planting season and the variety, rheological and pasting properties of taro starches studied were influenced not only by the amylose content but also by the chain-length distribution of amylopectin, whereas swelling power and solubility only depended on the amylose content of starch. Taro starch with relatively high amylose content, high short-to-long-chain ratio and long average chain length of long-chain fraction of amylopectin displayed high elasticity and strong gel during heating. Starch was isolated from taro corms with 98 % purity and 10.4 % amylose content (Simsek and El 2012). By application of heating, autoclaving, enzymatic debranching, retrogradation and drying processes to taro starch for two times, resistant starch (RS) content was increased 16-fold (35.1 %, dry basis).

The addition of mucilage caused a remarkable increase in the temperature of gelatinisation for taro, yam and sweet potato starches due to the competition for water during starch gelatinisation (Huang et al. 2010). Furthermore, adding mucilage increased the phase transition temperature range (T_c – T_o) of starches but decreased the enthalpy (ΔH). Addition of mucilage did not change the pasting temperature for taro starch. The peak viscosity of taro and sweet potato starches

decreased significantly as their mucilages were added into each starch suspension system.

Starch was extracted from taro corms with a yield of 858 g/kg, and it had 269.2 and 554.8 g/kg of amylose and amylopectin contents, respectively (Antonio-Estrada et al. 2009). Maltodextrins with dextrose equivalent (DE) of 15.12 and 17.48 % were obtained from taro starch by enzymatic hydrolysis at 95 °C during 48.6 and 79.4 minutes, respectively. Moisture content of taro maltodextrins (TM) was similar to commercial corn (CCM) maltodextrins for each DE (15 or 17.5 %), whereas the ash content of TM was higher than CCM with DE of 15 %. Fat content was higher in TM than CCM with DE of 15 or 17.5 %. There was no difference in pH between TM and CCM with the same DE. Average degree of polymerisation (DP) was lower in TM than CCM with DE of 15 %. Average molecular weight of TM was lower than CMM.

Taro Flour

Taro flours studied had lower protein, fat and starch contents and higher sugar and fibre contents than wheat flour (Godoy et al. 1992). Water and fat absorption capacities of raw and blanched taro flours were higher, whereas the foam capacity, foam stability, whippability and nitrogen solubility were generally inferior compared to wheat flour. Addition of salt up to 2 % concentration in the flour suspension increased the foam capacities of all flours studied. The least concentration endpoint (LCE) for gelation of both raw and blanched taro flours was comparable to that of wheat flour. While inferior to wheat flour in composition and most functional tests, the utilisation of taro flour may be enhanced by incorporation of protein supplements. Proximate analyses of the taro flours indicated they were low in fat, protein and ash but rich in starch and total dietary fibre (Tagodoe and Nip 1994). Heat processing affected the functional properties of taro flour.

Chemical composition (dry weight basis) of six taro varieties grown in Cameroon and Chad was reported as moisture 61.10–81.55 %, ash 3.54–5.65 %, total fat 0.34–0.73 %, crude starch 41.27–64.44 %, amylase 17.07–35.73 %, and

crude proteins 2.57–5.41 %, available carbohydrates 33.29–77.83 % and crude fibre 0.35–3.78 % (Mbofung et al. 2006). They reported the following amino acid composition (in g/100 g dry weight) of taro flours, respectively, from Ibo Ngdere and Sosso Chad varieties: essential amino acids, threonine 4.45, 4.10 g; isoleucine 4.04, 4.19 g; leucine 10.72, 10.37 g; lysine 5.43, 5.55 g; methionine + cysteine 0.12, 0.10 g; phenylalanine 5.93, 5.57 g; tyrosine 1.46, 1.05 g; valine 6.40, 6.27 g; and histidine 2.22, 2.52 g; nonessential amino acids, alanine 5.93, 6.08 g; aspartic acid 16.07, 15.23 g; glutamic acid 12.03, 12.33 g; glycine 6.18, 6.08 g; proline 4.78, 4.73 g; serine 6.07, 5.76 g; and arginine 6.32, 6.72 g; and other amino compounds, ethanolamine 0, 0.35 g; ornithine 0.11, 0.17 g; serine 0, 0.26 g; and GABA 1.61, 2.40 g. The major sugar found was a disaccharide. Wide variations were observed in the functional properties of the flours, water absorption capacity 242.45–374.86 %, oil absorption capacity 174.37–186.53 g/100 g, water solubility index 18.55–27.64 g/100 g, foam capacity 9.75–13.5 mL/100 mL, emulsion activity 38.41–43.45 mL/100 mL, emulsion stability 25.87–42.52 mL/100 mL, blue value index 5.69–28.37 eq. DO/100 g flour, bulk density 0.57–0.71 g/mL, titratable acidity 0.68–0.99 g oxalic acid/100 g and pH 6.24–7.04. Njintang et al. (2014) reported the proximate composition (g/100 g) of flour from six taro varieties as moisture 8.2–9.6 g, proteins 2.9–4.9 g, carbohydrates 90.5–94.8 g, lipids 0.3–1.17 g and ash 1.3–5.5 g.

C. esculenta flour showed higher crude fat; total, soluble and insoluble dietary fibre; and mineral (P, Ca, Fe, and Zn) contents, whereas *X. sagittifolium* flour showed higher starch, ash and reducing sugar content (Pérez et al. 2007). *X. sagittifolium* flour showed higher titratable acidity and relative density values, being darker and more yellowish than its counterpart. *X. sagittifolium* flour showed higher gelatinisation temperature than *C. esculenta* flour. Parameters such as viscosity during the holding time (95 °C for 30 minutes), viscosity at 50 °C, setback and consistency were lower in *C. esculenta* flour than *X. sagittifolium* flour. The viscosity peak and breakdown indexes were higher in *C. esculenta* flour than in the *X. sagittifolium*. Taro flour was significantly different

from other flours in exhibiting the highest carbohydrate and water absorption and lower protein, foaming capacity and setback viscosity (Kaur et al. 2013). Peak viscosity of taro flour was lower in comparison to potato flour but higher than that of soya and corn flours. Change in boiling time lead to a significant reduction in moisture, sugars, crude fat, crude fibre, total phenolic content and iodine affinity of starch, whereas total carbohydrate, water absorption capacity, water solubility index, paste clarity and foam capacity increased significantly (Amon et al. 2014). The crude protein and total ash contents of the flours from taro corm were not affected significantly by the change in boiling. Chemical composition and physico-functional properties of flour from raw and boiled (20 minutes) taro grown in Cote d'Ivoire was reported, respectively, as 8.1, 5.45; crude protein 2.4, 2.4 %; reducing sugar 0.73, 0.35 %; total sugar 3.3, 2.6 %; total carbohydrate 84.4, 87.4 %; crude fat 0.75, 0.6 %; crude fibre 1.7, 1.6; total ash 2.5, 2.5 %; total phenolic content 0.12, 0.076 %; minerals (mg/100 g) Ca 7.3 ,6.9 mg; Fe 8.6,4.9 mg; Mg 94.7, 93.2 mg; P 350, 354 mg; K 217.9, 221.7 mg; Na 3.7,3.9 mg; Zn 6.7,4.5 mg; and Cu 0.4, 0.43 mg; water absorption capacity 198 %, 506 %; water solubility index 7.8 %, 16 %; iodine affinity of starch 330 ppm, 220 ppm; paste clarity 28.56 %, 49.3 %T; and foam capacity 7.07, 10 %. Taro corm flours exhibited highest total carbohydrate, crude fibre, total ash contents, water absorption capacity and iodine affinity of starch and lowest crude protein and fat contents, foaming capacity and water solubility index.

Proximate composition and functional properties of taro flour was reported as moisture 7.75 %, ash 1.2 %, crude fat 1 %, protein 2 %, carbohydrate 95.7 %, bulk density 0.689 g/mL and foaming capacity 9 % (Kaur et al. 2013). Of the following flours, namely, potato, soybean, corn and taro, taro flour exhibited the highest water absorption capacity, peak viscosity and the lowest foaming capacity which afforded the flour good body for use as a thickener or gelling agent in various food products (Kaur et al. 2013). The paste formed by taro flour as a result of heating was stable upon cooling as evident by its lower setback viscosity 560 cP.

Taro flour was significantly different from other flours due to its highest ash, crude fibre, lower fat and protein content and exhibited lowest L^* , ΔE and foaming capacity (FC) and highest WSI (water solubility index), WAC (water absorption capacity) and OAC (oil absorption capacity) as compared to rice and pigeon pea flour (Kaushal et al. 2012). Taro flour contained higher oxalate, pasting temperatures (PT), peak viscosity (PV), trough viscosity and polyphenol content while lesser amount of phytate and lower setback viscosity than rice and pigeon pea flours.

Drying at high temperatures affected the colour and the susceptibility to gelatinisation of taro flour especially that obtained from gelatinised slices (Njintang and Mbofung 2003). Precooking induced significant decrease in foam capacity and penetrometric index and increase in least gelation concentration (LGC), emulsion stability and water absorption capacity (WAC) of taro flour used in the preparation of *achu* (Njintang and Mbofung 2006). Long precooking time (>45 minutes) and drying temperature (>60 °C) induced significant reduction of the in-vitro carbohydrate digestibility of taro *achu*. In general, taro flour which absorbed more water tended to produce *achu* with high level of Newtonian compliance and retarded elastic compliance (Njintang et al. 2007). The creep steady-state shear compliance and the viscoelasticity index of *achu* were significantly correlated to the sensory hardness. The *achu* paste made from traditional and freeze-dried chips consisted of starch-filled cells encased in a continuous amylose-amylopectin gel containing some vascular elements and mucilage (Njintang et al. 2008). Their study confirmed that cooking of whole taro corms/cormels before drying constituted a good approach in the processing of taro flour, usable in the preparation of *achu*.

Polysaccharides/Mucilage/Proteins

Taro roots contained abundant pectin which was found to be significantly lost early during infection by the fungus *Pythium myriotylum* (Boudjeko et al. 2006). The fungus caused a significant loss of pectin probably via degradation by hydrolytic enzymes. Also, a significant decrease in

galacturonic acid content occurred in infected root cell walls. Roots of taro exuded increasing concentrations of oxalate with increasing aluminium stress (Ma and Miyasaka 1998).

Cold-water-soluble polysaccharides (CWX) extracted from taro were tested for their influence on the pasting properties of taro starch and three other commercial starches (maize, rice and wheat). Addition of taro cold-water-soluble polysaccharides resulted in increased peak viscosity with maize and rice starch and a decrease in peak viscosity with wheat starch (Gaosong et al. 1997). Cold paste viscosity was decreased in wheat and taro starch, but not in maize and rice starch.

Studies had found taro to be rich in gums (mucilages). Taro mucilage yielded D-galactose (88 %), L-arabinose (8 %) and uronic acid (2 %) (Amin 1955). Hydrolysis of the main methylated fraction gave 2,3,4,6-tetra-*O*-methyl-D-galactose (19 %), 2,3,6-tri-*O*-methyl-D-galactose (87 %) and 2,4-di-*O*-methyl-D-galactose (2.5 %). Up to 10.7 % crude taro mucilages was extracted from taro corms and tubers with boiling water (Gaind et al. 1968). Studies reported that taro mucilage could be useful as binders for pills (Gaind et al. 1968, 1969; Abdel-Akher et al. 1972; Taki et al. 1972; Yamashita and Yoshikawa 1973). Those made with mucilage of taro dissolved as fast as or faster than pills prepared with acacia gum (Gaind et al. 1969). Purified gum (mucilage) (100 g) was isolated from fresh taro corms (1 kg) (Taki et al. 1972). It consisted of galactose and arabinose in a 6:1 ratio and contained a negligible amount of protein. In another study, the mucilage composition was found to contain moisture 16 %, crude ash 4 %, crude protein 51 % and total sugar (expressed as glucose) 16 % (Yamashita and Yoshikawa 1973). On hydrolysis, eight sugars and their derivatives were identified, including glucosamine, galactose, glucose, sorbose, arabinose, ribose, rhamnose and gluconolactone. On hydrolysis, the protein was found to contain leucine, isoleucine, phenylalanine, proline, valine and/or methionine, tyrosine, alanine, glutamine, threonine, glycine, lysine, histidine, arginine, cysteine, serine and aspartic acid. The N-terminal residues appeared to be DNP-glycine, DNP-serine and DNP-

aspartic acid, and in the C-terminal residue, DNP-threonine was found. In a separate study, the mucilage was found to be composed of galactose–arabinose in 8:1 ratio (Abder-Akher et al. 1972). Hydrolysis resulted in an early release of arabinose, leaving a degraded polysaccharide accounting for 91 % of the original mucilage. Approximately 70 % of arabinose residues terminated in furanose. On sulfuric acid hydrolysis, the degraded mucilage was found to have a galactose–arabinose ratio of 23:1. Periodate oxidation indicated that some galactopyranose molecules were nonreducing terminal residues adjacent to arabinose–furanose moieties in branches. Further investigations suggested a highly branched chain with 1,4 or 1,3 or 1,6 bonds.

Mucilage yields from the six taro varieties varied from 30.2 to 189.9 g/kg, total mucilage protein 0.3–0.5 mg/g, total mucilage carbohydrates 0.46–0.69 mg/g and uronic acid 9.4–16.3 µg/mg galacturonic acid equivalent (Njintang et al. 2014). Sugar composition (mg/g) of the mucilage comprised arabinose 4.4–8.3 mg, rhamnose 1.4–3.6 mg, fucose 1–3.5 mg, xylose 0.8–13 mg, galacturonic acid 4.2–12.3 mg, glucuronic acid 7–11.7 mg, mannose 6.4–16.2 mg, galactose 45.2–62 mg, glucose 2.7–4.1 mg, N-acetyl-galactosamine 0.12–1 mg, N-acetyl-glucosamine 0.32–0.72 mg, N-acetyl-mannosamine 0.9–4.4 mg and 2-*O*-methyl-xylose 0.21–0.9 g. Amino acid composition (mg/g) of the mucilage from varieties Ibo Ngaoundere and County Ekona was reported, respectively, as asparagine+aspartic acid 144.3, 159.7 mg; glutamine + glutamic acid 102.9, 117.3 mg; serine 77, 83.7 mg; glycine 101.7, 109.6 mg; histidine 183, 20.7 mg; arginine 60.3, 43.1 mg; threonine 62.9, 42.3 mg; alanine 81.2, 62.6 mg; proline 56.9, 50 mg; tyrosine 20.2, 26.4 mg; valine 39.9, 44.1 mg; methionine 7.8, 11.8 mg; cysteine 11.4, 13.8 mg; isoleucine 61.9, 60.4 mg; leucine 86, 86.2 mg; phenylalanine 38.4, 38.2 mg; and lysine 28.9, 30.1 mg.

Electrophoretic analysis of taro corm proteins revealed five patterns among the major cultivars (Hirai et al. 1989). These patterns were designated as E, D, I, T and A using the initials of the names of the typical cultivars Eguimo, Dodare, Ishikawa-wase, Tonoimo and Akame. Additional three protein

patterns designated as M, B and C were recognised for the minor cultivars Migashiki, Binroshin and Takenokoimo, respectively. Using the biochemical and morphological analyses, seven groups were recognised, i.e. Eguimo, Dodare, Hasubaimo, Ishikawa-wase, Kurojiku, Akame and Tonoimo groups, for the non-fasciculated taro cultivars, while two, Yatsugashira and Shogaimo, groups for the fasciculated ones. The Yatsugashira group showed electrophoretic patterns common to the non-fasciculated Tonoimo group. Similarly, the Shogaimo and Dodare groups exhibited a common electrophoretic pattern. The fasciculated cultivars were, therefore, assumed to be derived from the corresponding non-fasciculated cultivars by bud mutation.

The major albumin isolated from taro corms accounted for 11 % of the total soluble protein in the corms (Carneiro et al. 1990). The native protein had an M_r of 50,000 and appeared to be composed of homogeneous subunits with molecular weight of approximately 8,300. Three isoforms were found; the major one, accounting for more than 90 % of the protein, had an isoelectric point (pI) of 6.1. The two minor ones have pI values of 5.3 and 5.7. The isolated protein had a relatively high content of essential amino acids such as phenylalanine and leucine but was poor in sulfur-containing amino acids.

The globulins from taro corms accounted for ~80 % of total soluble corm proteins (Monte-Neshich et al. 1995). The presence of two non-related globulin families, denoted G1 and G2, was detected. The G1 family comprised a large number of isoforms of 12.5 kD with isoelectric points (pIs) ranging from 5.5 to 9.5. The G2 family was composed of two sets of proteins of 24 kD (G2a) and 22 kD (G2b), with pIs near 7.5. Both protein families were highly abundant and specifically found in taro tubers. Both were partially degraded in corms during sprouting, suggesting that they may be storage proteins.

A trypsin inhibitor was isolated from taro corm and was found to belong to the Kunitz inhibitor family (Hammer et al. 1989).

A proteinaceous α -amylase inhibitor named esculentamin was purified from taro cormel of taro (Seltzer and Strumeyer

1990). This protein was shown to be an acidic (pI = 4.4) glycoprotein with a carbohydrate content of 3.64 % and a molecular weight of 11,800 Da. It contained a predominance of acidic over basic amino acids and a lack of tryptophan. Taro corm extract yielded three major densely banding group of storage proteins (Hirai et al. 1993). Approximate molecular weights of the proteins in each group were 12, 27 and 55 kD; each was composed of two or three bands. Taro differed from sweet potato, cassava and yams in that it contained two major types of storage protein: a trypsin inhibitor related to sporamin and a mannose-binding lectin (Shewry 2003).

Rekha and Padmaja (2002) also isolated an α -amylase inhibitor from taro corms. Two proteins (A-1 and B-2) with α -amylase inhibitor activity were extracted and partially purified from taro corms (McEwan et al. 2010). The molecular weight of A-1 and B-2 were estimated to be about 17,000 and 19,000 Da, respectively. The α -amylase inhibitor purified from corms of *Colocasia* collected from Himachal Pradesh was found to be a monomer glycoprotein with molecular weight of 13,900 Da (Kumari et al. 2012). An α -D-galactose with a low K_m value (0.28 mM), a low molecular weight (40,000), and a neutral optimal pH (6.0) was isolated from taro stem portion (Chien and Lin-Chu 1991). Taro α -D-galactosidase also hydrolyses (1 $\rightarrow$ 4)- and (1 $\rightarrow$ 6)-linked α -D-galactopyranosyl groups from D-galactose-containing glycoconjugates. Yang and Yeh (2005) found copious amount of cysteine inhibitor in taro corms. They isolated a group-2 phytocystatin, from taro corms, named CeCPI, with molecular weight >23 kDa and demonstrated its anti-papain activity as well as antifungal activity. Tarocystatin, a group-2 phytocystatin and a defence protein against phytopathogenic nematodes and fungi and with papain inhibitory activity, was isolated from taro corm (Wang et al. 2008). It was composed of a highly conserved N-terminal region, which was homological to group-1 cystatin, and a repetitive peptide at the C-terminus. The purified recombinant proteins of tarocystatin comprised full-length (FL), N-terminus (Nt) and C-terminus (Ct) peptides with varying antifungal and papain inhibitory kinetics. FL peptide exhibited mixed-type inhibition and Nt peptide showed

competitive inhibition, whereas Ct peptide possessed weak papain activation properties.

The pH-activity optimum was pH 4.6 for taro polyphenol oxidase (tPPO) (Duangmal and Apenten 1999). The temperature-activity optimum was 30 °C for tPPO. tPPO was irreversibly inactivated by 10 minute heating at 70 °C. The activation enthalpy ($\Delta H^\ddagger$) and activation entropy ($\Delta S^\ddagger$) for tPPO heat inactivation were 87.4 kJ/mol and -56.2 J/mol/K, respectively. The apparent substrate specificity was established from values $V_{\max}/K_m$ as 4-methylcatechol > chlorogenic acid > dl-dopa > catechol > pyrogallol > dopamine >> caffeic acid for tPPO.

A novel soluble starch synthase II (SSII) gene was isolated from taro tubers (Lin and Jeang 2005a). This 2,939 bp SSII transcript encodes 804 amino acids with a putative transit peptide of 52 residues. Expression profile showed that more transcript and protein were accumulated in tubers of 597 g fresh weight, i.e. a stage of rapid starch synthesis, than tubers of other stages. SSII was found in both soluble and granule bound portions of tuber extracts, and more SSII protein was found in aged leaves than in leaves of other stages. Another soluble starch synthase I (SSSI) cDNA was isolated from taro (Lin and Jeang 2005b). More SSSI transcript was expressed in taro leaves than in tubers, with no evident expression in petioles; and more transcript and protein were found in tubers of 597 g of fresh weight than in smaller or larger ones. Two forms of SSSI, i.e. 72 and 66 kDa, existed in leaves, and only the 66 kDa form was found in tubers. A 22.4 kDa dimeric haemagglutinin was isolated from corms of *Colocasia esculenta* cv. 'Small Taro' (Chan et al. 2010).

Bezerra et al. (1995) isolated a corm-specific gene encoding tarin (ca. 28 kDa), a major globulin of taro from a lambda Charon 35 library, using a cDNA derived from a highly abundant corm-specific mRNA as probe. Storage protein with lectin activity was identified as tarin and found to be a 12 kDa polypeptide which was purified from taro (Pereira et al. 2014). The purified protein was present in Gl1a/Gl1d isoforms. Taro-4-I, a antimetastatic polysaccharide isolated

from taro corm, had a molecular weight of 200 kDa and composed of 64.4 % neutral sugars and 35.6 % uronic acid (Park et al. 2013). A lectin, *Colocasia esculenta* agglutinin (CEA), was purified from taro corms (Thakur et al. 2013). Studies showed the weight of taro cormels decreased all through during storage (Chibueze 2014). Immediately after harvest, the activity of ascorbate peroxidase was 15.49 unit/mL with a significant increase after 1 week to 73.05 U/mL. Thereafter, there was a significant decrease in activity of the enzyme after 3 weeks of storage to 33.33 U/mL. This increase in activity of ascorbate peroxidase after 3 weeks of storage may be related to increase in response to various biotic stresses.

The hydrolysate of purified cold-water-soluble taro mucilage contained galactose and arabinose was the main monosaccharide, and the main polymer present was an arabinogalactan protein (Jiang and Ramsden 1999). The yield of mucilage from 12 taro varieties varied from 75.7 to 137.0 g/kg (dry wt basis) among different varieties.

Taro corms contained mucilage and hydroxypropylmethylcellulose (Sarkar et al. 2014). The yield of mucilage fraction from taro corm varied from 30 to 190 g/kg (Njintang et al. 2014). The monosaccharide profiles revealed that galactose, mannose and arabinose were the main monosaccharides in the hydrolysate of the mucilage. From the 17 amino acids analysed, aspartic acid/asparagine (14.4–17.2 %) and glutamic acid/glutamine (10.3–13.6 %) were prominent in the mucilage as well as in the flour.

A high-purity (98 %), water-soluble gum was extracted from taro corms (Lin and Huang 1993). The major fraction of the gum had a peak molecular weight greater than 1 million daltons, with two shoulder peaks at 850,000 and 100,000 Da. D-galactose was identified to be the main constituent (61.6 %), followed by D-glucose (19.7 %) and D-arabinose (16.2 %). Small quantities of galacturonic acid and protein were also found in the gum. The gum was very soluble in water. The viscosity behaviour indicated the gum to be mainly a neutral carbohydrate polymer, probably highly branched.

Miscellaneous Phytochemicals

An antifungal compound was isolated from tubers of taro (*Colocasia antiquorum*) inoculated with black rot fungus (*Ceratocystis fimbriata*) and identified as 9,12,13-trihydroxy-(*E*)-10-octadecenoic acid together with two enzymes, lipoxygenase and lipid hydroperoxide-converting enzyme, which were responsible for the production of antifungal lipid peroxides (Masui et al. 1989). Two new dihydroxysterols were from taro corms and 14 α -methyl-5 α -cholesta-9, 24-diene-3b, 7 α -diol and 14 α -methyl-24-methylene-5 α -cholesta-9, 24-diene-3 α (Ali 1991). Five novel aliphatic compounds tetracos-20-en-1, 18-diol; 25-methyl triacont-10-one; octacos-10-en-1, 12-diol; pentatriacont-1, 7-dien-12-ol; and 25-methyl-tritriacont-2-en-1, 9, 11-triol were reported in the corms (Yannai 2003). Taro corm contained a high level of the antinutrient phytate 0.168 % of fresh weight (Phillippy et al. 2003).

A new sesquilignan, named colocasinol A (1), and a new acyclic phenylpropane lignanamide, named *cis*-grossamide K (2), together with ten known compounds isoamericanol A (3), americanol A (4), 2-hydroxy-3,2'-dimethoxy-4'-(2,3-epoxy-1-hydroxypropyl)-5-(3-hydroxy-1-propenyl)biphenyl (5), (-)-pinoresinol (6), (+)-yangambin (7), (-)-syringaresinol (8), kaempferol 3,7-*O*- α -L-dirhamnopyranoside (9), *trans*-cinnamic acid (10), β -sitosterol (11) and *N-trans*-feruloyl tyramine (12), were isolated from taro corm peel (Kim et al. 2010b). A new monoglyceride, (2'S)-1-*O*-(9-oxo-10(*E*), 12(*E*)-octadecadienoyl) glycerol (1), and nine fatty acid derivatives, (*R*)-(-)-9-hydroxydecanoic acid (2), (*R*)-(-)-9-hydroxydecanoic acid (3), (2*E*,4*S*)-4-hydroxy-2-nonenoic acid (4), (*S*)-15,16-didehydrocoriolic acid (5), 1-*O*-(octanoyl) glycerol (6), 12,13-epoxyoctadec-9-(*Z*)-enoic acid (7), (9*S*,10*E*,12*Z*)-10,12-octadecadienoic acid methyl ester (8), (9*S*, 10*E*,12*Z*)-10,12-octadecadienoic acid (9) and 12,13-epoxyoctadec-6(*Z*), 9(*Z*)-dienoic acid (10), were isolated from taro corm peel (Kim et al. 2010a).

The following chemicals were identified in taro corm: 8,11-octadecadienoic acid methyl ester (54.62 %),

hexadecanoic acid, methyl ester (20.55 %), 9,12,15-octadecatrienoic acid, methyl ester, (Z,Z,Z)- (12.06 %), 9-octadecenoic acid, methyl ester, (*E*)- (6.425), 3,5-di-*tert*-butyl-4-trimethylsiloxytoluene (1.96 %), cyclohexanol, 2-methyl-5-(1-methylethenyl)-, (1 α ,2 β ,5 α), unidentified (2.51 %) (Lee et al. 2011).

Anthocyanins isolated from taro corms and petioles were identified as pelargonidin 3-glucoside, cyanidin 3-rhamnoside and cyanidin 3-glucoside (Ghan et al. 1977). Levels of anthocyanins were highest in the skin of the corm, 16.0 mg%, with equal amounts, 4.29 mg%, in both corm and petiole. Anthocyanogens also were present. The major anthocyanins (mean, range) expressing mg/g cyanidin 3-glucoside equivalent found in 79 parent taro cultivars were total 12.33 mg, 0–306.79 mg; A21.0 0.12 mg, 0–5.58 mg; A22.1 10.06 mg, 0–243.26 mg; A24.2 0.29 mg, 0–12.74 mg; A26.6 0.72 mg, 0–32.86 mg; and A28.5 1.15 mg, 0–22.86 mg (Champagne et al. 2013). Taro corm in Vanuatu was found to be rich in flavonols (up to 326.7 mg QGE/100 g DW) like hyperoside and isorhamnetin 3-*O*-glucoside along with flavanols such as catechin and epicatechin and small amount of 3,5-dicaffeoylquinic acid (Champagne et al. 2011).

Salt tolerance in taro tissues cultured in-vitro on saline media (50–350 mOsm) was associated with increased levels of calcium oxalate, chlorophyll, protein and some secondary alkaloids (Nyman et al. 1989). The concentration of other secondary alkaloids as well as the levels of quaternary alkaloids decreased. Calcium, potassium, magnesium and sodium content of the tissues decreased with increased salinity. These findings are discussed in relation to salinity tolerance in taro.

A total of 62 aroma components were identified in cooked taro (MacLeod 1990). Many of the identified components were classic volatile products deriving from a specific oxidation/degradation; others were common volatiles deriving from the action of heat on amino acids and/or sugars. The most abundant component was octane (21.10 %), and pyridine was present at the unusually high level of 18.60 %.

Sixty volatile compounds isolated by steam distillation were identified in taro corms, among which aliphatic acids (50.3 %), heterocyclic compounds (16.6 %), phenols (9.3 %) and alcohols (7.8 %) were quantitatively significant (Wong et al. 1998). The major components were palmitic acid and linoleic acid. 1-Pyrroline and 2-acetyl-1-pyrroline were identified for the first time in taro volatiles.

Antinutrients

Japanese taro cv. Akame contained the highest levels of gastric soluble oxalates in the raw tissue (168.9 mg/100 g fresh weight (FW)) and was significantly higher than the other three cultivars (mean 86.5 mg/100 g FW) (Savage and Catherwood 2007). There was no significant difference in gastric-soluble oxalates between Ishikawa-wase, Yamato-wase and the unnamed cultivar. Raw Akame corms contained the highest levels of soluble oxalate after intestinal incubation 134.8 mg/100 g FW. This was significantly different from the other three cultivars, which contained a mean of 66.4 mg intestinal soluble oxalates/100 g FW. Boiling the Japanese taro corms for 40 minutes reduced the level of intestinal soluble oxalates in the cooked tissue to a low level (mean for all the cultivars, 17.7 mg/100 g FW). In addition, the mean moisture content of the boiled corms increased to 83.2 % compared to the mean moisture content of raw tissue (75.7 %). Baking the four cultivars at 180 °C for 40 minutes led to a significant reduction in the moisture content of the tissue (from a mean of 75.7 % moisture content in the fresh tissue to a mean of 50.7 % when baked) and an effective concentration of gastric soluble oxalates in the cooked tissue (overall mean 276.1 mg/100 g FW), while the mean intestinal soluble oxalates rose to 187.2 mg/100 g FW. The results confirm that baked taro corms contain moderate amounts of soluble oxalates. The total gastric soluble oxalates of the four different taro corms were similar to the total oxalate contents determined using hot acid method; however, the in-vitro method used to extract intestinal soluble oxalate appeared to extract more oxalates when compared to the hot water extraction method. Baked taro corms should be avoided by people who have an increased risk

of renal calcium oxalate stone formation because they contain high levels of intestinal soluble oxalates. Raw taro had highest oxalate content 156.33 mg/100 g, followed by taro powder 35.67 mg, taro cookies 32.21 mg and taro noodles 29.96 mg (Alcantara et al. 2013). Raw taro also had the highest phytate content 85.47 mg, followed by taro powder 71.97 mg, taro noodles 21.59 mg and taro cookies 12.34 mg. Studies found that boiling effected the highest oxalate reduction, especially in the flour of taro cv. Inimbu (Iwuoha and Kalu 1995). Gelatinisation temperature decreased, and water and oil absorpion capacities increased markedly due to steeping, boiling and roasting. Boiling and roasting effected reduction in cold paste viscosity, while an inconsistent trend resulted from steeping.

Other Plant Parts Nutrients/Phytochemicals

Food value of raw, taro leaves (*Colocasia esculenta*) per 100 g edible portion excluding 40 % midrib stem was reported as follows water 85.66 g, energy 42 kcal (1779 kJ), protein 4.98 g, total lipid (fat) 0.74 g, ash 1.92 g and carbohydrate 6.70 g; total dietary fibre 3.7 g and total sugars 3.01 g; minerals, calcium 107 mg, iron, 2.25 mg, magnesium 45 mg, phosphorus 60 mg, potassium 648 mg, sodium 3 mg, zinc 0.41 mg, copper 0.270 mg, manganese 0.714 mg and Se 0.9 µg; vitamins, vitamin C (total ascorbic acid) 52 mg, thiamine 0.209 mg, riboflavin 0.456 mg, niacin 1.513 mg, pantothenic acid 0.084 mg, vitamin B6 0.146 mg, folate (total) 126 µg, choline (total) 12.8 mg, vitamin A 4825 IU, β-carotene 2895 µg, lutein + zeaxanthin 1932 µg, vitamin E (α-tocopherol) 2.02 mg and vitamin K (phylloquinone) 108.6 µg; lipids, fatty acids (total saturated) 0.151 g, 16:0 (palmitic acid) 0.131 g and 18:0 (stearic acid) 0.020 g; fatty acids (total monounsaturated) 0.060 g, 18:1 undifferentiated (oleic acid) 0.060 g; fatty acids (total polyunsaturate) 0.307 g, 18:2 undifferentiated (linoleic acid) 0.214 g and 18:3 undifferentiated (linolenic acid) 0.093 g; and amino acids, tryptophan 0.048 g, threonine 0.167 g, isoleucine 0.260 g, leucine 0.392 g, lysine 0.246 g, methionine 0.079 g, cystine 0.064 g, phenylalanine 0.195 g, tyrosine 0.178

g, valine 0.256 g, arginine 0.220 g and histidine 0.114 g (USDA-ARS 2014).

Proximate nutrient per 100 g edible portion of taro leaves and petioles reported by Lambert (1982) was, respectively, moisture 79.6, 93.8 %; energy 8,569, 19 cal; carbohydrates 12.2, 4.6 g; protein 4.4, 0.2 g; fat 1.8, 0.2 g; fibre 3.4, 0.6 g; Ca 32,268, 57 mg; P 78.23 mg; Na 11, 5 mg; K 1,237, 367 mg; Fe 0.843, 1.4 mg; vitamin A 20,385, 335 IU; vitamin C 142,8 mg; thiamine 0.1, 0.01 mg; riboflavin 0.33, 0.02 mg and niacin 2, 0.2 mg.

The proximate composition (g/100 g DW) of taro leaves was reported as moisture 90.6 g, total energy 396.3 kcal, crude protein 30.7 g, true protein 20.9 g, total lipid 7.7 g, total fibre 30.3 g, total carbohydrate 52.4 g and ash 9.8 g; amino acids (g/16 g nitrogen), threonine 6.2 g, valine 9.4 g, methionine 1.7 g, isoleucine 12.7 g, leucine 12.7 g, phenylalanine 8.0 g, lysine 11.7 g, aspartic acid 13.3 g, serine 5.3 g, glutamic acid 17.2 g, proline 7.5 g, glycine 8.8 g, alanine 10 g, tyrosine 2.8 g, histidine 10.2 g and arginine 9 g; minerals (mg/100 g), Ca 86 mg, P 41 mg, Mg 17 mg, K 18 mg, Na 7 mg, Fe 11.7 mg, Mn 25.9 mg, Cu 1.2 mg and Zn 4.2 mg; total oxalic acid 2.41 mg; and soluble oxalic acid 1.13 mg (Ejoh et al. 1996). The proximate composition (g/100 g DW) of taro flowers was reported as moisture 88.8 g, total energy 388.9 kcal, crude protein 14.9 g, true protein 13.1 g, total lipid 5.3 g, total fibre 20.4 g, total carbohydrate 70.4 g and ash 9.4 g; amino acids (g/16 g nitrogen), threonine 4.4 g, valine 7.9 g, methionine 1.1 g, isoleucine 5.7 g, leucine 9 g, phenylalanine 5.3 g, lysine 6.9 g, aspartic acid 10.3 g, serine 4.1 g, glutamic acid 15.6 g, proline 6.5 g, glycine 6.2 g, alanine 9 g, tyrosine 1.7 g, histidine 8.8 g and arginine 7.2 g; minerals (mg/100 g), Ca 86 mg, P 49 mg, Mg 36 mg, K 28 mg, Na 10.4 mg, Fe 30.3 mg, Mn 16.9 mg, Cu 1.9 mg and Zn 8.2 mg; total oxalic acid 1.17 mg; and soluble oxalic acid 0.55 mg (Ejoh et al. 1996).

The leaves of *Colocasia esculenta* contained the highest crude protein value of 307 g/kg DW, and the flowers had 149 g/kg DW (Ejoh et al. 1996). The amino acid profiles in taro flowers and leaves were balanced and comparable to the reference FAO pattern. Ash values were high 98 g/kg in taro

leaves with potassium being the principal element. Iron and zinc levels were also high especially in taro flowers (with 303 and 82 mg/kg DW, respectively). Both foods also contained moderate quantities of calcium, phosphorus and magnesium but were poor in manganese and copper.

The mean concentrations (in mg/g) of oxalates, saponins, tannins, alkaloids, lectins, phytates, trypsin inhibitors and cyanogenic glycosides in taro leaves were found to be 13.23, 9.94, 7.38, 6.62, 4.63, 3.41, 2.04 and 0.97, respectively (Enechi et al. 2014). The results revealed that raw taro leaves contained very high concentration of oxalate; moderate concentrations of saponins, tannins, alkaloids, lectins and phytates in order of decreasing concentrations; low concentration of trypsin inhibitors; and very low concentration of cyanogenic glycosides. Young taro leaves contained 589 mg total oxalates/100 g fresh weight (FW), while older taro leaves contained (443 mg total oxalates/100 g FW) (Oscarsson and Savage 2007). Soluble oxalates were 74 % of the total oxalate content of the young and old leaves. The soluble oxalate content of the fresh baked tissue fell to a mean of 59 % for both samples of leaves. Baking the young and old leaves with milk led to a further reduction of the soluble oxalate content in the cooked leaves (mean 21.4 % of the total oxalates).

A red pigment was isolated from taro stalk (called zuiki) and identified it as cyanidin 3-rutinoside (Terasawa et al. 2007). Eight C-glycosylflavones and a flavone *O*-glycoside were isolated from taro leaves and identified as orientin, isoorientin, isovitexin, vicianin-2, orientin 7-*O*-glucoside, isovitexin 4'-*O*-glucoside, vitexin X'-glucoside and luteolin 7-*O*-glucoside (Iwashina et al. 1999). *C. esculenta* leaf was found to have a total antioxidant capacity of 130 mg TEAC/100 g; total polyphenols of 120 mg GAE/100 g; flavonols (mg/100 g) like myricetin 1 mg, quercetin 1 mg and isorhamnetin 1 mg; and carotenoids (mg/100 g) such as α -carotene 0.56 mg and β -carotene 19 mg (Lako et al. 2007). Six C-glycosylflavonoids and one *O*-glycosylflavonoid have been isolated from the shoot system of Taumu (*Colocasia esculenta*) (Leong et al. 2010). They were identified as schaftoside (apigenin-6-glucoside-8-C-arabinoside),

isoschaftoside (apigenin-6-C-arabinoside-8-C-glucoside), orientin, isovitexin, isoorientin, vitexin and luteolin 7-*O*-sophoroside. Isovitexin was the main compound in water and methanol extracts of the leaf, while schaftoside was the main compound of the water extract of the stem. Taro leaves were found to contain carbohydrate, saponins, tannins and flavonoids such as vitexin, isovitexin, orientin and isoorientin (Vasant et al. 2012).

Forty-one phenolic metabolites (11 hydroxycinnamic acid derivatives and 30 glycosylated flavonoids) were identified in the leaves of two taro varieties (Ferrerres et al. 2012). Giant 'white' and 'red' varieties contained, respectively, ca. 14 and 21 % of phenolic acids, 37 and 28 % of flavones mono-C-glycosides, 42 and 43 % of flavones di-C-glycosides, 3 and 4 % of flavones mono-C-(*O*-glycosyl)glycosides and both of them ca. 2 % of flavones di-C-(*O*-glycosyl)glycosides and 2 % of flavones-*O*-glycosides. Luteolin-6-C-hexoside was the compound present in higher amounts in both varieties. The phenolic acids were six caffeic acid derivatives, glucosyl-sinapic acid, caffeic acid, *p*-coumaric acid and two dihydrocaffeoylquinic acid isomers. The flavones mono-C-glycosides identified were luteolin-8-C-hexoside; luteolin-6-C-hexoside; apigenin-8-C-hexoside; apigenin-6-C-hexoside; chrysoeriol-8-C-hexoside; and chrysoeriol-6-C-hexoside. The flavones di-C-glycosides identified were luteolin-6,8-di-C-hexoside; luteolin-6-C-hexoside-8-C-pentoside; apigenin-6,8-di-C-hexoside; luteolin-6-C-hexoside-8-C-pentoside; luteolin-6-C-pentoside-8-C-hexoside; apigenin-6-C-pentoside-8-C-hexoside; luteolin-6-C-pento-side-8-C-hexoside; apigenin-6-C-pentoside-8-C-pentoside; chrysoeriol-6-C-hexoside-8-C-pento-side; diomestin-6-C-hexoside-8-C-pentoside; and diomestin-6-C-hexoside-8-C-pentoside. The flavones mono-C-(*O*-glycosyl)glycosides detected were luteolin-6-C-(6-*O*-hexosyl)hexoside; 16 apigenin-6-C-(6-*O*-hexosyl)hexoside; luteolin-6-C-(2-*O*-pentosyl)hexoside; and apigenin-8-C-(2-*O*-penytosyl)hexoside. The flavones di-C-glycoside-*O*-glycosylated found were apigenin-6-C-pentoside-8-C-hexoside-7-*O*->hexoside; luteolin-6-C-(3-*O*-hexosyl)hexoside-8-C-pentoside; apigenin-6-C-pentoside-8-C-(2-*O*-hexosyl)hexoside; and apigenin-6-C-(2-*O*-hexosyl)hexoside-8-

pentoside. The flavones *O*-glycosides identified were luteolin-7-*O*-rhamnosyl(1→2)hexoside; chrysoeriol-7-*O*-hexoside; and chrysoeriol-7-*O*-rhamnosyl(1→6)hexoside.

The following chemicals were identified in taro leaf: cyclohexanol, 2-methyl-5-(1-methylethyl)-, [1*S*- (1 α , 2 β , 5 β)]- (54.73 %), 4H-pyran-4-one, 2,3-dihydro-3,5—dihydroxy-6-methyl- (9 %), 3,5-di-tert-butyl-4-trimethylsiloxytoluene (8.12 %), 2-propanone, 1-hydroxy- (7.37 %), 9,11-octadecadienoic acid, methyl ester, (*E, E*)- (5.79 %), hexadecanoic acid, methyl ester (4.28 %), formic acid, 2-propenyl ester (3 %, 21 %), megastigmatrienone (2.84 %) and unidentified (4.66 %) (Lee et al. 2011).

The following chemicals were identified in taro stem (shoot): acetic acid (24.70 %), 4H-pyran-4-one, 2,3-dihydro-3,5—dihydroxy-6-methyl- (19.25 %), propanoic acid (11.83 %), 2-furancarboxaldehyde,5-(hydroxymethyl)- (6.82 %), 9,12-octadecadienoic acid, methyl ester, (*E,E*)- (3.64 %), 9,12,15-octadecatrienoic acid, methyl ester, (*Z,Z,Z*)- (5.37 %), 2-furanmethanol (4.74 %), butanoic acid, 2-methyl-3-oxo-, ethyl ester (4.18 %), cyclopentanol (2.69 %), 2,2'-bioxirane (2.33 %), propanoic acid, 2-oxo-,methyl ester (2.26 %), butanoic acid,4-hydroxy- (2.11 %) and unidentified (7.38 %) (Lee et al. 2011).

Ferredoxin with molecular weight of 120,000 was isolated and purified from taro (Rao 1969). The protein contained two atoms of iron, two molecules of labile sulfide and five cysteinyl groups per molecule. The amino acid composition is Lys₄₋₅, His₁, Ang₁, Cys₅, Asx₁₀, Thr₆, Ser₈, Glx₁₆, Pro₄, Gly₉₋₁₀, Ala₇, Val₁₀, Ile₄, Leu₆, Tyr₄, Phe₂ and Trp₁. The amino and carboxy terminals of the protein were alanine. Taro ferredoxin was found to consist of a single polypeptide chain of 97 amino acids (Rao and Matsubara 1970). A comparison of structures of five chloroplast ferredoxins showed 61 % identity in their sequences. The amino acid sequences of ferredoxins (Fd A and Fd B) from Japanese taro (*Colocasia esculenta*) consisted of single polypeptide chains of 98 residues, and both ferredoxins had molecular masses of 10,700 and 10,500, respectively (Sakai et al. 1994). There was a 92 % homology

between the sequences of the isoproteins (Fd A and Fd B). Two ferredoxin isoproteins from Hawaiian taro (*Colocasia esculenta*) were also isolated, and their N-terminal sequences were determined to be identical to those of Japanese taro.

Enzymes found in taro included aconitase, aldolase, diaphorase, phosphoglucumutase, malate dehydrogenase, phosphoglucose isomerase, isocitrate dehydrogenase, 6-phosphogluconate dehydrogenase, malic enzyme, shikimate dehydrogenase and alcohol dehydrogenase (Lebot and Aradhya 1991). A comparison of structures of five chloroplast ferredoxins showed 61 % identity in their sequences. pCeMT, a putative metallothionein was isolated from *Colocasia esculenta* plant (Kim et al. 2013). The results suggested that pCeMT could play an important role in the protection of plant cells from oxidative stress by reactive oxygen species (ROS) scavenging and in the detoxification of free metals by metal binding, leading to improved plant metal tolerance.

Taro leaves also contain useful amounts of calcium, phosphorus and iron. It also provides fibre, which is needed to make the intestines and bowels work properly. Corms and cormels are rich in starch, minerals and vitamins; the flesh is mealy to smooth and usually has a somewhat nutty flavour. The starch grains are very small and consist of a mixture of two types, one 1–1.5 µm and the other 3–4 µm in diameter. For this reason, taros are easily digested. Taro starch has relatively high amylose content, high short-to-long-chain ratio and long average chain length of long-chain fraction of amylopectin and displayed high elasticity and strong gel during heating. The corms are also an excellent source of energy, which the body needs to stay active. They are rich in mucilage, which on hydrolysis yields eight sugars, the predominant ones being D-GALACTOSE and l-arabinose.

Antioxidant Activity

Raw tannin exhibited antioxidant activity (% lipid peroxidation) of 74.68 % and contained phenols (mg/100 g expressed as g catechin eq./g) 34.83 mg, tannins (mg/100 g expressed as vanillin eq./g) 32.24 mg, flavonoids 9 mg/10 g

expressed as mg gallic acid eq./g) 28.56 mg and saponins (mg/100 g) 14.22 mg (Alcantara et al. 2013). Taro powder had 81.77 % antioxidant activity, 78.33 mg phenols, 32.24 mg tannins, 64.23 mg flavonoids and 26.96 mg saponins. Taro noodles had 65.91 % antioxidant activity, 16.27 mg phenols, 0 mg tannins, 2.96 mg flavonoids and 5.01 mg saponins. Taro cookies had 28.00 % antioxidant activity, 3.68 mg phenols, 0 mg tannins, 0.90 mg flavonoids and 2.73 mg saponins. The higher the per cent lipid peroxidation, the lower the antioxidant activity.

The radical scavenging activity of purified taro stalk (zuiki) anthocyanin was 114 mg equivalent to BHT/g (Terawasa et al. 2007). About half of the anthocyanin in fresh zuiki was washed out by boiling, and the radical scavenging activity of zuiki was markedly reduced.

The presence of catechol moiety in the B-ring of isoorientin, orientin and luteolin 7-*O*-sophoroside, isolated from taro shoot system showed strong antioxidant activity with different mechanisms of action in DPPH radical scavenging, β -carotene bleaching and superoxide radical inhibition assays (Leong et al. 2010). Methanol extract of taro leaf showed higher DPPH radical scavenging activity than water extract, while the opposite was observed for the stem. The amount of dry weight matter extract of water extracts was higher than methanol for both the leaf and the stem parts. Isovitexin was the main compound in water and methanol extracts of the leaf, while schaftoside was the main compound of the water extract of the stem. The results suggested the potential of the leaf of Taumu as a source of dietary antioxidant. *C. esculenta* stem extract exhibited the highest DPPH scavenging activity with IC_{50} 0.125 ppt (parts per thousand) compared to the corm and leaf (0.28 ppt), and the corm extract (4.8 ppt) was the lowest (Lee et al. 2011).

Under arsenic stress (high concentration), an increase in catalase, peroxidase, few nonenzymatic antioxidants and an induction of few stress-induced protein were observed, along with some anatomical changes in taro roots. The increase in antioxidant stress enzyme activities in response to arsenic

exposure may be taken as evidence for an enhanced detoxification capacity of *C. esculentum* towards reactive oxygen species (and derivatives) that might be generated in the stressed plants (Patel et al. 2012).

Antidiabetic Activity

Dasheen extract or commercial linamarin significantly increased the activities of intestinal disaccharidases compared to the streptozotocin-induced diabetic rats fed with normal diet (Grindley et al. 2002). In the upper segment of the intestine, yam or dasheen extract or commercial linamarin supplementation increased the activity of Na^+/K^+ ATPase activity above normal. This enzyme in the lower segment of the intestine was significantly reduced in diabetic rats compared to normal rats. These observations indicated the hypoglycaemic property of cyanoglucoside extract from dasheen and to a lesser extent yam. Experimental studies showed that oral administration of petroleum ether, chloroform, aqueous and ethanolic extracts of taro leaves at a dose of 500 mg/kg body weight significantly exhibited antidiabetic activity in streptozotocin (STZ)-induced diabetic rats by reducing and normalising the elevated fasting blood glucose levels as compared to those of STZ control group (Tripathi and Koli 2013). The ethanol and aqueous leaf extracts were most active. In another study, administration of taro and plantain (*Musa paradisiaca*) feeds for 21 days to the diabetic rats of groups 4 and 5 resulted in 58.75 % and 38.13 % decreases in hyperglycaemia and amelioration of their elevated urinary protein, glucose, specific gravity and relative kidney weights (Eleazu et al. 2013). The diabetic rats administered with taro-incorporated feeds had 2.71 % and 19.52 % increases in weight and growth rates, the diabetic rats administered with unripe plantain-incorporated feeds had 5.12 % and 29.52 % decreases in weight and growth rates while the diabetic control rats had 28.69, 29.46, 248.9 and 250.14 % decreases in weights and growth rates. The taro-incorporated feeds contained higher antioxidants, minerals and phytochemicals except alkaloids than unripe plantain feed.

Dasheen with a glycaemic index (GI) of 77 was deemed a higher GI food than eddoes with GI of 66 (Ramdath et al. 2004). In a study of ten healthy subjects aged between 20 and 30 years, consumption of brown rice elicited the highest postprandial glucose and insulin responses, followed by taro, adlay, yam and mung bean noodles, which produced the lowest (Lin et al. 2010). Among the five starchy foods, brown rice evoked the highest glycaemic index (GI) and glycaemic load (GL) at 82 and 18, followed by taro (69 and 12), adlay (55 and 10), yam (52 and 9) and mung bean noodles (28 and 7), respectively. The insulinaemic index (II) values of the test foods corresponded with GI values. Similarly, brown rice gave the highest II at 81, followed by taro (73), adlay (67), yam (64) and mung bean noodles (38). All five starchy foods had lower GI, GL and II than reference bread. The GI, GL and II values of starchy foods provide important information for people to manage their diet and could be useful for the prevention of lifestyle-related diseases such as diabetes mellitus.

The activity of taro α -amylase inhibitor named esculentamin was essentially stable to boiling for 3 hours (pH 7.0), to a pH range of 2.0–12.0 (at 4 °C) and to 6 M guanidine hydrochloride and 8 M urea (Seltzer and Strumeyer 1990). ‘Bifunctional’ inhibitory activity towards both α -amylase and proteases was not observed with esculentamin (i.e. it did not inhibit the several proteases tested, viz., trypsin and subtilisin). Two taro α -amylase inhibitors, isolated from corms, inactivated α -amylases of animal origin but had no effect on fungal amylase (McEwan et al. 2010). Inhibitor A-1 also exhibited activity towards plant amylases, while inhibitor B-2 has no activity on plant amylases. Inhibitor A-1 was the most active against human salivary amylase at pH 6. Inhibitor A-1 was completely destroyed at temperatures above 50°C, while inhibitor B-2 was stable up to 70 °C. In a recent study, purified α -amylase inhibitor from *Colocasia* corm was found to be heat stable and retained 81.50 % activity at 70 °C temperature to have pH optima of 6.9 (Kumari et al. 2012). It was found to have inhibitory activity against α -amylases extracted from the larvae of several insects and to inhibit the activity of human salivary α -amylase. It also had inhibitory activity against potato α -amylases and reduced sugar content in treated potato

slices. Inhibitory activity of α -amylase inhibitor against mammalian amylases could suggest its potential in treatment of diabetes and cure of nutritional problems, which result in obesity. The α -amylase inhibitors of taro were almost totally inactivated during oven drying of the chips at 90 and 100 °C for 24 hours (Rekha and Padmaja 2002). Cooking by boiling the corms resulted in retention of 11–16 % of the inhibitor in taro. Flour prepared from the corms retained only trivial amounts of the inhibitor. Microwave baking was a better method for inactivation of amylase inhibitors.

Ethanollic taro leaf extract (400 mg/kg) showed antihyperglycaemic activity in alloxan-induced diabetic rats (Kumawat et al. 2010). Taro leaf extract was found to have significant blood glucose-lowering effect and prevented weight loss. No mortality was observed with administration of the extract up to 500 mg/kg.

The expected glycaemic index (eGI) of taro starch and taro-resistant starch was determined as 60.6 and 51.9, respectively, and the decrease in the glycaemic index of taro-resistant starch was found to be statistically significant (Simsek and El 2012). The in-vitro binding of bile acids by taro starch and taro-resistant starch relative to cholesterol-decreasing drug cholestyramine were 5.2 % and 7.6 %, respectively.

Anxiolytic Activity

The anxiolytic activity of hydroalcoholic taro leaf HECE (100, 200 and 400 mg/kg) per os (p.o.) was characterised by increased time spent by adult Wistar rats and number of entries in open arms in the elevated plus maze paradigm as compared to control group (Kalariya et al. 2010). Taro leaf extract (100, 200 and 400 mg/kg, p.o.) showed dose-dependent significant reduction in duration of immobility in the behaviour despair test. At doses of 50 and 100 mg/kg, i.p., it produced a significant reduction in motor coordination of Swiss albino mice and prolongation of thiopental-induced sleeping time. The phytochemical screening revealed the presence of flavonoids, β -sitosterol and steroids in the extract.

Antihyperlipidaemic/Antihypercholesterolaemic Activities

Colocasia esculenta showed the highest inhibition (55 % inhibition at 300 µg/mL) of human lanosterol synthase, a key enzyme involved in cholesterol biosynthesis (Sakano et al. 2005). A purified taro fraction afforded three monogalactosyldiacylglycerols (MGDG 1–3) and five digalactosyldiacylglycerols (DGDG 1–4) that showed 28–67 % inhibitory activities at the concentration 300 µg/mL. DGDG-4 was a mixture of digalactosyldiacylglycerols with ‘one linoleate and one oleate’ and ‘one linoleate and one palmitate’ with the ratio of 1:5. In another study, digalactosyldiacylglycerol (DGDG) and monogalactosyldiacylglycerol (MGDG) were identified as anti-hyperlipidaemia active components in *Colocasia esculenta* (Tanaka et al. 2005). DGDG with two myristoyl groups at both sn-1 and sn-2 positions and with an oleoyl group at the sn-1 position showed the most potent inhibitory activity on human lanosterol synthase.

Feeding of arabinogalactan mucilage from taro corms at a dose of 4 mg/100 g body weight daily for 8 weeks exerted a hypolipidaemic effect in rats (Boban et al. 2006). The mucilage decreased the lipid levels both in the serum and tissues. There was a decrease in the synthesis and secretion of apo B-containing lipoproteins, mainly VLDL, by hepatocytes isolated from mucilage-fed rats when compared to control.

Antihypertensive Activity

Administration of aqueous taro leaf extract in renal artery-occluded hypertensive rats at concentrations of 100, 200 and 400 mg/Kg/day, p.o., and in noradrenalin-induced hypertension rats at concentrations of 20 and 40 mg/Kg, i.v., produced significant antihypertensive effects (Vasant et al. 2012). The leaf extract (400 mg/Kg, p.o.) showed positive diuretic activity at 5 hours. The antihypertensive and weak diuretic activity of the extract may be attributed due to acetylcholine inhibitory, vasodilatory, β-blocking and/ or Ca²⁺

channel-blocking activities, which were reported for the phytoconstituents, specifically flavonoids such as vitexin, isovitexin, orientin and isoorientin present in the leaves.

Anticancer Activity

Soluble extracts of poi, a starchy paste made from the taro corm, at 25 % concentration exerted the greatest suppression of YYT colon cancer growth via apoptosis (Brown et al. 2005). Poi enhanced the proliferation of normal mouse splenocyte control cells, suggesting that poi was not simply toxic to all cells but even had a positive immunostimulatory role. By flow cytometry, T cells (CD4+ and CD8+) were predominantly activated by the poi. A dimeric haemagglutinin isolated from taro corm exhibited slight antitumour activity towards hepatoma HepG2 cells and weak mitogenic activity towards murine splenocytes (Chan et al. 2010). It induced the expression of the cytokines interleukin-1 beta, interleukin-2, interferon-gamma and tumour necrosis factor-alpha. However, it was devoid of antifungal activity towards a number of fungal species.

A water-soluble extract of taro (TE) potently inhibited lung-colonising ability and spontaneous metastasis from mammary gland-implanted tumours, in a murine model of highly metastatic oestrogen receptor, progesterone receptor and HER-2-/neu-negative breast cancer (Kundu et al. 2012). TE modestly inhibited the proliferation of some, but not all, breast and prostate cancer cell lines. TE treatment also inhibited prostaglandin E2 (PGE2) synthesis and downregulated cyclooxygenase 1 and 2 mRNA expression. The active metastatic compound was isolated and had a native size of approximately 25 kDa with two fragments of nearly equal size. The N-terminal amino acid sequencing of both fragments revealed that the active compound was highly related to three taro proteins: 12-kDa storage protein, tarin and taro lectin with similar amino acid sequence and a carbohydrate-binding domain.

The administration of Taro-4-I (taro polysaccharide) significantly inhibited the lung metastasis of B16-BL6

melanoma cells (Park et al. 2013). However, the group treated with 50 µg/mouse Taro-4-I had a significantly lower number of tumours compared to the group injected with 500 µg/mouse Taro-4-I. Also, treatment of peritoneal macrophages with Taro-4-I significantly increased the production of interleukin (IL)-6 and tumour necrosis factor- α (TNF- α) in a dose-dependent manner. However, IL-12 production showed maximal activity at 56 µg/mL and subsequently decreased.

The extracts from edible parts of *Colocasia esculenta* and the skin of taro showed markedly greater inhibitory effects on adult T-cell human leukaemia Su9T01 cell line than genistein (Kai et al. 2011). At concentration of 20 and 30 µg/mL, corm and stem extract inhibited 30 % of human breast adenocarcinoma MCF-7 cancer cells, respectively. Leaf extract showed no anticancer activity (Lee et al. 2011).

Three unignified cell wall (dietary) preparations from taro edible parts exhibited ability to adsorb the hydrophobic environmental mutagen 1,8-dinitropyrene (Ferguson et al. 1992). The greatest adsorption occurred with cell walls from leaf blade, followed by petiole and corm walls, although the differences were not major. The amount of adsorption was intermediate between the low adsorption previously found with unignified dicotyledon walls (from the flesh of potato tubers and immature cabbage leaves) and the much higher adsorption found with unignified walls from monocotyledons of the grass and cereal family (Poaceae) (from leaves of seedling Italian ryegrass). The adsorption of carcinogenic mutagens by dietary fibres may assist to protect against colorectal cancer.

Hepatoprotective Activity

Taro leaf juice prevented the occurrence of lipid peroxidative reactions in the rat liver slices caused by the presence of free radicals generated by the hepatotoxins CCl₄ and acetaminophen (Patil and Ageely 2011b). Simultaneously marked elevations and prevention of depletion of total tissue glutathione were observed in the presence of taro leaf juice. Taro leaf juice also showed antihepatotoxic and

hepatoprotective efficacy against hepatotoxicity induced by CCl₄ and paracetamol causing oxidative stress and damage to various cell organelles consequently resulting in injury to the hepatocytes (Patil and Ageely 2011a). Taro leaf juice significantly reduced the leakage of marker enzymes AST, ALT and ALP in the medium indicating hepatocyte integrity.

Wound Healing Activity

C. esculenta wound healing potential could be attributed, at least in part, to the protection of the wound site against oxidative/nitrosative damage and prevention of hyaluronic acid degradation (Gonçalves et al. 2013). They found that *C. esculenta* varieties were able to scavenge several oxidant species and to inhibit hyaluronidase, but data suggested that metabolites other than phenolics were involved.

Mitogenic and Haemagglutination Activities

The haemagglutinating activity of the dimeric haemagglutinin isolated from taro corms could not be inhibited by simple sugars and was stable after exposure for 30 minutes to temperatures up to 40 °C and to ambient pH in the range of pH 2 to pH 13 (Chan et al. 2010). The activity decreased progressively when the ambient temperature was raised from 40 to 100 °C. Tarin, a storage lectin from taro, exhibited both agglutinating activity against hamster erythrocytes and mitogenic activity in-vitro and in-vivo towards mouse splenocytes (Pereira et al. 2014). Optimum cellular proliferation in-vitro was achieved by 625 ng of the crude extract or 500 ng of the purified tarin. Total mouse splenocyte proliferation measured after 5 days of intraperitoneal inoculation of purified tarin was increased 3.3-fold in comparison to the control group. Half of the proliferating cells were identified as B lymphocytes by flow cytometry. The lectin *Colocasia esculenta* agglutinin (CEA) was purified from taro corms and was found to be specific towards N-acetyl-D-LACTOSAMINE (LacNac), a disaccharide and asialofetuin, a

desialylated serum glycoprotein in haemagglutination inhibition assay (Thakur et al. 2013).

Taro α -D-galactosidase was found to convert B into group O red cells (Chien and Lin-Chu 1991). The blood group-converting activity was demonstrated by hemolysis and haemagglutination studies. At a final enzyme concentration of 30 units/mL in the incubation mixture, the conversion of group B into group O activity was completed within 2 hours, without apparent changes in the shape of the red cells. The recombinant taro α -Gal not only hydrolysed the α 1 $\rightarrow$ 4-linked galactosyl residues, which accumulated in the tissues from patients with Fabry disease, but also hydrolysed the α 1 $\rightarrow$ 3-linked galactoside of B red blood cells (Chern et al. 2012).

Antimelanogenic Activity

Among the compound isolated from taro corm skin, *cis*-grossamide K (2), isoamericanol A (3), americanol A (4), 2-hydroxy-3,2'-dimethoxy-4'-(2,3-epoxy-1-hydroxypropyl)-5-(3-hydroxy-1-propenyl)biphenyl (5) and (-)-pinoresinol (6) showed inhibitory effects on melanin production (Kim et al. 2010b). Compounds 2, 5 and 6 exerted a particularly strong antimelanogenic activity on the cells without high cell toxicity (IC_{50} = 54.24, 53.49 and 56.26 μ M and LD_{50} = 163.60, 110.23 and >500 μ M, respectively). Of the fatty acid derivatives isolated from taro corm peel, 12,13-epoxyoctadec-9-(*Z*)-enoic acid (7) dose-dependently inhibited melanin content with significant cell toxicity (Kim et al. 2010a). At 100 μ M concentration, compound 7 strongly inhibited melanin biosynthesis with an effective ratio of 35.43 in comparison to control. Monoglyceride 1-*O*-(octanoyl) glycerol (6) was also active in inhibiting melanin content at 10 μ M but exhibited cell toxicity at higher concentrations. Compound 12,13-epoxyoctadec-6(*Z*),9 (*Z*)-dienoic acid (10) containing an epoxy group slightly reduced the melanin content but displayed toxicity at higher concentrations. It was concluded that the fatty acid derivatives 6, 7 and 10 could be used as effective depigmenting agents and for cosmetic development.

Anti-inflammatory Activity

An ethanolic extract of *C. esculenta* leaves produced significant anti-inflammatory activity when compared with the standard and untreated control (Shah et al. 2007). The ethanolic extract (100 mg/kg, p.o.) inhibited carrageenan-induced rat paw oedema. It also showed an inhibitory effect on leucocyte migration and a reduction on the pleural exudates as well as reduction on the granuloma weight in the cotton pellet granuloma method. The ethanolic taro leaf extract (100 mg/kg, p.o.) inhibited carrageenan-induced rat paw oedema (Biren et al. 2007). It also showed an inhibitory effect on leucocyte migration and a reduction on the pleural exudates as well as reduction on the granuloma weight in the cotton pellet granuloma method. The results indicated that the ethanolic extract produced significant anti-inflammatory activity.

Antimicrobial Activity

Aqueous taro leaf extract exhibited antibacterial activity in-vitro against *Vibrio alginolyticus*, *V. cholerae*, *V. harveyi*, *V. parahaemolyticus* and *V. vulnificus* but not the stem and corm extracts (Lee et al. 2004). Aqueous taro leaf extract exhibited maximum activity in-vitro against *Streptococcus mutans* among the selected microbial strains (Singh et al. 2011). The antimicrobial MIC values of different parts of *C. esculenta* ranged from 7.81 to 500 mg/L in which the MIC of the corm extract against *Edwardsiella tarda* *Escherichia coli*, *Flavobacterium* sp., *Pseudomonas aeruginosa* and *Vibrio cholera* was 15.6 mg/L and *Klebsiella* sp., *Aeromonas hydrophila* and *Vibrio alginolyticus* was 31.4 mg/L, and it was able to control the growth of *Salmonella* sp. and *Vibrio parahaemolyticus* at 125 mg/L (Lee et al. 2011). The MIC values of the shoot against *Edwardsiella tarda* *Escherichia coli*, *Flavobacterium* sp., *Pseudomonas aeruginosa* and *Vibrio cholerae* was 7.81 mg/L and *Klebsiella* sp., *Aeromonas hydrophila* and *Vibrio alginolyticus* was 15.61 mg/L, and it was able to control the growth of *Salmonella* sp. and *Vibrio parahaemolyticus* at 62.5 mg/L. At concentration of 62.5 mg/L, the leaf extract was found to inhibit the growth of

Edwardsiella tarda, *Escherichia coli*, *Flavobacterium* sp., *Pseudomonas aeruginosa* and *Vibrio cholera*, whereas at 125 mg/L, *Klebsiella* sp., *Aeromonas hydrophila* and *Vibrio alginolyticus* failed to grow. Taro plant extract was able to control the growth of *Salmonella* sp. and *Vibrio parahaemolyticus* at 500 mg/L.

Probiotic Activity

Researchers in Hawaii found that poi, a pasty starch made from the cooked, mashed corm of the taro, contained significantly more of lactic acid-producing bacteria *Lactococcus lactis* (95 %) and *Lactobacilli* (5 %) bacteria per gram than yogurt and could have potential use as a probiotic albeit more research needed to be conducted (Brown and Valiere 2004). A probiotic is defined by FAO/WHO as ‘live microorganisms which when administered in adequate amounts confer a health benefit to the host’. Documented evidence suggested that poi showed promise for use in infants with allergies or failure to thrive (Derstine and Rada 1952).

Poi for Allergic People/Infants

According to the survey of doctors and paediatricians, poi’s most popular therapeutic uses were in convalescent or soft diets (90 %), elderly persons with no teeth (90 %), malnutrition (70 %), cereal allergies (60 %), gastric ulcers (40 %) and hyperacidity (40 %) (Derstine and Rada (1952). The idea that fermentation of poi reduces the bacterial load of the fresh product, and improves digestibility, was raised, but research was not available to confirm it, and the physicians surveyed lacked knowledge of this aspect. Glaser et al. (1967) found poi to be a practical substitute for the true cereals in the feeding of full-term and premature infants and for feeding at any age in patients allergic to the true cereals. It should also be invaluable in the feeding of potentially allergic infants for the prophylaxis of allergy to cereals and in the treatment of celiac disease as it contained no gluten. They asserted that its use in cystic fibrosis as well as gastrointestinal disturbances of other origin merited full investigation.

Anthelmintic Activity

Aqueous and ethanolic taro leaf extract exhibited anthelmintic activity against earthworm *Pheretima posthuma* in a dose-dependent manner giving the shortest time of paralysis (P) and death (D) at 50 mg/mL concentration (Kubde et al. 2010). The ethanolic taro leaf extract caused paralysis of 16 minutes and time of death of 42 minutes, while water extract revealed paralysis of 31.25 minutes and death of 60.34 minutes against the earthworm. The reference drug piperazine citrate showed the same results at 12 and 26 minutes, respectively.

Phytochemical screening of the crude extracts revealed the presence of riboflavin, niacin, oxalic acid, calcium oxalate and sapotoxin; anthocyanins perlargonidin 3-glucoside, cyanidin 3-rhamnoside and cyanidin 3-glucoside; and saponins.

Drug Delivery Activity

Taro corms mucilage/hydroxypropylmethylcellulose (HPMC)-based transdermal patch (matrix type) was found to be an efficient device for the delivery of the drug diltiazem hydrochloride (Sarkar et al. 2014). In-vitro drug release time of mucilage/HPMC-based transdermal patches was prolonged with increasing mucilage concentration in the formulation.

Effect on Growth

Feeding of weanling Wistar rats with different accessions (with different morphological traits) of cooked taro-based diets for 28 days was found to enhance growth performance (Lewu et al. 2011). Taro-based diet accessions UFCe1, UFCe2, UFCe4, UFCe5 and UFCe6 increased the average weekly water intake, feed consumption, total body weight, liver–body weight ratio and kidney–body weight ratio of the animals; while UFCe3 and UFCe7 decreased these measures. All the accessions of taro-based diets did not significantly alter the serum levels of albumin, globulin, inorganic phosphorus, calcium, magnesium and uric acid of the animals (Lewu et al. 2010). All the accessions of cooked *Colocasia esculenta* (taro)-based diets (UFCe1–UFCe7) decreased the serum

alkaline phosphatase activity; γ -glutamyl transferase activity was increased in weanling rats. Overall, the results revealed that all the accessions of *C. esculenta* produced selective effects on the hepatic and renal functional indices of the weanling rats. The highest alterations were produced by UFCe4, whereas the least was from UFCe2. These alterations may have consequential effects on the normal functioning of the liver and kidney of the animals.

Removal of Antinutrient Factors

The acidity of the leaves, petioles and tubers is due to raphides, but this usually had been reported to disappear on boiling or cooking (Green well 1947; Murai et al. 1958). Taro contained an irritant preventing its corm from being eaten raw or incompletely cooked; the irritation could be removed by prolonged baking or boiling (Moy et al. 1979). Results suggested that the acidity of taro was not caused solely by the calcium oxalate raphides but was also associated with a boiling water and ethanol labile factor. Separation of the idioblasts reduced the acidity. Extraction with ethanol either removed the factor or rendered the cell's ability to deliver the factor useless. In nine taro cultivars, total oxalate contents ranged from 43 to 156 mg/100 g fresh weight (FW), and soluble oxalate contents ranged from 19 to 87 mg/100 g FW (Huang and Tanudjaja 1992). Insoluble oxalate accounted for 29.35–73.97 % of the total oxalate contents in the taro corms.

Taro tuber was the most potent source of anti-trypsin and anti-chymotrypsin activities (Prathiba et al. 1995). When tubers were processed by pressure cooking, there was significant reduction/complete elimination in inhibitory activity. Partial retention of inhibition was observed in the case of chymotrypsin inhibitor and trypsin inhibitor in taro. Taro corms contained antinutrients in the form of trypsin and chymotrypsin inhibitors which could be partially or wholly eliminated by thermal inactivation (Kiran and Padmaja 2003). Trypsin inhibitors (TI) in taro corms could be inactivated by thermal processing. Heating at 100 °C led to rapid inactivation of TI; only 3–10 % of TI were retained in taro cultivars. More effective inactivation of TI of taro could be obtained through

microwave baking. Flour prepared from taro was devoid of TI activity.

The Akame cultivar contained the highest level of total oxalate (171.4 mg/100 g fresh weight (FW)) in the raw corm tissue and was significantly higher than the other three Japanese cultivars (Ishikawa-wase, Yamato-wase and an unnamed cultivar) (Catherwood et al. 2007). The raw tissue of the four cultivars contained a mean of 60.6 % soluble oxalates; boiling reduced the level of soluble oxalate in the cooked tissue to below detectable levels as soluble oxalates leached into the cooking water. Baking led to a significant reduction in the moisture content of the taro concentrating oxalates in the cooked tissue (overall mean, 229.0 mg/100 g FW).

The soluble oxalate content of the raw taro leaves was 236.10 mg oxalate/100 g wet matter (WM) (Savage and Duboi 2006). Soaking the raw leaves in water for 30 minutes marginally reduced the soluble oxalate content by leaching into the tap water. Soaking for 18 hours resulted in a 26 % reduction in the soluble oxalate content of the raw leaves. Boiling the taro leaves resulted in a 36 % loss of soluble oxalates, while the soluble oxalate content of baked tissue was very similar to the raw tissue. The mean insoluble oxalate content of the raw, boiled and baked tissue was 226.28 mg oxalate/100 g WM. Overall, boiling taro leaves was an effective way of reducing the soluble oxalate content of the cooked tissue. Wilting of taro leaves and petioles for 18 hours resulted in an overall 5.9 % reduction of soluble oxalates, and washing in cold water for 5 minutes resulted in a 26.2 % reduction in soluble oxalate content (Du et al. 2013). Soaking the petioles and the petioles and leaves for 10 hours in water kept at 36–38 °C resulted in a mean 69.5 % reduction in the soluble oxalate content of the raw tissues. Boiling for 60 minutes was the most effective way to reduce the soluble oxalate levels in the cooked tissue. A mean 84.2 % reduction in soluble oxalate in the petioles and the petioles and leaves was achieved after boiling for 60 minutes, while mean reductions of 62.1 % were achieved when both materials were boiled for only 10 minutes.

Oke and Bolarinwa (2012) found that fermentation of taro flour effected a significant reduction in oxalate level (58–65 %) depending on the fermentation period. The amylose content was higher in 48-hour-fermented flour (55.52 %) than in 24-hour-fermented flour (54.55 %). Pasting (gelatinisation) temperature decreased, and water absorption capacity increased markedly due to fermentation. Studies by Olajide et al. (2011) found that contents of antinutrient factors such as tannins, phytate, oxalate, saponin and hydrocyanide (HCN) in taro corms were significantly reduced by processing methods with raw sun-dried taro recording the highest value. Fermentation had the highest percentage reductive values of 42.86, 69.23, 95.05, 73.58 and 57.91 % in condensed tannins, hydrolysable tannins, phytate, oxalate and HCN, respectively, while the highest percentage reduction of 48.39 % in saponin was obtained in cooked corms. There were no activities detected for trypsin inhibitors in all the processed forms of taro corms. Crude protein was significantly highest in fermented corms and significantly lowest in cooked corms. Crude fibre significantly decreased by the processing methods with the highest values obtained in raw and soaked corms.

Toxicity Issues

A case report of an otherwise healthy 2-year-old boy with a history of pica, associated with iron deficiency anaemia, was reported in conjunction with earlier ingestion of *C. esculenta* leaf (Mihailidou et al. 2002). He had an acute episode of sialorrhoea, difficulty in speaking, dysphagia and repeated swallowing movements. An uncertain episode of a brief-duration still gaze was also reported.

Traditional Medicinal Uses

The leaf juice of the plant is styptic, stimulant and rubefacient and is useful in internal haemorrhages, otalgia, adenitis and buboes; the juice of the corm is laxative, demulcent and anodyne (Warrier et al. 1993). Medicinal taro varieties were used to treat or cure human ailments.

According to Watt (2014) in India, the pressed juice of the petioles is styptic and may be used to arrest arterial haemorrhage. It is occasionally used in treating earache and otorrhea and also an external stimulant and rubefacient. The juice of the corm is used in cases of alopecia. Internally, it acts as a laxative and is used in cases of piles and congestion of the portal system and also an antidote to the stings of wasps, snakes and other insects. In Punjab and in Cashmere, the roots are used in catarrh and colic (Kirtikar and Basu 1975; Chopra et al. 1986; Nadkarni 2001). The ash of the tuber mixed with honey is applied for aphthae in the mouth. Stems are sometimes used medicinally, notably in the treatment of snakebites. The heated tubers are locally applied to painful parts. Taro corm juices are widely used for traditional treatment of body ache and baldness (Prajapati et al. 2011). *Colocasia esculenta* was one of the several plants used to treat diabetes mellitus by the rural community of Dhemaji district of Assam, Northeast India (Tarak et al. 2011).

In Hawaii, the raw juice of taro is given to drink, mixed with sugar, as a febrifuge. In Asia and Africa, this species is also used in traditional medicine to treat arterial hypertension, liver problems, ulcers, snakebites and rheumatism (Onwueme 1999; Safo-Kantaka 2004). In Gabon, raspings from the corm are applied as a poultice to mature boils and to treat snakebites and rheumatism. In Mauritius, boiled young leaves are consumed to treat arterial hypertension and liver affections, and the juice is applied externally to treat eczema. In Madagascar, the corms are employed to treat boils and ulcers.

Other Uses

Corms and cormels are rich in mucilage and can be utilised in the paper industry or possibly in medicinal tablet manufacture. Spray drying conditions used produced spherical aggregates of taro starch that presented physicochemical and functional characteristics with potential for encapsulation of substances (Gonzalez-Soto et al. 2011).

Because of its small granular size, taro starch has been considered a good filling agent for biodegradable polyethylene film (Griffin and Wang 1983) and as a fat substitute. When taro starch is used in the production of plastics in an appropriate formulation, the result can be a useful acceleration of the biodegradability of the parent polymer. High fructose-enriched syrup (HFES), a sweetener (a liquid sugar), can be made from taro starch. Also taro can be a source of alcohol. The estimated alcohol yield from taro was estimated at 142 L/MT with a crop cycle of 9–15 months. Roughly, the starch-to-alcohol conversion ratio has been accepted to be 1.76 kg of starch to 1 L of alcohol.

Taro tops can be satisfactorily ensiled, and fermentation characteristics are comparable with other silages for animal feed. Taro silage can meet much of the feed needs for brood sows with no reproductive problems and good litter performance (Carpenter and Steinke 1983). Peelings and leaves and corms from wild types and inferior cultivars are fed to pigs. Boiled taro cormels were found to be comparable to maize as an energy source in the diets of weanling pigs (Agwunobi et al. 2002). Boiling significantly reduced the amounts of the antinutritional factors in the taro cormels. Samarasinghe and Rajaguru (1992) found that the feeding value of taro corms could be easily improved by boiling in water for 30–45 minutes and processed taro corm meal could be used to replace maize in broiler diets at levels up to 100 g/kg without any adverse effects. Processed taro corm meal had gross energy 14.9–15.0 MJ/kg dry matter and was comparable with maize meal as an energy source.

Studies showed that *Colocasia esculenta* was one of the several wetland aquatic plants that could be used for phytoremediation of submerged soil polluted by arsenic (Jomjun et al. 2011). Taro was recognised as the largest and fastest arsenic remover in the study. Its arsenic removal rate was 68 mg As/m²/day, while those rates of *Canna glauca*, *Cyperus papyrus* and *Typha angustifolia* were 61, 56, and 56 mg As/m²/day, respectively.

Tarocystatin a group-2 phytocystatin was isolated from *Colocasia esculenta* and found to be a defence protein against phytopathogenic nematodes and fungi (Yang and Yeh 2005; Wang et al. 2008). The lectin *Colocasia esculenta* agglutinin (CEA) purified from taro corms significantly decreased the per cent pupation and emergence of *Bactrocera cucurbitae* with respect to control. CEA affected normal growth and development and presented stress to the larvae, activating their detoxification and antioxidant systems. Thus, the lectin may be a useful candidate for the control measures of *B. cucurbitae* under the integrated pest management (IPM) system. Taro corm agglutinin CEA was found to have insecticidal activity against *Bemisia tabaci* and *Lipaphis erysimi* (Roy et al. 2014). CEA interacted with insect midgut receptors that probably led to disruption of cellular processes causing growth retardation and loss of fecundity of target insects. Taro was found to be an effective trap crop for managing *Spodoptera litura* on tobacco; however, it did not attract *S. litura* in the seedling stage, indicating that taro should either be planted 20–30 days before tobacco or alternative control methods should be employed during the seedling stage (Zhou et al. 2010). The purified α -amylase inhibitor from *Colocasia* corm was found to inhibit activity against α -amylases extracted from the larvae of *Callosobruchus chinensis*, *Tribolium castaneum* and *Corcyra cephalonica* and midgut α -amylase of *Spodoptera littoralis* (Kumari et al. 2012). One hundred percent larval mortality of *C. cephalonica* was observed when fed on wheat flour mixed with 0.0036 % (w/w) of purified inhibitor. The ability of the inhibitor to inhibit insect amylases highlighted its possible role in pest resistance and postharvest decay of crop plants.

Studies found that taro can be used as a vermicompost for the growth and proliferation two epigeic species (*Eisenia foetida* and *Eudrilus eugeniae*) of earthworms (Kurien and Ramasamy 2006).

Kalo is also steeped in cultural and religious beliefs. Kalo was the *kinolau* (body form) of the Hawaiian gods Kane (the great life giver) and Lono (god of peace, planting and fertility) (Abbott 1992). As such, kalo was one of the foods offered to appease these two gods in particular.

Leaves and petioles of the taro plant were used to make dyes for *kappa*. Kalo is also used in landscaping or horticultural use where horticultural varieties are used primarily to incorporate in garden, lawn and exterior plant design, not necessarily for consumption. Fibre obtained from the leaf stalk has been used for plaiting in Africa.

Comments

Colocasia esculenta is a very variable species that is widely cultivated throughout tropics and many wild or naturalised clones found in S. Asia, Malesia and the Pacific islands. Its taxonomy had been controversial. Bailey (1925), Hill (1939) and Jonker-Verhoef and Jonker (1959) recognised *Colocasia esculenta* as one of the main species, while Barrau (1957) recognised them as two separate species *C. esculenta* and *C. antiquorum*. Haudricourt (1941) retained the name *C. antiquorum* for the main species and made a number of botanical varieties based on vegetative characters. Purseglove (1972) recognised two botanical varieties of cultivated *C. esculenta*, namely, var. *esculenta* and var. *antiquorum*. He suggested that the dasheen of the West Indies (which is generally referred to as taro in the Pacific) should be considered as *C. esculenta* var. *esculenta* and that the eddoe of the West Indies (generally referred to as dasheen in the Pacific and in Asia) is considered as *C. esculenta* var. *antiquorum*.

In *C. esculenta* var. *esculenta* (dasheen, taro type), stolons are absent, appendix is short, leaf lamina is adaxially matte waxy glaucous and water shedding, infructescence is not erect and the central corm is large, cylindrical, up to 35 cm long and 15 cm in diameter, with small side cormels. In *C. esculenta* var. *antiquorum* (eddoes type), stolons are present, appendix is elongated, leaf blade is adaxially glossy and wettable, infructescence is erect and the central corm is much smaller and bears many small secondary cormels.

Origin/Distribution

Swamp taro is native to Malesia (probably Malaysia and Indonesia) and was introduced to and spread among western Melanesia and the Pacific islands in pre-European times. It is common in Malaysia, Singapore and Indonesia and rare in Papua New Guinea. Formerly a popular crop through Malaysia and Indonesia and a staple in the Philippines; today hardly any cultivation is seen there. An important food and staple crop in Micronesia but a minor food crop in Polynesia.

Agroecology

The plant grows in coastal swamps, swamp forests, riverbanks, in shallow water or brackish water. It grows on a wide range of soil types and acidity. It is also tolerant of saline and calcareous soils. In parts of Micronesia, it is grown in man-made, muck-filled, freshwater swamps and also on artificial elevations. It prefers natural swamp land rich in humus and covered with 0.2–0.7 m of slow running water. It can be cultivated in areas of moderate rainfall provided the soil is deep and swampy. It thrives in full sun or partial shade and should be sheltered from strong winds.

Edible Plant Parts and Uses

The large tuberous rootstocks are eaten after thorough cooking by boiling, steaming or roasting. The tubers can be peeled, sliced, fried and eaten with sugar. The tubers can be preserved by peeling, slicing, scalding and drying in the sun for future use. The tubers are also used to produce starch and flour. Young leaves and inflorescences are also eaten cooked as vegetables.

The starchy rhizomes are important staple in Micronesia. In Kiribati which comprises three groups of atoll islands – Gilbert group with 17 islands, Phoenix group with 8 and Line group with 8 – *C. merkusii* has been and is the biggest root crop grown for centuries. Swamp taro is second to coconut as source of vegetable food and is consumed for its high-valued starch. The tubers are often cooked with coconut milk in various cuisines. Some common Micronesian recipes with swamp taro (Manner 2011) are:

- (a) Wūdeñ – with cooked and pounded breadfruit, swamp taro, bananas or nuts mixed with grated coconut

- (b) Jebwater – food with grated swamp taro mixed with coconut milk, wrapped in taro leaves and baked in oven

- (c) Totaimon – food with swamp taro grated and mixed with coconut oil and coconut sap

- (d) Kōmālij – mashed swamp taro or potato

- (e) Jukjuk – pounded swamp taro mixed with coconut

- (f) Te buatora – grated babai corm mixed with sugar or kaimaimai and cooked in boiling water or baked in oven by wrapping in leaves

- (g) Te bekei te buatoro – babai mixed with coconut cream and more sugar

- (h) Te korokoro – raw babai cut into small slices and boiled in water or baked in oven

- (i) Te rebun – boiled or baked babai pieces added with coconut cream or kaimaimai

- (j) Te tanganimanam – babai pieces already boiled or cooked are meshed together and mixed with grated coconut

Botany

Tall, robust, perennial herb reaching 3–5 m high, with typically six to eight huge leaves arising from a short stem (Plate 1). The stem thickens at the base becoming a large subterranean rhizome corm, varying in shape from cylindrical to conical. The size of corm varies with cultivar and age; 15–25 kg is common, but it can weigh up to 90 kg or more in a 10-year-old plant. Leaves are coriaceous, dark olive green, huge, 1–2 m long, erect, hastate–sagittate with long basal lobes and tapering apices, deep sinus, anterior lobe shorter than the posterior lobes and tip pointing upwards, with long stout, 2.5 m long petioles, covered with spines near the base, arising spirally from top of corm; venation is reticulate and prominent on undersurface (Plate 2). The inflorescence is a solitary spadix on a long peduncle (Plate 3). The spadix is enclosed by hard, marcescent spathe, purple coloured often with yellowish stripes, sometimes leaf-like and greenish white. The spadix is sessile or stipitate, yellowish, with hermaphrodite flowers throughout its length, with four to six free tepals. Fruits are small, globose, orange to scarlet berries ripening from the tip of the spadix downwards. Seeds are tiny, kidney to helical shaped, often ornamented.

Nutritive/Medicinal Properties

Food value of the raw giant swamp taro corm per 100 g edible portion was reported as water 75 g, energy 308 kcal (75 kJ), protein 0.5 g, total fat 0.2 g, available carbohydrates 18 g, dietary fibre 2.8 g, sodium 72 mg, potassium 67 mg, calcium 182 mg, magnesium 21 mg, iron 0.6 mg, zinc 2.1 mg, total vitamin A equivalent 5 µg, β -carotene equivalent 30 µg, thiamine 0.03 mg, riboflavin 0.02 mg, niacin traces, vitamin C 15.7 mg and vitamin E 2 mg (Dingan et al. 1994).

Studies reported that β -carotene concentrations of giant swamp taro cultivars varied from 50 to 4,486 µg/100 g (Englberger et al. 2008). Alpha-carotene content varied from 9 to 2,040 µg/100 g and β -cryptoxanthin from <10 to 120 µg/100 g. Australian analyses found in five cultivars lutein levels of 852–1,548 µg/100 g, while Swiss analyses of 24 cultivars found mean lutein level of 67 µg/100 g and maximum level was 260 µg/100 g. Zeaxanthin and lycopene occurred at low levels 10–20 µg/100 g or not detected in all samples. Yellow-fleshed cultivars generally contained higher carotenoid concentrations. Of the ten cultivars analysed for mineral content (wet weight basis) per 100 g, substantial concentrations of zinc 5.4–46.1 mg, iron 0.3–0.8 mg and calcium 121–305 mg were found, and other minerals were potassium 111–282 mg, magnesium 11–51 mg, manganese 1.7–5.1 mg, sodium 13–78 mg, phosphorus 21–24 mg were found. All cultivars were acceptable for taste and production factors. The researchers suggested that the carotenoid- and mineral-rich cultivars should be considered for promotion in Micronesia and other areas for potential health benefits.

Workers in the Philippines have reported a starch content ranging from as low as 7.5 % up to 22.6 %. The starch granules are of medium size, from 4 to 18 µm, and rounded or angular (Kay 1973).

Slices of the yellow and mixed sections of the tubers were processed into flours by sun-drying (temperature about 35 °C) and hot air electric drying at varying temperatures (50, 60, and 70 °C) before milling (Nguimbou et al. 2013). Drying

temperature and technique exerted marginal effect on the protein, fat, fibre, ash and carbohydrate content of taro flours. Colour attributes, physical and functional properties, 1,1-diphenyl-2-picryl-hydrazyl radical antioxidant activity, as well as reducing power of flours were found to vary significantly due to either the drying temperature or method. Hot air electric drying at lower temperatures (<70 °C) produced flour with higher water absorption capacity (WAC), water solubility index (WSI), porosity, bulk density and preserved antioxidant activity of flour, whereas sun-drying was associated with flours of higher WSI but lower WAC and lower antioxidant capacity. It was noticed that carotenoids and ascorbic acid contributed to the antioxidant activity in swamp giant taro flours.

Traditional Medicinal Uses

The plant has limited medicinal use. According to Guerrero (1921), the spadix in decoction is used as an emmenagogue and ecbolic.

Other Uses

The plant is often grown as ornamental because of its large size (up to 4 m tall), and in certain parts of Micronesia it is a highly valued prestige plant.

Comments

The plant is commonly propagated from suckers (sprouting cormels), though the top of the corm of the harvested plant (setts) is also used.

Origin/Distribution

This tropical species is believed to have originated from northern South America and spread to the Caribbean and Mesoamerica and subsequently introduced elsewhere into Africa, Asia and the Pacific.

Agroecology

The species is adapted to the wet, humid and warm tropics. It requires moist but well-drained, fertile soil and prefers partial shade. The mean temperature for their optimum growth must exceed 20 °C. In its natural habitat, it grows commonly under the rainforest canopy or naturalised along shady stream banks, but does not grow under flooded or swampy conditions. Although of tropical origins, the plant can withstand short periods of low cold temperature.

Studies by Caesar (1980) found that Barbados nut eddoe (*Xanthosoma sagittifolium*) produced the highest dry matter yield under shade and full water supply by developing long petioles and large leaf blades. Under shade and water stress, only the corm grew, and the growth of cormels was negligible. As a result of the increased development of above-ground plant organs, the plant was able to survive stress conditions but with a low yield of edible organ material.

Edible Plant Parts and Uses

This tropical plant is an important food crop – its edible corms provide energy-rich carbohydrates. They are eaten in various ways: boiled, steamed, baked, grilled, fried, mashed, creamed, pureed, in soups, chowders, stews and salads or barbecued whole (Kay 1987; Jansen and Premchand 1996). The corms are also dried, peeled and ground to flour or meal for pastry that can be stuffed with meat or other fillings or to prepare puddings.

Cocoyam was found to be superior to barley or sorghum for brewing beer due to its higher carbohydrate content (71–78 %) (Onwuka and Eneh 1996). The kiln-dried *X. sagittifolium* afforded a dark lager beer (4.16 % w/v alcohol content) with good aroma (68 %) and very good flavour (73 %) when compared with a commercial lager beer (Monarch) as standard (100 %).

The young leaves are valued as boiled vegetable.

Botany

A robust herbaceous, unarmed, lactiferous perennial (Plates 1 and 2), reaching 1.5–2 m high with a corm or main subterranean stem in the form of rhizome with the main part short, thick, globose or cylindrical giving rise to lateral off-shoots (cormels) (Plates 3, 4 and 5). Corm pale brown and flesh white, pale yellow or pink. Several large leaves also sprout from the main part. Leaves are thick, dark green or purplish, long petioled (petioles up to 1.5 m long), sagittate or hastate not peltate lamina, up to 90 cm long and up to 60 cm wide, acute apices and wide basal lobes with prominent marginal nerves or pedatisect (Plates 1 and 2). Spathe with an ovoid or oblong convolute tube and a narrow boat-shaped blade exceeding the spadix. The large spathe is light green, silver green, yellow green or purple. The large cylindrical spadix, 15–20 cm long, is divided into female (lower) and male (upper) parts separated by a sterile zone. Staminate flowers of four to six stamens united in synandria; pistillate flowers with broad and coherent styles, disc-like stigma and the ovaries 2–4-locular with many subanatropous ovules borne near the centre of the axillary placenta. Berry polyspermous with few ovoid sulcate seeds.
