The proximate nutrient food value of raw cocoyam corm based on analyses conducted in Nigeria is reported as per 100 g edible portion: Na 66 mg, K 525 mg, Mg 46.6 mg, C 18.64 mg, Fe 0.42 mg, P 70.4 mg, Zn 0.4 mg and Mn 0.63 mg. Both white- and red-fleshed corms provide good sources of Na, K, Mg and Ca.

Approximate composition of tannia per 100 g edible portion was reported by Kay (1987) as energy 556 kJ/100 g, moisture 70–77 %, protein 1.3–3.7 %, fat 0.2–0.4 %, carbohydrate 17–26 %, fibre 0.6–1.9 %, starch 17–34.5 %, ash 0.6–1.3 %, Ca 20 mg, Fe 1 mg, thiamine 1.1 mg, riboflavin 0.03 mg, niacin 0.0005 mg and ascorbic acid 6–10 mg. Tannia was reported to have larger starch grains (mean diameter of 17–20 μ m) that were less easily digested than *Colocasia esculenta* (taro) starch grains. However, tannia starch was reported as palatable as cassava flour and more nutritious. Noodles made from mixes of soy, wheat and tannia flours had been made experimentally (Kay 1987).

The mean values of the proximate composition of *X. sagittifolium* (red flesh), *X. sagittifolium* (white flesh) and *Colocasia esculenta* corms per 100 g edible portion DM were reported, respectively, as moisture 57.63–77.41 g, 54.46–71.97 g and 59.30–72.06 g; protein 3.94–4.09 g, 4.92–5.50 g and 2.98–4.69 g; starch 12.3–33.61 g, 18.03–36.64 g and 17.81–32.53 g; fat 0.43–0.74 g, 0.28–0.58 g and 0.64–0.97 g; ash 2.68–3.93 g, 1.98–3.29 g and 1.56–1.88 g; fibre 1.16–1.77 g, 1.11–1.72 g and 2.74–3.00 g; Ca 7.70–24.33 mg, 7.91–18.99 mg and 4.68–7.09 mg; Fe 2.62–3.73 mg, 3.34–3.89 mg and 2.68–3.75 mg; Mg 64.48–85.03, 58.86–67.57 and 48.71–64.78 mg; Zn 20.87–51.05 mg, 28.33–51.09 mg and 16.98–28.41 mg; K 769.61–1525.80 mg, 963.05–1388.68 mg and 763.98–1004.63 mg; Na 21.07–23.70 mg, 28.91–49.14 mg and 28.48–34.622 mg; P 47.71–63.07 mg, 41.58–52.51 mg and 54.72–61.25 mg; and oxalate 253.49–380.55 μ g, 269.49–322.82 μ g and 328.41–488.9 μ g (Afoakwa et al. 2003). The *Xanthosoma* (white flesh) variety had the highest levels of nutritive value. Similarly, the distal sections of the three yams studied had comparatively higher amounts proximate composition than the middle and apical sections. High levels of minerals were located at the apical sections as compared to the distal and middle sections. The apical section of all the species had high-protein content, while the distal section had high levels of ash, fibre

and minerals. Potassium, zinc, magnesium and phosphorus were the most abundant minerals. Oxalate contents were lower in *X. sagittifolium* and higher in *C. esculenta*. The various processing methods used reduced the oxalate levels by approximately 50 % (Afoakwa et al.). The greatest reduction was observed for the drum-dried products. No significant differences were found between the oven-dried and solar-dried samples. The results implied that solar-, oven- and drum-drying techniques which reduced the oxalate contents to safer levels could be used for the development of marketable dehydrated products.

Xanthosoma sagittifolium (white flesh) was composed of Na (1365.05), K (3057.16), Mg (313.70), Ca (190.93), Fe (8.28), P (44.39), Zn (2.49) and Cu (0.52) (mg/100 g) and *X. sagittifolium* (red flesh) was found to contain Na (1297.89), K (1737.48), Mg (314.30), Ca (107.38), Fe (9.11), P (44.94), Zn (3.10) and Cu (0.78) (mg/100 g) (Njoku and Ohia 2007).

The mean values of the proximate composition of *X. sagittifolium* (white flesh), *X. sagittifolium* (red flesh) and *Colocasia esculenta* cormels evaluated were crude protein 2.98–5.50 g/100 g, total fat 0.28–0.97 g/100 g, ash 1.56–2.98 g/100 g, starch 12.2–36.0 g/100 g and crude fibre 1.11–3.00 g/100 g (Sefa-Dedeh and Kofi-Agyir 2004). The different sections of the cocoyam cormels studied were significantly different in chemical composition. The apical section of all the species had high-protein content, while the distal section had high levels of ash, fibre and minerals. Potassium was the most abundant mineral (763–1,451 µg/100 g) with appreciable amounts noted for zinc (17–51.1 µg/100 g), magnesium (46.7–85.0 µg/100 g) and phosphorus (41.6–63.1 µg/100 g). Oxalate compositions of the fresh samples were in the range of 254–381 µg/100 g for the *X. sagittifolium* (red flesh), 302–323 µg/100 g for the *X. sagittifolium* (white flesh) and 328–460 µg/100 g for the *Colocasia esculenta*. No significant differences were found between the oven-dried and solar-dried samples. However, drum drying reduced the oxalate levels by approximately 50 % to average levels ranging from 99.9 to 191 µg/100 g.

Protein, fat, ash and fibre contents of the raw cocoyam (% dry weight) were 2.83, 0.93, 1.74 and 0.88 respectively (Akpan and Umoh 2004). The protein, fat, ash and fibre contents decreased to 1.48, 0.72, 1.70 and 0.76 in the sample cooked without tetracycline (C₂). Significant decreases were observed when cocoyam samples C₃–C₆ were cooked with 1 g (1,000 mg) of tetracycline as the values decreased to 1.13, 0.48, 1.33 and 0.57 (% dry wt), respectively.

Mineral elements analysis showed general decreases in the cooked samples. There was a 17 % reduction in calcium between C₁ and C₆, and similar trend was observed for other mineral elements. A general reduction in the level of antinutrients was observed after heat and tetracycline treatments. There was an improvement in food quality with respect to the antinutrients but with decreased values of the desired nutrients. However, there was also a general reduction in the undesirable properties of the cocoyam such as the acidity factors caused by crystal of oxalate when the corms of cocoyam were cooked with and without tetracycline. Studies showed that boiling (90 °C) affected the highest oxalate reduction in *Colocasia esculenta* cultivars and *Xanthosoma sagittifolium* corm flours, especially in the former (Iwuoha and Kalu 1995). Boiling and roasting (165 °C) affected reduction in cold paste viscosity, while an inconsistent trend resulted from steeping (30 °C). Gelatinisation temperature decreased, and water and oil absorption capacities increased markedly due to the three processes. Process time variation in steeping and boiling of *C. esculenta* on both water and oil absorption was significant. On the other hand, only the effect of cultivar on viscosity of both steeped and boiled samples was significant.

Starch granules sizes in the ranges of 0.74–1.19 and 0.74–1.10 µm were obtained for the *X. sagittifolium* (red flesh) and (white flesh), respectively (Sefa-Dedeh and Kofi-Agyir 2002). Significantly, smaller sizes (0.05–0.08 µm) of starch granules were observed for *Colocasia esculenta*. *C. esculenta* showed lower hot paste viscosity but higher thermal stability than the *Xanthosoma* varieties. Peak viscosity was highest in the *X. sagittifolium* (red flesh) variety, while the white-flesh variety showed the least tendency to retrogradation. Significant differences in raphide sizes were observed among the varieties, with the *C. esculenta* having more pronounced needlelike structures.

Ash content, fat content, crude fibre, protein and amylose contents of new cocoyam starch were reduced following modifications by oxidation (oNCS), acetylation (aNCS) and acid-thinning (atNCS) (Lawal 2004). The starch granules were round and polygonal in shape, the sizes ranged from 15 to 40 µm and the granule morphology was not altered by the modifications. The X-ray pattern of native starch was A type, with similar pattern in modified derivatives. Acetylation improved swelling capacity, while oxidation and acid-thinning reduced it. Both oxidation and acid-thinning markedly improved solubility, whereas acetylation reduced it. Hydrophilic tendency of the starch improved after oxidation and

acetylation, whereas acid-thinning reduced it. Oil absorption capacity increased after oxidation and acetylation but was reduced following acid-thinning. Oxidation and acetylation reduced the gelation capacity of native starch, while atNCS had better gelating property than nNCS. The pasting temperature of nNCS (76 °C) was reduced after oxidation and acetylation but increased following acid-thinning. Setback tendency of the native starch was reduced after oxidation and acetylation but increased following acid-thinning. Oxidation and acetylation reduced peak temperature of gelatinisation (T_p) of native starch, opposite to the increase in T_p after acid-thinning. Enthalpy of gelatinisation (ΔH) was reduced after oxidation and acetylation but increased following acid-thinning. Retrogradation tendency was reduced after oxidation and acetylation but increased following acid-thinning. Hydro-thermal modification of native *X. sagittifolium* did not alter granule morphology; starch granules were round and polygonal shapes with sizes ranging from 15 to 40 μm and with 'A' X-ray diffraction pattern (Lawal 2005). Swelling power and solubility were reduced following hydrothermal modifications. At all pH studied (2–12), native new cocoyam starch exhibited higher swelling capacity and solubility than the modified derivatives. Hydrothermal modifications improved water absorption capacity but reduced oil absorption capacity. Pasting temperature of native starch shifted to higher values following annealing and heat moisture treatment. Hot paste viscosity (Hv), viscosity after 30 minutes holding at 95 °C (Hv30) and cold paste viscosity (Cv) reduced after annealing and heat moisture treatment. The result also indicated that hydrothermal treatments reduced the tendency for setback. Following annealing and heat moisture treatment, gelatinisation temperature increased. Starch hydrothermal modifications reduced retrogradation as enthalpies of regelatinisation reduced following modifications.

Studies showed that the amylose content of the starch isolated from *Xanthosoma sagittifolium* was higher than those shown by *Colocasia esculenta* and *Manihot esculenta* starches (Pérez et al. 2005). The phosphorous content was higher in *Xanthosoma sagittifolium* than *Colocasia esculenta* or the commercial *Manihot esculenta* C. starches. The gelatinisation profile range was wider in *Manihot esculenta* C. than the other two starches. The most significant relationship between parameters was found between the amylose and gelatinisation profile and enthalpic change and ash. *C. esculenta* flour showed higher crude fat, total, soluble and insoluble dietary fibre and mineral (P, Ca, Fe and Zn) contents, whereas *X. sagittifolium* flour showed higher starch and ash and reducing sugar content (Pérez et al. 2007). *X. sagittifolium* flour showed higher

titratable acidity and relative density values, being darker and more yellowish than its counterpart. *X. sagittifolium* flour showed higher gelatinisation temperature than *C. esculenta* flour. Parameters such as viscosity during the holding time (95 °C for 30 minutes), viscosity at 50 °C, setback and consistency were lower in *C. esculenta* flour than *X. sagittifolium* flour. The viscosity peak and breakdown indices were higher in *C. esculenta* flour than in the *X. sagittifolium*.

Cocoyam corms planted in the summer showed higher contents of total starch than corms planted in other seasons (Lu et al. 2005). Starches from both cultivars (KCX01 and KCX02) of cocoyam corms planted in the summer season had significantly higher average granule sizes, higher contents of amylose, higher ratios of short-to-long chains of amylopectin and lower values of the average degree of polymerisation (DP) of the chain length distribution profiles. The distinct properties of the fine structure of cocoyam starch from corms planted in summer season were associated with lower values of onset and peak temperatures and enthalpies of gelatinisation. *Xanthosoma sagittifolium* and *Colocasia esculenta* starches were white in colour and had granule sizes varying significantly in length (6.47–13.63 µm) and width (5.36–8.45 µm), while amylose content ranged from 11.55 to 33.77 % (Falade and Okafor 2013). Peak (49.09–141.96 RVU) (rapid visco units), breakdown (49.09–141.96 RVU), final (189.79–327.42 RVU) viscosities, pasting temperature (84.53–88.75 °C) and time (4.55–4.97 minutes) varied significantly among cultivars. Also, water absorption capacity (21–36 %), pH (4.8–5.3), gelling point (60.5–69.5 °C), foam capacity (4.46–18.28 %), bulk density (0.14–1.15 g/mL) and swelling power (2.31–10.09) varied significantly among the cultivars. The average yield of the starches varied significantly from 10.03 to 18.61 %.

Cocoyam peels were found to contain 6.30–17.6 % protein, 10.7–19.7 % fibre, 41.2–46.0 % carbohydrate and 0.70–2.14 % lipids (Yahaya et al. 2013). Macrominerals (Na, K, Ca and P) being the highest while the micromineral nutrients such as Mg, Zn, Fe and Cu were found to be generally lower than the dietary mineral requirement for animal feeds. The peels collected during dry season contained lower concentration of phytate which ranged between (1.26–1.43 %), hydrogen cyanide (3.17–3.20 %), soluble oxalate (1.18–1.69 %) and tannin (1.43–8.24 %) than the peels collected during wet season. The proximate analysis of the peels suggested that they could serve as supplementary sources of essential nutrients for livestock production, especially with their low levels of antinutritional factors.

The polygalacturonase inhibitory action, phenol oxidase and peroxidase activities were higher in cocoyam corms of the *X. sagittifolium* varieties infected by *Sclerotium rolfsii* than in those of the *Colocasia esculenta* varieties (Ohazurike and Arinze 1996). The levels of phenol oxidase, peroxidase and polygalacturonase inhibitory activities also decreased as the postharvest age of the corms increased.

Trypsin inhibitors with molecular weights 19,950, 17,780 and 23,390 isolated and purified cocoyam corms (Obidairo and Ofuru 1982). They showed varied trypsin inhibitory activity which was lost on boiling for 40 minutes and exhibited maximum activity at pH 7.5–8.0.

Uhegbu (1997) found that cocoyam (*X. sagittifolium*) contained diethylamine, dimethylamine, morpholine, ethylaniline and proline (ranging between 0.80 and 0.91 µg N/kg).

Leaf Phytochemicals

X. sagittifolium petioles were found to contain raphides, needlelike crystals about 50 µm long and with maximum dimensions of approximately 850 by 250 nm (Sakai et al. 1972). The raphides had two distinct end structures: narrow, acute and tapered to a point at one end and broad, acute and abruptly pointed on the other. Barbs, about 750 Å long with tips oriented away from the narrow end, occurred along the length of the raphide on ridges on either side of two longitudinal grooves. These grooves, located opposite each other, gave the raphide cross section an H-shape. Mean dry matter (DM) content of new cocoyam leaves was 9.7 %, crude protein was 29.7 % DM, ash 11.9 %, neutral detergent fibre 31.5 % and acid detergent fibre 11.9 %, while total oxalates content was 2.79 g/100 g DM (Lumu and Katongole 2011). Wilting of chopped leaves after 3 hours affected the lowest reduction (21.1 %) in total oxalate content. Boiling (52.1 %), ensiling (43.7 %) and soaking (41.8 %) were equally effective (there was no significant difference) in reducing total oxalate content.

Six tropical leafy vegetables (*Vernonia amygdalina*, *Pterocarpus soyauxii*, *Manihot utilissima*, *Xanthosoma sagittifolium*, *Colocasia esculenta* and *Amaranthus hybridus*) were found to be 10.3–34.4 mg ascorbic acid 100 g fresh weight (Oteng-Gyang and Mbachu 1987). Cooking led to significant losses (60–90 % after 15 minutes). During market sale, when the leaves remained exposed in the sun for several hours, losses as high as 97 % of the remaining ascorbic acid were

recorded. Some of the vitamins were leached into the water which was not sold to the consumer, but discarded. Studies found that cocoyam (*Xanthosoma sagittifolium*) and white yam *Dioscorea alata* with GI (glycaemic index) 60 and 62, respectively, were considered as intermediate GI (glycaemic index) food in comparison to dasheen (77) and cassava (99), the high GI food (Ramdath et al. 2004). The moderate GI of *X. sagittifolium* was also separately confirmed by Lako et al. (2004).

Antioxidant Activity

Animal studies showed that the ingestion of purslane or malanga leaves may have a protective effect against oxidative stress caused by vitamin A deficiency (Arruda et al. 2004). Rats fed with β -carotene, malanga and purslane leaves showed lower liver and heart thiobarbituric acid-reactive substances (TBARS) concentrations, lower liver GSH (reduced glutathione) concentration and lower heart GSSG (oxidised glutathione) concentration compared with vitamin A-deficient rats. Liver and heart catalase activities were not significantly different among the groups, nor was the heart glutathione peroxidase (GPX) activity; however, the β -carotene rats showed the highest liver GPX activity. In further studies, they reported that liver and heart lipid peroxidation was lower in rats fed with β -carotene and malanga carotenoids extract than the vitamin A-deficient rats, while no difference was observed for the malanga leaf powder group (Arruda et al. 2005). All three groups showed lower liver protein oxidation than the vitamin A-deficient group, and only the malanga carotenoids extract group had lower heart protein oxidation in relation to vitamin A-deficient group. The malanga leaf powder group had a lower liver GSSG concentration and higher GSH/GSSG ratio than the vitamin A-deficient group, while no difference was observed for heart glutathione concentration among the groups. The results indicated that at physiological levels, β -carotene, malanga carotenoids extract and malanga leaf powder had antioxidant effects in rats.

Xanthosoma sagittifolium corm contained 0.32 g 100 g⁻¹ total phenolic; 0.26 g 100 g⁻¹ flavonoid and exhibited good scavenging activity of DPPH (78.22 %), hydroxyl radical (69.11 %), superoxide radical (83.27 %) and ABTS radical cations (76.11 %). The study confirmed that the methanol extracts had potential in-vitro antioxidant activity (Nishanthini and Mohan 2012).

Anticancer Activity

Studies showed that healthy Wistar rats fed with lyophilised *X. sagittifolium* leaves for 4 weeks had increased faecal mass and fat excretion and improved bile acid profiles by diminishing the proportion of secondary acids, thus suggesting that consumption of taioaba leaf may have the property of lowering the risk of colon cancer (de Almeida et al. 2013b). The leaves contained high contents of total fibre, predominantly comprising insoluble dietary fibre with glucose as the major monomer.

Hypolipidaemic Activity

The addition of lyophilised new cocoyam leaves to Wistar rats' diet resulted in reduced weight gain, reduced liver fat and increased faecal mass and lipid, in addition to higher faecal short-chain fatty acid and bile salt concentrations, compared to rats fed with a high-fat diet containing 3.67 % (w/w) cellulose (LCEL) for 4 weeks (de Almeida et al. 2013a). Additionally, only the group fed with a high-fat diet supplemented with 28.4 % cocoyam leaves exhibited a lower serum cholesterol concentration and a higher body ash content than the LCEL group. Both the high bile salt-binding capacity and high fermentability of lyophilised new cocoyam leaves suggested that *X. sagittifolium* may have a protective effect against cardiovascular diseases and bowel cancer.

Antidiabetic Activity

Administration of the ethanol extract of *Xanthosoma sagittifolium* corm at a dose of 200 mg/kg and 500 mg/kg body weight to alloxan-induced diabetic rats for 14 days elicited significant reductions of alloxan-induced-elevated blood glucose, serum creatine, urea, protein, albumin, globulin, glycosylated haemoglobin and hepatic enzymes serum glutamate pyruvate transaminase (SGPT), serum glutamate oxaloacetate transaminase (SGOT) and alkaline phosphatase (ALP) back to normal levels (Shajeela et al. 2013). The extract also caused significant increase in plasma insulin in the alloxan diabetic rats. The extract also reverted the alloxan-elevated lipid profile parameters: total cholesterol (TC), triglycerides (TG), low-density lipoprotein cholesterol (LDL-C), very-low-density lipoprotein cholesterol (VLDL-C) and phospholipids back to normal levels and significantly increased high-density lipoprotein cholesterol level. The highly significant reduction of activity of mitochondrial enzymes, reduced glutathione (GSH), oxidised glutathione (GSSG), GSH/GSSG, glutathione reductase (GR), glutathione peroxidase (GPx) and glutathione S-transferase (GST), and lipid peroxidation

observed in alloxan-induced rats was reverted to normal values by *X. sagittifolium* ethanol extract.

Antiosteoporotic Activity

Fresh and cooked leaves of *X. sagittifolium* were found to have a low calcium content at 273.17 and 369.81 mg/100 g, respectively (de Oliveira et al. 2012). *X. sagittifolium* and *Laportea aestuans* represented two medicinal plant species used as food and to prevent and treat bone diseases, such as osteoporosis, in traditional Brazilian medicine. They showed that each species may be used as a health supplement in poor communities.

Antimicrobial Activity

Among 16 plants species tested, the best antifungal activity in-vitro against *Candida albicans*, *Trichophyton rubrum* and *Cryptococcus neoformans* was shown by *Xanthosoma sagittifolium* supernatant (Schmourlo et al. 2005). The most susceptible fungus was *Trichophyton rubrum*.

Vitamin A Replenishment Activity

Graebner et al. (2004) fed vitamin A-depleted rats with a basal diet (AIN-93G) in which the synthetic vitamin A content was replaced by nonconventional leaves. At the end of the 30-day repletion period, 1 µg of retinol was accumulated in the liver after the intake of 43.1, 95.3 or 178.9 µg β-carotene from *Sonchus oleraceus* (So), *Amaranthus viridis* (Av) and *Xanthosoma sagittifolium* (Xs) leaves, respectively. The relative bioavailability of β-carotene from the leaves was 36 %, 16 % and 9 % for So, Av and Xs leaves, respectively. The results showed that the carotenoids from the three dark-green leaves were absorbed, converted to retinol and stored in the liver of rats.

Traditional Medicinal Uses

In Peninsular Malaysia, the large leaves are used as blanket for patients with fever as they are pleasantly cool and provide temporary relief (Burkill 1966). Patients also bathe in the plant decoction. In Palawan, Philippines, the inflorescence sap is used to heal wounds and as an antidote for insect bites and stings. In northwest Amazonia, the Ketchwas people used a *Xanthosoma* sp. to treat snake bites (Schultes and Raffauf 1990).

Other Uses

All parts of the plant can be fed cooked to animals, particularly pigs. Cattle, sheep and goats like the leaves, which are unusually nutritious for leaves of a root crop and compare favourably with good pasture.

The results of feeding studies indicated the potential of fresh new cocoyam leaves to replace up to half the soybean protein in diets based on sugar cane juice for growing pigs (Rodriguez et al. 2006). Rodríguez and Preston (2009) found that mixed leaves and petioles of new cocoyam, in the proportions that occur naturally in the plant, can be ensiled successfully without the need for additives and ensure a permanent supply of silage for the pigs. Acceptability by pigs, ducks and hens was found to be excellent. Growing pigs (23 kg live weight) were able to consume diets containing up to 80 % of the DM (dry matter) as ensiled new cocoyam leaves at levels close to 40 g DM/kg live weight (Rodriguez et al. 2009). Maximum N retention was achieved with the ensiled new cocoyam leaves providing 65 % of the diet DM, providing a protein level of 130 g/kg diet DM and 5 g crude protein per kg live weight. Studies showed that boiled cocoyam meals could effectively replace maize at 50 % inclusion level in finishing diets of broiler chickens (Abdulrashid and Agwunob 2012).

Comments

Most cocoyam varieties taste acrid and can cause the sharp irritation and burning sensation of the lips, mouth and throat when cocoyam leaves or corms are eaten raw (Bradbury and Nixon 1998). This acidity is caused by needlelike calcium oxalate crystals (raphides) that can penetrate soft skin and an irritant present on the raphides, probably a protease can cause discomfort in the tissue. Removal of the thick layer of skin and long period of cooking are required to remove acidity. Other methods of removal of acidity include fermentation, baking or extraction with ethanol.

Panax ginseng

T. K. Lim¹✉

(1) Canberra, Aust Capital Terr, Australia

Scientific Name

***Panax ginseng* C.A. Meyer**

Synonyms

Aralia ginseng (C.A. Meyer) Baill., *Aralia quinquefolia* var. *ginseng* (C.A. Meyer) auct., *Panax schinseng* Nees, *Panax quinquefolius* var. *ginseng* (C.A. Meyer) Regel & Maack ex Regel, *Panax schinseng* var. *coraiensis* T. Nees, *Panax verus* Oken

Family

Araliaceae

Common/English Names

Asian Ginseng, Asiatic Ginseng, Chinese Ginseng, Five Fingers, Ginseng, Korean Ginseng, Korian Ginseng, Manchurian Ginseng, Oriental Ginseng, Red Ginseng (Steamed and Dried Peeled Roots), Tartar root, White Ginseng (Sun-Dried Roots)

Vernacular Names

Brazil: Ginsão, Ginseng Da China, Ginseng Da Coreia Do Sul, Jinsão (Portuguese)

Chinese: Jen-Shen, Ren-Shen, Ts'ao Shen, Yang Shen, Yuan Shen

Czech: Všehoj ženšenový, Ženšen pravý

Danish: Ægte Ginseng, Ginseng, Koreansk ginseng, Kraftrod, Orientalisk ginseng

Dutch: Echte ginseng, Ginseng, Koreaanse, Vingerplant

Estonian: Harilik ženšenn, Ženšen

Finnish: Ginseng, Ginsengjuuri

French: Ginseng, Ginseng asiatique, Ginseng coréen, Racine de ginseng

German: Asiatischer Ginseng, Chinesischer Ginseng, Gin-Seng, Ginseng-Wurzel, Koreanischer Ginseng, Kraftwurz, Kraftwurzel

Hungarian: ginszeng, koreai ginszeng, Kínai ginseng, kinai koreai ginseng

Italian: Ginseng

Japanese: Chousen Ninjin, Ninjin, Otane Ninjin, Yakuyou Ninjin

Korean: In-Sam, San Sam

Norwegian: Asiatisk ginseng, Ekte ginseng Ginseng, Kinesisk ginseng, Koreansk ginseng

Polish: Żeń-szeń, Zen-, Żeń-szeń prawdziwy

Portuguese: Jinsão Da China

Russian: Zhen'shen', Zhen'shen' Obyknovennyi

Spanish: Ginseng, Ginseng Asiático, Ginseng Chino, Ginseng Coreano, Ginseng Rojo

Swedish: Ginseng

Thai: Som, Som Kao Li

Origin/Distribution

P. ginseng is indigenous to the mountainous forests of the northern temperate zone of Eastern Asia – Manchuria, northeastern China and Korea. It is widely cultivated in China, Korea and Japan.

Agroecology

Ginseng is a cool-temperate species, growing in partial or full shade of deciduous, moist forest. Wild population is scarce and the plant is mainly cultivated commercially in China and Korea. Commercially produced ginseng is either grown as undergrowth in shady forests or shaded by mats in the open in well-drained, moist, fertile soil.

Edible Plant Parts and Uses

The sliced roots of Chinese ginseng are eaten raw (in small quantities) and in salads or cooked with chicken in broth, porridge and soups. In Korea, a very popular and highly relished traditional chicken ginseng soup dish called *Samgyetang* is served in specialty restaurants all over Korea. The recipe comprises a whole young chicken stuffed with glutinous rice boiled in broth of Korean ginseng, dried Chinese jujubes, garlic and ginger. *Samgyetang* is traditionally served as a tonic in the summer for its supposed nutrients, which replaces those that are easily lost through excessive sweating and physical activity. Another popular dish is ginseng chicken noodles.

Botany

A small perennial herb, 30–80 cm high with fleshy, fusiform, aromatic, thick and branched roots with characteristic horizontal lines (Plates 1 and 2). The stem is cylindrical, smooth, green, often with a tinge of red, regularly divided at the top into three petioles, with a flower stalk in their centre. The petiole is cylindrical, smooth and swollen at the base. Leaves borne in whorls, 3–4, palmately compound; leaflets 5, long-petioled, obovate, 7–20 cm long, abruptly acuminate to caudate, margin serrate. Umbel solitary in the middle of leaf whorls. Flowers small, yellowish green, bisexual, in single terminal umbels; sepals 5 minute, petals 5 ovate, imbricate; stamens 5 with oblong anthers; ovary 2–3 celled, inferior; styles 2 reflexed and persistent. Fruit a drupe, red, globose, about 5 mm in diameter.

Plate 1 Fresh ginseng roots

Plate 2 Preserved ginseng roots

Nutritive/Medicinal Properties

Root Nutrient/Phytochemicals

Ginseng root was reported to contain ginseng saponins, ginseng oils and phytosterol, carbohydrates and sugars, organic acids, nitrogenous substances, amino acids and peptides, vitamins and minerals, certain enzymes (Hou 1977), saponins, polyphenols, polyacetylenes, alkaloids and polysaccharides (Jeon et al. 2011). Among these, ginseng saponins called ginsenosides or panaxosides, triterpenes of dammarane and oleanane structures, were proven to be the principal and most active constituents (Jeon et al. 2011; Park et al. 2005a).

Lin (1961) reported the following constituent of ginseng: sugars – glucose, arabinose, sucrose, rhamnose, sterols such as stigmasterol, β -sitosterol, high molecular weight fatty acids (panax acids) fatty acid esters and the triterpenoid genin oleanolic acid.

Free amino acids (mg/100 g) found in washed fresh ginseng roots were aspartic acid 78.05 mg, threonine 52.14 mg, serine 244.21 mg, glutamic acid 57.20 mg, proline 43.63 mg, glycine 172.20 mg, alanine 58.71 mg, methionine 45 mg, isoleucine 72.12 mg, leucine 54 mg, tyrosine 123.31 mg, phenylalanine 158.18 mg, β -alanine 113.87 mg, lysine 138.53 mg, histidine 30.09 mg, arginine 330.68 mg and total amino acids 4,770.42 mg (Lee et al. 2009c). After six repeated boiling and the addition of sugar to boiled ginseng roots (Jung Kwa process), crude saponin of Jung Kwa (JKG6) increased fourfold, while ginsenoside RF and RD contents increased 77- and 16-fold more than raw ginseng, respectively; other ginsenosides (RB₁, RB₂, RB₃, Rc, Re, Rg₁, Rg₂, Rg₃, Rh₁ and Rh₂) decreased. Concomitant with the number of boiling repeats, crude protein and total free amino acids decreased by 84.9 % and 94.7 % of raw ginseng in JKG but increased by 98.2 % and 78.9 % in JKGS (solution), respectively. The arginine content in the last boiled ginseng, JKG 6, decreased 49.18-fold, while γ -aminobutyric acid and two unknown

compounds not present in fresh ginseng were formed as intermediate products during the Jung Kwa heating process. The γ -aminobutyric content was 34.13 mg/100 g in JKG 6. The carbohydrate and ginsenoside profile of wild and cultivated ginseng root was reported as follows: soluble sugars 34.42, 26 mg/g; starch 14.38, 32.78 mg/g; polysaccharides 43.61, 51.22 mg/g; pectin 13.48, 10.61 mg/g; total ginsenosides 24.06, 15.08 mg/g; protopanaxatriol 8.36, 5.16 mg/g; and protopanaxadiol 15.69, 9.92 mg/g, respectively (Zhang et al. 2013a). Content (mg/g) of ginsenosides in wild and cultivated at year 6 growth stage was reported as follows: Rg₁ 3.61, 2 mg; Re 4.29, 2.82 mg; Rf 1.32, 0.55 mg; Rb₁ 6.14, 4.21 mg; Rc, 5.38, 4.01 mg; Rb₂ 4.40, 4.05 mg; and Rd 1.84, 1.88 mg, respectively.

Monosaccharide, D-fructose and D-glucose were identified, and the total amount of these monosaccharides in the dried ginseng root was 1.5 %; disaccharides were present in 3.3 % amount, and sucrose and maltose were separated as crystals (Takiura and Nagakawa 1963a). Four kinds of trisaccharide, A, B, C and D, were found in the aqueous digest solution of ginseng root (Takiura and Nakagawa 1963b). Trisaccharide A was identified as *O*- α -D-glucopyranosyl-(1 $\rightarrow$ 2)-*O*- β -D-fructofuranosyl-(1 $\rightarrow$ 2)- β -D-fructofuranoside and B as *O*- α -D-glucopyranosyl- (1 $\rightarrow$ 6)-*O*- α -D-GLUCOPYRANOSYL- (1 $\rightarrow$ 4)-*O*- α -D-glucopyranose. Trisaccharide C was found to be α -Maltulosyl- β -D-fructofuranoside (Takiura and Nakagawa 1963c).

Lin (1961) reported the presence of sugars glucose, arabinose, sucrose and rhamnose; sterols such as stigmasterol; β -sitosterol; high molecular weight fatty acids (panax acids); fatty acid esters; and the triterpenoid genin oleanolic acid. The following compounds were found in ginseng roots: fatty acid methyl esters, fatty acids, β -sitosterol, esters of β -sitosterol and fatty acids (palmitic and linoleic), 6-*O*-acyl derivatives of β -sitosterol glucoside and β -sitosterol glucoside and ginsenosides RG₁, Rf, Rc, RB₂, RB₁ and RO as main components and ginsenosides Rd, NG-R2 and Z-R1 as minor components (Malinovskaya et al. 1991). The following fatty acids (μ g/g) were found in ginseng: myristic acid 0.16 μ g,

pentadecanoic acid 0.47 µg, palmitic acid 13.93 µg, palmitoleic acid 0.71 µg, heptadecanoic acid 0.36 µg, stearic acid 1.41 µg, oleic acid 3.88 µg, linoleic acid 28.22 µg, α-linolenic acid 1.71 µg, arachidic acid 0.45 µg and eicosadienoic acid 0.52 µg (Zhang et al. 2013b). Nineteen fatty acids were identified in ginseng and the major components were unsaturated fatty acids such as 9,12-octadecadienoic acid and 9-octadecenoic acid (Yang et al. 2007). Twenty fatty acid compounds were isolated and identified from several ginseng varieties (Chen et al. 2010). The major components were (Z,Z)-9,12-octadecadienoic acid, hexadecanoic acid and (Z,Z,Z)-9,12,15-octadecatrienoic acid, but the content varied with varieties: (Z,Z)-9,12-octadecadienoic acid was 47.896 % in Damaya, 50.901 % in Ermaya, 50.254 % in Yuanbangyuanlu and 49.456 % in Changbo; hexadecanoic acid content was 12.370 % in Damaya, 12.535 % in Ermaya, 12.614 % in Yuanbangyuanlu and 11.983 % in Changbo; (Z,Z,Z)-9,12,15-octadecatrienoic acid content was 10.407 % in Damaya, 12.487 % in Ermaya, 12.026 % in Yuanbangyuanlu and 12.026 % in Changbo.

Studies found that most free amino acids were decreased significantly by steam treatment, with the greatest reduction observed in ginseng steamed at 120 °C (SG) (Cho et al. 2008). The total content of free amino acids, 17.9 mg/g in white ginseng (WG), was reduced to 12.2 mg/g in red ginseng (RG, ginseng steamed at 100 °C) and 2.79 mg/g in SG. As for arginine, the most predominant amino acid in ginseng, the content, 10.4 mg/g in WG, decreased significantly to 1.38 mg/g in SG. In particular, β-N-oxalyl-L-α,β-diaminopropionic acid (β-ODAP), a well-known neurotoxin, was reduced by 92.9 % in SG. In contrast, the level of Maillard reaction products (MRPs), powerful antioxidants, increased with steam treatment, indicating that the reduction of most amino acids was attributed to the extent of the Maillard reaction.

Phenolic Compounds/Metabolites

Six types of phenolic acids – *p*-hydroxybenzoic acid, vanillic acid, syringic acid, *p*-coumaric acid, ferulic acid and sinapic acid – were identified in ginseng adventitious roots irradiated

with red (630 nm) and blue (465 nm) LED light or fluorescent lamp (FL) light (Park et al. 2013c). The insoluble (bound form) phenolic acid levels were higher than the soluble (free and esterified forms) levels in all ginseng samples. The major portion of phenolic acids in ginseng roots consisted of ferulic, *p*-coumaric and *p*-hydroxybenzoic acids. Compared to white FL-irradiated ginseng roots, roots irradiated with two different LED lights had higher concentrations of total phenolic acids, which increased by 87 % in blue LED light-irradiated ginseng roots. A significant increase was presented only in the *p*-coumaric acid content in red LED light ginseng roots, while *p*-coumaric and ferulic acids were markedly increased in blue LED light-irradiated ginseng roots. Forty-six metabolites comprising 35 hydrophilic and 11 lipophilic metabolites were identified from ginseng adventitious root extracts irradiated with fluorescent lamp and red and blue LED lights. Hydrophilic compounds identified included pyruvic acid, lactic acid, glycolic acid, phosphoric acid, succinic acid, glyceric acid, fumaric acid, shikimic acid, citric acid, quinic acid, malic acid, ethanolamine, glycerol, inositol, 4-aminobutyric acid, alanine, valine, isoleucine, proline, serine, threonine, β -alanine, tryptophan, glycine, asparagine, glutamine, aspartic acid, methionine, glutamic acid, phenylalanine, pyroglutamic acid, xylose, fructose, galactose and sucrose; lipophilic metabolite compounds detected included hexadecanoic acid, *cis,cis*-9,12-octadecadienoic acid, *cis*-9-octadecadienoic acid, octadecanoic acid, eicosanoic acid, docosanoic acid, α -tocopherol, campesterol, stigmasterol, β -sitosterol and β -amyirin. LED light-irradiated ginseng roots had higher sucrose and lower amino acids compared to fluorescent lamp-irradiated ginseng roots. On alkaline hydrolysis, 13 lipophilic compounds comprising 6 policosanols (C20-ol (eicosanol), C21-ol (heneicosanol), C22-ol (docosanol), C23-ol (tricosanol), C24-ol (tetracosanol), C28-ol (octacosanol)), 5 phytosterols (campesterol, cholesterol, stigmasterol, β -sitosterol, β -amyirin) and two tocopherols (α -tocopherol, β -tocopherol) were identified in ginseng roots irradiated with different light emission spectra. The most notable findings were in the α -tocopherol and β -amyirin content, which was 2.54- and 1.94-

fold higher in blue LED light-irradiated ginseng roots compared to those in FL light-irradiated ginseng roots.

Total phenolic acids in white and red ginsengs were 27.2 and 26.8 mg/100 g, respectively (Jung et al. 2002). Seven free phenolic acids were identified and their total contents in white and red ginsengs were 4.70 and 4.14 mg/100 g, respectively. *trans*-Ferulic acid was the predominant free phenolic acid, representing 47.9 and 57.7 % of total free phenolic acids in white and red ginsengs, respectively. Esterified phenolic acids represented 71.9 and 77.1 % of total phenolic acids in white and red ginsengs, respectively. The most predominant esterified phenolic acids were *cis*-ferulic acid and *trans*-ferulic acid. Total insoluble-bound phenolic acid contents in white and red ginsengs were 2.93 and 1.99 mg/100 g, respectively. Ferulic acid (*cis* and *trans* isomers) were also the major insoluble-bound phenolic acids. Eight aromatic acids were found in white ginseng roots: salicylic acid 4.30 ppm, cinnamic acid 18.2 ppm, vanillic acid 4.22 ppm, gentisic acid trace, syringic acid 6.69 ppm, *p*-coumaric acid 13.3 ppm, ferulic acid 21.9 ppm and caffeic acid 24.3 ppm (Park et al. 1994). The phenolic compounds vanillic acid, caffeic acid, ferulic acid, *p*-coumaric acid, protocatechuic acid and maltol were identified in the ethyl acetate fraction of Korean red ginseng methanol extract (Wee et al. 2010). Ginseng was found to contain choline in 0.100.2 % weight of roots (Takatori et al. 1963).

Studies in a bioreactor found that CO₂ induced accumulation of total phenolics in a concentration- and duration-dependent manner in ginseng roots in suspension culture (Ali et al. 2005a). Total phenols, flavonoids and 1,1-diphenyl-2-picrylhydrazyl (DPPH) activity increased by 2.5 % CO₂ after 45 days compared to control in *P. ginseng* roots which indicated that phenolics compounds played an important role in protecting the plants from CO₂. Also high CO₂ progressively stimulated the activities of glucose 6 phosphate dehydrogenase (G6PDH), shikimate dehydrogenase (SKDH), phenylalanine ammonia lyase (PAL), cinnamyl alcohol dehydrogenase (CAD), caffeic acid (CA) peroxidase

and chlorogenic acid (CGA) peroxidase after 15, 30 and 45 days. Increased CO₂ levels resulted in increases in accumulation of total protein (45 %), nonprotein thiol (NPSH) (30 %) and cysteine contents (52 %) after 45 days compared to control, and increased activities of beta-glucosidase (GS) and polyphenol oxidase (PPO) in ginseng roots indicated that they played an important role in protecting the plants from CO₂. Ali et al. (2005b) also demonstrated that methyl jasmonate or salicylic acid treatments in bioreactor suspension culture caused an increase in the carbonyl and hydrogen peroxide (H₂O₂) contents, total phenolic, flavonoid, ascorbic acid, nonprotein thiol (NPSH) and cysteine contents and 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical reducing activity. The highest total phenolics (62 %), DPPH activity (40 %), flavonoids (88 %), ascorbic acid (55 %), NPSH (33 %) and cysteine (62 %) contents compared to control were obtained after 9 days in salicylic acid-treated roots. The activities of glucose 6-phosphate dehydrogenase, phenylalanine ammonia lyase and substrate-specific peroxidases (caffeic acid peroxidase, quercetin peroxidase and ferulic acid peroxidase) were higher in methyl jasmonate-treated roots than the salicylic acid-treated ones. Increased shikimate dehydrogenase, chlorogenic acid peroxidase and beta-glucosidase activities and proline content were observed in salicylic acid-treated roots than in methyl jasmonate-treated ones. Cinnamyl alcohol dehydrogenase activity remained unaffected by both methyl jasmonate and salicylic acid. These results strongly indicated that methyl jasmonate and salicylic acid induced the accumulation of phenolic compounds in ginseng root by altering the phenolic synthesis enzymes.

Ginseng Oil/Volatiles

Takahashi et al. (1961) reported the presence of β -sitosterol, β -sitosterol glucoside daucosterin, phytosterin, panaquilon, panaxsapogenol, panaxin, stearic acid, palmitic acid and linoleic acid in the essential oil of ginseng roots. The main constituents in *P. ginseng* essential oil were spathulenol (11.55 %) and 2-*epi*-(E)- β -caryophyllene (10.88 %) (Smiglielski et al. 2006). Forty-six compounds were found in ginseng volatile

oil, and the major compounds were 2,2'-methylene-bis[6-(1,1-dimethylethyl)-4-methylphenol (10.56 %), 1,2-benzenedicarboxylic acid diisooctyl ester (6.52 %), 7,11-dimethyl-3-methylene-1,6,10-dodecatriene (5.45 %) and 13-tetradecen-1-ol acetate (4.14 %) (Yang et al. 2007). Thirty-six terpenoids were tentatively identified in ginseng volatile oil (Qiu et al. 2008). It was found that the relative abundances of α -cadinol, α -bisabolol, thujopsene and *n*-hexadecanoic acid significantly increased with increase in age. A total of 47 volatile were identified in fresh, white and red ginseng (Abd El-Aty et al. 2008). Fresh ginseng was characterised by a high proportion of 3-acetyl-1-(3,4-dimethoxyphenyl)-5-ethyl-4,5-dihydro-7,8-dimethoxy-4-methylene-3H-2,3-benzodiazepine (64.24 %) and 23,24-dinor-3-oxolean-4,12-dien-28-oic acid (21.42 %); 2-furanmethanol (20.26 %) and 3-hydroxy-2-methyl-4H-pyran-4-one (17.95 %) were detected as the major components in white ginseng, while the main components of the red ginseng were found to be 1,2-benzenedicarboxylic acid dibutyl ester (16.27 %) and 2-furanmethanol (13.82 %). Main volatile compounds of ginseng species including *Panax ginseng* were sesquiterpenes, such as bicyclogermacrene, (*E*)- β -farnesene, β -panasinsene, calarene, α -humulene, β -elemene, etc. (Cho et al. 2012). In particular, α -selinene, α -terpinolene, β -bisabolene, β -phellandrene, β -sesquiphellandrene, zingiberene, germacrene D, limonene, α -gurjunene, (*E*)-caryophyllene, δ -cadinene, (*E*)- β -farnesene, α -humulene, bicyclogermacrene, longiborn-8-ene, β -neoclovene and (+)-spathulenol were mainly associated with the difference between *P. ginseng* and *P. notoginseng* versus *P. quinquefolius* species. In contrast, the discrimination between *P. ginseng* and *P. notoginseng* could be constructed by hexanal, 2-pyrrolidinone, (*E*)-2-heptenal, (*E*)-2-octenal, heptanal, isospathulenol, (*E,E*)-2,4-decadienal, 3-octen-2-one, benzaldehyde, 2-pentylfuran and (*E*)-2-nonenal.

Polysaccharides/Proteinaceous Compounds and Enzymes

Ginseng was found to have β -amylase (Yamasaki et al. 1989). The molecular weight of the enzyme was estimated to be 63

kDa, and it was of 512 amino acid residues. The content of neutral sugars was 8.5 %, and no amino sugar was detected. A superoxide dismutase (SOD) with the molecular weight of 31,079 was purified as a homodimer from *Panax ginseng* (Li et al. 2010a). Arginase was purified from ginseng roots (Hwang et al. 2001). Specific activities of the enzyme in sliced ginseng roots were increased by plant hormones such as GA₃, IAA, kinetin and putrescine, whereas the activities of the purified enzyme were unaffected by putrescine. Increases in arginase activities by these plant hormones could affect metabolism of polyamine intracellularly. Han et al. (2010) found that the expression of two squalene epoxidase genes *PgSQE1* and *PgSQE2* were regulated in a different manner and that *PgSQE1* will regulate ginsenoside biosynthesis, but not that of phytosterols in *P. ginseng*. Squalene epoxidase catalysed the first oxygenation step in phytosterol and triterpenoid saponin biosynthesis. RNA interferences of *PgSQE1* in transgenic *Panax ginseng* completely suppressed the *PgSQE1* transcription and resulted in the reduction of ginsenoside production but rather stimulated phytosterol accumulation. The following nucleosides and free bases of nucleic acids uridine, guanine, adenosine, adenine and uracil were found in white ginseng roots (Hiyama et al. 1978). A metal binding tetradecapeptide was isolated from ginseng root (Kajiwara et al. 1996). The ginseng tetrapeptide H-L-Val-γ-D-Glu-D-Arg-Gly-OH was found to have a rigid backbone based on three intramolecular hydrogen bonds between D-Arg NH and L-VAL CO, between Gly NH and D-Glu CO and between Gly NH and Gly CO (Ishizu et al. 1998). A novel tetradecapeptide was purified from ginseng polypeptides, and its structure had the amino acid sequence of Lys-Ser-Leu-Thr-Leu-Thr-Ser-Ser-Leu-Ser-Tyr-Thr-Asp-Ser (Luo et al. 2013).

From the roots of the Chinese ginseng, a protein designated panaxagin with ribonuclease activity was isolated (Ng and Wang 2001). The purified protein was composed of two identical subunits, each with a molecular weight of 26 kDa. Its N-terminal amino acid sequence exhibited sites of similarity with the sequences of plant ribosome-inactivating proteins and fungal ribonucleases. A novel glycolipoprotein

named gintonin was isolated from ginseng (Pyo et al. 2011). Gintonin existed in at least six different forms. The native molecular weight of gintonin was about 67 kDa, but its apparent molecular weight was about 13 kDa, indicating that gintonin might be a pentamer. Gintonin was rich in hydrophobic amino acids with glucose and glucosamine as its main carbohydrates and with lipid components linoleic, palmitic, oleic and stearic acids. Gintonin was found to be novel lysophosphatidic acids (LPAs)-ginseng protein complex (Shin et al. 2012) and lysophosphatidic acid (LPA) receptor-activating ligand (Hwang et al. 2012a, b).

A hypoglycaemic principle, panaxan B, obtained from ginseng roots, was shown to be a peptidoglycan with M_r of about 1,800,000 and mainly composed of α -1 $\rightarrow$ 6 linked D-glucopyranose residues with branching at the C-3 position, the ratio of terminals, branching positions and intermediate units being about 1:1:1.8 (Tomoda et al. 1985). Four glycans, panaxans I, J, K and L, were isolated from ginseng roots (Oshima et al. 1985). Five glycans, panaxans Q, R, S, T and U, were isolated from ginseng roots (Konno et al. 1985). Two lignans named gomisin N and gomisin were isolated from hexane-soluble fraction of Korean red ginseng (Huh et al. 1990). Chemical composition of ginseng polysaccharide fractions were 85.0 % carbohydrate and 15.0 % protein for the neutral fraction and 28.4 % carbohydrate, 10.0 % protein and 29.0 % uronic acid for the acidic fraction (Kim et al. 1990). Kim et al. (1999a) isolated antithrombin active heteropolysaccharide with molecular mass of 177 kDa from red ginseng. It contained uronic acid moiety (40.2 %), sulfate group (9.2 %) and protein (1.5 %) in addition to neutral sugar of rhamnose, mannose, galactose, arabinose, glucose, fucose and xylose in a molar ratio of 1.00:0.88:0.86:0.78:0.70:0.33:0.22. First- and third-grade 6-year-old Korean ginseng starches showed typical biphasic differential scanning calorimetry (DSC) endotherm, while second-grade ginseng starch revealed monophasic DSC endotherm with relatively narrow transition temperature (Koo et al. 2005). First- and third-grade ginseng starches showed

higher degree of retrogradation and faster retrogradation rate than second-grade ginseng starch.

Water-soluble polysaccharides isolated from ginseng roots were completely fractionated into two neutral fractions (WGPN and WGPA-N) and six acidic fractions (WGPA-1-RG, WGPA-2-RG, WGPA-1-HG, WGPA-2-HG, WGPA-3-HG and WGPA-4-HG) (Zhang et al. 2009). WGPN was a starchlike glucan; WGPA-N was a mixture of starchlike glucan and arabinogalactan; and WGPA-1-RG and WGPA-2-RG were composed of major neutral sugars and minor acidic sugars that belong to the type-I rhamnogalacturonan (RG-I)-rich pectins, while fractions WGPA-1-HG to WGPA-4-HG were mainly composed of galacturonic acid (GalA, 62.4–92.1 %) and have been identified to be homogalacturonan (HG)-rich pectins with different degrees of methyl-esterification, ranging from 0 to 30 %. PG-F2, an acidic polysaccharide with high uronic acid content, was purified from the root of *Panax ginseng* (Lee et al. 2004a, 2006a). PG-F2 was found to be a pectin-type polysaccharide with a mean molecular weight of 1.2×10^4 Da and consists primarily of galacturonic and glucuronic acids along with rhamnose, arabinose and galactose as minor components.

Five rhamnogalacturonan I (RG-I) domains, RG-I-1, RG-I-2, RG-I-3A, RG-I-3B and RG-I-4, were isolated from ginseng pectin by endo-polygalacturonase hydrolysis (Yu et al. 2010). The five domains all contained galacturonic acid, rhamnose, galactose and arabinose as main components, and their rhamnose/galacturonic acid was from 0.26 to 0.64, among the range of RG-I. The molecular weights of RG-I-1 (5 kDa), RG-I-2 (4 kDa) and RG-I-3B (6 kDa) were smaller than those of RG-I-3A (45 kDa) and RG-I-4 (60 kDa). RG-I-2 and RG-I-3B contained RG-I domains linked with highly methyl-esterified and acetylated homogalacturonan domains and the side chains probably belonging to type I and type II arabinogalactans, while RG-I-3A and RG-I-4 may have the side chains of type I arabinogalactans. 4-*O*-methyl- β -D-glucuronic acid residues were present at nonreducing terminals of RG-I-2.

Two pectic polysaccharides, named as GP50-dHR (56.0 kDa) and GP50-eHR (77.0 kDa), were purified from hot water

extract of ginseng (Baek et al. 2010). Both polysaccharides had common structural features of homogalacturonan backbone with hairy regions of rhamnogalacturonan type I. Arabinose-rich side chains with abundant branch points were unique in GP50-eHR and may contribute to a greater antirotavirus effect of GP50-eHR than GP50-dHR. The acidic polysaccharide portion of the plant (WGPA) was found to contain arabinogalactan-, type-I rhamnogalacturonan (RG-I)- and homogalacturonan (HG)-rich pectins (Wang et al. 2010a). The ginseng pectic fraction WGPA-2-RG was identified to have rhamnogalacturonan-I structure (Zhang et al. 2012). WGPA-2-RG had a small backbone and long arabinogalactan-II side chains. Most of the galactose were close to molecular core and all arabinose were on the molecular surface. Arabinose residues were important to lymphocyte proliferation and NO production. Sugar composition of polysaccharide fractions from ginseng was as follows: for WGPA fraction 34.4 % uronic acid, 18.5 % glucose (Glu), 15.5 % arabinose, 18 % galactose (Gal), 44.2 % Gal A, 2.5 % rhamnose and Glu A 1.3 % (Zhang et al. 2009; Wang et al. 2014a); for WGPA-A fraction 43.5 % uronic acid, 3.7 % glucose, 22.7 % arabinose, 13.3 % galactose, 51.7 % Gal A, 6 % rhamnose, mannose 0.5 % and Glu A 2.2 %; for WGPA-N fraction 0 % uronic acid, 66.3 % glucose, 15.7 % arabinose and 18 % galactose (Wang et al. 2014a). Cell-cultured ginseng polysaccharides (CCGPS) consisted of glucose, rhamnose, arabinose, xylose, mannose and galacturonic acid (Ding et al. 1993). Comparing with GPS (ginseng polysaccharide), the percentage of rhamnose, arabinose, xylose and galactose were higher than that of GPS, whereas mannose and glucose were less. The starch was 50–50 % in the cultivated GPS. However, no starch was found in the CCGPS in which two monosomes of water-soluble polysaccharides PC1 and PC2 with molecular weight 122,000 and 25,000 D, respectively, were obtained. A major protein GMP, composed of two subunits of approximately 28 kDa, was isolated from ginseng root (Yoon et al. 2002). It was found that carbohydrates were bound non-covalently to GMP whose amino acid composition analysis showed high amounts of acidic amino acids.

An acidic polysaccharide ginsan, with a molecular weight of 150,000, devoid of lectin properties, was purified from *Panax ginseng* (Lee et al. 1997). Another acidic polysaccharide ginsenan S-IIA was isolated from ginseng root (Sonoda et al. 1998). Two neutral polysaccharide fractions named GPII and GPIII, with a molecular weight of 3×10^5 and 4×10^5 , respectively, and comprising mainly glucose, were obtained from boiled ginseng extracts (Luo and Fang 2008). GP II was composed of 60.06 % (1 $\rightarrow$)-glycosidic linkage or (1 $\rightarrow$ 6)-glycosidic linkage and 39.94 % (1 $\rightarrow$ 3)-glycosidic linkages, and GPIII was composed of 16.23 % (1 $\rightarrow$)-glycosidic linkage or (1 $\rightarrow$ 6)-glycosidic linkage, 25.98 % (1 $\rightarrow$ 2)-glycosidic linkages and 57.79 % (1 $\rightarrow$ 3)-glycosidic linkages. Polysaccharides PG-F2, a pectin-type polysaccharide, and PG-HMW, an arabinogalactan, were isolated from *Panax ginseng* (Lee et al. 2009b). Ginsan, an acidic polysaccharide, was extracted from ginseng roots (Ivanova et al. 2006; Shim et al. 2010; Hwang et al 2011; Park et al. 2011). The oligosaccharides were identified as maltose, maltotriose, maltotetraose, maltopentaose, maltohexaose and maltoheptaose from 30 % ethanol elution of ginseng roots (Wang et al. 2010b). A homogeneous polysaccharide (PGPW1) from ginseng root with molecular weight 3.5×10^5 Da was found to contain glucose, galactose, mannose and arabinose in the molar ratio of 3.3:1.2:0.5:1.1 (Li et al. 2012a). Water-soluble ginseng oligosaccharides (designated as WGOS) with a degree of polymerisation ranging from 2 to 10 were obtained from warm water extract of ginseng roots and fractionated into five purified fractions (i.e. WGOS-0, WGOS-1, WGOS-2, WGOS-3 and WGOS-4) (Wan et al. 2012). α -Glc-(1 $\rightarrow$ 6)- α -Glc, α -Glc-(1 $\rightarrow$ 6)- α -Glc-(1 $\rightarrow$ 4)- α -Glc, α -Glc-(1 $\rightarrow$ 6)- α -Glc-(1 $\rightarrow$ 6)- α -Glc-(1 $\rightarrow$ 4)- α -Glc and other six maltooligosaccharides (i.e. maltopentaose, maltohexaose, maltoheptaose, maltooctase, maltononaose and maltodecaose) were detected in ginseng. Four glycoproteins were isolated from ginseng root (Wang et al. 2013b). Results of studies by Hu et al. (2013) found that the recombinant dammarenediol synthase (DS) protein could increase the production of dammarenediol and the expression of DS played a vital role in the biosynthesis of ginsenosides in *P. ginseng*.

Ginseng root polysaccharide (PGP2a) an acidic protein–polysaccharide, with molecular weight of 3.2×10^4 Da, was found to consist of galactose, arabinose, glucose and galacturonic acid in the molar ratio of 3.7:1.6:0.5:5.4, respectively (Li et al. 2014).

Saponins

To date, approximately 70 kinds of ginsenosides had been isolated from *P. ginseng* (Cho et al. 2013a). Most of them were saponins of protopanaxadiol (diol, PPD) and protopanaxatriol (triol, PPT), which were aglycones of dammarane-type triterpenoids. Only a few ginsenosides, such as ginsenoside Ro, had oleanolic acid as the aglycone. Ginsenosides were primarily classified into two groups, the 20(*S*)-protopanaxadiol (PD) and the 20(*S*)-protopanaxatriol (PT) (Popovich et al. 2012). These two types of ginsenoside comprised the bulk of the reported ginsenosides. The PD type included commonly reported ginsenosides Rb₁, Rb₂, Rc and Rd and rarer types known as Rg₃ and Rh₂, while the PT type includes Re, Rf, Rg₁, Rg₂ and Rh₁. The third type of ginsenoside had been detected in ginseng and had been referred to as oleanane type.

In *Panax ginseng*, both ginsenosides and phytosterols were suggested to be derived from the precursor 2,3-oxidosqualene (Haralampidis et al. 2002; Lee et al. 2004c; Han et al. 2010). Triterpenoid saponins were reported to be synthesised via the isoprenoid pathway by cyclisation of 2,3-oxidosqualene to give primarily oleanane (beta-amyrin) or dammarane triterpenoid skeletons (Haralampidis et al. 2002). Lee et al. (2004c) demonstrated that squalene synthase (PgSS1) was a key regulatory enzyme not only for phytosterol but also for triterpene biosynthesis and overexpression of *PgSSI* conferred the hyperproduction of triterpene saponins to *P. ginseng*. The enzymes cycloartenol synthase (CS) and dammarenediol synthase (DS) were responsible for ginsenoside and phytosterol biosynthesis, respectively (Liang et al. 2009). They found that antisense inhibition of cycloartenol synthase gene following suppression in transgenic ginseng hairy roots resulted in decreased phytosterol levels and enhanced

ginsenoside levels. Earlier Kushiro et al. (1997) reported that (RS)-[3-3H]-2,3-oxidosqualene was converted into (20S)-dammarenediol and not to (20R)-dammarenediol by a microsomal fraction prepared from *P. ginseng* hairy root (Kushiro et al. 1997).

A compound named panaquilon was extracted from ginseng root on hydrolysis with concentrated sulfuric acid to yield panacone (Garriques 1854). The saponin fraction of ginseng extract on acid hydrolysis yielded panaxsapogenol (Kondo and Tanaka 1915; Kondo and Yamaguchi 1918; Kondo and Amano 1920). Yonekawa (1926) isolated a glycoside called ginsenin, and Kotake (1930) isolated a glycoside called panaxin which on acid hydrolysis gave a prosapogenin α -panaxin which on further acid hydrolysis afforded glucose and a chlorinated aglucone (Hou 1977). Panaxatriol, a genin of ginsenoside Rg₁, was isolated in high yield from ginseng callus (Furuya et al. 1970).

Eight saponins and small amounts of panaxadiol, panaxatriol, daucosterol, mannitol, sucrose and glucose were isolated from the ethanol-insoluble aqueous extract of ginseng (Kaku et al. 1975). A prosapogenin and a sapogenin (panaxadiol) C₃₀H₅₂O₃, m.p. 250°, were isolated from the roots of *P. ginseng* (Fujita et al. 1962). The genuine sapogenin of Rg₁ was found to be 20S-protopanaxatriol (=6 α -hydroxy-20S-protopanaxatriol) (Iida et al. 1968). On hydrolysis with dilute mineral acid, ginseng saponins ginsenosides Rb₁, Rb₂, Rb₃, Rc and Rd yielded panaxadiol, and ginsenosides Re, Rf, Rg₁ and Rg₂ and 20-glucoginsenoside Rf afforded panaxatriol (Sakamoto et al. 1975).

A new panaxadiol, neopanaxadiol, was obtained from the acid hydrolysate of the total ginsenosides of *Panax ginseng*, and its structure was elucidated to be dammar-(E)-20(22)-ene-3 β ,12 β ,25-triol (Tao et al. 2009). A comparative study suggested that panaquilon (Garriques 1854), panaxin (Kotake 1930) and ginsenin (Yonekawa 1926) would be similar saponins, while panacon (Garriques 1854) and α -panaxin (Kotake 1930) would be identical with their prosapogenin, m.p. 330°C. The active principles of *Panax ginseng* were not

panaquilon and panax acid as previously considered (Yamada 1955). Elyakov et al. (1962, 1965a) isolated from ginseng root methanolic extracts a series of sugar-linked compounds called panaxosides A and B in 1962 and panaxosides C, D, E and F in 1964 (Elyakov et al. 1964, 1965b; Uvarova et al. 1965). When panaxosides D, E and F were hydrolysed, panaxadiol was formed as the main product of the decomposition of the genins, and hydrolysis of saponin glycosides panaxosides A, B and C yielded panaxatriol. Panaxosides D and F were pentaglucoside and hexaglucoside, respectively (Uvarova et al. 1965). Panaxoside E contained one arabinose and four glucose residues. Among the decomposition products of the genin obtained in the acid hydrolysis of panaxosides D, E and F, panaxadiol and panaxagenin B were identified. Panaxoside C was found to be a tetroside with glucose and rhamnose in a ratio of 3:1 in the carbohydrate moiety and panaxoside B to be trioside with two carbohydrate side chains with glucose fragments connected by a 1→2 bond (Uvarova et al. 1970). The methylation of panaxoside C afforded a hydrolysate containing two terminal methylated monosaccharides: 2, 3, 4, 6-tetra-*O*-methyl-*D*-glucose and 2, 3,4-tri-*O*-methyl-*L*-rhamnose and also 3,4, 6-tri-*O*-methyl-*D*-glucose. The extract of a ginseng suspension cell culture contained as the main components β-sitosterol, β-sitosterol β-*D*-glucoside and an oleanolic acid glucoside (Uvarova et al. 1987). A feebly polar fraction of the crude glycosidic fraction of the methanol ginseng extract afforded a mixture of β-sitosterol and palmitoyl- and linoleoyl-β-*D*-glucosides in addition to the compounds isolated earlier (Uvarova et al. 1987). Thus, a cell culture of ginseng (strain BIO-2) produced, in addition to substances isolated previously, 6-*O*-acyl derivatives of β-sitosterol β-*D*-glucoside.

A sapogenin named panaxadiol was isolated from ginseng root (Shibata et al. 1962). panaxadiol C₃₀H₅₂O₃ was determined to be tetracyclic triterpene of dammarane series having hydroxyls at the 3- and 12-positions and trimethyltetrahydropyrane ring at C₍₁₇₎ (Shibata et al. 1963a, b). Prosapogenin was obtained from ginsenosides RB₁, Rb₂ and Rc by partial hydrolysis with hot aqueous acetic acid

(Shibata et al. 1966a). Dilute acid hydrolysis of ginsenosides Rb₁, Rb₂ and Rc yielded protopanaxadiol and panaxadiol (Shibata et al. 1966b). Protopanaxadiol and panaxadiol from ginseng were found to have a C/D *trans*-17 α -H structure, and dihydro protopanaxadiol was found to be correlated stereochemically to dammaranediol-I (Tanaka et al. 1966). The saponins ginsenosides Ro, Rb₁, Rb₂, Rc and Rd were isolated from ginseng roots (Sanada et al. 1974a). The structures of ginseng root ginsenoside Ro was identical with chikusetsusaponin V, isolated from *P. japonicum*, while ginsenoside Rb₁ was identical with saponin-D isolated from *P. pseudoginseng* subsp. *himalaicus* var. *angustifolius*. The structure of Rb₁ was established as 20*S*-protopanaxadiol-3-[*O*- β -D-GLUCOPYRANOSYL(1 $\rightarrow$ 2)- β -D-glucopyranoside]-20-[*O*- β -glucopyranosyl(1 $\rightarrow$ 6)- β -D-glucopyranoside]. The structures of ginsenosides Rb₂, Rc and Rd were established respectively as 20*S*-protopanaxadiol-3-[*O*- β -D-GLUCOPYRANOSYL(1 $\rightarrow$ 2)- β -D-glucopyranoside]-20-[*O*- α -L-arabinopyranosyl(1 $\rightarrow$ 6)- β -D-glucopyranoside]; 20*S*-protopanaxadiol-3-[*O*- β -D-GLUCOPYRANOSYL(1 $\rightarrow$ 2)- β -D-glucopyranoside]-20-[*O*- α -L-arabinofuranosyl(1 $\rightarrow$ 6)- β -D-glucopyranoside]; and 20*S*-protopanaxadiol-3-[*O*- β -D-GLUCOPYRANOSYL(1 $\rightarrow$ 2)- β -D-glucopyranoside]-20-[*O*- β -D-glucopyranoside]. The structures of ginsenosides Re, Rf and Rg₂ were elucidated as 20*S*-protopanaxatriol-6-[*O*- α -L-RHAMNOPYRANOSYL(1 $\rightarrow$ 2)- β -D-glucopyranoside]-20-*O*- β -D-glucopyranoside; 20*S*-protopanaxatriol-6-*O*- β -D-glucopyranosyl(1 $\rightarrow$ 2)- β -D-glucopyranoside; and 20*S*-protopanaxatriol-6-*O*- α -L-rhamnopyranosyl(1 $\rightarrow$ 2)- β -D-glucopyranoside, respectively (Sanada et al. 1974b).

Crude hesperidinase hydrolysed ginsenoside Rg₁ to give its genuine sapogenin, 20(*S*)-proto-panaxatriol, and glucose in almost quantitative yield (Kohda and Tanaka 1975), whereas a mixture of ginsenosides Rb₁, Rb₂ and Rc gave compound K (=20-*O*- β -glucosyl-20(*S*)-protopanaxadiol) as a main product with this crude enzyme preparation. The structures of ginseng root ginsenoside Rb₃ and 20-glucoginsenoside Rf were established to be 20*S*-protopanaxadiol-3-[*O*- β -D-

GLUCOPYRANOSYL (1→2)-β-D-lucopyranoside]-20-[*O*-β-D-xylopyranosyl (1→6)-β-D-glucopyranoside] and 20*S*-protopanaxatriol-6-[*O*-β-D-glucopyranosyl (1→2)-β-D-glucopyranoside]-20-*O*-β-D-glucopyranoside, respectively (Sanada and Shoji 1978). A saponin named ginsenoside Rh₁ with the structure established as 6-*O*-β-D-glucopyranoside of 20 (*S*)-protopanaxatriol was isolated from ginseng root (Yahara et al. 1979). A ginsenoside Rg₂ was isolated from ginseng root (Kaku and Kawashima 1980). Two new dammarane saponins, named ginsenoside Ra₁ and ginsenoside Ra₂, were isolated from ginseng roots and their structures established as 20(*S*)-protopanaxadiol 3-*O*-β-D-glucopyranosyl-(1→2)-β-D-glucopyranoside-20-*O*-β-D-XYLOPYRANOSYL (1→4)-α-L-arabinopyranosyl (1→6)-β-D-glucopyranoside and 20 (*S*)-protopanaxadiol 3-*O*-β-D-glucopyranosyl (1→2)-β-D-glucopyranoside-20-*O*-β-D-XYLOPYRANOSYL (1→2)-α-L-arabinofuranosyl (1→6)-β-D-glucopyranoside, respectively (Besso et al. 1982). The presence of ginsenoside Ra in ginseng root was demonstrated and shown to be a mixture of more than two saponins (Koizumi et al. 1982). Among them, ginsenoside Ra₁ was isolated and its structure was as 20 (*S*)-protopanaxadiol 3-*O*-β-D-glucopyranosyl (1→2)-β-D-glucopyranosido-20-*O*-β-D-XYLOPYRANOSYL (1→4)-α-L-arabinopyranosyl (1→6)-β-D-glucopyranoside. Besides compound K (8), three prosapogenins – 20 (*S*)-protopanaxadiol 3-*O*-β-D-glucopyranosido-20-*O*-β-D-glucopyranoside (7); 20 (*S*)-protopanaxadiol 3-*O*-β-D-glucopyranosido-20-*O*-β-D-xylopyranosyl (1→4)-α-L-arabinopyranosyl (1→6)-β-D-glucopyranoside (9); and 20 (*S*)-protopanaxadiol 20-*O*-β-D-xylopyranosyl (1→4)-α-L-arabinopyranosyl (1→6)-β-D-glucopyranoside (10) – were obtained in the course of enzymatic hydrolysis of ginsenoside Ra₁. Further, 20 (*S*)-protopanaxadiol 3-*O*-β-D-glucopyranosido-20-*O*-α-L-arabinopyranosyl (1→6)-β-D-glucopyranoside (6), 7 and 8 were obtained by enzymatic hydrolysis of ginsenoside Rb₂. From red ginseng, all of the known saponins of white ginseng, namely, ginsenosides R0 (chikusetsusaponin V), G-Ra1, G Ra2, Rb1, Rb2, Rb3, Rc, Rd, Re, Rf, Rg1, Rg2, Rg3, Rh1, 20-gluco-ginsenoside Rh2 were

isolated in yields similar to those obtained from white ginseng (Kasai et al. 1983). Two additional minor saponins, notoginsenoside R₁ (the saponin of *Panax notoginseng* roots) and quinquenoside R₁ (the saponin of *P. quinquefolium* roots), were also isolated and identified. Besides these known saponins, two new minor saponins named ginsenosides Rs₁ and Rs₂ were also isolated and established to be monoacetates at the 6-hydroxyl group of the terminal glucosyl moiety of the sophorosyl unit of ginsenosides Rb₂ and Rc, respectively. A new dammarane saponin named ginsenoside Ra₃ was isolated from both white and red Ginseng with yields of 0.005 %, and its structure was established to be (20*S*)-protopanaxadiol 3-*O*-(β-D-glucopyranosyl (1→2)-β-D-glucopyranosido)-20-*O*-β-D-xylopyranosyl(1→3)-β-D-glucopyranosyl (1→6)-β-D-glucopyranoside (Matsuura et al. 1984b). Further, notoginsenoside R₄, previously isolated from sanchi ginseng *Panax notoginseng* roots, was also isolated from red ginseng with a yield of 0.002 %. Four new malonylated dammarane-type triterpene oligosaccharides named malonyl-ginsenosides Rb₁, Rb₂, Rc and Rd were isolated from ginseng roots (Kitagawa et al. 1983).

Ten saponins were isolated from Chinese red ginseng: 20(*R*)-ginsenoside Rh₁, ginsenoside Rg₃, 20(*R*) ginsenoside Rg₂, 20(*R*)protopanaxatriol, ginsenoside Rg₁, ginsenoside Re, ginsenoside Rd, ginsenoside Rc, ginsenoside Rb₂ and ginsenoside Rb₁ (Xu et al. 1986). Fresh ginseng root was found to contain malonyl-ginsenosides Rb₁, Rb₂, Rc and Rd and ginsenosides Rd, Re, Rf, Rg₁ and Rg₂, palmitic acid, linoleic acid, panaxynol, panaxydol, 1-*O*-β-D-GALACTOPYRANOSYL-D-glycerol and steryl glucoside fatty acid ester (Kitagawa et al. 1987). Red ginseng roots were found to contain ginsenoside Rg₂, 20(*R*)-ginsenoside Rg₂; 20(*s*)-ginsenoside Rg₈; ginsenoside Rg₃; ginsenoside Rh₁; 20(*R*)-ginsenoside Rh₁; ginsenoside Rh₂; ginsenosides Rd, Re, Rf, Rg₁, Ro, Rb₁, Rb₂ and Rc; palmitic acid; linoleic acid; panaxynol; panaxydol; heptadec-1-ene-4,6-diyne-3,9-diol; panaxytriol and -*O*-β-D-galactopyranosyl-D-glycerol; and

steryl glucoside fatty acid ester. White ginseng root was found to contain ginsenosides Ro, RB₁, Rb₂, Rc, Rd, Re, Rf, Rg₁ and Rg₂; malonyl-ginsenosides Rb₁, Rb₂, Rc and Rd; and palmitic acid, linoleic acid, panaxynol, panaxydol, steryl glucoside and fatty acid ester (lesser amounts).

Neutral saponins ginsenosides Rb₁, Rb₂, Rc, Rd, Re, Rf and RG₁ and acidic manolates of the dammarane saponins malonyl-ginsenosides Rb₁, Rb₂ and Rd and ginsenoside Ro which was identical with chikusetsusaponin V were found in ginseng rhizomes and roots (Yamaguchi et al. 1988). Four malonylated dammarane-type triterpene oligoglycosides, named malonyl-ginsenosides Rb₁, Rb₂, Rc and Rd, were isolated from the water-soluble portion of the dried ginseng root (Kitagawa et al. 1989). Their structures were elucidated respectively as 3-*O*-[6-*O*-malonyl-β-D-glucopyranosyl(1→2)-β-D-glucopyranosyl]-20-*O*-[β-D-glucopyranosyl(1→6)-β-D-glucopyranosyl]-20(*S*)-protopanaxadiol; 3-*O*-[6-*O*-malonyl-β-D-glucopyranosyl(1→2)-β-D-glucopyranosyl]-20-*O*-[α-L-arabinopyranosyl(1→6)-β-D-glucopyranosyl]-20(*S*)-protopanaxadiol; 3-*O*-[6-*O*-malonyl-β-D-glucopyranosyl(1→2)-β-D-glucopyranosyl]-20-*O*-[α-L-arabinofuranosyl(1→6)-β-D-glucopyranosyl]-20(*S*)-protopanaxadiol; and 3-*O*-[6-*O*-malonyl-β-D-glucopyranosyl(1→2)-β-D-glucopyranosyl]-20-*O*-[β-D-glucopyranosyl]-20(*S*)-protopanaxadiol.

More than 25 dammarane-type saponins had been identified as the characteristic principles of white and red ginseng (Shibata 2001). White ginseng was found to contain Rb₁, Rb₂, Rc, Rd, Rg₃ 20(*S*) protopanaxadiol-type ginsenosides; Re, Rf, Rg₁, Rg₂, Rh₁ 20(*S*) protopanaxatriol-type ginsenosides; and Ro oleanane-type ginsenoside. Red ginseng was found to contain 20(*S*) protopanaxadiol-type ginsenosides: Rb₁, Rb₂, Rc, Rd, Rg₃ (20*R*), Rg₃ (20*S*), Rh₂; 20(*S*) protopanaxatriol-type ginsenosides: Re, Rf, Rg₁, Rg₂ (20*R*), Rg₂ (20*S*), Rh₁ (20*R*), Rh₁ (20*S*); and oleanane-type ginsenoside Ro. Three new ginsenosides named ginsenosides Rh₁₀, Rg₁₁ and 12-*O*-glucoginsenoside Rh₄ were isolated from

heat-processed ginseng roots, and their respective structures were determined to be 3 β ,12 β ,25-trihydroxydammar-20E(22)-ene-3-*O*- β -D-glucopyranoside; 3 β ,12 β ,23-trihydroxy-24,25-epoxydammar-20E(22)-ene-3-*O*- β -D-glucopyranosyl(1 $\rightarrow$ 2)- β -D-glucopyranoside; and 3 β ,6 β ,12 β -trihydroxydammar-20E(22),24-diene-6-*O*- β -D-glucopyranosyl-12-*O*- β -D-glucopyranoside (Cho et al. 2013a).

Four chemical constituents were isolated from fresh ginseng root cultivated in China, and three of them were elucidated as malonyl-ginsenosides Rb1, Rb2 and Rd (Wang et al. 1993). Two new minor dammarane saponins named koryoginsenosides R₁ and R₂ were isolated from ginseng roots, along with 14 known saponins (Kim et al. 1995a). The structures of the new saponins were elucidated as 6-*O*-[*trans* butenoyl-(1 $\rightarrow$ 6)- β -D-glucopyranosyl]-20-*O*- β -D-glucopyranosyl dammar-24-en-3 β ,6 α ,12 β ,20(*S*)-tetrol and 3-*O*-[β -D-glucopyranosyl-(1 $\rightarrow$ 2)- β -D-glucopyranosyl]-20-*O*-[β -D-glucopyranosyl-(1 $\rightarrow$ 6)- β -D-glucopyranosyl] dammar-22-en-3 β ,12 β ,20(*S*),-25-tetrol, respectively. A genuine dammarane glycoside, named ginsenoside Rg₅, was isolated from the methanol extract of Korean red ginseng (Kim et al. 1996). The chemical structure of ginsenoside Rg₅ was determined as 3-*O*-[β -D-glucopyranosyl (1 $\rightarrow$ 2)- β -D-glucopyranosyl] dammar-20(22),24-diene-3 β ,12 β -diol. A genuine glycoside, named ginsenoside Rh₄, was isolated from Korean red ginseng, and its chemical structure was established to be 6-*O*- β -D-glucopyranosyldammar-20(22),24-diene-3 β ,6 α ,12 β -triol (Baek et al. 1996). A genuine dammarane glycoside, (20*E*)-ginsenoside F₄ was isolated from Korean red ginseng (Ryu et al. 1996). A new dammarane glycoside, named ginsenoside Rg₆, was isolated from the Korean red ginseng (Ryu et al. 1997). Its chemical structure was established to be 3 β ,6 α ,12 β -trihydroxydammar-20(21),24-diene-6-*O*- α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)- β -D-glucopyranoside. Four new dammarane glycosides named ginsenosides Rg₅, Rh₄, Rs₃ and Rf₂ were isolated from Korean red ginseng, and their chemical structures were elucidated as 3-*O*-[β -D-glucopyranosyl (1 $\rightarrow$ 2)- β -D-glucopyranosyl]dammar-20(22),24-diene-3 β ,12 β -diol

(ginsenoside Rg₅), 6-*O*-β-D -glucopyranosyl-dammar-20(22), 24-diene-3β, 6α,12β-triol (ginsenoside Rh₄), 3-*O*-[6''-*O*-acetyl-β-D-glucopyranosyl(1→2)-β-D-glucopyranosyl] 20(*S*)-protopanax adiol(ginsenoside Rs₃) and 6-*O*-[α-L-rhamnopyranosyl(1→2)-β-D-glucopyranosyl]dammarane-3β,6α,12β,20(*R*),25-pentol (ginsenoside Rf₂) (Park et al. 1998a). Ginsenoside Rs₄ (an acetylated analogue of ginsenoside Rg₅), a new ginseng saponin, was isolated from *Panax ginseng* (Kim et al. 1999e). The ginsenoside-β-glucosidase that hydrolyses the β-(1→2)-glucoside of the ginsenoside Rg₃ sugar moiety to ginsenoside Rh₂ was isolated from ginseng root (Zhang et al. 2001). It had a molecular weight of 59 kDa. Ca²⁺ ion had a positive effect on ginsenoside-β-glucosidase, while Cu²⁺ had a negative effect on it. Rg₃ was found to be a 20(*S*)-ginsenoside Rh₂, i.e. a 3-*O*-(β-D-glucopyranosyl)-dammar-24-en-3β,12β,20(*S*)-triol. Polyacetyleneginsenoside Ro, a new oleanolic acid-derived saponin, was isolated along with the known ginsenosides Ro methyl ester, ginsenoside Rf, ginsenoside Rg₁, ginsenoside Rg₂ and ginger glycolipid B from ginseng roots (Zhang et al. 2002). Four new acetylated ginsenosides named ginsenoside Rs₄, Rs₅, Rs₆ and Rs₇ were isolated from processed ginseng (SG, sun ginseng) (Park et al. 2002a). Their structures were determined to be 3β,12β-dihydroxydammar-20(22),24-diene-3-*O*-β-D-glucopyranosyl(1→2)-P-D-6''-*O*-acetylglucopyranoside; 3β,12β-dihydroxydammar-20(21), 24-diene-3-*O*-β-D-glucopyranosyl(1→2)-β-D-6''-*O*-acetylglucopyranoside; 3β, 6α,12p-trihydroxydammar-20(22),24-diene-6-*O*-β-D-6'-*O*-acetylglucopyranoside; and 3β,6α, 12β-trihydroxydammar-20(21),24-diene-6-*O*-β-D -6'-*O*-acetylglucopyranoside, respectively. Fourteen major ginsenosides Rg₁, Re, Rf, Rh₁, Rg₂, Rb₁, Rc, Rb₂, Rb₃, Rd, Rg₃, Rk₁, Rg₅ and Rh₂ were determined as marker compounds of Korean red ginseng by reverse-phase HPLC-ELSD (Kim et al. 2007c).

Artificial triterpenoids, (20*R*)-20,25-epoxy-dammaran-2-en-6α,12β-diol; (20*R*)-20,25-epoxy-3-methyl-28-

nordammaran-2-en-6 α ,12 β -diol and isodehydroprotopanaxatriol, were isolated from an acidic hydrolysate of *Panax ginseng*, along with three known triterpenes: (20*R*)-panaxadiol, (20*R*)-panaxatriol and oleanolic acid (Wei et al. 2009). Two malonyl-ginsenosides, malonyl-ginsenoside Rc and malonyl-ginsenoside Rb₂, were isolated from the fresh ginseng root, and their structures were elucidated as 3-*O*-[6-*O*-malonyl- β -D-glucopyranosyl(1 $\rightarrow$ 2)- β -D-glucopyranosyl]-20-*O*-[α -L-arabinofuranosyl(1 $\rightarrow$ 6)- β -D-glucopyranosyl]-20(*S*)-protopanaxadiol and 3-*O*-[6-*O*-malonyl- β -D-glucopyranosyl-(1 $\rightarrow$ 2)- β -D-glucopyranosyl]-20-*O*-[α -L-arabinopyranosyl(1 $\rightarrow$ 6)- β -D-glucopyranosyl]-20(*S*)-protopanaxadiol, respectively (Sun et al. 2005). Ginsenoside Rh₁ and compound K were purified from fermented ginseng (Kim et al. 2008a). Hydrolysis of ginsenoside Rb₁, Rb₂ and Rc with 50 % aqueous acetic acid afforded 20*R*-prosapogenin, 20*S*-prosapogenin and delta 20-prosapogenin. Ginsenosides found in the roots included Rb₁, Rb₂, Rc, Rd, Re and RG₁ (Sugimoto et al. 2009). A new panaxadiol ginsenoside was isolated from ginseng acid hydrolysate, and its structure was elucidated as dammar-(*E*)-20(22)-ene-3 β ,12 β ,25-triol (Li et al. 2009). A new dammarane-glycoside, ginsenoside Rz₁ (1), was isolated from heat-treated *P. ginseng* with ginsenosides Rk₁ and Rg₅ (Lee et al. 2009e). The structure of 1 was established to be (Z)-12 β -hydroxydammara-20(22),24-dien-3 β -yl *O*- β -D-glucopyranosyl-(1 $\rightarrow$ 2)- β -D-glucopyranoside. The ginsenosides Rz₁, Rk₁ and Rg₅ were present in the ratios of 1:2:6, respectively.

A new saponin, malonyl-ginsenoside Ra₃, with the structure (20*S*)-protopanaxadiol-3-*O*-(6-*O*-malonyl- β -D-glucopyranosyl(1 $\rightarrow$ 2)- β -D-glucopyranoside-20-*O*- β -D-xylopyranosyl(1 $\rightarrow$ 3)- β -D-glucopyranosyl(1 $\rightarrow$ 6)- β -D-glucopyranoside was isolated from the fresh ginseng root, along with four known ginsenosides, namely, malonyl-ginsenoside Rb₁, malonyl-ginsenoside Rb₂, malonyl-ginsenoside Rc and malonyl-ginsenoside Rd (Ruan et al. 2010). Six new natural protopanaxatriol (PPT)-type ginsenosides, ginsenosides Re₁–Re₆, along with ten known

PPT-type ginsenosides, were isolated from ginseng roots (Zhu et al. 2011b). Six new protopanaxadiol-type ginsenosides, named ginsenosides Ra₄–Ra₉, along with 14 known dammarane-type triterpene saponins, were isolated from ginseng root (Zhu et al. 2011a). The structures of the new compounds were determined as (20*S*)-3-*O*-{β-D-6-*O*-[(*E*)-but-2-enoyl]glucopyranosyl-(1→2)-β-D-glucopyranosyl}-20-*O*-[β-D-xylopyranosyl-(1→4)-α-L-arabinopyranosyl-(1→6)-β-D-glucopyranosyl]protopanaxadiol; (20*S*)-3-*O*-[β-D-6-*O*-acetylglucopyranosyl-(1→2)-β-D-glucopyranosyl]-20-*O*-[β-D-xylopyranosyl-(1→4)-α-L-arabinopyranosyl-(1→6)-β-D-glucopyranosyl]protopanaxadiol; (20*S*)-3-*O*-{β-D-6-*O*-[(*E*)-but-2-enoyl]glucopyranosyl-(1→2)-β-D-glucopyranosyl}-20-*O*-[β-D-glucopyranosyl-(1→6)-β-D-glucopyranosyl]protopanaxadiol; (20*S*)-3-*O*-{β-D-6-*O*-[(*E*)-but-2-enoyl]glucopyranosyl-(1→2)-β-D-glucopyranosyl}-20-*O*-[α-L-arabinopyranosyl-(1→6)-β-D-glucopyranosyl]protopanaxadiol; (20*S*)-3-*O*-{β-D-4-*O*-[(*E*)-but-2-enoyl]glucopyranosyl-(1→2)-β-D-glucopyranosyl}-20-*O*-[α-L-arabinofuranosyl-(1→6)-β-D-glucopyranosyl]protopanaxadiol; and (20*S*)-3-*O*-{β-D-6-*O*-[(*E*)-but-2-enoyl]glucopyranosyl-(1→2)-β-D-glucopyranosyl}-20-*O*-[α-L-arabinofuranosyl-(1→6)-β-D-glucopyranosyl]protopanaxadiol, respectively. One new dammarane triterpene saponin named ginsenjilinol was isolated from ginseng roots and rhizomes together with two known saponins ginsenoside Rf and ginsenoside Re₅ (panajaponol A) (Wang et al. 2013a). The chemical structure of the new saponin was elucidated as 3β,12β,20*S*,26-tetrahydroxydammar-24*E*-en-6α-*O*-β-D-glucopyranosyl-(1→2)-*O*-β-D-glucopyranoside. A new ginsenoside, 20(*R*)-ginsenoside Rf, was purified from red ginseng extract (Lee et al. 2013g). Park et al. (2013a) using an ultra-performance liquid chromatography simultaneously determined 30 ginsenosides in ginseng roots: ginsenosides Ro, Rb₁, Rb₂, Rc, Rd, Re, Rf, Rg₁, 20(*S*)-Rg₂, 20(*R*)-Rg₂, 20(*S*)-Rg₃, 20(*R*)-Rg₃, 20(*S*)-Rh₁, 20(*S*)-Rh₂, 20(*R*)-Rh₂, F₁, F₂, F₄, Ra₁, Rg₆, Rh₄, Rk₃, Rg₅, Rk₁, Rb₃, Rk₂, Rh₃, compound Y and compound K and notoginsenoside R₁. Three derivatives were synthesised

from 25-hydroxyprotopanaxadiol from ginseng root, namely, (20R)-12 β -O-(1-chloroacetyl)-dammarane-3 β , 20, 25-triol; (20R)-3 β -O-(1-alanyl)-dammarane-12 β , 20, 25-triol; and (20R)-3 β -O-(Boc-1-arginyl)-dammarane-12 β , 20, 25-triol (Xia et al. 2014).

Nineteen ginsenosides (Rg₁, Re, Rf, Rb₁, Rc, Rb₂, Rd, F₄, Rg₆, Rk₃, Rh₄, 20(S)-, 20(R)-Rg₃, 20(S)-, 20(R)-Rs₃, Rk₁, Rg₅, Rs₄ and Rs₅) were identified and quantified in black ginseng (Korean white ginseng that was subjected to nine cycles of steam treatment) (Sun et al. 2009). Nineteen ginsenosides (Rg₁, Re, Rf, Rb₁, Rc, Rb₂, Rd, F₄, Rg₆, Rk₃, Rh₄, 20(S)-, 20(R)-Rg₃, 20(S)-, 20(R)-Rs₃, Rk₁, Rg₅, Rs₄ and Rs₅) were identified and quantified in black ginseng (Korean white ginseng that was subjected to nine cycles of steam treatment) (Sun et al. 2009). Ultra-high pressure (UHP) (600 MPa for 5–15 minute) extracted ginseng showed relatively higher extraction yield (312.2–387.1 mg) and amounts of crude saponins (19.3–32.6 mg/g ginseng) than control ginseng (189.9 and 17.5 mg/g ginseng, respectively) (Shin et al. 2010). Amounts of measured total ginsenosides (Rb₁, Rb₂, Rc, Rd, Re and Rg₁) increased with UHP processing, but pressure level and pressing time did not proportionally influence the ginsenosides content. The levels of ginsenosides Rg₁ and Re in hydroponic-cultured ginseng roots (HGR) decreased with increasing heating temperature. Ginsenosides F₂, F₄, Rk₃, Rh₄, Rg₃ (S form), Rg₃ (R form), Rk₁ and Rg₅, which were absent in the raw ginseng, were formed after heat treatment (Hwang et al. 2014). The levels of ginsenosides Rg₁, Re, Rf and Rb₁ in hydroponic ginseng leaves (HGL) decreased with increasing heating temperature. Conversely, ginsenosides Rk₃, Rh₄, Rg₃ (R form), Rk₁ and Rg₅ increased with increasing heating temperature. In addition, ginsenoside contents of heated HGL were slightly higher than those of HGR. The highest extraction yield was 14.39 % at 130 °C, whereas the lowest value was 10.30 % at 150 °C. After heating, polyphenol contents of HGR and HGL increased from 0.43 mg GAE eq./g and 0.74 mg GAE eq./g to 6.16 mg GAE eq./g and 2.86 mg GAE eq./g, respectively.

Samukawa et al. (1995a) found that in *P. ginseng* cultivated in Nagano, Japan, the ratio (total ginsenosides content/total dry root weight) increases annually for 3 years, and it decreased at the fourth year and increased again at the fifth and the sixth years. Concerning the distribution of ginsenosides in the parts of ginseng plant, ginsenosides were found at the highest level in a lateral root followed by rhizome > root hair > main root. They were also more abundantly distributed at periderm than at phloem or at xylem of a main root. The contents of panaxadiol and panaxatriol saponins gradually increased with the growth year, whereas an oleanane saponin, ginsenoside Ro, markedly increased at the sixth year to 15-fold. The following saponins in ginseng root were simultaneously analysed by high-performance liquid chromatography (HPLC): ginsenoside Ro, ginsenoside Rb₁, ginsenoside Rb₂, ginsenoside Rb₃, ginsenoside Rc, ginsenoside Rd, ginsenoside Re, ginsenoside Rf, ginsenoside Rg₁, ginsenoside Rs₁, 20(S)-ginsenoside Rg₂, 20(S)-ginsenoside Rg₃, 20(S)-ginsenoside Rh₁, 20(R)-ginsenoside Rg₂, 20(R)-ginsenoside Rg₃, 20(R)-ginsenoside Rh₁ and quinquenoside R₁ (Samukawa et al. 1995b).

Hairy root culture of ginseng transformed with *Agrobacterium rhizogenes* synthesised the same saponins, ginsenosides, as those of the native root, up to about 2.4 times in the quantity and up to two-fold in comparison with that of the ordinary cultured roots, on a dry weight basis (Yoshikawa and Furuya 1987). The amount of the Rb group was calculated as the total of ginsenosides Ra and Rd, having protopanaxadiol as the sapogenin, and the Rg group was the total of ginsenosides Re, Rf, Rg₁, Rg₂ and Rh, having protopanaxatriol as sapogenin. Agropine and mannopine synthesised in the ginseng hairy roots were also extracted. Both of the elicitors tested, yeast extract and methyl jasmonate, significantly improved saponin production in ginseng cell suspensions (Lu et al. 2001). The highest additive level of the seven ginsenosides tested was 2.07 % (dry weight basis), which was 28-fold higher than that in the control. When yeast extract was used as the elicitor, Rg₁, Rf, Rb₁, Rc and Rd contributed to the

increase in total saponin content, while the change in Re was insignificant. When methyl jasmonate was used, the increase in saponin content was mainly due to a dramatic increase in the level of Rb₁, followed by Rc. The increases in Rg₁, Re and Rf were much less significant; Rd was undetectable. The maximum content of ginsenosides was found in the suspension culture cultivated in the bioreactor (4.34 % dry mass); however, the saponin content was limited to two major ginsenosides, Rb₁ and Rg₁ (Langhansova et al. 2005). The production of ginsenosides in adventitious roots was lower (1.45 or 1.72 % dry mass); nevertheless, the full range of ginsenosides (Rg₁, Re, Rf, Rb₁, Rb₂, Rc and Rd) was detected. A combination of steaming and *Aspergillus niger* isolated from soil biotransformed black ginseng Rg₃(S, R) into 20(S)-protopanaxadiol (PPD(S)) with 100 % conversion (Liu et al. 2010b). The biotransformation pathways were Rg₃(S)→Rh₂(S)→PPD(S) and Rg₃(R)→Rh₂(R)→20(R)-protopanaxadiol (PPD(R)), respectively. In addition, 12 ginsenosides including three pairs of epimers, namely, Rg₃(S), Rg₃(R), Rh₂(S), Rh₂(R), PPD(S) and PPD(R), were simultaneously determined.

The yield of methanolic extract of fresh ginseng roots harvested in winter was found to be more than twofold greater than from roots collected in summer; this notable increase was mainly due to the large increase of sucrose in roots in winter (Kim et al. 1981). In contrast, active dammarane saponins in the roots increased in summer indicating that roots should be harvested in summer for the production of high-quality ginseng extracts. Cultivation year and storage period affected total ginsenosides in fresh ginseng, while cultivation locations and cultivation year affected phenolics in fresh ginseng (Chung et al. 2012). Processed ginsengs especially red ginseng contained larger amounts of ginsenosides and phenolics. Total ginsenosides decreased to 20–80 % in all ginsengs (fresh, white, taegeuk and red ginseng) after 1 year storage. The total content of 30 phenolics increased to 30–100 % only in processed ginsengs after 1-year storage.

Incubation of ginseng sapogenins 20(S)-protopanaxadiol and 20(S)-protopanaxatriol with microsomes from rat liver resulted in the formation of their 20, 24-epoxides as major metabolites, i.e. 20(S)-protopanaxadiol oxide I (24R epimer) and 20(S)-protopanaxadiol oxide II (24S-epimer) and 20(S)-protopanaxatriol (24S-epimer) and 20(S)-protopanaxatriol (24R-epimer) (Kasai et al. 2000).

Polyacetylene Compounds

Panaxydol, a new polyacetylenic epoxide with the structure 9,10-epoxy-3-hydroxyheptadeca-1-en-4,6-diyne (Poplawski et al. 1980); heptadeca-1-en-4,6-diyn-3,9-diol (Dabrowski et al. 1980); heptadeca-1-ene-4,6-diyne-3,9,10-triol (Sang et al. 1983); and heptadeca-1,8-dien-4,6-diyn-3,10-diol (Shim et al. 1987), was isolated from ginseng roots. Two new polyacetylenes, viz. heptadeca-3-oxo-4,6-diyne-9,10-diol and its dihydro derivative (Fujimoto and Satoh 1987), and new chlorine-containing polyacetylene, chloropanaxydol and panaxydol were isolated from ginseng callus (Fujimoto and Satoh 1988). From ginseng roots cytotoxic polyacetylene compounds: panaxyne epoxide with the structure tetradeca-13-ene-1,3-diyne-6,7-epoxide (Kim et al. 1989a); and 10-acetyl panaxytriol with the structure heptadeca-1-ene-4,6-diyne-3,9-diol-10-acetate (Kim et al. 1989b) were isolated. Two new polyines, 3-acetyloxy-9,10-epoxy-heptadec-1-en-4,6-diyne (acetylpanaxydol) and 10-chloro-3,9-dihydroxyheptadec-1-en-4,6-diyne (panaxydol chlorohydrin), were isolated from the roots (Ahn et al. 1989). The heptadeca-1-ene-4,6-diyne-3,9,10-triol (panaxytriol) contents of red ginseng and white ginseng were determined as 0.38 and 0.25 mg/g, respectively (Matsunaga et al. 1989a). Three polyacetylene compounds, panaxynol, panaxydol and panaxytriol, were found in *P. ginseng* (Matsunaga et al. 1990). Three new acetylated polyacetylenes named ginsenoynes F, G and H were isolated from the hexane extract of ginseng roots (Hirakura et al. 1991b). Five new polyacetylenes named ginsenoynes A, B, C, D and E were isolated from the hexane extract of ginseng root (Hirakura et al. 1991a). Three new acetylenic compounds named ginsenoynes I–K were isolated from a hexane extract of

ginseng roots (Hirakura et al. 1992). The following polyacetylenic compounds were isolated from ginseng roots: ginsenoyne A, panaxyne epoxide, panaxydol and panaxynol (Hirakura et al. 1994). Polyacetylene compounds identified as panaxynol, panaxydol, panaxydiol and panaxytriol were isolated from ginseng hairy roots (Kwon et al. 1997). The absolute stereostructures of panaxytriol and panaxydol, two polyacetylenic constituents red ginseng roots, were determined to be (3*R*,9*R*,10*R*)-heptadec-1-ene-4,6-diyne-3,9,10-triol and (3*R*,9*R*,10*S*)-9,10-epoxy-heptadec-1-ene-4,6-diyn-3-ol, respectively (Kobayashi et al. 1997). Panaxytriol was presumed to be formed from panaxydol via a regioselective hydrolysis of the epoxy moiety in panaxydol.

Sixteen acetylenic compounds were isolated from ginseng roots: panaxynol; panaxydol; panaxydol chlorohydrins; panaxytriol; panaxyne epoxide; ginsenoynes A, C, D, E, H, I, J and K; panaxynol linoleate; panaxydol linoleate; and ginsenoyne A linoleate (Hirakura et al. 2000). Four possible stereoisomers of (9,10)-epoxyheptadecan-4,6-diyn-3-one were synthesised, and the absolute configuration of the naturally occurring (9*R*,10*S*)-epoxyheptadecan-4,6-diyn-3-one, a diacylglycerol acyltransferase inhibitor from ginseng, was elucidated (Oh et al. 2004b). Polyacetylenic compounds, (9*R*,10*S*)-epoxyheptadecan-4,6-diyn-3-one and 1-methoxy-(9*R*,10*S*)-epoxyheptadecan-4,6-diyn-3-one (Lee et al. 2004d) and (9*R*,10*S*)-epoxy-16-heptadecene-4, 6-diyne-3-one (Rho et al. 2005) were obtained from the petroleum ether extract of ginseng. Using a new HPLC method, white ginseng and red ginseng were found to contain three polyacetylenes (panaxynol, panaxydol and 1,8-heptadecadiene-4,6-diyne-3,10-diol), 0.02–0.073 % in white ginseng and 0.019–0.055 % in red ginseng, and six ginsenosides (RB₁, Rb₂, Rc, Rd, Re and Rg₁), 1.072–3.029 % in white ginseng and 1.588–2.811 % in red ginseng (Washida and Kitanaka 2003). Ginseng root samples were found to contain polyacetylenes (panaxydol and panaxynol), 1.93–2.72 mg/g, and saponins (ginsenosides Rg₁, Re, Rf, Rg₂, Rb₁, Rc, Rb₂, Rb₃ and Rd), 12.67–18.64 mg/g, and no flavonoid (panasenoside) (Qian et al. 2009). Seven polyacetylenes – panaxynol, ginsenoyne-A, panaxydol, 10-

methoxy heptadeca-1-ene-4, 6-dyne-3, 9-diol, (3*R*, 9*R*, 10*R*)-panaxytriol, panaxyne and ginsenoyne-C – were isolated from the roots of cultivated wild ginseng (Jangnoisam) (Yang et al. 2008). A polyacetylenic compound, (9*R*,10*S*)-epoxyheptadecan-4,6-diyn-3-one (EHD), was isolated from ginseng root extract (Choi et al. 2008). Panaxfuraynes A and B and two new tetrahydrofuranic polyacetylene glycosides were isolated from ginseng roots (Lee et al. 2009d). Two new polyacetylenes, 1-hydroxydihydropanaxacol and 17-hydroxypanaxacol, were isolated from *Panax ginseng* hairy root culture, along with dihydropanaxacol, panaxacol and ginsenoyne D (Fukuyama et al. 2012).

Other Phytochemicals

Horhanmer et al. (1961) isolated from ginseng roots a pentacyclic, oleanane-type (5–8) triterpene compound named oleanolic acid (5–9). New glucosides 1 and 2 were isolated from a non-saponin fraction of a water extract of red ginseng (steamed ginseng root) (Matsuura et al. 1984a). One was identified as 2-oxopropyl α-D-glucopyranoside (acetol α-D-glucoside) which showed negligibly weak mutagenicity in *Salmonella typhimurium* TA100 with and without S9 and no mutagenicity in the strains TA98 and Ta1537. Glucoside 2 was an unstable C-2-epimeric mixture, which was readily decomposed to give maltol and glucose, suggesting it to be an intermediate in the formation of maltol from maltose during the steaming process.

The unknown ninhydrin-positive substances (UK-I, UK-II, UK-III) were detected in ginseng water extract (Matsuura et al. 1994). UK-II was isolated and identified as maltulosyl arginine (Arg-Fru0Glc), and UK-III was identified as Arg-Fru. Korean red ginseng contained more Maltulosyl arginine than white ginseng. Maltulosyl arginine was found to be produced by Maillard reaction of maltose with arginine during the heating process in the preparation of red ginseng. Maltulosyl arginine was found to inhibit maltase activity. Five ninhydrin-positive compounds were isolated from red ginseng water extract including arginine and a new compound determined as 1'-Nα-arginine-1'-deoxy-4'-O-(α-D-glucopyranosyl)-D-

fructose (argininyl-fructosyl-glucose) (Zheng et al. 1998). Two Amadori compounds, arginyl-fructose and arginyl-fructosyl-glucose, were found in Korean red ginseng extracts and rat plasma (Joo et al. 2008).

Five new compounds (three esters and two glycosides) elucidated as digitoxigenin stearate, digitoxigenin palmitate, digitoxigenin myristate, 3-epidigitoxigenin β -D- gentiobioside and digitoxigenin β -D-sophoroside and seven previously reported compounds were isolated as biotransformation products of digitoxigenin by ginseng hairy root cultures (Kawaguchi et al. 1990). Nine compounds, including a new compound (digitoxigenin β -D-glucoside malonyl ester), were isolated as biotransformation products of digitoxigenin by cell suspension cultures of *Panax ginseng* (Pg-3 cell line) (Kawaguchi et al. 1996). On administration of 18 β -glycyrrhetic acid to hairy root cultures of *Panax ginseng*, three new biotransformation products – 30-O-[β -D-glucopyranosyl-(1 $\rightarrow$ 2)- β -D- glucopyranosyl]18 β -glycyrrhetic acid, 30-O-(6- O-malonyl- β -D-glucopyranosyl)18 β -glycyrrhetic acid and 3-O-[6-O-malonyl- β -D-glucopyranosyl-(1 $\rightarrow$ 2)- β -D-glucopyranosyl]18 β -glycyrrhetic acid – were isolated together with three known compounds (Asada et al. 1993). Upon addition of hydroquinone to ginseng hairy root culture, arbutin was obtained as biotransformed product in 24 hours, the bioconversion rate was 89.0 %, and the content of arbutin in dry root was 13.0 % (Zhao et al. 2001).

Ginseng root culture was able to convert 3,5-dimethoxyphenol (taxicatigenin) into its glucoside (taxicatin), primeveroside and gentiobioside; methyl salicylate into its glucoside and gentiobioside; *p*-hydroxyacetophenone into its glucoside (picein); and coniferyl alcohol into dihydroconiferin [3-(3-methoxy-4-O- β -D-glucopyranosylphenyl)propan-1-ol] (Ushiyama and Furuya 1989). Root cultures of *P. ginseng* were able to convert (*RS*)-2-phenylpropionic acid into (*RS*)-2-phenylpropionyl β -D-glucopyranoside, (2*RS*)-2-O-(2-phenylpropionyl)-D-glucose, (2*S*)-2-phenylpropionyl 6-O- β -D-xylopyranosyl- β -D-glucopyranoside and a *myo*-inositol ester of (*R*)-2-phenylpropionic acid (Furuya et al. 1989). Ginseng root

culture was able to convert aromatic carboxylic acids into glucose and/or sophorose substituted conjugates (Ushiyama et al. 1989). 2-(4-hydroxyphenyl) propionic acid was converted into its *R* and *S* glucosyl esters and glucosides, its ethyl ester into a glucoside and a small amount of a glucosyl ester, (4-hydroxyphenyl) acetic acid into its glucoside, tropic acid into its glucose esters and glucosides and 2-(3-benzoylphenyl) propionic acid and 2-[2-(6-methoxy)-naphthyl] propionic acid into their glucosyl and sophorosyl esters.

Panax ginseng root cultures biotransformed umbelliferone into its 7-*O*- β -D-glucopyranoside; 7-*O*- β -D-glucopyranosyl (1 $\rightarrow$ 6) β -D-glucopyranoside, 7-*O*- β -D-xylopyranosyl (1 $\rightarrow$ 6) β -D-glucopyranoside; and 7-*O*- α -L-rhamnopyranosyl (1 $\rightarrow$ 2) β -D-glucopyranoside (Li et al. 2002). The glycosylation was catalysed by glycosyltransferase rather than glycosidase. Also, *Panax ginseng* root and cell cultures were shown to biotransform paeonol into its 2-*O*- β -D-glucopyranoside (Li et al. 2005).

P. ginseng root cultures were also able to biotransform paeonol into 2-*O*- β -D-xylopyranoside, 2-*O*- β -D-glucopyranosyl(1 $\rightarrow$ 6)- β -D-glucopyranoside and 2-*O*- β -D-xylopyranosyl (1 $\rightarrow$ 6)- β -D-glucopyranoside, and its demethylated derivate, 2',4'-dihydroxyacetophenone. *p*-Hydroxybenzoic acid and *m*-hydroxybenzoic acid were converted into their corresponding glycosides and glucosyl esters, while no metabolite of *o*-hydroxybenzoic acid was detected in ginseng root cultures (Chen et al. 2008). A new compound, *m*-hydroxybenzoic acid β -D-xylopyranosyl (1 $\rightarrow$ 6)- β -D-glucopyranosyl ester, was identified as a biotransformation product of *m*-hydroxybenzoic acid.

Eighty-two components were detected in non-fumigated and sulfur-fumigated white ginseng samples; among them 35 sulfur-containing compounds were detected only in sulfur-fumigated white ginseng and its decoction were assigned to be sulfate or sulfite derivatives of original ginsenosides. These were deduced to be generated via reactions of esterification, addition, hydrolysis and dehydration during sulfur fumigation and decocting of white ginseng (Li et al. 2012e).

Two panasinsane-type sesquiterpene alcohols, panasinsanol A and panasinsanol B, were isolated from ginseng rootlets together with known sesquiterpene hydrocarbons: α -panasinsene, β -panasinsene, α -neoclovene and β -neoclovene (Iwabuchi et al. 1987). Their syntheses from (–)- β -caryophyllene were established. A novel sesquiterpene alcohol named ginsenol was isolated from the rootlets and its structure established as (1*R*,4*S*,7*R*, 11*S*)-3,3,7,11-tetramethyltricyclo-[5.4.0.0^{4,11}]undecan-1-ol (Iwabuchi et al. 1988). A tricarboxylic sesquiterpenoid, isolated from the ethereal extract of ginseng, showed almost identical nuclear magnetic resonance data to those reported for senecrassidiol (Iwabuchi et al. 1990).

Three β -carboline alkaloids, namely, N9-formylharman, ethyl B-carboline-1-carboxylate and perlolyrine, were isolated from ginseng and 12 alkaloids detected (Han et al. 1986). An alkaloid 4,5,6,7-tetrahydroimidazo(4,5-c) pyridine-6-carboxylic acid or spinacine was isolated from ginseng roots (Han et al. 1987). Two carboline alkaloids were isolated from an ether-soluble alkaloidal fraction of ginseng and identified as 1-carbobutoxy- β -carboline and 1-carbomethoxy- β -carboline (Park et al. 1987). From the ether-soluble alkaloidal fraction of *Panax ginseng*, 4-methyl-5-thiazoleethanol, norharman and harman were isolated (Park et al. 1988). Three sesquiterpene hydrocarbons were isolated from ginseng root essential oil and identified as (1*R*,2*S*,5*S*)-2-ethenyl-1(1-methylethenyl)-2,6,6-trimethylbicyclo[3.2.0]heptane (panaxene), (1*S*,8*S*,11*R*)-4,7,7,11-tetramethyltricyclo[6.3.0.0(1,5)]undec-4-ene (panaginsene) and (1*R*,6*R*,7*R*)-3,7,10,10-tetramethyltricyclo[4.3.2.0(2,6)]undec-2-ene (ginsinsene) (Richter et al. 2005). A characteristic fragrant and sweet aroma compound was isolated from red ginseng and identified as 3-hydroxy-2-methyl-pyran-4-one (Lee et al. 2005).

Pgy-thionin protein was found to be localised to cell wall-bound extracellular spaces and to be ubiquitously expressed in the leaf, flower bud, stem, root and rhizome, with its highest expression in the roots of *P. ginseng* (Lee et al. 2011). *Pgy*-thionin contained two exons coding a 225-bp open reading frame with its deduced 75 amino acid sequence interrupted by

1 internal intron. *Pgy*-thionin was responsive to both biotic and abiotic stresses.

Leaf–Stem Phytochemicals

Ginseng leaf–stem extract contained numerous active ingredients, such as ginsenosides, polysaccharides, triterpenoids, flavonoids, volatile oils, polyacetylenic alcohols, peptides, amino acids and fatty acids (Wang et al. 2009a). The extract contained larger amounts of the same active ingredients than the root.

A new natural flavonoid, named panasenoside, together with kaempferol and trifolin (kaempferol-3-*O*-galactoside) was isolated from ginseng leaves and stem (Komatsu et al. 1969). Saponins such as ginsenosides Rb₁ and Rg₁ and sapogenins such as panaxadiol, panaxatriol and oleanolic acid were obtained from ginseng petiole callus grown on Murashige and Skoog's agar medium (minus glycine) supplemented with 2,4-dichlorophenoxyacetic acid (Furuya et al. 1973). The saponins were similar to those of ginseng roots. Phytosterols simultaneously obtained were shown to be a mixture of a large amount of β -sitosterol and smaller amounts of stigmasterol and campesterol. Saponins I, II and III were isolated from ginseng stem (Yang 1987).

From ginseng leaves, six saponins – I, II, III, IV, V and VI – were isolated (Yahara et al. 1976b). Saponins IV, V and VI were proved to be identical, respectively, with ginsenosides Rg₁, Re and Rd isolated from ginseng roots. The high contents of these saponins in the leaves indicated significance of the leaves as the source of the dammarane-type saponins and their sapogenins. New saponins I, II and III designated as ginsenosides-F1, -F2 and -F3 were established as 20-*O*- β -glucopyranosyl-20 (*S*)-protopanaxatriol, 3, 20-di-*O*- β -glucopyranosyl-20 (*S*)-protopanaxadiol and 20-*O*-(α -arabinopyranosyl-(1 $\rightarrow$ 6)- β -glucopyranosyl)-20 (*S*)-protopanaxatriol, respectively. Ginsenosides Rb₁, Rb₂ and Rc were isolated from the leaves (Yahara et al. 1979). Four minor compounds were isolated from the leaves and were characterised as 20(*R*)-protopanaxatriol; daeosterin; 3 β , 12 β -

dihydroxy-dammar-20(22), 24-diene-3-*O*- β -D-glucopyranoside (named as ginsenoside Rh₃); and 20(*R*)-protopanaxadiol-3-*O*- β -D-glucopyranoside (named as 20(*R*)-ginsenoside Rh₂) (Cheng et al. 1987). Two minor compounds 20(*R*)-protopanaxadiol and ginsenoside Rg₄ with the structure 3 β , 6 α , 12 β -trihydroxydammar-20 (22), 24-diene-6-*O*- α -L-rhamnosyl-(1 $\rightarrow$ 2)- β -D-glucopyranoside were isolated from the leaves (Zhang et al. 1989a). A novel minor saponin, named ginsenoside La, was isolated from ginseng leaves, and its structure was determined to be a diglucoside of 23-oxygenated protopanaxadiol derivative (Zhang et al. 1989b). A new minor saponin named ginsenoside La was isolated from the leaves (Chen et al. 1990). Six new minor saponins, named as ginsenosides Rh₅, Rh₆, Rh₇, Rh₈, Rh₉ and Rg₇, together with known ginsenosides, namely, majoroside F₂, ginsenoside RH₁, chikusetsusaponin L₈, notoginsenoside Fe, majoroside F₄, 20(*R*)-ginsenoside Rh₁, ginsenoside F₁, ginsenoside F₂, ginsenoside F₃, ginsenoside Rg₁, ginsenoside Re, ginsenoside Rd, ginsenoside Rc and ginsenoside Rb₂, were isolated from the leaves (Dou et al. 2001). The structures of the new saponins were elucidated as follows: ginsenoside Rh₅: 3 β ,6 α ,12 β ,24zeta-tetrahydroxy-dammar-20(22),25-diene 6-*O*- β -D-glucopyranoside; ginsenoside Rh₆: 3 β ,6 α ,12 β ,20(*S*)-tetrahydroxy-25-hydroperoxy-dammar-23-ene 20-*O*- β -D-glucopyranoside; ginsenoside Rh₇: 3 β ,7 β ,12 β ,20(*S*)-tetrahydroxy- dammar-5,24-diene 20-*O*- β -D-glucopyranoside; ginsenoside Rh₈: 3 β ,6 α ,20(*S*)-trihydroxy-dammar-24-ene-12-one 20-*O*- β -D-glucopyranoside; ginsenoside Rh₉: 3 β ,6 α ,20(*S*)-trihydroxy-12 β ,23-epoxy-dammar-24-ene 20-*O*- β -D-glucopyranoside; and ginsenoside Rg₇: 3-*O*- β -D-glucopyranosyl 3 β ,12 β ,20(*S*),24(*R*)-tetrahydroxy-dammar-25-ene 20-*O*- β -D-glucopyranoside.

Two compounds isolated from ginseng leaves were identified as 3 β ,6 α ,12 β -triol-22,23,24,25,26,27-hexanordammaran-20-one and dammar-20(22),24-diene-3 β ,6 α ,12 β -triol (Wu et al. 2007). A new compound, 3,6,20(*S*)-trihydroxy-12,23-epoxydammar-24-ene,6,20-di-*O*- β -D-

glucopyranoside, was isolated from ginseng leaves (Wang et al. 2008). Eleven compounds were isolated from ginseng stem and leaves and identified as β -sitosterol; daucosterol; docosanoic; dammar-24-ene- $3\beta,6\alpha,12\beta,20(R)$ -tetraol; $20(R)$ -ginsenoside Rh₂; $20(S)$ -ginsenoside Rh₂; $20(R)$ -ginsenoside Rh₁; $20(S)$ -ginsenoside Rh₁; $20(S)$ -ginsenoside Rg₃; $20(S)$ -ginsenoside Rg₂; and $20(R)$ -dammaran- $3\beta,6\alpha,12\beta,20,25$ pentol (Shen et al. 2008). Three new dammarane-type triterpene ginsenosides, ginsenoside Rh₁₁, ginsenoside Rh₁₂ and ginsenoside Rh₁₃, together with six known ginsenosides, were isolated from the leaves, and their structures were elucidated as (20S)- $3\beta,6\alpha,12\beta,20$ -tetrahydroxydammar-25-ene-24-one 20-*O*- β -D-glucopyranoside (1), (20S)- $3\beta,12\beta,20,24,25$ -pentahydroxydammarane 20-*O*- β -D-glucopyranoside (2) and (20S,23E)- $3\beta,12\beta,20,25$ -tetrahydroxydammar-23-ene 20-*O*- β -D-glucopyranoside (3), respectively (Liu et al. 2010a). The known ginsenosides were identified as ginsenoside M_(7cd), ginsenoside Rg₆, ginsenoside Rb₃, gypenoside XVII, gypenoside IX and 20-(*E*)-ginsenoside F₄. Two new dammarane-type saponins, named ginsenoside Ki and ginsenoside Km, along with 15 known ones, namely, ginsenoside Re, ginsenoside Rg₁, notoginsenoside R₁, floralgin-senoside M, floralginsenoside N, ginsenoside F₁, ginsenoside F₅, ginsenoside F₃, vinaginsenoside R₄, ginsenoside Ia, ginsenoside Rd, ginsenoside Rc, ginsenoside Rb₂, ginsenoside Rb₁ and ginsenoside Rh₁, were isolated from the leaves of *Panax ginseng* (Tung et al. 2009). Three new dammarane-type glycosides, named ginsenosides SL₁–SL₃, and 11 known compounds – (20S)-ginsenoside Rh₁, ginsenoside F₁, ginsenoside Rh₄, (20S)-ginsenoside Rg₂, (20R)-ginsenoside Rg₂, ginsenoside Rg₆, ginsenoside F₄, ginsenoside Rh₃, ginsenoside Rk₂, (20S)-ginsenoside Rh₂ and (20R)-ginsenoside Rh₂ – were isolated from the heat-processed ginseng leaves (Tung et al. 2010d). Three new dammarane-type triterpene saponins ginsenosides Rh₁₈, Rh₁₉ and Rh₂₀, along with two new triterpene sapogenins

12 β ,23(*R*)-epoxydammar-24-ene-3 β ,6 α ,20(*S*)-triol and dammar-(20*E*)22,25-diene-3 β ,6 α ,12 β ,24*S*-tetrol, were isolated from ginseng stems and leaves (Li et al. 2012d). Three dammarane triterpenes, including two new compounds 27-demethyl-(*E,E*)-20(22),23-dien-3 β ,6 α ,12 β -trihydroxydammar-25-one and 3 β ,20(*S*)-dihydroxydammar-24-en-12 β ,23 β -epoxy-20-*O*- β -d-glucopyranoside, were isolated from ginseng leaves (Tran et al. 2014).

The total saponin content of the leaves analysed on 15th April, 25th April, 5th May and 25th May were 97.29, 66.42, 67.61 and 36.24 mg/g, respectively, in which the content of Re, Re₁ and Rd was more than two third amount of total saponin (Choi et al. 2009). The saponin content of leaves decreased according to the sequential collection days, in which the similar results were observed from the flowers and stems of ginseng. The total saponin content in above-ground parts of ginseng was in the order leaves > flowers > stems. The total saponin content of the stem was 13.32, 9.85, 8.00 and 4.65 mg/g, respectively. The content of Re, Rg₁ and Rd in stems was more than 9/10 amount of total saponins. Ginseng leaf samples were found to contain flavonoid (panasenoside), 2.03–7.40 mg/g, and saponins (ginsenosides Rg₁, Re, Rf, Rg₂, Rb₁, Rc, Rb₂, Rb₃ and Rd), 59.14–111.55 mg/g, and a few samples contain polyacetylenes (panaxydol and panaxynol) (Qian et al. 2009).

Four anticomplementary polysaccharides, GL-PI to GL-PIV, were isolated from ginseng leaves (Gao et al. 1988). These four polysaccharides possessed a rhamnogalacturonan backbone consisting of 4-linked GalA and 2-linked Rhap. Some 6-linked Galp was attached to GalA or GlcA. GL-PI had the highest molecular weight which is 50,000. GL-PI and GL-P II consisted mainly of Rha, Gal and GalA, and GL-PIII contained Fuc in addition, whereas GL-PIV consisted mainly of Gal, Glc and GalA. GL-PI and GL-P II contained mainly (1→2)-linked Rhap and (1→4)-linked GalA. GL-P II contained, in addition, 2,4-di-*O*-substituted Rhap, nonreducing terminal Galp and (1→6)-linked Galp as the major glycosidic linkages. GL-PIV also contained mainly (1→4)-linked GalA, nonreducing terminal Galp and (1→6)-linked Galp, whereas

GL-PIII contained mainly nonreducing terminal GalA and 3,4-di-*O*- and 2,4-di-*O*-substituted GalA, in addition to (1→4)-linked GalA and (1→2)-linked Rha. Three potent anticomplementary polysaccharides, GL-PI, GL-PII and GL-PIV, were isolated from ginseng leaves (Gao et al. 1990). β-Eliminative degradation of GL-PI and GL-PII each afforded neutral (IN and IIN) and acidic (IA and IIA) fractions. Each fraction N consisted of Ara, Rha, Gal and Glc, whereas each fraction A comprised a large proportion of GalA in addition to Rha, Gal, Glc and GlcA. Fractions IN and IIN contained Rha-(1→2)-Rha-ol-1-d, Rha-(1→4)-Rha-ol-1-d, Ara-(1→4)-Rha-ol-1-d, Gal-(1→4)-Rha-ol-1-d, Gal-(1→6)-Gal-ol-1-d and GlcA-(1→4)-Rha-ol-1-d, and fractions IA and IIA contained Rha→Rha-ol-1-d, HexA→Rha-ol-1-d and HexA→Rha→Rha-ol-1-d. IN and IIN also contained high molecular weight 6-linked galactan and 4-linked glucan, and IA and IIA consisted mainly of 2-linked Rha, 4-linked GalA and terminal and 6-linked Gal. IIA contained more 2-linked Rha than IA. GL-PIV contained a high molecular weight fraction (PG-1) which was rich in neutral sugars, fragments of intermediate size (PG-2) and oligosaccharides (PG-3). PG-1 contained a rhamnogalacturonan core, galactan (which mainly comprised of terminal 6-linked and 4,6-disubstituted Gal) and 4-linked glucans. PG-2 contained (1→4)-linked α-galacturonan partially branched at position 2 or 3 and a rhamnogalacturonan core in addition to small proportions of Gal and Glc. PG-3 contained large proportions of oligogalacturonides. *Panax ginseng* extract G-115 had anticomplementary activity, and the major potent anticomplementary polysaccharide, G-115I₁-IIa-2-3, was obtained from the extract (Yamada et al. 1995). G-115I₁-IIa-2-3 was homogeneous, and its molecular weight was estimated to be 3.68×10^5 . G-115I₁-IIa-2-3 consisted mainly of arabinose, galactose and glucose in addition to small amounts of galacturonic acid, glucuronic acid and rhamnose.

An antiulcer polysaccharide (GL-BIII) was purified from ginseng leaves (Kiyohara et al. 1994). GL-BIII consisted mainly of terminal Arap, 4- or 5-substituted Ara, 2,4-disubstituted Rha, 4- and 6-substituted Gal and 3,6-disubstituted Ga and also contained terminal 4-substituted and

3,4-disubstituted GalA and terminal and 4-substituted GlcA. Some 2-substituted Rha in GL-BIII was attached to position 4 of a 4-substituted uronic acid. GL-BIII also contained a small proportion of a β -(1 $\rightarrow$ 3,6)-galactan moiety, a GalA-(1 $\rightarrow$ 4)-Rha unit in addition to longer acidic units consisting of 2-substituted Rha and 4-substituted GalA. Fractions of GL-BIII were found to contain long and intermediate neutral oligosaccharide-alditols and a large amount of a fraction containing short oligosaccharide-alditols. The long neutral oligosaccharide-alditol fraction mainly comprised of 4- or 5-substituted Ara, terminal Galf, 6-substituted Glc and 2-substituted Man, whereas the intermediate oligosaccharide-alditol fraction consisted mainly of terminal and 6-substituted Galp, 6-substituted Glc and 2-substituted Man.

A complex pectic polysaccharide (GL-4IIb2) was isolated from ginseng leaves (Shin et al. 1997). GL-4IIb2 consisted of 15 different monosaccharides which included rarely observed sugars, such as 2-*O*-methylfucose, 2-*O*-methyl-xylose, apiose, 3-*C*-carboxy-5-deoxy-L-xylose (acetic acid, AceA), 3-deoxy-D-manno-2-octulosonic acid (Kdo) and 3-deoxy-D-lyxo-2-heptulosonic acid (Dha). Another three different polysaccharides, GL-RI, GL-RII and GL-RIII, were isolated from polysaccharide subfraction GL-5 from ginseng leaves (Shin et al. 1998). The three polysaccharides consisted of the same substitution patterns of 2-*O*-methyl-fucose, 2-*O*-methyl-xylose, apiose, 3-*C*-carboxy-5-deoxy-L-xylose (acetic acid, AceA), 3-deoxy-D-manno-2-octulosonic acid (Kdo) and 3-deoxy-D-lyxo-2-heptulosaric acid (Dha), being characteristic monosaccharides of rhamnogalacturonan-II, but no other pectic components.

Purification of the weakly acidic polysaccharide fraction, GL-4 (from ginseng leaves), yielded the bioactive polysaccharide, GL-4IIb1III, with average relative molecular mass 16,000 Da, and comprising a pectic polysaccharide composed mainly of galactose and galacturonic acid with small proportions of rhamnose, arabinose, mannose, glucose and glucuronic acid (Sun et al. 1992b). Three flavonoids – kaempferol, sophoraflavonolloside and prunin – were isolated from the leaves (Tung et al. 2010b). Panasenoside

[kaempferol-3-*O*- β -D-glucopyranosyl(1 $\rightarrow$ 2)- β -D-galactopyranoside] was extracted from ginseng leaves, and the average recovery was 98.5 % (Li et al. 2010b).

Flower Phytochemicals

A new natural flavonoid, named panasenoside, was isolated from ginseng buds (Komatsu et al. 1969). Ginsenosides Rd, Re and Rg₁ were isolated from dried mixture of ginseng buds and flowers (Yahara et al. 1976a). Ginsenoside Re was isolated in high yield of ca 2.5 %. A new saponin ginsenoside M7cd with the structure established as 20-*O*- β -D-glucopyranoside of dammar-25-ene-3 β , 6 α , 12 β , 20 (*S*), 24 ζ -pentaol was isolated from ginseng flower bud together with ginsenosides Rb₁, Rb₂, Rc and F₃ (Yahara et al. 1979).

Ginsenoside Rb₃ and ginsenoside Rc were isolated from the flower buds (Shao 1984). Two tetracyclic triterpenic saponins, FC1 and FD3, were isolated from ginseng flower buds and the structures established as ginsenoside Rb₂ and 20-

glucoginsenoside Rf (Shao et al. 1984). From flower buds of *P. ginseng*, ginsenosides Ro (=chikusetsusaponin V), Rb₁, Rb₂, Rb₃, Rc, Rd and Re; 20-glucoginsenoside Rf; and ginsenosides Rf, Rg₁ and Rg₂ were isolated (Shao et al. 1989).

Thirteen compounds were identified from ginseng flower buds: β -sitosterol, daucosterine, ginsenoside Rh₁, 20-(*S*)-ginsenoside Rg₂, 20-(*R*)-ginsenoside Rg₂, ginsenoside Rf, ginsenoside Re, ginsenoside Rg₃, ginsenoside Rd, ginsenoside Rc, ginsenoside Rb₂, palmitic acid and *trans-p*-hydroxycinnamic acid (Wang et al. 1992). Eleven of 15 compounds, isolated from ginseng flower buds, were identified: β -sitosterol, 20(*R*)-protopanaxatriol, 20(*R*)-ginsenoside Rh₁, 20(*R*)-ginsenoside Rg₂, 20(*S*)-ginsenoside Rg₂, ginsenoside Re, ginsenoside Rd, ginsenoside Rc, ginsenoside Rb₂, gypenoside XVII and notoginsenoside-E (Qui et al. 1997). A new minor dammarane-type triterpene saponin named ginsenoside III together with nine known saponins was isolated from dried flower buds (Qui et al. 1998). The structure of the new saponin was elucidated as 3-*O*-[β -D-

glucopyranosyl(1→2)-β-D-glucopyranosyl]-20-*O*-β-D-glucopyranosyl-3β,12β,20(*S*)-trihydroxy-dammar-25-en-24-one. A pair of new 24-epimers of dammarane-type saponins named ginsenosides I and II were isolated from ginseng flower buds (Qui et al. 2001). The structures of the epimers were characterised as 3-*O*-[β-D-glucopyranosyl-(1→2)-β-D-glucopyranosyl]-20-*S-O*-β-D-glucopyranosyl-3β, 12β,20(*S*)-trihydroxy-24 α -hydroperoxydammar-25-ene, except for their C-24 configurations.

From the oligoglycoside fraction of ginseng flower buds, new dammarane-type triterpene tetraglycosides, floralginsenosides M, N, O and P, were isolated together with the major oligoglycosides ginsenoside Rd and Re (Yoshikawa et al. 2007b). Six new dammarane-type triterpene diglycosides with a hydroperoxide group, floralginsenosides A, B, C, D, E and F, were isolated from ginseng flower and flower buds together with seven known dammarane-type triterpene oligoglycosides ginsenoside F1, ginsenoside F3, ginsenoside F5, ginsenoside RG1, ginsenoside RG2, gypenoside XVII and pseudoginsenoside RC1 (Yoshikawa et al. 2007a). New dammarane-type triterpene triglycosides, floralginsenosides G, H, I, J, K, La and Lb, were isolated from the flower buds together with ten known dammarane-type triterpene oligoglycosides (Nakamura et al. 2007). Ginsenosides found in the flower buds included Rb₁, Rb₂, Rc, Rd, Re and RG₁ (Sugimoto et al. 2009). The content of ginsenosides in *P. ginseng* flower buds was reported by Ko et al. (2011) as follows: Rb₁ 1.104 %, Rb₂ 0.669 %, Rc 0.565 %, Rd 0.942 %, Re 3.445 %, Rf 0.046 %, Rg₁ 0.421 % and Rg₂ 0.0955 – total ginsenosides 7.30 % PD (protopanaxadiol)/PT (protopanaxatriol) 0.82. Six dammarane-type saponins, including three new compounds, floralginsenosides Ta–Tc, and three known, floralginsenoside Td, ginsenoside F₁ and ginsenoside F₅, were isolated from ginseng flower buds (Tung et al. 2010c). Chemical components of steamed flower buds included a new dammarane-type saponin named ginsenoside SF and 19 known compounds, namely, ginsenoside Rh₄, ginsenoside Rk₃, ginsenoside F₁, (20*E*)-ginsenoside F₄,

ginsenoside Rg₂, pseudoginsenoside RC₁, ginsenoside Rg₆, ginsenoside F₄, ginsenoside Rg₁, 6'-acetyl- ginsenoside Rg₁, ginsenoside Rd, ginsenoside Rc, ginsenoside Rb₂, ginsenoside Re, vinaginsenoside R₄, ginsenoside Mb, ginsenoside Rb₁, ginsenoside Rs₄ and 6'-acetyl-ginsenoside F₁ (Tung et al. 2010a). Three new dammarane-type saponins, named floralginsenosides Ka, Kb and Kc, along with 17 known ones, were isolated from ginseng flowers (Tung et al. 2010e). The total saponin contents of the flowers analysed on 15th April, 25th April, 5th May and 25th May were 141.09, 143.84, 139.25 and 133.47 mg/g, respectively, in which the content of Re, Rd and Rb₂ in flowers accounted for more than 2/3 amount of total saponins (Choi et al. 2009).

A ribonuclease, with a molecular mass of 23 kDa and much higher activity towards poly(U) than poly(C) and only negligible activity towards poly(A) and poly(G), was isolated from the aqueous extract of Chinese ginseng flowers (Wang and Ng 2004).

Fruit/Seed Phytochemicals

Ginsenosides Rb₂, Rc, Rd, Re and Rg₁ were isolated from the fruits; ginsenoside Re was obtained in high yield of 6 % (Yahara et al. 1979). Eleven saponins were extracted from *P. ginseng* fruits and identified as 20(*R*)-dammarane-3 β ,12 β ,20,25-tetrol (25-OH-PPD); 20(*R*)-dammarane-3 β ,6 α ,12 β ,20,25-pentol (25-OH-PPT); 20(*S*)-protopanaxadiol (PPD); daucosterine; 20(*S*)-ginsenoside Rh₂ (Rh₂); 20(*S*)-ginsenoside Rg₃ (Rg₃); 20(*S*)-ginsenoside Rg₂ (Rg₂); 20(*S*)-ginsenoside Rg₁ (Rg₁); 20(*S*)-ginsenoside Rd (Rd); 20(*S*)-ginsenoside Re (Re); and 20(*S*)-ginsenoside Rb₁ (Rb₁) (Wang et al. 2007). Ginsenosides found in the mature fruit flesh included Rb₁, Rb₂, Rc, Rd, Re and Rg₁; Rd was not detected in flesh of young fruit (Sugimoto et al. 2009).

A new dammarane-type triterpene ketone, panaxadione, was isolated from ginseng seeds together with 20(*S*)-protopanaxatriol; 3-keto-20(*S*)- protopanaxatriol; 3 β -*trans*-

feruloyloxy-16 β -hydroxyup-20(29)-ene; daucosterol; 5 α -,6 β -dihydroxydaucosterol; saringosteryl glucoside; phenethyl alcohol xylopyranosyl(1 $\rightarrow$ 6)glucopyranoside; and ginsenosides Rg₂, Re and Rd (Sugimoto et al. 2009). A new phenolic glucoside, isoconiferoside, was isolated from ginseng seeds, and its structure was determined to be 9-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 6)- β -D-glucopyranosyl]-*trans*-coniferyl alcohol (Kim et al. 2011b). Three new dammarane-type sapogenins, 20(*R*)-25-methoxyl-dammarane-3 β ,12 β ,20-triol, 20(*R*)-20-methoxyl-dammarane-3 β ,12 β ,25-triol and (12*R*,20*S*,24*S*)-20,24-; 12,24-diepoxy-dammarane-3 β -ol, together with two known ones, 20(*R*)-25-methoxyl-dammarane-3 β ,6 α ,12 β ,20-tetrol and 20(*R*)-20,25-dimethoxyl-dammarane-3 β ,12 β -diol, were isolated from ginseng berry (Zhao et al. 2011).

The ginseng seed oil yield showed that the yield was higher in roasted ginseng seed compared to that of unroasted ginseng seeds (Lee et al. 2013e). The yield of ginseng seed oil was 16.53 % with compress extraction (200 °C, 20 minutes), 13.7 % with n-hexane solvent extraction (200 °C, 30 minute) and 17.48 % with supercritical fluid extraction (SFE) (500 bar, 65 °C). Based on the preceding extraction conditions, fatty acid (g/100 g) of seed oil from compress extraction was palmitic acid (16:0) 2 g, stearic acid (18:0) 0.3 g, palmitoleic acid (16:1) 0.3 g, oleic acid (18:1) 79.8 g, linoleic acid (18:2) 16.2 g, linolenic acid (18:3) 0.1 g and gadoleic acid (20:1) 0.1 g unknown 1.2 %; for n-hexane solvent extraction palmitic acid 2 g, stearic acid 0.3 g, palmitoleic acid 0.2 g, oleic acid 79.7 g, linoleic acid 16.3 g, linolenic acid 0.1 g and gadoleic acid 0.1 g unknown 1.2 %; for SFE palmitic acid (16:0) 2 g, stearic acid (18:0) 0.3 g, palmitoleic acid (16:1) 0.3 g, oleic acid (18:1) 79.8 g, linoleic acid (18:2) 16.2 g, linolenic acid (18:3) 0.1 g and gadoleic acid (20:1) 0.1 g unknown 1.2 %; for n-hexane solvent extraction palmitic acid 1.9 g, stearic acid 0.3 g, palmitoleic acid 0.3 g, oleic acid 79.8 g, linoleic acid 16.3 g, linolenic acid 0.1 g and gadoleic acid 0.1 g unknown 1.2 %. Phenolic acids detected in ginseng seed oil were gentisic acid, vanillic acid, ferulic acid and cinnamic acid. Ferulic and cinnamic acids were detected following

compression extraction, with almost no difference in content depending on the roasting treatment. Cinnamic acid was detected at 0.007–0.029 µg/g, and gentisic acid was detected at 1.438 µg/g in unroasted ginseng seed oil following solvent extraction. The phenolic acids detected in ginseng seed oil following supercritical fluid extraction were vanillic and ferulic acids, and the vanillic acid content tended to decrease as pressure and temperature increased. Stigmasterol and β -sitosterol were obtained from all extraction methods. A phytosterol content analysis in ginseng seed oil showed that the phytosterol content of oil following supercritical fluid extraction was 100.4–135.5 mg/100 g, whereas that following compression extraction and solvent extraction was 71.8–80.9 mg/100 g. A new sterol glucoside, 3-*O*- β -D-glucopyranosyl-5,22,24-stigmastatrienol and a known sterol, 5,22-stigmastadienol were isolated from ginseng seeds (Kim et al. 2013e).

Plant/Calluses Phytochemicals

Free indole-3-acetic acid was identified and extracted from ginseng calluses (Nishio et al. 1976). A water-soluble polysaccharide was isolated from ginseng callus culture with a yield of 16–20 % (Solov'eva et al. 1989). It comprised of starch A and acidic polysaccharides – arabinogalactans and a xyloglucan. Among neutral monosaccharides found, galactose and arabinose predominated and, in addition to these, there were glucose, xylose and rhamnose. The polysaccharides also contained uronic acid residues. Triterpene saponins (ginsenosides) were the main bioactive compounds in *P. ginseng* (Kim et al. 2014e). The isoprene units of triterpene were derived from the mevalonic acid (MVA) pathway. The ginsenosides RG1, RE, Rf, Rg2, Rh1, Rb1, Rc, Rb2, Rb3 and Rd were found in the ginseng red berry, leaf, petiole, stem, main root, lateral root and fine root. The total ginsenoside contents in different organs were ranked in the following descending order: leaf > fine root > lateral root > red berry > main root > petiole > stem. The transcript levels of 11 genes involved in the terpenoid pathway in different organs and cell suspension cultures of *P. ginseng* were investigated: HMGS,

HMG-CoA synthase; MVD, mevalonate diphosphate decarboxylase; SE, squalene epoxidase; CAS, cycloartenol synthase; HMGR, 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase; FPS, farnesyl diphosphate synthase; β -AS, beta-amyrin synthase; SS, squalene synthase; DDS, dammarenediol-II synthase; PMK phosphomevalonate kinase; and lanosterol synthase. Four genes involved in the MVA pathway were cloned using rapid amplification of cDNA ends by polymerase chain reaction. The full-length cDNA sequences were as follows: PgHMGS (1,764 bp; 1,407-bp ORF), PgHMGR (1,992 bp; 1,722-bp ORF), PgPMK (2,170 bp; 1,530-bp ORF) and PgMVD (1,759 bp; 1,263-bp ORF). Campesterol and stigmasterol were detected in all organs but at different concentrations. Cholesterol was found only in the lateral and fine root. The total phytosterol content was highest in fine root (147.8 μ g/100 mg dry weight (DW)) and was lowest in the stem (86.4 μ g/100 mg DW). β -amyrin was found in the red berry, lateral and fine root.

Pharmacological Activities Overview

Studies had demonstrated the pharmacological efficacy of ginseng in improving cerebral function, enhancing immune system and liver functions, adjusting blood pressure, improving climacteric disorder and sexual functions, as well as its pain-relieving, antitumour, antidiabetic, antifatigue, antistress, antioxidative and anti-ageing effects (Choi 2008). The number of ginsenoside types contained in Korean ginseng (38 ginsenosides) is substantially more than that of ginsenoside types contained in American ginseng (19 ginsenosides). Furthermore, Korean ginseng had been identified to contain more main non-saponin compounds, phenol compounds, acid polysaccharides and polyethylene compounds than American ginseng and Sanchi ginseng. Takagi et al. (1972a, b) had reviewed the pharmacological properties of ginseng extracts such as hypotensive, analeptic, stimulatory activity on central nervous system, the respiration and the adrenal cortex, motility of digestive system and correction of nutritional disorders. *P. ginseng* is the most commonly used as an adaptogenic agent and has been shown

to enhance physical performance, promote vitality, increase resistance to stress and ageing and has immunomodulatory activity (Kim 2012). Ginseng leaf–stem extract had also been reported to have antifatigue, antihyperglycaemic, antiobesity, anticancer, antioxidant and anti-ageing properties (Wang et al. 2009a).

Antioxidant Activity

In-Vitro Studies

Ginseng extract scavenged hydroxyl radical by the Fenton reaction and directly inhibited unsaturated fatty acids from decomposition caused by iron-mediated lipid peroxidation as shown by the inhibition of thiobarbituric acid reactive substances (TBARS) and loss of arachidonic acid (Zhang et al. 1996). Heat treatment of ginseng at a temperature higher than that applied to the conventional preparation of red ginseng yielded a mixture of saponins with potent antioxidative properties (Keum et al. 2001). Thus, the methanol extract of heat-processed neo-ginseng (designated as “NGMe”) attenuated lipid peroxidation in rat brain homogenates induced by ferric ion or ferric ion plus ascorbic acid. The extract protected rats against strand scission in øX174 supercoiled DNA induced by UV photolysis of H₂O₂ and was also capable of scavenging superoxide generated by xanthine–xanthine oxidase or by 12-*O*-tetradecanoylphorbol-13-acetate (TPA) in differentiated human promyelocytic leukaemia (HL-60) cells.

In in-vitro studies, ginseng extract inhibited the formation of glycated haemoglobin; glycation is a well-known cause of various forms of diabetic complications (Bae and Lee 2004). The inhibitory effect could be attributed to the antioxidative activity of ginseng. The extracts of *Panax ginseng* showed a remarkable capacity to protect brain tissue proteins from oxidative damage in-vitro, even at extreme (2,000 kRads) dosage levels of hydroxyl (OH.) or superoxide (O₂.) free radical species generated by cobalt 60 irradiation in-vitro (Siddique et al. 2000). It was suggested, therefore, that the beneficial effect of ginseng extract in preventing brain tissue damage in-vivo (e.g. following ischaemia–reperfusion) may

result from their action in protecting brain proteins from oxidative damage, in addition to their previously reported capacity to reduce free radical-induced lipid peroxidation. Ginseng extracts completely eliminated DPPH radical at 2 mg/ml (Kim et al. 2002b). About 0.5 mg/ml ginseng extracts quenched 80 % carbon-centred free radicals generated from 2,2'-azobis(2-amidinopropane) dihydrochloride (AAPH). Ginseng extracts scavenged 40 % of hydroxyl radical at 0.1 mg/ml. Two milligrammes/millilitre ginseng extracts completely scavenged superoxide radical. Ginseng extracts did not scavenge nitric oxide. Of two neutral polysaccharide fractions GPII and GPIII from ginseng extract, GPII exhibited equivalent inhibiting power for self-oxidation of 1,2,3-phentriol to vitamin C, a little higher scavenging activity of superoxide radical and hydroxyl radical than vitamin C, and could be explored as a novel potential antioxidant (Luo and Fang 2008).

Among various solvent extracts in cultivated and wild ginseng leaves, ethyl acetate (EA) extracts in both cultivated and wild ginseng leaves showed the most powerful scavenging activities against DPPH radicals (Jung et al. 2005b). Data on other antioxidant activities, measured by inhibition rates against lipid peroxidation and linoleate oxidation, revealed similar results, showing the highest activities in EA extracts, followed by butanol, water, chloroform and hexane extracts, in both cultivated and wild ginseng leaves. EA extracts of wild ginseng leaves contained more phenolics than cultivated ginseng leaves (9.71 g vs. 4.87 g/100 g, dry basis) and flavonoids (3.03 g vs. 2.34 g/100 g, dry basis). When EC extracts were acid-hydrolysed, two aglycones of flavonoids, quercetin (0.43 and 0.66 g/100 g, dry basis) and kaempferol (1.23 and 1.50 g/100 g, dry basis), were detected in cultivated and wild ginseng leaves. Water, methanol and ethanol extracts of freeze-dried leaves of wild ginseng exhibited antioxidant (free radicals scavenging) activity (Jung et al. 2006). The ethanol extract showed the highest DPPH, hydroxyl radical scavenging and ferrous ion-chelating activity. Otherwise, the highest superoxide radical scavenging activity was found in water extract followed by ethanol and methanol extracts of wild ginseng leaves. Ethanol extracts contained more

phenolics (2,333.2 mg/100 g) and flavonoids (1,199.1 mg/100 g) than other extracts.

Red ginseng (steamed ginseng at 98–100 °C) and sun ginseng (steamed ginseng at 120 °C) showed better superoxide ($O_2^{\cdot-}$), peroxynitrite ($ONOO^-$) and hydroxyl ($\cdot OH$) scavenging activities than white ginseng (WG) (Kang et al. 2006a, b, 2009). Sun ginseng extract showed the strongest activity among the three ginseng extracts. None of the ginsenosides used in this experiment showed nitric oxide ($\cdot NO$) scavenging activity, but the phenolic compounds, such as *p*-coumaric and vanillic acids, and maltol inhibited $\cdot NO$ production in a concentration-dependent manner. Of the principal antioxidant components, maltol, salicylic acid, vanillic acid, syringic acid and *p*-coumaric acid, in the three ginsengs, maltol, vanillic acid and *p*-coumaric acid exhibited $ONOO^-$ scavenging activity. In addition, maltol and *p*-coumaric acid showed strong $\cdot OH$ scavenging activity. Moreover, maltol levels markedly increased by heat processing. The $ONOO^-$ scavenging activities of phenolic acids and maltol were dependent on the degrees of their proton donating ability.

Red ginseng (steamed ginseng at 98–100 °C) and sun ginseng (steamed ginseng at 120 °C) showed better superoxide ($O_2^{\cdot-}$), peroxynitrite ($ONOO^-$) and hydroxyl ($\cdot OH$) scavenging activities than white ginseng (WG) (Kang et al. 2006a, b, 2009). Sun ginseng extract showed the strongest activity among the three ginseng extracts. None of the ginsenosides used in this experiment showed nitric oxide ($\cdot NO$) scavenging activity, but the phenolic compounds, such as *p*-coumaric and vanillic acids, and maltol inhibited $\cdot NO$ production in a concentration-dependent manner. Of the principal antioxidant components maltol, salicylic acid, vanillic acid, syringic acid and *p*-coumaric acid, in the three ginsengs, maltol, vanillic acid and *p*-coumaric acid exhibited $ONOO^-$ scavenging activity. In addition, maltol and *p*-coumaric acid showed strong $\cdot OH$ scavenging activity. Moreover, maltol levels markedly increased by heat processing. The $ONOO^-$ scavenging activities of phenolic acids and maltol were dependent on the degrees of their proton donating ability.

Steam treatment of ginseng, white and red ginseng, increased Maillard reaction products (MRPs) and also increased radical 2,2'-azobis-(2-amidinopropane) dihydrochloride (AAPH) scavenging activity (Cho et al. 2008). Further, MRPs-rich fraction in ginseng showed powerful antioxidant activity, indicating MRPs to be major contributors to antioxidant activity enhanced by steam treatment. Antioxidant activities of hydroponic-cultured ginseng roots (HGR) and hydroponic ginseng leaves (HGL) measured by 1,1-diphenyl-2-picrylhydrazyl and 2,2-azino-bis-3-ethylbenzothiazoline-6-sulfonic acid radical scavenging ability increased with increasing heating temperature (Hwang et al. 2014). After heating, polyphenol contents of HGR and HGL increased from 0.43 mg GAE eq./g and 0.74 mg GAE eq./g to 6.16 mg GAE eq./g and 2.86 mg GAE eq./g, respectively.

The antioxidant potential of the methanol extracts from ginseng plants dose dependently increased (Chon and Kim 2011). DPPH free radical scavenging activity was higher in leaves (36.9–82.8 %) than in roots (14.8–39.4 %) and in young plants than in old ones. Total phenolics level [mg ferulic acid equivalents (FAE)/kg DW] was higher in leaves (22.0–76.3 mg/kg) than in roots (19.0–28.3 mg/kg) of *P. ginseng*. The total content of phenolics in roots increased with increase in plant age from 1 to 6 years. However, the content of phenolics in *P. ginseng* leaf decreased with the increase in age. Total flavonoid [mg naringin equivalents/kg DW] was found more in leaves (30.3–138.6 mg/kg) than in roots (0.0–10.6 mg/kg). The total flavonoid level in leaves decreased with increase in plant age. The total phenolics content in both leaves and roots was highly correlated with the DPPH radical scavenging ($R^2 = 0.7366$ – 0.7870) and nitrite scavenging ($R^2 = 0.5604$ – 0.8794) activities, suggesting that they contribute to the antioxidant properties of the plant.

Heating and solvent use had an impact on the ginsenoside composition and antioxidant activity of fresh ginseng (Hwang et al. 2010). When water and ethanol were used, the ginsenoside compositions significantly changed at 100 and 121 °C, respectively, and it was rapidly decreased at 150 °C.

After heating, the level of three ginsenosides (Re, Rf and Rg1) decreased and that of five other ginsenosides [Rb1, Rb2, Rb3, Rc and Rg2(S)] increased up to 121 °C compared to raw ginseng. Ginsenoside F2, F4, Rg2(R), Rk3, Rh4, Rg3(S), Rg3(R), Rk1 and Rg5, which was absent in raw ginseng, was detected in heated ginseng. Ginsenoside Rg3(S), Rg3(R), Rk1 and Rg5 were markedly produced after thermal processing. After heating, the phenolic compounds (1.43–11.62 mg/g), 50 % inhibition concentration (IC₅₀) value (1.48–3.11 mg/g), and ABTS radical scavenging activity (0.66–9.09 mg AA eq./g) of heated ginseng were increased.

In-vitro antioxidant tests showed that water-soluble ginseng oligosaccharides (WGOS) from roots (WGOS-R) exhibited higher antioxidant activity than WGOS-F from flowers and WGOS-L from leaves (Jiao et al. 2014a). In-vivo antioxidant tests showed that WGOS-R significantly enhanced activities of superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GSH-Px) and total antioxidant capability (T-AOC) in the serum and liver and decreased malondialdehyde (MDA) level in the serum and liver. The sugar content of WGOS-R, WGOS-F and WGOS-L were 95.87 %, 87.07 % and 83.09 %, respectively. The ginsenosides and total phenols content decreased in the order of WGOS-L > WGOS-F > WGOS-R. WGOS-R comprised of only Glc; WGOS-F and WGOS-L comprised of glucose (Glc) and rhamnose (Rha) in a molar ratio of 6.0:1.0 and 7.0:1.0, respectively. Among the saponins isolated from ginseng flowers, floralginsenoside Ka displayed potent scavenging activity with the inhibition value of 64 % at 10 µM, and ginsenoside Rb₁, floralginsenoside Kc, floralginsenoside Kb, vinaginsenoside R₉, majoroside F₁, ginsenoside I and ginsenoside II showed moderate scavenging capacity with the inhibition rate of 28, 33, 35, 35, 35, 38 and 38 % at 10 µM, respectively, as evaluated by the intracellular ROS radical scavenging 2',7' dichlorofluorescein diacetate (DCFH-DA) assay (Tung et al. 2010e).

Animal Studies

Studies suggested that consumption of Korean red ginseng reduced lipid peroxidation and restored antioxidant capacity by suppressing oxidative stress in aged rats through enhancement of enzymatic antioxidants such as superoxide dismutase, catalase, glutathione peroxidase, glutathione reductase and glutathione-*S*-transferase and nonenzymatic antioxidants such as reduced glutathione, vitamin E and vitamin C (Ramesh et al. 2012a). Won et al. (2014) found that administration of a pectinase-treated *P. ginseng* extract enhanced dysfunctional testicular function of aged rats by elevating GPx and GST activity, thus resulting in increased glutathione, which prevented lipid peroxidation in the testis. Studies showed that ginseng ginsenoside Rg₃ significantly inhibited cyclophosphamide-induced oxidative stress in mice by increasing the indices of the spleen and thymus and total antioxidant capacity, elevating the activities of catalase, superoxidase dismutase and lysozyme as well as decreasing the activity of xanthine oxidase and the levels of malondialdehyde and nitric oxide (Wei et al. 2012). Rg₃ was stereospecific in antioxidant activities as the R form exhibited significantly higher antioxidant effects than the S form.

In-vivo studies showed that ginseng extract modulated oxidative stress and DNA fragmentation and upregulated gene expression in rats subchronically treated with aflatoxin B1 and fumonisin B1 (Hassan et al. 2014). The combined treatments with AFB1 and/or FB1 plus ginseng extract suppressed DNA fragmentation only in the liver, normalised lipid peroxidation and increased glutathione in the liver and kidney as well as upregulated the expression of GPx, SOD1 and CAT mRNA. It could be concluded that AFB1 and FB1 had synergistic genotoxic effects. Ginseng extract induced protective effects against their oxidative stress and genotoxicity through its antioxidant properties.

Clinical Studies

In a double-blind randomised controlled design involving 82 healthy participants (21 men and 61 women), administration of *P. ginseng* led to significant decreases in the levels of serum

reactive oxygen species and malondialdehyde (Kim et al. 2011b). Notably, the total glutathione content and glutathione reductase activity considerably improved in the groups that received 2 g of *P. ginseng*. The findings indicated that *P. ginseng* exerted considerably antioxidant properties in healthy people.

Anticancer Activity

In-Vitro Studies

In the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay, the methanol extracts from a 5-year-old ginseng root showed the highest cytotoxicity against human lung adenocarcinoma cell line Calu-6, followed by 2- and 3-year-old ginseng roots (Chon and Kim 2011). However, the methanol extracts from 6- to 4-year-old roots exerted lower cytotoxicity. The 70 % methanolic extract from red ginseng at oral doses of 200–500 mg/kg inhibited solid tumour but was ineffective in the case of rat ascites hepatoma AH 130 (Matsunaga et al. 1992). Ginseng extract when combined with mitomycin C showed a stronger antitumour effect than mitomycin C alone. Moreover, ginseng extract inhibited the pulmonary metastases of the tumour cells, as well as the decrease of blood platelet counts and the fibrinogen level induced by the infusion of the tumour cells in rats. Further, ginseng extract promoted the uptake of mitomycin C into the tumour cells and enhanced in-vitro the cytotoxicity of mitomycin C against the cultured tumour cells. Red ginseng methanol extract combined with mitomycin C showed stronger antitumour effects against the ascites form of mouse Ehrlich ascites carcinoma and rat ascites hepatoma AH 130 than mitomycin C combined with white ginseng methanol extract (Tong et al. 1992). From the ethyl acetate-soluble portion of red ginseng methanol extract, 20(S)- and 20(R)-ginsenoside Rg₃ and ginsenoside Rh₂ were isolated and promoted the uptake of mitomycin C into the tumour cells, but ginsenosides from the n-BuOH soluble portion had no effect on the tumour cells.

Ginsenosides Rh₁ and Rh₂ cause the differentiation of F9 teratocarcinoma stem cells, and the effects of ginsenosides might be exerted via binding with a glucocorticoid receptor or its analogous nuclear receptor (Lee et al. 1996). They found that Rh₁ and Rh₂ may induce the differentiation of F9 cells by stimulating the nuclear translocation of glucocorticoid receptor (Lee et al. 1998). Further, they found that ginsenosides Rh₂ and Rh₃ induced differentiation of human myeloid leukaemia (HL-60) cells into morphological and functional granulocytes, but ginsenoside Rh₁ and ginsenoside Rh₄ did not (Kim et al. 1998c). Ginsenosides Rh₂ and Rh₃ arrested the cell cycle at the G1/S phase, consistent with the ability to induce differentiation in a decreasing order of retinoic acid > G-Rh₂ > G-Rh₃. In-vitro invasion assay showed that ginsenoside Rh₂ reduced the highly metastatic HT1080 human fibrosarcoma cell invasion through a reconstituted basement membrane in a transwell chamber more than ginsenoside Rh₁ (Park et al. 1998b). The results suggested that downregulation of matrix metalloproteinase-9 (MMP-9) contributed to the anti-invasive activity of ginsenosides Rh₁ and Rh₂ in the HT1080 cells. Ginseng saponin metabolite, 20-*O*-β-D-glucopyranosyl-20(*S*)-protopanaxadiol (IH-901), inhibited proliferation of human myeloid leukaemia (HL-60), pulmonary adenocarcinoma (PC-14), gastric adenocarcinoma (MKN-45) and hepatoma (Hep G2) cell lines with IC₅₀ values of 24.3, 25.9, 56.6 and 24.9 μM, respectively (Lee et al. 1999). Ginsenoside Rh₂ induced apoptosis of human hepatoma SK-HEP-1 cells via Bcl-2-insensitive activation of caspase-3, followed by proteolytic cleavage of PARP (Park et al. 1997). Ginsenoside Rs₄, an acetylated analogue of ginsenoside Rg₅, was found to induce apoptosis in human hepatoma SK-HEP-1 cells; the effect was closely associated with the downregulation of both cyclins E- and A-dependent kinase activity as a consequence of selectively elevating protein levels of p53 and p21^{WAF1} in SK-HEP-1 cell (Kim et al. 1999d).

Ginseng ginsenoside Rg₃ displayed growth inhibitory activity in-vitro on human prostate carcinoma LNCaP cell line

(Liu et al. 2000). Results suggested that ginsenoside Rg₃ activated the expression of cyclin-kinase inhibitors p21 and p27, arrested LNCaP cells at G1 phase and subsequently inhibited cell growth through a caspase-3-mediated apoptosis mechanism. Ginsenoside Rh₂ (G-Rh₂) induced apoptosis in human neuroblastoma SK-N-BE(2) and rat glioma C6Bu-1 cells (Kim et al. 2000). During apoptosis induced by ginsenoside Rh₂ in SK-N-BE(2) cells, PKC subtypes alpha, beta and gamma were progressively increased with prolonged treatment, whereas PKC delta increased transiently at 3 and 6 hours and PKC epsilon was gradually downregulated after 6 hours following the treatment. On the other hand, PKC subtype zeta markedly increased at 24 hours when maximal apoptosis was achieved. In C6Bu-1 cells, no significant changes in PKC subtypes were observed during apoptosis induced by ginsenoside Rh₂. Ginsenoside Rh₂ was found to induce apoptosis independently of Bcl-2, Bcl-xL or Bax in C6Bu-1 cells (Kim et al. 1999g).

Among ginsenoside Rg₃ and its metabolites, 20(S)-protopanaxadiol and 20(S)-ginsenoside Rh₂ exhibited the most potent cytotoxicity against tumour cell lines: L1210 (mouse lymphocytic leukaemia cell line), P388 (mouse lymphoid neoplasm cell line), A549 (human lung carcinoma) and Me180 (human cervix uterine carcinoma) with IC₅₀ values of 18–33 µM and 22–33 µm, respectively (Bae et al. 2002b). 20-*O*-(β-D-glucopyranosyl)-20(S)-protopanaxadiol (IH901), an intestinal bacterial metabolite of ginseng saponin formed from ginsenosides Rb₁, Rb₂ and Rc, was found to induce apoptosis in human hepatoblastoma HepG2 cells via a mitochondria-mediated pathway and its downstream caspase-8 activation and Bid cleavage (Oh and Lee 2004). The very low toxicity in normal hepatocytes and high activity in hepatoblastoma HepG2 cells suggested IH901 to be a promising experimental cancer chemopreventive agent.

Acid-treated ginseng (AG) extract, fermented AG extract, ginsenoside Rh₂ and protopanaxadiol showed potent cytotoxicity against tumour cell lines (Bae et al. 2004). Red ginseng ginsenoside Rg₃, inhibited [3H] vinblastine efflux and

reversed p-glycoprotein-mediated multidrug resistance to doxorubicin, colchicine, vincristine and VP-16 in drug-resistant cancer KBV20C cells (Kim et al. 2003c). Further, Rg₃ increased lifespan in mice implanted with doxorubicin-resistant murine leukaemia P388 cells in-vivo and inhibited body weight increase significantly. Protopanaxatriol ginsenosides (PTG), ginsenosides Rb1, Rb2, Rc, Rg1 and Re, showed cytotoxicity in both daunorubicin- and doxorubicin-resistant acute myelogenous leukaemia sublines (AML-2/D100 and AML-2/DX100) and was able to reverse resistance in the AML-2/D100 subline in a concentration-dependent manner (Choi et al. 2003). The effect of PTG (100 µg/mL) on drug accumulation of daunorubicin in the AML-2/D100 subline was two-fold higher than that observed in the presence of verapamil (5 µg/mL) and 1.5 times less than cyclosporin A (3 µg/mL). The maximum non-cytotoxic concentrations of PTG did not appear to increase the P-glycoprotein (PgP) levels, which was in contrast to verapamil and cyclosporin A, PTG at 200 µg/mL, or more completely inhibited the azidopine photolabeling of PgP. The results suggested that PTG had a chemosensitising effect on PgP-mediated MDR cells by increasing the intracellular accumulation of drugs through direct interaction with PgP at the azidopine site. In addition, PTG may have a beneficial effect on cancer chemotherapy with respect to the possibility of long-term use without the concern of Pgp activation.

Ginseng ginsenoside Rh₂ inhibited the growth of B16 melanoma cells at the concentration of 10 µg/ml (IC₅₀: 4.1 µg/ml) in-vitro (Xia and Han 1996). Morphologically, ginsenoside Rh₂-induced B16 cells turned out to be epithelioid cells. B16 cells became dendrite shaped morphologically at higher concentration of Rh₂. Flow cytometry demonstrated that the B16 melanoma cells treated with Rh₂ were blocked at G1 phase. Ginsenoside Rh₂ suppressed the growth of human malignant melanoma A375-S2 cells in-vitro by inducing apoptosis (Fei et al. 2002). G-Rh₂-induced apoptosis was partially dependent on caspase-8 and caspase-3 pathway in A375-S2 cells. Ota et al. (1987) showed that ginsenosides Rh₁

and Rh₂ controlled the phenotypic expression of mouse B16 melanoma cells in different ways. Rh₂ inhibited the growth of and stimulated melanogenesis in B16 melanoma cells. Rh₂ caused morphological changes of the cells and caused significant increase in cell-to-cell adhesiveness and cell-to-substrate adhesiveness. In contrast, Rh₁, which showed no effect on cell growth, but did stimulate melanogenesis, did not cause morphological changes of the cells and exerted no effect on cell adhesiveness or cell surface lectin binding. Also Rh₁ was not detected in the lipid fraction of B16 melanoma cells. The effects of Rh₂ and protopanaxadiol on B16 melanoma cells were identical, and there was no difference in the lag periods before the appearance of their effects, despite their differing rates of uptake (Ota et al. 1991). Differences in affinity for bovine serum albumin (BSA) and the release rate constants were suggested to be the cause of the difference in uptake kinetics between the compounds.

Although ginseng extract (1 mg/mouse) and ginsenosides Rb₁, Rb₂ and Rc (0.5 mg/mouse) significantly inhibited lung metastasis produced by i.v. injection of B16-BL6 melanoma cells in syngeneic mice (27–61 % of untreated control), they hardly inhibited the invasion and migration of B16-BL6 melanoma and HT1080 fibrosarcoma cells in-vitro (Wakabayashi et al. 1997). In contrast, the intestinal bacterial metabolite M1 formed from ginseng protopanaxadiol saponins inhibited lung metastasis of melanoma cells and in-vitro tumour cell invasion and migration at nontoxic or marginally toxic concentrations. The findings suggested that the in-vivo antimetastatic effect by oral administration of ginsenosides was mediated by their metabolic component M1. Ginsenoside Rh₂ suppressed the growth of human malignant melanoma A375-S2 cells in-vitro by inducing apoptosis (Fei et al. 2002). G-Rh₂-induced apoptosis was partially dependent on caspase-8 and caspase-3 pathway in A375-S2 cells.

Ginseng ginsenosides Rb₁ and Rb₂ anaerobically incubated with human faecal microflora afforded compound K (IH-901) while ginsenoside Rg₃ was similarly metabolised to

ginsenoside Rh₂. All were found to have cytotoxicity activity (Shin et al. 2003). Among ginsenosides, compound K and 20(*S*)-ginsenoside Rh₂ exhibited the most potent cytotoxicity against tumour cells. The cytotoxicity potency of ginsenosides was compound K > 20(*S*)-ginsenoside Rh₂ > ginsenoside Rh₂ > 20(*S*)-ginsenoside Rg₃ > ginsenoside Rb₁ = Rb₂. Treatment of guinea pigs with 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) increased the total cytochrome P450 content 2.86-fold, but this was markedly inhibited by the administration of *Panax ginseng* extracts (Lee et al. 2002a). The administration of TCDD resulted in a 1.73-fold increase in microsomal NADPH-cytochrome P450 reductase activity in the guinea pig liver, and this was significantly inhibited by ginseng extracts. They found that ginseng may act as an inhibitor of cytochrome P450 CYP1A rather than that of CYP2B. Ginsenoside Rh₂ was found to induce apoptosis of human neuroblastoma SK-N-BE(2) cells via activation of caspase-1 and -3 and upregulation of Bax (Kim and Jin 2004).

20-*O*-(β-D-glucopyranosyl)-20(*S*)-protopanaxadiol (IH-901), a novel intestinal bacterial metabolite of ginseng protopanaxadiol saponins, had been reported to induce apoptosis in a variety of cancer cells (Ming et al. 2007). IH-901 inhibited cell growth of human hepatocellular carcinoma SMMC7721 cells in a dose- and time-dependent manner, inducing apoptotic cell death concurrent with cell cycle arrest in G₀–G₁ phase in SMMC7721 cells. At the molecular level, it was found that IH-901 upregulated cytochrome *c*, p53 and Bax expression and downregulated pro-caspase-3 and pro-caspase-9 expressions in a dose-dependent manner, while the levels of Bcl-2 and Bcl-X_L were unaltered in IH-901-treated SMMC7721 cells. Panaxydol, a ginseng polyacetylene compound, inhibited the proliferation of human hepatocarcinoma cell line HepG2, induced a cell cycle arrest at the G₁ to S transition and caused morphological and ultrastructural changes in HepG2 cells resembling more mature forms of hepatocytes (Guo et al. 2009). It significantly decreased the secretion of alpha-fetoprotein and the activity of gamma-glutamyl transferase. Panaxydol markedly increased

the secretion of albumin and the alkaline phosphatase activity, protein levels of p21 and pRb, and the hypophosphorylated pRb in a dose-dependent manner while reducing mRNA content of Id-1 and Id-2.

3,6,20(*S*)-Trihydroxy-12,23-epoxydammar-24-ene,6,20-di-*O*- β -D-glucopyranoside, isolated from ginseng leaves, showed the moderate cytotoxic activities against human leukemic lymphoma U937 and human cervical cancer HeLa cells (Wang et al. 2008). Korean red ginseng hot aqueous extract treatment to U937 human leukaemia cells resulted in growth inhibition and induction of apoptosis in a concentration-dependent manner (Park et al. 2009b). The increase in apoptosis was associated with the downregulation of antiapoptotic Bcl-2, Bcl-X_L and IAPs family members and the activation of caspase-3. Ginseng polysaccharide (GPS) induced tumouricidal activity against human leukaemia K562, HL-60 or KG1 α cancer cells in mouse peritoneal macrophages (Wang et al. 2010d). The treatment enhanced phagocytic activity, NO production and increased the levels of cytokines, including tumour necrosis factor- α (TNF- α), interleukin 1 (IL-1) and interleukin 6 (IL-6). Korean red ginseng extract alone was sufficient to induce granulocytic differentiation accompanied with growth inhibition in acute promyelocytic leukaemia cells (Jo et al. 2013). The results suggested a sequential molecular mechanism from MYC and SKP2 gene expression reduction, Cdkn1b protein stabilisation and G1 phase arrest to granulocytic differentiation by KRGE in acute promyelocytic leukaemia.

Two new polyacetylenes, viz. heptadeca-3-oxo-4,6-diyne-9,10-diol and its dihydro derivative from ginseng callus, exhibited growth inhibition against Yoshida sarcoma cells in tissue culture (Fujimoto and Satoh 1987). A new chlorine-containing polyacetylene and chloropanaxydiol from ginseng callus exhibited growth inhibition against leukaemia cells (L-1210) in tissue culture (Fujimoto and Satoh 1988). Two new polyines, 3-acetyloxy-9,10-epoxy-heptadec-1-en-4,6-diyne (acetylpanaxydol) and 10-chloro-3,9-dihydroxyheptadec-1-en-4,6-diyne (panaxydolchlorohydrin), from Korean ginseng roots exhibited good cytotoxic activity against L1210 cells and were

isolated from with ED₅₀ values 0.52 µg/ml and 0.50 µg/ml, respectively (Ahn et al. 1989) Panaxyne epoxide (Kim et al. 1989a) and 10-acetyl panaxytriol with ED₅₀ of 1.2 µg/ml (Kim et al. 1989b) were cytotoxic against lymphoid leukaemia L1210 cells. Panaxytriol from ginseng showed a growth inhibitory activity against several tumour cell lines: human gastric adenocarcinoma MK-1 cells, mouse melanoma B16 cells, mouse fibroblast-derived tumour L929 cells, human colon adenocarcinoma SW620 cells, human uterus carcinoma HeLa cells and human erythroleukemic K562 cells, with ED₅₀ values of 0.8, 1.7, 2.2, 2.3, 10.7 and 11.7 µg/ml, respectively (Matsunaga et al. 1989b). Three polyacetylene compounds, panaxynol, panaxydol and panaxytriol, exhibited in-vitro cytotoxicity activity against several tumour cells (Matsunaga et al. 1990). ED₅₀ values of panaxynol, panaxydol and panaxytriol against nude mouse-transplantable human gastric adenocarcinoma MK-1 cells were 0.027, 0.016 and 0.171 µg/ml; against murine melanoma B16 cells 1.23, 1.50 and 2.23 µg/ml; and against human fibroblast-derived tumour L-925 cells 2.50, 2.60 and 4.39 µg/m, respectively. The cell growth inhibitory activity of these compounds was much stronger against malignant cells than against normal cells. Ginseng panaxydol inhibited cell cycle progression of a human malignant melanoma cell line, SK-MEL-1, at G₁-S transition by decreasing cyclin-dependent kinase 2 (Cdk2) activity and upregulating p27^{KIP1} protein expression (Moon et al. 2000).

Ginseng saponin 20-*O*-(β-D-glucopyranosyl)-20(*S*)-protopanaxadiol (IH-901) formed from ginsenosides Rb1, Rb₂ and Rc, exhibited significant, dose- and time-dependent inhibition of proliferation and induction of apoptosis of human myeloid leukaemia cell line HL-60 with IC₅₀ of 24.3 µM (Lee et al. 2000b). Apoptosis was mediated via mitochondrial cytochrome C-mediated activation of caspase-3 protease. Of 16 acetylenic compounds isolated from ginseng roots, panaxydol showed the most potent cytotoxic activity with IC₅₀ values of 0.65 µM against Kirsten murine sarcoma virus-transformed NIH/3T3 cells (DT cells), 1.3 µM against NIH/3T3 cells and 0.19 µM against murine lymphoma L1210

cells (Hirakura et al. 2000). Panaxytriol exerted both significant cytotoxicity and inhibition of DNA syntheses in various tumour cells tested in both time- and dose-dependent manner (Kim et al. 2002a). For P388D1, a mouse lymphoma cell line, IC₅₀ values for cytotoxicity and inhibition of DNA synthesis were 3.1 and 0.7 µg/ml, respectively. It also induced the cell cycle arrest of P388D1 at the G2/M phase, with corresponding decreases in the proportion of cells at the G0/G1 phase. The S phase also decreased during the 36 hour treatment. Steaming ginseng at high temperature increased its cytotoxicity to SK-Hep-1 hepatoma cancer cells (Park et al. 2002). Ginsenosides Rg3, Rg5, Rk1, Rs5 and Rs4 were found to be the active principles. Their 50 % growth inhibition concentration (GI₅₀) values were 41, 11, 13, 37 and 13 µM, respectively. Cisplatin had a GI₅₀ of 84 µM in the same assay conditions.

Ginsenosides derived from 20(*S*)-protopanaxatriol (PT) and 20(*S*)-protopanaxadiol (PD) groups exerted similar characteristic cytotoxic effects on the growth of two intestinal cells lines, Int-407 (HeLa derivative) and Caco-2 (human colon carcinoma) (Popovich and Kitts 2004). Pure Rh₂, a ginsenoside structurally related to PD, inhibited intestinal cell growth at greater than twice the concentration of PD, while Rh₁, a ginsenoside structurally related to aglycone PT, had no cytotoxic effect. Concentrations causing growth inhibition of 50 % of cells (LC₅₀) for the compounds PD, PT and Rh₂ were 23, 26 and 53 µg/mL, respectively, for Int-407 cells. In comparison, the LC₅₀ for PD and PT was determined to be 24 µg/mL and that for Rh₂ was 55 µg/mL in Caco-2 cells. Ginsenoside Rh₂ inhibited cell growth by G1 arrest at low concentrations and induced apoptosis at high concentrations in a variety of tumour cell lines possibly through activation of caspases (Jia et al. 2004). Rh₂ could act either additively or synergistically with chemotherapy drugs (paclitaxel) on cancer cells. Cheng et al. (2005) found that the antiproliferative effect of Rh₂ in human lung adenocarcinoma A549 cells was mediated by G1 growth arrest and apoptosis. The increase in the expression level of TRAIL-RI (DR4) death receptor may

play a critical role in the initiation of Rh2-triggered apoptosis, and the activation of the caspase-8/caspase-3 cascade acts as the executioner of the Rh2-induced death process. Recent studies by Kim et al. (2014c) found that a combination with inhibitor of AMP-activated protein kinase (AMPK) or p38 MAPK (mitogen-activated protein kinase) could augment the anticancer potential of ginsenoside Rh2.

Among the 11 saponins from ginseng fruit, 25-OH-PPD, 20(*S*)-protopanaxadiol and ginsenoside Rh₂ were the most effective inhibitors of cell growth and proliferation and inducers of apoptosis and cell cycle arrest in several human cancer cell lines in-vitro (Wang et al. 2007). For 25-OH-PPD, the IC₅₀ values for most cell lines were in the range of 10–60 μM, at least twofold lower than for any of the other compounds. Compounds 25-OH-PPD 20(*S*)-protopanaxadiol had significant, dose-dependent effects on apoptosis, proliferation and cell cycle progression. Dammarane-type sapogenins from ginseng fruit, 20(*R*)-25-methoxyl-dammarane-3β,12β,20-triol and 20(*R*)-20-methoxyl-dammarane-3β,12β,25-triol, showed significant cytotoxic activity against six tumour cell lines (MCF-7, HepG2, Du145, Colon205, A549 and HL-60), and the IC₅₀ values of the latter, HepG2, Colon 205, A549 and HL-60, were much lower (Zhao et al. 2011). Panaxydol and panaxyne from wild ginseng roots showed significant and selective cytotoxicity against human SK-OV-3 cancer cells with ED₅₀ values 2.93 and 1.40 μM, respectively (Yang et al. 2008).

Floralginsenoside Ta, ginsenoside F₁ and ginsenoside F₅, from ginseng flower buds exhibited cytotoxic activities towards the HL-60 human leukaemia cell line with respective IC₅₀ values of 36.3, 23.2 and 62.4 μM (Tung et al. 2010c). Several apoptosis events, including chromatin condensation and increase in the population of sub-G1 hypodiploid cells, were observed in ginsenoside-treated HL-60 human leukaemia cells. Fan et al. (2010) found that ginseng pectin inhibited the migration of murine fibroblast L-929 cells and reduced their migration speed by up to 50 % of control in the presence or absence of serum, suggesting it worked on both serum-

dependent and serum-independent migration pathways. Ginseng pectin impaired cell migration via decreased cell spreading. Ginseng leaf ginsenosides Rh₃ and Rk₂ exhibited potent effects against human leukaemia HL-60 cells with IC₅₀ values of 0.8 and 0.9 μM (Tung et al. 2010d). In addition, ginsenosides SL₃, (20S)-ginsenoside Rg₂, ginsenoside F₄ and (20S)-ginsenoside Rh₂ displayed strong activity with IC₅₀ values of 9.0, 9.0, 7.5 and 8.2 μM, respectively. Two flavonoids, sophoraflavonolloside and prunin, isolated from the leaves, were found to inhibit the growth in-vitro of human leukaemia HL-60 cells with IC₅₀ values of 29.8 and 21.4 μM by induction of apoptosis (Tung et al. 2010b). Polysaccharide (PGPW1) from ginseng root dose dependently displayed potent in-vitro antiproliferation and antimetastatic activities (Li et al. 2012a). PGPW1 could significantly inhibit the proliferation of human bladder T24 cells. PGPW1 had an efficient antimetastatic activity to T24 cells. The binding of ³H-NMS to M3 muscarinic receptors of T24 cells was suppressed by PGPW1. All the data indicated the potential of its clinical application for the prevention and treatment of bladder cancer metastasis. Ginsenoside compound K, a metabolite of the protopanaxadiol-type saponins of *Panax ginseng*, inhibited angiogenesis via inhibition of sphingosine 1-phosphate (S1P) production and sphingosine kinase 1 (SPHK1) activity in human umbilical vein endothelial cells (Shin et al. 2014b). Expression of the pro-apoptotic sphingolipids, sphingosine and ceramide was increased in response to ginsenoside K. Ginsengenin, isolated from *P. ginseng*, exhibited in-vitro cytotoxicity against human colorectal carcinoma SW1116, human colon cancer HCT116 and human lung cancer A549 cells with IC₅₀ values in the range of 2.96–30.9 μmol/L (Guan et al. 2013). Three derivatives synthesised from 25-hydroxyprotopanaxadiol from ginseng root, namely, (20R)-12β-*O*-(L-chloroacetyl)-dammarane-3β, 20, 25-triol; (20R)-3β-*O*-(L-alanyl)-dammarane-12β, 20, 25-triol; and (20R)-3β-*O*-(Boc-L-arginyl)-dammarane-12β, 20, 25-triol, significantly inhibited the growths of human colorectal HCT116 cancer cells by induction of apoptosis via caspase-signalling pathways

activation (Xia et al. 2014). 20(S)-Protopanaxadiol, a metabolite of ginseng, exerted potent anticarcinogenic effects on colon carcinogenesis by increasing Ca^{2+} influx, mainly through transient receptor potential canonical (TRPC) channels and by targeting AMP-activated protein kinase (Hwang et al. 2013a).

Gintonin from ginseng and LPA C18:2 inhibited ATX activity and metastasis-related cellular activities in melanoma cells (Hwang et al. 2013b). Ginseng-derived gintonin (containing 9.5 % lysophosphatidic acid (LPA), mainly LPA C18:2) and LPA C18:2 inhibited the purified and secreted autotaxin activity from B16/F10 melanoma cells in a concentration-dependent manner. Gintonin also inhibited cell migration with a minimal inhibition of cell growth. The oral administration of gintonin or LPA C18:2 inhibited lung metastasis induced by tail-vein inoculations of melanoma cells. Moreover, the oral administration of gintonin significantly suppressed the tumour growth induced by subcutaneous grafts of melanoma cells. Also oral administration of gintonin reduced tumour necrosis, the pleomorphism of tumour cells and tumour cell mitosis and angiogenesis. The study demonstrated that the gintonin-induced inhibition of activity may be the molecular basis of ginseng-induced antimetastatic and antitumour activities. Ginseng root polysaccharide (PGP2a) exhibited potent inhibitory effect on the growth of human gastric cancer HGC-27 cells in a dose-dependent fashion (Li et al. 2014). It caused apoptosis and growth cycle arrest in the G2/M phase in HGC-27 cells. Protein expressions of Twist and AKR1C2 were suppressed by PGP2a, whereas an increase of NF1 was observed at protein level. Ginseng root polysaccharide dose dependently decreased migration and invasion of HGC-27 cells by regulation of Twist, AKR1C2, NF1, E-cadherin, vimentin and N-cadherin expression (Cai et al. 2013). Ginsenosides Re and Rg₁ inhibited ubiquitin-activating enzyme (E1), but ginsenosides Re and Rg₁ and ginsenosides Rb₁, Rb₂, Rc and Rd increased ubiquitination on E1 enzyme (Chang et al. 2014). Moreover, ginsenoside Rg₁ inhibited both the chymotrypsin-like activity of 26S proteasome and E1

activity suggesting ginsenoside Rg₁ to be a potential functional food application for cancer prevention because of its specific E1 inhibitory effects.

Animal Studies

Oral administration of ginsenoside Rh₂ (Rh₂) inhibited tumour growth in nude mice bearing human ovarian cancer cells (Tode et al. 1993a, b). In particular, tumour growth in mice treated with 15, 30 and 120 µM Rh₂ was significantly inhibited compared to that in cisplatin (CDDP)-treated mice as well as in untreated mice. Consequently, 50 % survival in nude mice treated with 15, 30 and 120 µM Rh₂ was significantly prolonged compared to that not only in untreated mice but also in CDDP-treated mice. Multiple administrations of ginseng ginsenoside Rb₂, after the intravenous inoculation of B16-BL6 melanoma cells in syngeneic mice, resulted in a significant inhibition of lung metastasis as compared with the untreated control (Sato et al. 1994). The results suggested that the inhibition of tumour-associated angiogenesis by ginsenoside Rb₂ may partly contribute to the inhibition of lung tumour metastasis. Further, they found that both ginseng saponins, 20(*R*)- and 20(*S*)-ginsenoside Rg₃, possessed an ability to inhibit the lung metastasis of tumour cells of B16-BL6 melanoma and lung metastasis produced by colon 26-M3.1 carcinoma in syngeneic mice (Mochizuki et al. 1995). The mechanism of their antimetastatic effect was related to inhibition of the adhesion and invasion of tumour cells and also to anti-angiogenesis activity.

Ginsenoside Rh₂ (Rh₂), isolated from an ethanol ginseng extract, inhibited proliferations of various established human ovarian cancer cell lines in a dose-dependent manner between 10 and 60 µM in-vitro and induced apoptosis at around the IC₅₀ dose (Nakata et al. 1998). Although i.p. administration of Rh₂ alone to mice with ovarian cancer cells hardly inhibited tumour growth, when Rh₂ was combined with *cis-diamminedichloroplatinum* (II) (CDDP), the tumour growth was significantly inhibited, compared to treatment with CDDP

alone. When mice were treated p.o. with Rh₂ daily (but not weekly), the tumour growth was significantly inhibited, compared to CDDP treatment alone. When Rh₂ was combined with CDDP, the degree of tumour growth retardation was not potentiated. It was found that p.o. but not i.p. treatment with Rh₂ resulted in the induction of apoptotic cells in the tumour in addition to augmentation of the natural killer activity in spleen cells from tumour-bearing nude mice. Panaxytriol (40 mg/kg) administered intramuscularly produced significant tumour growth delays of B16 melanomas in C57BL/6 mice (Katano et al. 1990).

Red ginseng extracts at 50–400 mg/kg inhibited DMBA/croton oil-induced skin papilloma in mice, decreased the incidence of papilloma, prolonged the latent period of tumour occurrence and reduced tumour number per mouse in a dose-dependent manner (Chen et al. 1998). Red ginseng extract B effectively inhibited the Fe²⁺/cysteine-induced lipid peroxidation of rat liver microsome, suggesting that red ginseng extract B had a stronger antioxidative effect than that of extract A. The results indicated that red ginseng extracts (50–400 mg/kg) could significantly inhibit the growth of transplantable mouse sarcoma S180 and melanoma B16. Red ginseng extracts A (0.5 mg/ml) and B (0.1 and 0.25 mg/ml) could effectively promote the transformation of T lymphocyte, but there was no influence on lymphocyte proliferation stimulated by concanavalin A. The results suggested that red ginseng extracts had potent tumour therapeutic activity and improved the cell immune system. Use of red ginseng extract elicited 22 % decrease in the incidence of urethane-induced lung adenoma in mice (Yun et al. 2001a). In mice sacrificed at 56 weeks after the treatment with aflatoxin B1, the incidence of hepatoma significantly decreased to 75 % by the addition of red ginseng extract. In lung tumour models in mice, significant anticarcinogenic effects of powders and extracts of the 6-year-old dried fresh ginseng, 5- and 6-year-old white ginsengs and 4-, 5- and 6-year-old red ginseng were confirmed. The anticarcinogenicity of ginseng was enhanced in aged or heat-treated extracts of ginseng and red ginseng made by steaming. Among the semisynthetic ginsenosides tested, Rg₃ and Rg₅

showed statistically significant reduction of lung tumour incidence, and Rh₂ had a tendency of decreasing the incidence. Ginsenoside Rg₃, Rg₅ and Rh₂ were found to be active anticarcinogenic compounds.

Topical application of methanol extract of heat-processed neo-ginseng (designated as “NGMe”) onto shaven backs of female ICR mice 10 minute prior to 12-*O*-tetradecanoylphorbol-13-acetate (TPA) significantly ameliorated skin papillomagenesis initiated by 7,12-dimethylbenz[*a*]anthracene (Keum et al. 2001). Moreover, TPA-induced enhancement of epidermal ornithine decarboxylase (ODC) activity and ODC mRNA expression was abolished by a topical dose (0.68 mg) of NGMe. Likewise, TPA-induced production of tumour necrosis factor in mouse skin was inhibited by NGMe pretreatment. Studies suggested that the antitumour promoting activity of ginsenoside Rg₃ may possibly be mediated through downregulation of NF-κB and AP-1 transcription factors (Keum et al. 2003). Pretreatment of dorsal skins of female ICR mice with Rg₃ significantly inhibited 12-*O*-tetradecanoylphorbol-13-acetate (TPA)-induced ornithine decarboxylase activity and 7,12-dimethylbenz[*a*]anthracene-initiated papilloma formation. In another experiment, Rg₃ pretreatment abrogated the expression of cyclooxygenase-2 in TPA-stimulated mouse skin. Rg₃ also inhibited the TPA-induced activation of the eukaryotic transcription factor, NF-κB, in both mouse skin and cultured human pro-myelocytic leukaemia (HL-60) cells. Also, Rg₃ exerted potent inhibitory effects on the activation of another transcription factor, activator protein-1 (AP-1), that is responsible for *c-jun* and *c-fos* oncogenic transactivation.

The oral administration of *Panax Ginseng* extract (EFLA400, processed *Panax ginseng* extract containing a high titre of ginsenoside Rg₃ (>3.0 % w/w) known as Phoenix ginseng) at 1, 3 and 10 mg/kg body weight at pre-, peri- and post-initiation phases showed significant reductions in the number, size and weight of the papillomas in Swiss albino mice (Panwar et al. 2005a). A significant reduction in tumour

incidence (71.41 %, 72.19 % and 70.46 % at 1, 3 and 10 mg/kg body weight, respectively) was observed in animals in the EFLA400-treated group compared with 100 % tumour incidence in the control group. The average tumour weight was recorded as 128.55, 116.00 and 57.5 mg in 1, 3 and 10 mg/kg body weight EFLA400-treated groups, respectively. In the EFLA400-treated groups, significantly reduced frequencies of chromosomal aberrations and micronuclei induced by DMBA and croton oil were observed. However, the maximum decrease in the frequencies of chromosomal aberrations and micronuclei was recorded in the 10 mg/kg body weight EFLA400-treated group than that of the 1 and 3 mg/kg body weight EFLA400-treated animals. They also demonstrated that oral administration of EFLA400 (10 mg/kg body weight) showed significant reduction in number of adenomas and weight of the lungs induced by benzo(a)pyrene (BP) in newborn Swiss albino mice (Panwar et al. 2005b). A significant reduction in lung adenoma incidence in EFLA400-treated mice was observed as compared to the 68.3 % lung adenoma incidence in BP-alone group. In EFLA400-treated group, significantly reduced frequencies of chromosomal aberrations and micronuclei induced by BP were observed.

In-vitro and in-vivo studies demonstrated that two novel ginsenosides, 25-OH-PPD (20(R)-dammarane-3 β ,12 β ,20,25-tetrol) from *P. ginseng* and 25-OCH₃-PPD (20(S)-25-methoxyl-dammarane-3 β ,12 β ,20-triol) from *P. notoginseng*, inhibited proliferation, caused cell cycle arrest and induced apoptosis in human pancreatic cells and also both inhibited the growth of Panc-1 xenograft tumours without any host toxicity (Wang et al. 2009b). Preliminary investigations suggested that their effects may be partially mediated by their inhibition of the murine double minute (MDM2) oncogene and related pathways. Kim et al. (2013c) found that *Panax ginseng* extract exerted antiproliferative effects on rat hepatocarcinogenesis by induction of cell cycle arrest but not extracts of *Panax japonicus* or *P. quinquefolius*. Ginseng diet downregulated the expression of Cyclin D1, Cyclin G1, Cdc2a and Igf-1, which were involved in the p53 signalling pathway. Treatment of rats with ginseng extract during, before or after the treatment with

aflatoxin B1 and fumonisin improved all biochemical parameters and histological picture of the liver (Abdel-Wahab et al. 2010). Moreover, treatment with ginseng extract after the administration of the mycotoxins was found to be more effective. It was concluded that ginseng had protective effects as precancerous lesions and therapeutic effects as well.

Antimutagenic/Antigenotoxic Activity

Total saponins from ginseng stem and leaf (TSPG) significantly reduced the genotoxicity of cyclophosphamide in bone marrow cells and peripheral lymphocyte cells and decreased the apoptotic cell number induced by cyclophosphamide in bone marrow cells (Zhang et al. 2008b). TSPG antagonised cyclophosphamide-induced reduction of T-SOD, GPx, CAT activities and the GSH contents.

Panax ginseng extract standardised with ginsenoside Rg₃ (ginsenoside Rg₃ content was 3.6 % w/w, i.e. 36 µg/mg *P. ginseng* extract) was found to have a protective effect against ethylenediaminetetraacetic acid (EDTA)-induced biochemical, genotoxic and histological changes in rats (Khalil et al. 2008). EDTA is widely used in food and other industries to sequester metal ions and to prevent their disadvantageous effects. EDTA administration to rats caused a significant decrease in the serum biochemical parameters and antioxidant enzymes activity, increased lipid peroxidation and the incidence of micronucleated polychromatic erythrocytes (MnPCEs), caused appearance of some changes in polymorphism band patterns and induced different histopathological lesions in the livers, kidneys and testis. Treatment with *P. ginseng*, garlic alone or plus EDTA significantly improved all the tested parameters. Furthermore, *P. ginseng* extract was found to be more effective than garlic in restoring the parameters that were altered by EDTA.

Antiplatelet/Antithrombotic Activities

A 70 % methanol extract of Korean red ginseng prevented the exchanges of values of clinical examination (blood platelet,

fibrinogen and prothrombin time) at a dose of 500 mg/kg in rats on disseminated intravascular coagulation (DIC) induced by endotoxin or thrombin (Matsuda and Kubo 1983). The extract exhibited fibrinolytic activity in rats in the fibrinolytic system. In the in-vitro experiments, incubation of the extract in the plasminogen-containing fibrin plate promoted activation of urokinase action. Ginsenoside Ro (50 mg/kg, p.o.) prevented the decrease of fibrinogen in endotoxin-induced models of disseminated intravascular coagulation (DIC) in rats (Matsuda et al. 1986b). Ginsenoside Ro also inhibited the formation of fibrin thrombin in the renal glomeruli in thrombin-induced DIC. Ginsenoside Ro showed a promotive effect on the activation of the fibrinolytic system. Ginsenoside Rg₂ also showed strong inhibitory activity on platelet aggregation induced by three aggregating agents (endotoxin, collagen and arachidonic acid) as compared with aspirin at a concentration of 1.0 mM (Matsuda et al. 1986a). Ginsenoside Ro inhibited the conversion of fibrinogen to fibrin induced by thrombin at concentrations of 0.1–1.0 mM. Ginsenosides Ro, Rb₁, Rb₂, Rc, Re, Rg₁ and Rg₂ may promote the action of urokinase in the fibrinolytic system on the basis of its action on plasminogen-containing fibrin plates. Ginseng ginsenoside Rb₂ enhanced fibrinolytic activity of bovine aortic endothelial cells (BAEC) (Liu et al. 2003). Ginsenoside Rb₂ enhanced the plasminogen activator activity levels as well as the surface plasmin activity in BAEC. Rb₂ stimulated the secretion of urokinase-type PA (uPA) without enhancing the gene expression of uPA, uPA receptor (uPAR) and/or its inhibitor PAI-1.

The non-saponin fraction (NSF; lipophilic fraction) from ginseng roots dose dependently inhibited the aggregation of human platelets induced by thrombin and inhibited Ca²⁺-influx into platelets (Park et al. 1995). NSF induced the elevation of cGMP concentration in human platelets in a similar manner to molsidomine, a known vasodilator, and potently inhibited the thromboxane A₂ (TXA₂) production. The results suggested that NSF may regulate the levels of

cGMP and TXA₂ to inhibit platelet aggregation induced by thrombin.

Panaxynol was found to be the most potent antiplatelet agent in ginseng, and its mechanism of action was primarily attributed to the inhibition of thromboxane formation (Teng et al. 1989). Panaxynol (0.1 mg/ml) inhibited markedly the aggregation of washed platelets induced by collagen, arachidonic acid, ADP, ionophore A23187 and PAF. Ginsenosides had no significant effect on the aggregation, but ginsenoside Ro (1 mg/ml) inhibited the ATP release of platelets. Thromboxane B₂ formation of platelets was inhibited by panaxynol but not by ginsenosides. 20(*S*)-Ginsenoside and delta20-ginsenoside Rg₃ and protopanaxadiol-type saponins from ginseng were found to be relatively potent platelet activating factor antagonists (IC₅₀ = 4.9 × 10⁻⁵ M and 9.2 × 10⁻⁵ M, respectively) (Jung et al. 1998). Total saponin from Korean red ginseng extract was found to be a beneficial herbal substance elevating cAMP level in thrombin–platelet interaction, which may result in the prevention of platelet aggregation-mediated thrombotic diseases (Lee et al. 2013b). The extract dose-dependently inhibited thrombin-induced platelet aggregation with IC₅₀ value of 81.1 µg/mL, decreased the level of cytosolic-free Ca²⁺ and inhibited thrombin-elevated adenosine triphosphate (ATP) release from platelets. The extract significantly dose-dependently elevated intracellular level of cAMP.

Studies by Park et al. (1996) found that the lipophilic fraction (LF) from *Panax ginseng* increased cGMP directly and cAMP indirectly and thus inhibited thrombin- or collagen-induced rat platelet aggregation. Both the thrombin time (TT) and activated partial thromboplastin time (APTT) were prolonged more in citrated platelet-poor plasma from 15 % corn oil plus LF-administered rats (COLF) than that from 15 % corn oil only-administered rats (CO). The level of lipids such as triglyceride, total cholesterol, high-density lipoprotein cholesterol and low-density lipoprotein cholesterol was decreased in serum from COLF more than in that of CO. Kim et al. (1999a) isolated antithrombin active

heteropolysaccharide from red ginseng; it inhibited blood coagulation via the intrinsic pathway like heparin in a dose-dependent manner. The clotting of fibrinogen by thrombin was also mitigated by the presence of this polysaccharide. In rats with blood stasis induced by high molecular weight dextran, Korean red ginseng (KRG) and its herbal prescription (KRGP) consisting of five herbs such as Korean red ginseng, *Ganoderma*, *Cinnamomi cortex*, *Glycyrrhizae radix* and *Laminaria* not only significantly restored the number of platelets and fibrinogen but also suppressed the fibrin degradation products (FDP) to normal range (Yun et al. 2001b). In platelet aggregation assay with human platelet-rich plasma (PRP), KRG and KRGP significantly inhibited thrombin- and collagen-induced platelet aggregation. In coagulation assay, KRG and KRGP significantly prolonged activated partial prothrombin time (APPT) and prothrombin time (PT) as compared with control data. KRGP was found to be more effective than KRG alone on antithrombotic activity.

Administration of Korean red ginseng (KRG) to rats not only prevented carotid artery thrombosis in-vivo in a dose-dependent manner but also significantly inhibited ADP- and collagen-induced platelet aggregation ex vivo while failing to prolong coagulation times such as activated partial APTT and PT, indicating that the antithrombotic effect of KRG might be due to its antiplatelet aggregation rather than anticoagulation effect (Yu et al. 2006; Jin et al. 2007). KRG inhibited U46619-, arachidonic acid-, collagen- and thrombin-induced rabbit platelet aggregation in-vitro in a concentration-dependent manner, with IC₅₀ values of 620, 823, 722 and 650 µg/mL, respectively. Accordingly, KRG also inhibited various agonists-induced platelet serotonin secretions as it suppressed platelet aggregation. Thus, KRG intake may be beneficial to the individuals with high risks of thrombotic and cardiovascular diseases. Administration of Korean red ginseng water extract (KRG-WE) (200 mg/kg/day) to high-cholesterol-diet-fed rabbits for 8 weeks potently inhibited the platelet aggregation induced by low doses of agonists (0.5 µg/mL collagen and 0.025 unit/mL thrombin), whereas it weakly reduced the blood cholesterol levels and formation of atheromatous lesions (Hwang et al. 2008). Further, KRG-WE

significantly suppressed collagen-induced 1,2-diacylglycerol liberation but had no significant effect on arachidonic acid liberation. The results suggested that the antiplatelet effect of KRG-WE may, at least partly, be due to the inhibition of 1,2-diacylglycerol generation rather than regulation of blood lipid levels. In a screening of various fractions of Korean red ginseng, Wee et al. (2010) found that the ethyl acetate fraction possessed potent anticoagulant activity in-vitro, and phenolic acids vanillic, caffeic, ferulic and p-coumaric were identified as the active components in this fraction. Ginsenosides Rg₆, F₄ and Rk₃ from processed ginseng showed inhibitory activity (IC₅₀ = 76 µM, 114 µM and 128 µM, respectively) on arachidonic acid-induced platelet aggregation (Lee et al. 2010a). The corresponding IC₅₀ values were comparable to that of acetylsalicylic acid (ASA) (63 µM). Compared to ASA (IC₅₀ = 468 µM), ginsenosides Rg₆, F₄, Rk₃ and Rh₄ were found to be more inhibitive (IC₅₀ = 286 µM, 87 µM, 187 µM and 119 µM, respectively) against U46619 (thromboxane A₂ mimetic drug)-induced aggregation. In contrast, most of the ginsenosides (Rg₆, F₄, Rh₄, Rs₃, Rs₅) showed negligible effects on adenosine diphosphate- and collagen-induced platelet aggregation. The acetylated ginsenosides (Rs₃, Rs₄ and Rs₅) had only mild effects on aggregation induced by the four stimulators. Rg₁ significantly inhibited platelet aggregation induced by thrombin, ADP, collagen and U46619 via the inhibition of ERK phosphorylation and attenuated arterial thrombus formation in-vivo (Zhou et al. 2014). Rg₁ also reduced thrombin-enhanced fibrinogen binding and P-selectin expression of single platelet and decreased the rate of clot retraction in platelet-rich plasma. Rg₁ was found to prolong the mesenteric arterial occlusion time.

Ergogenic (Antifatigue)/Adaptogenic Activity

Ginseng had been used by athletes as an ergogenic aid for many years despite the lack of compelling research evidence

in support of its use for this purpose (Bahrke and Morgan 1994). Ginseng root had been considered a tonic or adaptogenic that enhanced physical performance (including sexual), promoted vitality and increased resistance to stress and ageing (Nocerino et al. 2000). The adaptogenic properties of ginseng were believed to be due to its effects on hypothalamic–pituitary–adrenal axis, resulting in elevated plasma corticotropin and corticosteroids levels. When used appropriately, ginseng appeared to be safe.

Animal Studies

All ginseng saponins showed antifatigue action (Kaku et al. 1975). They markedly increased the movement after compulsory gait, and the action was consistent and independent of their action on the movement before compulsory gait. Ginseng water extract significantly accelerated the recovery of exploratory movements in mice, increased motor activity index in exploratory movement (EM) and elevated rectal temperature (RT) test (Saito et al. 1974). However, water extract decreased the index in hole cross (HC) and grip tone in spring balance (SB) test. An in-vivo study showed that administration of ginseng did not significantly alter the lifespan of mice, but it did cause an exaggeration of the behavioural responses to mild stress (Bitties et al. 1979). This effect was noticeable soon after ginseng administration and subsequently was maintained. Banerjee and Izquierdo (1982) found both piracetam and ginseng treatment provided good protection against electroshock stress when compared to the untreated mice; fighting scores, incidence of tonic convulsion and mortality were significantly less in the treated groups. In the heat stress experiments, both piracetam and ginseng provided significant protection to the treated mice against exposure to heat. In the fatigue stress of forced swim test, ginseng treatment provided effective adaptation to fatigue and increased endurance in both male and female mice; piracetam showed some antifatigue effects on the male mice only. In the locomotor activity tests, ginseng did not depress motility, while piracetam did so in the later part of the tests. Avakian et al. (1984) found that during exercise, ginseng

extract-treated rats had higher blood glucose levels than control rats and markedly lower concentrations of circulating lactic acid, pyruvic acid and free fatty acid levels. The data suggested that ginseng ginsenosides could significantly alter mechanisms of fuel homeostasis during prolonged exercise, presumably by increasing the biochemical capacity of skeletal muscle to oxidise free fatty acids in preference of glucose for cellular energy production. In an earlier animal study, they found that ginseng extract had pronounced inhibitory effects on endogenous glycogen utilisation in white skeletal muscle during exercise (Avakian and Evonuk 1979). The findings indicated that ginseng extract had carbohydrate-sparing actions during prolonged exercise and suggested a possible physiological basis for ginseng's antifatigue properties.

Lasarova et al. (1987) found that standardised ginseng extract, administered in a dose of 30 mg/kg orally for 10 days prior to the beginning of the training session, markedly tended to eliminate the memory-impairing effect of electroconvulsive shock in rats. *Panax ginseng* root and *Ginkgo biloba* leaf extracts exhibited positive endurance-promoting properties of rats using both cold-hypoxia-restraint model and cold swimming models (Ramachandran et al. 1990). The cold-hypoxia-restraint model was found to provide more precise results compared with the cold-swimming model. In contrast, studies by Lewis et al. (1983) found no significant difference in stamina or longevity between mice drinking infusions of two preparations of Siberian ginseng, Oriental ginseng or American ginseng and control mice when subjected to swimming trials in cold water 38, 46 and 96 days after treatment began. Consequently, ingestion of adaptogenic glycosides did not significantly affect the survival of mice under major environmental stress.

Antifatigue effects of ginsenoside Rg₁ were obvious in every test. Lipophilic fraction significantly speeded up recovery from fatigue in EM, rotating rod (RR), RT and SB tests but delayed recovery in HC and sliding angle (SA) tests. In separate studies, ginseng extract (GNo. 3), ginseng lipophilic fraction (GNo. 5) and ginsenoside Rg₁, at small consecutive doses, expedited recovery from exhaustion in

mice after 4 hour oscillation period (Takagi et al. 1974). Ginsenoside Rg was found to stimulate the central nervous system, while ginsenoside Rb exerted a sedative effect. Administration of ginseng and its ginsenosides to mice before but not after ethanol treatment was found to enhance exercise endurance and reduce the plasma level of ethanol (Koo 1998). Gastric emptying was slowed by ginseng, ginsenosides or ethanol administration. An additive effect was observed when the mice were pretreated with ginseng or ginsenosides 10 minutes before ethanol administration.

Administration of *Panax ginseng* extract G115 significantly increased hepatic glutathione peroxidase activity (GPX) and reduced glutathione (GSH) levels in the liver, with a dose-dependent reduction of the thiobarbituric acid reactive substances (TBARS) (Voces et al. 1999). After the exercise, there was reduced hepatic lipid peroxidation, as evidenced by the TBARS levels in both the control and treated animals. The GPX (glutathione peroxidase) and SOD (superoxide dismutase) activities were also significantly increased in the groups receiving G115, compared with the controls. The hepatic transaminase levels, ALT (alanine aminotransferase) and AST (aspartate aminotransferase), in the recuperation phase 48 hours after the exercise indicated a clear hepatoprotective effect related to the administration of the standardised ginseng extract G115. At hepatic level, G115 increased the antioxidant capacity, with a marked reduction of the effects of the oxidative stress induced by the exhaustive exercise. Oral administration of red ginseng for 30 days resulted in improvement of Cornell Medical Index (CMI) and the State-Trait Anxiety Inventory (STAI) psychological scores in postmenopausal women suffering climacteric syndromes, particularly fatigue, insomnia and depression (Tode et al. 1999). The ameliorating effect of red ginseng was in part attributed to its effects on stress-related hormones as shown by a decrease in cortisol/dehydroepiandrosterone-S ratio. Intraperitoneal administration of a bioactive water-soluble saponin-free fraction (RG-ws-l-l-l) from red ginseng (200 mg/kg, 14 days) to mice resulted in an increase in oxygen consumption at 37 °C (Larina et al. 2001). Oxygen consumption and formation of superoxide radicals (FSR) by

neutrophils were suppressed when cells obtained from the control animals were incubated at 42 °C. Preincubation of neutrophils with RG-ws-1-I-1 reduced heat stress-related depression of FSR. In-vivo administration of RG-ws-1-I-1 to mice decreased heat stress-related suppression of oxygen consumption. Thus, RG-ws-1-I-1 subfraction significantly improved an oxygen-dependent antimicrobial function of neutrophils under heat stress.

Ginseng total saponins, ginsenosides Rb₂, Rg₁ and Rd, administered intraperitoneally attenuated the immobilisation stress-induced increase in plasma interleukin IL-6 level in mice (Kim et al. 2003a). Results suggested that the inhibitory action of ginseng saponins against the immobilisation stress-induced increase of plasma IL-6 level would be in periphery, at least in part mediated by blocking norepinephrine- and/or epinephrine-induced increase of IL-6 level in macrophage rather than in the brain. Lee et al. (2006c) reported that administration of total saponins (GTS), ginsenosides Rg₃ and Rb₁, led to an antistress effect in immobilisation-stressed gerbil mice. Pretreatment of GTS and ginsenosides Rg₃ and Rb₁ reduced the stress-elevated polyamine putrescine level in the brain. Voces et al. (2004) showed that oral administration of ginseng extract for 3 months to male Wistar rats was able to protect muscle from exercise-induced oxidative stress irrespective of fibre type. Lipid peroxidation, measured on the basis of malondialdehyde levels, was significantly higher in all muscles after exercise and again was reduced by about 74 % by the use of ginseng extract. The results showed a membrane-stabilising capacity of the extract since mitochondrial function measured on the basis of citrate synthase and 3-hydroxyacyl-CoA dehydrogenase activities was reduced, on average, by 20 % after exercise, but the activities remained unchanged in animals treated with a ginseng dose of 100 mg/kg. Pannacci et al. (2006) found that administration of ginseng G115 to mice enhanced the production of proinflammatory cytokine linked to an increased expression of toll-like receptor 4 (TLR4) RNA in peritoneal macrophages during swimming stress. A significant increase of lipopolysaccharide (LPS)-stimulated interleukin IL-1β and TNF-α concentrations was present in

trained animals with similar patterns of TLR4 expression. A crude extract and a standardised ginseng extract (G115) of different saponin compositions appeared to be equally effective in reducing injuries and inflammation caused by eccentric muscle contractions in rats (Cabral de Oliveira et al. 2001). Both extracts reduced lipid peroxidation by approximately 15 % as measured by malondialdehyde levels. β -Glucuronidase concentrations and glucose-6-phosphate dehydrogenase (G6PDH) levels, which can be considered markers of inflammation, were also significantly reduced. Ginseng treatment (100 mg/kg) protected muscles from eccentric exercise injuries (Cabral de Oliveira et al. 2005). It was effective in preserving mitochondrial membrane integrity and reduced nitrate concentration in vastus and rectus (46 % and 26 %, respectively). It also reduced carbonyl contents by approximately 27 % in all the muscles studied. Animal studies demonstrated that ginseng ginsenoside Rg₃ mimicked improved cardiac adaptations to exercise by regulating mitochondrial dynamic remodelling and enhancing the quantity and quality of mitochondria (Sun et al. 2013). Both aerobic exercise training and Rg₃ supplementation enhanced peroxisome proliferator-activated receptor coactivator 1 alpha (PGC-1 α) and nuclear factor-E2-related factor 2 (Nrf2) protein levels in the rat cardiac muscle. Red ginseng appeared to inhibit oxidative stress-inducible peptidyl arginine deiminase type 4 (PADI4) by upregulating oestrogen receptor (ER)- β expression in the brain of immobilisation-stressed mice, thus protecting brain cells from apoptosis (Kim et al. 2013a).

Clinical Studies

The water extract of *Panax ginseng* had a preventative action against somatic fatigue in the human body, associated probably to its central stimulant action (Yamada 1955). In a study on the effects of ginseng in fatigued night nurses, nurses assessed night duty as impairing performance in all mood scales and most of the bodily feeling scales; ginseng improved the self-rating scales for competence, mood and performance in one of the psychophysical tests (Hallstrom et al. 1982). Compared to placebo, ginseng had no effect on the blood tests.

A double-blind, randomised, crossover study in 50 healthy male sports teachers aged 21–47 years, found that the six-week administration of ginseng preparation containing ginseng extract, dimethylaminoethanol bitartrate, vitamins, minerals and trace elements, increased the subjects' work capacity by improving muscular oxygen utilisation compared to placebo (Pieralisi et al. 1991). In a study of seven healthy male subjects, administration of ginseng extract significantly increased exercise duration on the treadmill until exhaustion by 1.5 minutes (Kim et al. 2005). It was found that the elevation in catalase and superoxide dismutase activities as scavenger enzymes after ginseng extract administration resulted in the decrease of malondialdehyde level and consequently prolonged exercise duration until exhaustion. The findings supported scientific claims that ginseng had ergogenic properties in facilitating recovery from exhaustive exercise. Ginseng polysaccharides were found to have antifatigue activity, also reflected in the effects on the physiological markers for fatigue (Wang et al. 2010c). Ginseng polysaccharides (WGP) and its fractions neutral (WGPN) and acidic (WGPA) inhibited forced swim test-induced reduction in glucose and glutathione peroxidase and increase in creatine phosphokinase, lactic dehydrogenase and malondialdehyde levels, all indicators of fatigue. The acidic polysaccharide was more potent than the neutral polysaccharide. In a subsequent paper, they reported that oral administration of ginseng acidic polysaccharide WGPA and its active fraction WGPA-A prolonged swimming time of mice in the forced swimming test (Wang et al. 2014a). Malondialdehyde and lactate dehydrogenase levels in the serum were enhanced, while those of superoxide dismutase and glutathione peroxidase were lowered. Also, the structural degeneration of mitochondria was ameliorated. The results suggested that WGPA-A may have potential therapeutic effects for chronic fatigue syndrome and that oxidative stress may be involved in the disorder.

In a study of seven healthy male subjects, administration of ginseng extract significantly increased exercise duration on the treadmill until exhaustion by 1.5 minutes (Kim et al. 2005). It was found that the elevation in catalase and superoxide dismutase activities as scavenger enzymes after

ginseng extract administration resulted in the decrease of malondialdehyde level and consequently prolonged exercise duration until exhaustion. The findings supported scientific claims that ginseng had ergogenic properties in facilitating recovery from exhaustive exercise. In a randomised, double-blind, placebo-controlled and parallel designed trial of 90 subjects (21 men and 69 women) with idiopathic chronic fatigue (ICF), 4-week administration of ginseng extract decreased the total NRS score, but this was not statistically significant compared with placebo score (Kim et al. 2013c). Mental NRS score was significantly improved by 1 g and 2 g *P. ginseng* administrations compared with placebo. Only 2 g *P. ginseng* significantly reduced the visual analogue scale (VAS) score from 7.3 to 4.4 compared with the placebo 7.1–5.8. Reactive oxygen species (ROS) and malondialdehyde levels were lowered by *P. ginseng* compared to placebo. *P. ginseng* 1 g increased total glutathione (GSH) content and glutathione reductase (GSH-Rd) activity. The results provided evidence of the antifatigue effects of *P. ginseng* in patients with ICF attributable to its antioxidant potential. The study by Wong et al. (2011) found that ingestion of 200 mg of *Panax ginseng* by recreational runners 1 hour before endurance performance could increase lipolysis, ease heart rate, reduce plasma lactate concentration and maintain good health.

Anti-allergic Activity

Among ginsenoside Rc and its metabolites, compound K exhibited the most potent anti-allergic activity on the IgE-induced RBL-2H3 basophilic leukaemia cell line as well as potent cytotoxic activity against L1210 (mouse lymphocytic leukaemia cell line), P388 (mouse lymphoid neoplasm cell line) and A549(human lung carcinoma) cell lines (Bae et al. 2002a). Compound K and Rh₂ metabolites from ginseng ginsenosides exhibited the most potent inhibitory activity on beta-hexosaminidase release from RBL-2H3 cells and on the passive cutaneous anaphylaxis reaction (PCA) reaction (Choo et al. 2003; Park et al. 2003). The inhibitory activity of both compounds was more potent than that of disodium cromoglycate, one of the commercial anti-allergic drugs. The

anti-allergic action of compound K and ginsenoside Rh₂ emanated from its cell membrane-stabilising activity. Also, the ginsenosides of ginseng were found to be prodrugs with extensive anti-allergic properties. Ginseng ginsenoside Rh₁ potently inhibited histamine release from rat peritoneal mast cells and the IgE-mediated PCA in mice (Park et al. 2004a). Its inhibitory action on PCA reaction was more potent than that of disodium cromoglycate. Rh₁ was also found to have a membrane-stabilising action and also inhibited inducible nitric oxide synthase (iNOS) and cyclooxygenase-2 (COX-2) protein expression in RAW 264.7 cells and the activation of the transcription factor, NF-κB, in nuclear fractions. Studies suggested that red ginseng inhibited allergic reactions to food by preventing reductions in the ratio of interferon IFN-γ to interleukin IL-4 and in IL-12 production induced by dietary antigens in spleen cells and/or increasing the expression of CD8 and IFN-γ in the small intestine (Sumiyoshi et al. 2010). It was concluded that red ginseng roots may be a natural preventative of food allergies.

Ginsenoside Rh₁ and compound K purified from fermented ginseng exhibited anti-allergic effects in compound 48/80-induced anaphylactic shock model in mice (Kim et al. 2008a). Ginsenoside RH1 exerted better anti-allergic effects than compound K. The results suggested that fermented ginseng extracts with enriched Rh₁ may be utilised as a potential biomaterial of functional food for the alleviation of allergic symptoms.

Panax ginseng treatment restored the expression of eosinophil major basic protein (EMBP), mucin 5AC glycoprotein (Muc5ac), CD40 and CD40 ligand (CD40L), as well as the mRNA and protein levels of interleukin (IL)-1β, IL-4 and IL-5 and tumour necrosis factor (TNF)-α in lung tissues (Kim and Yang 2011). Additionally, ginseng inhibited the numbers of goblet cells, and further, small G proteins and MAP kinases in bronchoalveolar lavage cells and lung tissues increased in ovalbumin-induced allergic asthma in mice. The results suggested that ginseng may be used as a therapeutic agent in asthma, based on reductions of various allergic

responses. Both red ginseng (RG) and fermented red ginseng (FRG) decreased serum IgE, OVA-IgE and proinflammatory cytokines in ovalbumin-sensitised female BALB/c mice (Lee et al. 2012a). Serum β -lactoglobulin, a marker of gut permeability, was significantly higher in sensitised animals and was decreased in mice-fed RG or FRG. Furthermore, intestinal barrier-related markers such as MMCP-1, IL-4, TNF- α , COX-2 and iNOS mRNA expressions were decreased by RG or FRG.

Ginseng berry extract significantly inhibited the histamine releases in human leukemic mast cells at the concentration of 30 μ g/mL and 10 μ g/mL (Bae et al. 2012). The ginsenoside Re from ginseng berry at concentrations of 1, 3, 10 and 30 μ M significantly reduced histamine secretion exhibiting 49.6 %, 47.2 %, 51.3 % and 79.0 %, respectively. In the cytokine assay experiments using human alveolar epithelial cells, the most effective inhibitory dosages of ginseng berry and ginsenoside Re were determined to be 30 μ g/mL and 30 μ M, respectively. Ginseng berry extract and Re reduced interleukin IL-1 α , IL-8 and IL-10 and RANTES (regulated and normal T cell expressed and secreted) secretion induced by lipopolysaccharide treatment.

Cognitive Enhancing Activity

Ginseng had been reported to possess a plethora of physiological effects that could potentially benefit cognitive performance or mood (Kennedy and Scholey 2003). Animal studies showed that ginseng and its constituent ginsenosides could modulate indices of stress, fatigue and learning. Recent research had demonstrated that single doses of ginseng most notably engendered cognitive benefits in terms of improved memory but could also be associated with “costs” in terms of attention task deficits following less mnemonically beneficial doses. A single dose of ginseng had also been shown to modulate cerebroelectrical (EEG) activity. The authors suggested that ginseng would benefit from more rigorous research further delineating its acute effects and exploring the relationship between acute effects and those seen during and following chronic administration regimens.

Whereas single administration of Rf, Re and Rd significantly suppressed the conditioned avoidance response, repeated administration of them caused facilitation of the response (Kaku et al. 1975). In contrast, Rb₂ always showed very weak suppressant action. Rg₁, Rf, Re and Rd significantly suppressed the fighting of mice induced by footshock, while Rb₁, Rb₂ and Re little affected the fighting. Intraperitoneal administration of ginseng neutral saponins (GNS), a water-soluble fraction (GF4) free of saponins and a lipid-soluble fraction (GNo. 5) in Wistar male rats inhibited conditioned avoidance response (CAR) and discrimination ability between 500 Hz sound with electrical shock (SD) and 1,000 Hz sound without shock (Sdelta (Saito et al. 1977). Data from these tests indicated that *P. ginseng* root contained at least three sedative compounds. Acute intraperitoneal administration of crude ginseng saponin (CGS) (50 and 100 mg/kg) and pure ginsenoside Rb₁ (GS-Rb₁) (2.5 and 5 mg/kg) significantly suppressed maternal aggression in a dose-dependent manner, whereas ginsenoside Rg₁ (GS-Rg₁) was ineffective (Yoshimura et al. 1988a). The results indicated that ginseng root contained a psychoactive ingredient, GS-Rb₁, which could suppress maternal aggression. When the resident mouse was treated with crude ginseng saponins (25, 50 and 100 mg/kg i.p.), aggressive episodes (offensive sideways posture and attack bite) were significantly suppressed in a dose-dependent manner (Yoshimura et al. 1988b). However, the agonistic behaviour was not altered when the intruder mouse was treated with crude ginseng saponins. GS-Rb₁ (2.5, 5 and 10 mg/kg i.p.) also significantly suppressed aggressive episodes when given to the resident, whereas GS-Rg₁ (2.5, 5 and 10 mg/kg i.p.) was ineffective. Neither Gs-Rb₁ nor GS-Rg₁ given to the intruder caused any significant changes in the behaviour of the resident. Although the highest dose of crude ginseng saponins suppressed locomotion frequency, it appeared that both crude ginseng saponins and GS-Rb₁ possessed a specific psychotropic action on agonistic behaviour.

Studies by Petkov and Mosharrof (1987) showed that ginseng at appropriate doses improved learning, memory and locomotive capabilities in mice. They found that administration of Gincosan (a combination preparation of ginseng and ginkgo) in rats elicited favourable effects on learning and memory using some conditioned reflex methods with punishment or positive reinforcement for active and passive avoidance (shuttle-box, step-down, step-through and water maze) (Petkov et al. 1993). Intraperitoneal administration of ginseng of protopanaxadiol (PD) and protopanaxatriol (PT) saponins improved the scopolamine-induced learning impairment at 50 and 100 mg/kg dosages in mice (Jin et al. 1999) but not in normal mice. Korean red ginseng saponin with a low PD/PT ratio improved spatial working memory, but the saponin with a high PD/PT ratio did not.

Lee et al. (2000a) suggested that repeated administration of red ginseng total saponins (RGTS) and *N*-methyl-D-glucamine (nootropic drug) ameliorated the impairing effect of ethanol on acquisition in passive avoidance performance, and the effect of RGTS on ethanol-induced amnesia was dependent on the catecholaminergic but not serotonergic neuronal activity, while RGTS and *N*-methyl-D-glucamine appeared to have a different mechanism on ethanol-induced amnesia. Treatment with red ginseng significantly ameliorated place navigation deficits in young rats with hippocampal lesions on the place-learning task (PLT) in a circular open field (Zhong et al. 2000). Similarly, red ginseng improved performance of aged rats on the PLT task. The results suggested that red ginseng ameliorated learning and memory deficits through effects on the central nervous system, partly through effects on the hippocampal formation. The results of studies with three types of spatial-learning task [distance movement task (DMT), random-reward place search task (RRPST) and place-learning task (PLT)] in a circular open field suggested that pretreatment with the non-saponin fraction of red ginseng improved learning and memory in aged rats and that this amelioration by non-saponin might be attributed partly to augmentation of long-term potentiation in the hippocampal CA3 subfield in rats (Kurimoto et al. 2004). Qiao et al. (2005) found that an

increase in contextual fear conditioning (CFC)-related neurogenesis may be one mechanism of ginseng's properties to enhance learning ability in rats. Neurogenesis in the hippocampus had been shown to be necessary for hippocampus-/amygdala-dependent learning tasks. Co-administration of ginseng and bromodeoxyuridine (BrdU) increased the percent freezing time and the number of BrdU-positive cells in the dentate gyrus of rats that received CFC.

A 30 % ethanol elution of ginseng roots was found to enhance memory in scopolamine-induced memory deficit rats after intraperitoneal administration (Wang et al. 2010b). Oligosaccharides and peptides were isolated from 30 % ethanol elution of ginseng roots. The oligosaccharides were identified as maltose, maltotriose, maltotetraose, maltopentaose, maltohexaose and maltoheptaose. Ginsenoside Rb₁, a potential phytoestrogen, had been shown to improve central nervous system dysfunctions, comparable to the oestrogen treatment (Hao et al. 2011). Administration of ginsenoside Rb₁ and oestradiol to ovariectomised mice increased the neural 5-hydroxytryptamine (5-HT) concentration, elevated tryptophan hydroxylase and depressed monoamine oxidase activities in the frontal cortex and striatum. Ginsenoside Rb₁ and oestradiol also improved object recognition and decreased immobility time in the forced swimming test. Treatment of mice with ginseng ginsenosides Rg₅ or Rh₃ increased the latency time reduced by scopolamine in passive avoidance test and significantly reversed the lowered spontaneous alteration induced by scopolamine in Y-maze task (Kim et al. 2013b). Ginsenoside Rg₅ or Rh₃ (10 mg/kg) significantly shortened the escape latencies prolonged by treatment with scopolamine on the last day of training trial sessions in Morris water maze task. The protective effects of both ginsenosides on memory impairment induced by scopolamine were mediated by inhibiting acetylcholinesterase activity and increasing hippocampal brain-derived neurotrophic factor expression and cAMP response element-binding protein activation.

A novel tetradecapeptide purified from ginseng polypeptides exhibited memory enhancing activity in mice using Morris water maze task (Luo et al. 2013). Chu et al. (2014) demonstrated that ginseng ginsenoside Rg₅ improved cognitive dysfunction and attenuated neuroinflammatory responses in streptozotocin (STZ)-induced memory impaired rats. Cognitive deficits were ameliorated with Rg₅ (5, 10 and 20 mg/kg) treatment in a dose-dependent manner together with decreased levels of inflammatory cytokines TNF- α and IL-1 β in brains of STZ rats. Acetylcholinesterase activity was also significantly reduced by Rg₅, whereas choline acetyltransferase activity was markedly increased in the cortex and hippocampus of STZ-induced Alzheimer's disease rats. Rg₅ enhanced the expressions of insulin-like growth factors 1 (IGF-1) and brain-derived neurotrophic factor (BDNF) but decreased significantly A β deposits in the hippocampus and cerebral cortex. The expressions of COX-2 and iNOS which were significantly upregulated in STZ-induced Alzheimer's disease rats were downregulated strongly by Rg₅ compared with control rats.

Clinical Studies

In a double-blind, placebo-controlled clinical study of 16 healthy male volunteers, administration of Korean ginseng (G 115; 100 mg twice a day for 12 weeks) was found to be superior to placebo in improving certain psychomotor functions in healthy subjects (D'Angelo et al. 1986). Korean ginseng G 115 elicited a favourable effect relative to baseline performance in attention (cancellation test), processing (mental arithmetic, logical deduction), integrated sensory motor function (choice reaction time) and auditory reaction time. In a 12-week placebo-controlled, double-blind, randomised study involving 185 subjects taking placebo and 205 subjects taking a combination of vital substances, including ginseng extract G115, the latter had significant, favourable advantages over placebo therapy (Wiklund et al. 1994). According to the visual analogue scales scores, subjects receiving the combination of active substances improved

significantly more in alertness, relaxation, appetite and overall score. Among a subgroup of subjects with the 20 % lowest scores at baseline, the combination treatment improved both vitality and depressed mood.

In a placebo-controlled, double-blind, balanced crossover study of 20 healthy young adult volunteers, acute administration of *P. ginseng* modulated mood and cognitive performance (Kennedy et al. 2001). There was a significant improvement in “Quality of Memory” and associated “Secondary Memory” factor at all times following 400 mg ginseng. Both 200 and 600 mg doses were associated with a significant decrease of the “Speed of Attention” factor at later testing times only. In another 20-week double-blind placebo-controlled crossover study of 25 volunteers, chronic ingestion of ginseng G115 elicited improvements in working memory and decrements in aspects of cognition and mood (Reay et al. 2008). In a double-masked, randomised, test–retest design of 112 healthy subjects (>40 years old), the group administered with ginseng (55) showed a tendency to faster simple reactions and significantly better abstract thinking than the placebo group (57) (Sørensen and Sonne 1996). However, there was no significant difference between the two groups in concentration, memory or subjective experience.

Hypolipidemic Activity

Administration of ginseng ginsenoside Rb₁ to rats during early feeding was found to reverse adverse effects of high-fat diet characterised by a higher level of cholesterol in liver and a lower incorporation of ¹⁴C-acetate into liver cholesterol and a repressed activity of HMG-CoA reductase, a key enzyme in cholesterol biosynthesis (Ikehara et al. 1978). Streptozotocin-induced diabetic rats treated with ginsenoside Rb₂ showed significant decreases in triglyceride, nonesterified fatty acid and total cholesterol in the serum (Yokozawa et al. 1985b, 1987b). A lipid-improving action in the serum was observed in rats with hyperlipidemia. Further, the lipolytic activity of lipoprotein lipase was stimulated with a concomitant decrease in the levels of triglyceride and very low-density lipoprotein in

the serum, while a repressive effect on hormone-sensitive lipase activity was observed. The accumulation of lipid in the adipose tissue was also observed. The rats treated with ginsenoside Rb₂ showed a significant decrease of glucose in the hepatic tissue. The level of hepatic glycogen was slightly increased after ginsenoside Rb₂ administration. The glucose-6-phosphate level tended to increase, the pyruvate level was unchanged and the lactate level tended to decrease. There was, however, no accumulation of total lipid in hepatic tissue. Besides the hypolipidemic effect, ginsenoside Rb₂ lowered serum levels of 3-hydroxybutyrate and acetoacetate in streptozotocin-induced diabetic rats, indicating an improvement of diabetic ketoacidosis. A single intraperitoneal administration of ginsenoside Rb₂ produced a significant decrease of total cholesterol, free cholesterol, low-density lipoprotein (LDL) cholesterol, triglyceride, 3-hydroxybutyrate and acetoacetate levels in the serum in rats fed on a high-cholesterol diet (Yokozawa et al. 1985a). However, a significant increase of high-density lipoprotein (HDL) cholesterol level in the serum was observed after the treatment. Repeated administration of ginsenoside Rb₂ to rats with hyperlipidemia induced by a high-cholesterol diet resulted in a striking decrease in the levels of total cholesterol, free cholesterol, LDL cholesterol and triglyceride, whereas the level of HDL cholesterol was again increased. Further, the lipolytic activity of lipoprotein lipase was stimulated with a concomitant decrease in the levels of triglyceride and very low-density lipoprotein (VLDL)-triglyceride in the serum. Accumulation of lipid in the adipose tissue was observed.

Cholesteryl ester transfer protein (CETP) inhibitors identified as polyacetylene analogues were isolated from Korean ginseng root extract (Kwon et al. 1996). These compounds inhibited human CETP with IC₅₀ values of around 20–35 mg/ml. Acyl-CoA cholesterol acyltransferase (ACAT) inhibitors were isolated from ginseng hairy roots and identified as panaxynol, panaxydol, panaxydiol and panaxytriol (Kwon et al. 1997). These active compounds inhibit rat liver ACAT with IC₅₀ values of 94, 80, 45 and 79 μM, respectively. Ginseng saponins very mildly inhibited

Acyl-CoA cholesterol acyltransferase (ACAT) in-vitro; however, ginseng saponins produced from ginseng saponins showed strong inhibitory activity on microsomal ACAT, indicating them to be key ingredients of ginseng in lowering of the serum total cholesterol level (Kwon et al. 1999). Oral administration of ginseng saponins at a dose of 0.01 g/kg for 4 weeks was found to reverse the increase in serum triglycerides (TG) and concomitant increase in cholesterol produced by cyclophosphamide treatment in fasted rabbits, especially in chylomicrons and very low-density lipoprotein (VLDL) (Inoue et al. 1999). In addition, ginseng saponins treatment led to a recovery in postheparin plasma lipoprotein lipase activity and heparin-releasable heart lipoprotein lipase activity, which were markedly reduced by cyclophosphamide treatment. In rats given 15 % glycerol/15 % fructose solution, postheparin plasma lipoprotein lipase activity declined to two thirds of normal rats, whereas ginseng saponins reversed it to normal levels. Phenolic compound-rich extracts from white ginseng were found to be effective in part in improving hyperlipidemia and atherosclerosis induced by a high-cholesterol diet among New Zealand white rabbits (Lee et al. 2013d). Antioxidant enzyme activities and morphological changes of the aorta showed that white ginseng small compounds had a positive effect on hypercholesterolemia.

Serum total cholesterol, triglyceride, low-density lipoprotein and plasma malondialdehyde levels were decreased by administration of *Panax ginseng* extract for 8 weeks (6 g per day) in humans; however, high-density lipoprotein, catalase and superoxidase activities were increased (Kim and Park 2003). The results supported scientific claims that ginseng had hypolipidemic potential and that the antioxidant potential of ginseng extract might induce hypolipidemic effect as one of the mechanism. Two polyacetylenic compounds, (9*R*,10*S*)-epoxyheptadecan-4,6-diyn-3-one and 1-methoxy-(9*R*,10*S*)-epoxyheptadecan-4,6-diyn-3-one (Lee et al. 2004b) and (9*R*,10*S*)-epoxy-16-heptadecene-4, 6-diyne-3-one (Rho et al. 2005), obtained from the petroleum ether extract of ginseng, showed significant Acyl-CoA cholesterol acyltransferase (ACAT) inhibition.

Antihyperglycaemic/Antidiabetic Activity

In-Vitro Studies

A hypoglycaemic principle, panaxan B, was obtained from ginseng roots (Tomoda et al. 1985). The aqueous ethanolic extract of Korean red ginseng significantly evoked a stimulation of insulin release from isolated rat pancreatic islets in a glucose-independent manner (Kim and Kim 2008). The results suggested that red ginseng may have beneficial effects in the treatment of diabetes. Ginsenoside Rg₂ significantly inhibited hepatic glucose production and induced phosphorylations of liver kinase B1 (LKB1), AMP-activated protein kinase (AMPK) and glycogen synthase kinase 3 β (GSK3 β) in time- and concentration-dependent manners in human HepG2 hepatoma cells (Yuan et al. 2012). Rg₂ markedly enhanced the gene expression of small heterodimer partner (SHP).

Studies by Gao et al. (2013b) found that ginsenoside Re exhibited the action of reducing insulin resistance through activation of PPAR- γ (peroxisome proliferator-activated receptor gamma) pathway by directly increasing the expressions of PPAR- γ 2 and its responsive genes – adiponectin, IRS-1 (insulin receptor substrate-1) and ap2 (fatty acid binding protein). Re also inhibited TNF- α (tumour nuclear factor-alpha) production and facilitated the translocation of GLUT4 (glucose transporter type 4) in promoting glucose uptake and disposal in 3T3-L1 adipocytes. Compound K (CK), a final intestinal metabolite of protopanaxadiol-type ginsenosides from *Panax ginseng*, exhibited antidiabetic activity; it significantly enhanced insulin secretion, increased cellular ATP content and upregulated the expression of GLUT2 in MIN6 pancreatic β -cell lines in-vitro (Gu et al. 2013).

Animal Studies

The hyperglycaemia induced by adrenaline or alloxan could be restrained by ginseng in rabbits (Yamada 1955). Streptozotocin-induced diabetic rats treated with ginsenoside

Rb₂ showed a significant decrease of blood glucose level (Yokozawa et al. 1985c). A moderate (but statistically insignificant) increase in the hepatic glycogen content was observed. Further, the ginsenoside Rb₂-treated group showed a significant rise of glucokinase activity in the liver, while there was a significant decrease in the activity of glucose-6-phosphatase. The results suggested that the changes of glucokinase and glucose-6-phosphatase levels may be one of the mechanisms of the hypoglycaemic action produced by ginsenoside Rb₂.

Five types of hypoglycaemic and insulinomimetic substances had been discovered on ginseng (Ng and Yeung 1985). These included five glycans designated panaxans A–E, adenosine, a carboxylic acid, a peptide with a molecular weight of 1,400 and lacking in basic amino acid residues and a fraction designated DPG-3-2 prepared from the water extract of ginseng. The glycans had been demonstrated to elicit hypoglycaemia in both normal and diabetic mice. DPG-3-2 exerted its hypoglycaemic action or provoked insulin secretion in diabetic and glucose-loaded normal mice while having no effect on normal mice. Adenosine inhibited catecholamine-induced lipolysis in rat epididymal fat pads. Four glycans, panaxans I, J, K and L from ginseng roots, markedly reduced blood sugar levels in normal and alloxan-induced hyperglycaemic mice (Oshima et al. 1985). Panaxans Q, R, S, T and U isolated from ginseng roots displayed marked hypoglycaemic action in normal and alloxan-induced hyperglycaemic mice (Konno et al. 1985).

C57BL/Ks *db/db* mice treated with daily intraperitoneal injections of ginseng berry extract at 150 mg/kg body weight for 12 consecutive days had lower fasting glucose levels and improved glucose tolerance compared with vehicle-treated mice (Xie et al. 2002). Adult mice and littermates treated with ginseng berry showed marked weight loss. In another study, Dey et al. (2003) found that ginseng berry exhibited more potent antihyperglycaemic activity than ginseng root and only ginseng berry also showed marked antiobesity effects in *ob/ob* mice. After 12 days of treatment with ginseng berry extract, overall glucose exposure improved significantly, and the AUC

decreased by 31.0 %. Additionally, body weight did not change significantly after ginseng root extract (150 mg/kg body wt.) treatment, but the same concentration of ginseng berry extract significantly decreased body weight.

Wild ginseng leaf extract supplementation suppressed a sudden increase in blood glucose levels and a consequent decrease in TBARS levels in streptozotocin (STZ)-induced diabetic rats (Jung et al. 2005a). TBARS levels in the liver, kidney and spleen of ginseng extract-fed diabetic groups were also significantly lower than in the control diabetic group indicating that oral administration of ginseng extract effectively suppressed lipid peroxidation that occurred in the organs of diabetic rats. Additionally, ginseng extract supplementation further suppressed activities of antioxidant-related enzymes, such as glutathione peroxidase (GSH-Px), catalase (CAT) and superoxide dismutase (SOD), in organs of diabetic rats. The results confirmed the effectiveness of WGLE ginseng leaf extract supplementation in detoxifying free radicals that were produced excessively in diabetic-induced complications. Intraperitoneal injections of diabetic C57BL/6J *ob/ob* mice with total ginsenosides in Chinese ginseng significantly lowered the fasting blood glucose levels and body weight and markedly improved glucose tolerance (Xie et al. 2005). Studies demonstrated that ginseng ginsenoside Re could lower blood glucose and lipid levels and exerts protective actions against the occurrence of oxidative stress in the eye and kidney of streptozotocin-induced diabetic rats (Cho et al. 2006). The data also provided evidence that ginsenoside Re could be used as an effective antidiabetic agent particularly in the prevention of diabetic microvasculopathy. Oral administration of *Panax ginseng* root (125.0 mg/kg) into rats three times daily for 3 days after receiving fructose-rich chow for 4 weeks reversed the increased glucose–insulin index, indicating that ginseng root had the ability to improve insulin sensitivity and delay the development of insulin resistance (Liu et al. 2005). Further they found that single intravenous injection of ginsenoside Rh2, from ginseng root, decreased the plasma glucose concentrations in 60 minutes in a dose-dependent manner from 0.1 to 1 mg/kg in rats with insulin resistance induced by fructose-rich chow (Lee et al.

2007c). Repeated intravenous injection of ginsenoside Rh₂ (1 mg/kg per injection, three times daily) into rats which received fructose-rich chow for three consecutive days decreased the value of glucose–insulin index, the product of the areas under the curve of glucose and insulin during the intraperitoneal (i.p.) glucose tolerance test. Further, repeated injection of ginsenoside Rh₂ at the same dosing (1 mg/kg, three times daily) into streptozotocin-diabetic rats for 10 days elicited an increase of the responses to exogenous insulin. Lee et al. (2006c) found from their studies that ginsenoside Rh₂ may be applied as an adjuvant for the management of diabetes as it possessed plasma glucose-lowering action and had the ability to increase insulin secretion as a result of the release of acetylcholine from nerve terminals that then stimulated muscarinic M₃ receptors in pancreatic cells. The results of studies by Su et al. (2007) suggested that *P. ginseng* root had the ability to increase the release of acetylcholine from nerve terminals in Wistar rats so as to stimulate muscarinic M₃ receptors activity located in the pancreatic cells for the enhanced secretion of insulin, which in turn lowered plasma glucose. Ninety minutes after the oral administration of *P. ginseng* root to fasting Wistar rats, plasma glucose decreased in a dose-dependent manner. Ginseng modified the diabetic phenotype and genes associated with diabetes in the male Zucker diabetic fatty rat (Banz et al. 2007). Animals treated with ginseng exhibited increased body weight and decreased kidney weight and cholesterol levels compared to control animals. Furthermore, ginseng exerted marked effects on the expression of genes involved in PPAR actions and triglyceride metabolism compared to controls.

Intravenous injection of malonyl-ginsenosides (MGR) (120 mg/kg), extracted from ginseng roots, to streptozotocin-induced diabetic mice reduced fasting blood glucose level (Liu et al. 2009). The same dose also exerted a marked improvement in glucose tolerance of 80 % in diabetic mice after 4 days. Korean red ginseng (KRG) extract significantly lowered blood glucose levels and improved glucose challenge testing when applied as prophylaxis in streptozotocin-induced type 1 diabetes (T1D) mice (Hong et al. 2012). Immune

compartments of diabetic mice were found to be preserved in KRG-treated mice suggesting that Korean red ginseng may benefit T1D patients, not only for its hypoglycaemic but also for its immunomodulatory effects. Administration of taurine or ginseng or their mixture elicited marked amelioration in glucose, glycosylated haemoglobin (HbA1C), insulin and free T₃ levels in streptozotocin-diabetic rats (Saleh 2012).

Combination treatment induced a significant reduction in serum cholesterol, triglycerides and low-density lipoprotein levels and a significant decrease in the activities of cardiac enzymes, aspartate aminotransferase (AST), creatine kinase (CK), lactate dehydrogenase (LDH) and the levels of serum endothelin-1 with a significant elevation in the levels of serum total nitric oxide (TNO) in diabetic rats. Treatment of high-fat/streptozotocin-induced diabetic mice with ginseng protopanaxadiol-type ginsenoside and its metabolite compound K exerted a hypoglycaemic effect as demonstrated by lowering of fasting blood glucose, and insulin-sensitising effects were seen during oral glucose tolerance testing (Li et al. 2012f). Gluconeogenic genes, phosphoenolpyruvate carboxykinase (PEPCK) and glucose-6-phosphatase (G6Pase) were decreased in the two treatment groups with compound K showing greater effects. Administration of ginseng malonyl ginsenosides alleviated hyperglycaemia, hyperlipidemia and insulin resistance of high-fat diet-fed and streptozotocin-induced diabetic rats (Liu et al. 2013). Twelve-week supplementation with Korean red ginseng aqueous extract significantly decreased blood glucose of spontaneously diabetic Goto-Kakizaki rats compared to control (Kim and Kim 2012). The results suggested that glucose transporter (GLUT) 4 in adipose tissue, protein tyrosine phosphatases (PTP)-1B in adipose tissue and skeletal muscle, insulin, uncoupling protein (UCP) 2, Bax and poly (ADP-ribose) polymerase (PARP) in pancreas may be the primary targets of red ginseng that resulted in increase in insulin action and in insulin secretion and decrease in β -cell mass, and that normalised glucose homeostasis. Korean red ginseng (KRG) supplementation to high-fat diet-fed rats improved whole body insulin resistance and plasma lipid profiles (Jung and Kang 2013). Plasma free fatty acid concentrations and resting

plasma insulin and glucose levels were significantly decreased after KRG supplementation. Liver and muscle triglyceride concentrations were also decreased in the KRG treatment group. Studies found that compound K, a final metabolite of ginseng panaxadiol ginsenosides, could improve body weight and food intake of high-fat diet/streptozotocin-induced diabetic rats (Jiang et al. 2014). CK exhibited dose-dependent reduction of fasting blood glucose, total glycerides and total cholesterol of diabetic rats; enhanced fasting serum insulin and insulin sensitivity; and improved glucose tolerance. The expression of InsR (insulin receptor), IRS1 (insulin receptor substrate-1), PI3Kp85 (phosphatidyl inositol 3-kinase p85), pAkt (serine/threonine kinase Akt phosphorylation) and Glut4 were enhanced in skeletal muscle tissue of diabetic rats. The results indicated that the hypoglycaemic activity of CK was mediated by improvement of insulin sensitivity, which was closely related to PI3K/Akt signalling pathway.

Clinical Studies

In a randomised, double-blind, placebo-controlled study of 19 participants with well-controlled type 2 diabetes, 12 weeks of supplementation with a Korean red ginseng preparation gave good glycaemic control and improved plasma glucose and plasma insulin regulation safely beyond usual therapy (Vuksan et al. 2008). Korean ginseng rootlets had >sixfold total ginsenosides more than the Korean ginseng root but did not significantly affect postprandial glucose in healthy individuals (De Souza et al. 2011). Despite a reduced ginsenoside profile, Korean ginseng root lowered postprandial glucose levels at 45, 60, 90 and 120 minutes during the test, rendering an overall reduction of 27 % in incremental area under the glucose curve compared to the control.

Immunomodulatory Activity

The phagocytosis index increases by oral application of ginseng in rabbits, and an increase of γ -globulin in blood serum was proven (Yamada 1955). Ginseng total saponin interacted with multilamellar liposomes (composed of egg

phosphatidylcholine, phosphatidic acid and/or cholesterol) and prevented them from behaving as an ideal osmometer (Yu et al. 1985). 20-*S*-Protopanaxadiol saponin showed similar activity but 20-*S*-protopanaxatriol saponin had weak activity. Ginsenoside Rb₁ disturbed osmotic behaviour of cholesterol-free liposomes, but not cholesterol-containing liposomes as monomers, and lysed both liposomes as micelles. Rg₁, whose genin was 20-*S*-protopanaxatriol, showed no activity on liposomes with or without cholesterol. The study suggested that ginseng saponins may interact with and destroy liposomal membranes and that structure of sugar moiety was an important factor to their activities. Porcine parvovirus (PPV) vaccines containing ginseng fraction Rb₁ induced serum-detectable amounts of IL-4 and IL-10 as early as 24 hours after primary injection in mice (Rivera et al. 2005). Five weeks after booster, immune lymphocytes were still producing large amounts of cytokines including IFN- γ , IL-2, IL-4, IL-10 and TNF- α , and the antibody titres were still similar to those titres recorded 1-week post-booster. The Rb₁ adjuvanted vaccines stimulated similar titres of antigen-specific IgG1, IgG_{2a} and IgG_{2b}. Thus, the cytokine and the serological data indicated that the Rb₁ fraction of ginseng elicited a balanced Th1 and Th2 immune response.

Su et al. (2010) found that total saponins of *Panax ginseng* could inhibit the immune maturation of dendritic cells induced by oxidised low-density lipoprotein partly via the PPAR- γ pathway and may have beneficial effects on atherosclerosis. Ginsenoside Rg₆ and ginsenoside F₄ from steamed ginseng flowers and leaves exhibited particularly inhibitory effect on LPS-induced interleukin IL-12 production with the inhibition values of 80 and 82 %, and ginsenoside ST₁, ginsenoside SL₂, ginsenoside SL₃, ginsenoside Rh₃, ginsenoside Rk₂ and ginsenoside Rs₄ showed moderate effects with inhibition rates of 63, 65, 67, 68, 71, 73 and 67 %, respectively (Tung et al. 2011).

Seventy percent methanol red ginseng extract was found to promote phagocytic activity of the reticuloendothelial system

in normal mice and carrageenan- or cyclophosphamide-treated mice (Matsuda et al. 1985). The acidic fraction of ginseng polysaccharide was more effective in increasing the ratio of spleen to body weight, the number of antibody secreting cells to sheep red blood cells (SRBC) and phagocytic activity of reticuloendothelial system, as well as antitumour activity against the solid form of sarcoma 180 in ICR mice than the neutral fraction (Kim et al. 1990). All polysaccharide fractions were mitogenic to cultured spleen cells of C57BL/6 mice. Both crude and acidic fractions potentiated remarkably the mitogenic activity of phytohaemagglutinin-P (PHA-P) or lipopolysaccharide (LPS) in dose-dependent manner, but the neutral fraction enhanced only that of LPS. All three polysaccharide fractions had no effect on that of concanavalin A. The results suggested that the acidic fraction may stimulate B and T cells as well as macrophages, while the neutral fraction may stimulate only B cells and macrophages. Administration of GL-4IIb2, acidic ginseng leaf polysaccharide containing 33 % uronic acid, to mice significantly and dose dependently enhanced immune complexes clearance from circulation compared to control (Sun et al. 1994). It was found that the carbohydrate moiety of GL-4IIb2 activated the mononuclear phagocytic system in-vivo through an increase of Fc receptor (FcR) expression mediated by de novo synthesis of the receptor protein and resulted in enhanced immune complexes clearance.

The extracts of hot water-soluble fraction from wild *Panax ginseng* but not from cultured *Panax ginseng* showed mitogenic activity to lymphocytes (Mizuno et al. 1994). The mitogenic activity of wild *Panax ginseng* (100 µg/well) was almost equal to concanavalin A (0.1 µg/well) which was well known as one of the T cell mitogens. The percentages of Thy1.2-(pan T cells), L3T4-(helper T cells) and Lyt2-(cytotoxic T cells) positive cell population were significantly increased in mice orally administered hot water-soluble fraction from wild *Panax ginseng* as compared to control by 31.2, 17.9 and 30.1 %, respectively. The pectic polysaccharide (GL-4IIb2) isolated from ginseng leaves was found to be a macrophage Fc receptor expression enhancing polysaccharide (Shin et al. 1997). Other polysaccharides from the leaves, GL-

4IIb2 and GL-RIII, had relatively potent interleukin 6 (IL-6) production enhancing activity of macrophages; however, GL-RI and GL-RII had negligible and weak enhancing activities, respectively (Shin et al. 1998).

Cell cultured ginseng polysaccharides (CCGPS) increased the weight of spleen and enhanced the clearance rate of intravenous charcoal particles in mice and significantly promoted the production of activity of haemolysins antibody and also raised the level of IgG in mice serum (Ding et al. 1993). They also enhanced delayed-type hypersensitivity of footpad induced by SRBC in mice indicating that CCGPS also strengthened body resistance and restored normal functioning of the body. Intraperitoneal administration of ginseng acidic polysaccharide generated a high-output nitric oxide synthase (iNOS) in female BALB/c mice (Park et al. 2001). This study showed that the immunomodulating activities of the acidic polysaccharide were mediated by the production of nitric oxide. A study suggested that ginseng acidic polysaccharide played marked immunostimulating role on the maturation of murine B bone marrow dendritic cells through precise modulation of phagocytosis and acid phosphatase activities inside the dendritic cells (Wang et al. 2013c).

In-vitro and in-vivo studies showed that the acidic polysaccharide ginsan could potentially be an ideal nontoxic antineoplastic immunostimulator by activating multiple effector arms of the immune system (Lee et al. 1997). Ginsan induced the proliferation of T cells and B cells, generated ginsan-activated killer (AK) cells and stimulated macrophages to produce reactive nitrogen intermediates and become tumouricidal. Ginsan exhibited significant in-vivo antitumour activity against B16 melanoma cells lines and in the benzo(a)pyrene-induced autochthonous lung tumour model, at much lower doses than the maximum tolerated doses. Studies also demonstrated that ginsan generated lymphokine-activated killer (LAK) cells from both NK and T cells through endogenously produced multiple cytokines (Kim et al. 1998b). This property may contribute to its effectiveness in the immunoprevention and immunotherapy of cancer. Ginsan synergised with rIL-2 to generate LAK cells (2.0–15-fold) and

the most dramatic synergy was seen at rIL-2 concentrations below 3 U/ml. Ginsan alone inhibited pulmonary metastasis of B16-F10 melanoma cells and enhanced the inhibition of lung colonies by rIL-2. Another acidic polysaccharide from ginseng root, ginsenoside S-IIA, was found to be a potent inducer of interleukin IL-8 production by human monocytes and THP-1 cells, and this induction was accompanied by increased IL-8 mRNA expression (Sonoda et al. 1998). Administration of ginseng total saponin ameliorated morphine-induced immune suppression by blocking morphine-induced apoptosis of thymocytes and elevation of serum corticosterone (Kim et al. 1999f). Atrophy of thymus and spleen and decrease in body weight increment rate caused by morphine were partly reversed by concomitant administration of ginseng total saponin.

In-vitro studies showed that ginsan exerted effective immunomodulatory activity and enhanced antitumour activity of macrophages (Song et al. 2002). Murine peritoneal macrophages on in-vitro treatment with ginsan induced mRNA of cytokines such as tumour necrosis factor (TNF)- α , interleukin 1 (IL-1) β , interleukin 6 (IL-6) and interleukin 12 (IL-12). Ginsan enhanced the lytic death of L929 cells through TNF- α activation. The mRNA expression of nitric oxide synthase (iNOS) was highly induced after 24 hour treatment of ginsan, and then NO production was maximum after 48 hour treatment with a low dose of 1 μ g/ml. The tumouricidal activity of macrophage cultured with ginsan on Yac-1 cells was enhanced in a dose-dependent manner; growth inhibition increased 1.6-fold with 100 μ g/ml ginsan. Ginsan restored the T lymphocytes function that had been suppressed by gamma irradiation in allogeneic MLR (mixed lymphocyte reactions) (Han et al. 2005). Ginsan was found to stimulate murine normal splenocytes by inducing the mRNA expressions of Th1 and Th2 type cytokines and also restored the mRNA expression of IFN- γ , Th1 cytokine, after its inhibition by whole-body gamma irradiation. Ginsan exhibited immunomodulatory effects on dendritic cells (DCs) (Kim et al. 2009a). Ginsan markedly increased the levels of production by DCs of IL-12 and TNF- α and enhanced the expression of

CD86 on DC surfaces. In ^3H -thymidine incorporation assays, ginsan-treated DCs stimulated significantly higher proliferation of allogeneic CD4^+ T lymphocytes than did medium-treated DCs. The study demonstrated that ginsan stimulated dendritic cells by inducing maturation. Ginsan significantly enhanced viability and proliferation of spleen cells (Ko and Joo 2010). Multiple clusters, indicating proliferation, were observed in ginsan-treated spleen cells, and carboxyfluorescein succinimidyl ester and surface marker staining assay revealed that ginsan promoted proliferation from $\text{CD19}(+)$ B cells rather than $\text{CD4}(+)$ or $\text{CD8}(+)$ T cells. In addition, ginsan decreased the percentage of late apoptotic cells. Ginsan increased the surface expression of CD25 and CD69 as well as production of interleukin 2 from spleen cells, suggesting increased activation. Taken together, these results demonstrate that ginsan increases the viability and proliferation of spleen cells via multiple mechanisms. Ginsan effectively enhanced the humoral immune response to orally delivered *Salmonella* antigen, mediated by CCL3 mRNA expression via COX (Na et al. 2010). The results suggested that ginsan may serve as a potent vaccine supplement for oral immunisation.

Ginseng acidic polysaccharide, ginsan, significantly ameliorated the progression of experimental autoimmune encephalomyelitis (an animal model of human multiple sclerosis) by inhibiting the proliferation of autoreactive T cells and the production of inflammatory cytokines such as $\text{IFN-}\gamma$, $\text{IL-1}\beta$ and IL-17 (Hwang et al. 2011). More importantly, ginsan promoted the generation of immunosuppressive regulatory T cells (Tregs) through the activation of transcription factor, Foxp3. The results suggested that ginsan may serve as an effective therapy for multiple sclerosis and other autoimmune diseases. Treatment of water-extracted oligosaccharide from ginseng roots significantly increased phagocytosis of macrophages and promoted NO, tumour necrosis factor- α (TNF- α) and reactive oxygen species production (Jiao et al. 2012). Further, ginseng oligosaccharide extract dose dependently stimulated NO formation through the upregulation of inducible NO synthase (iNOS) activity.

Ginseng oligosaccharide extract was found to possess high immunopotentiating activity and could be developed as a novel immunostimulant. Treatment of hepatoma-22 (H22)-bearing mice with water-soluble ginseng oligosaccharides (WGOS) inhibited tumour growth and significantly increased relative spleen and thymus weight, serum tumour necrosis factor- α level, spleen lymphocyte proliferation, natural killer cell activity, phagocytic function and nitric oxide production secreted by macrophage (Jiao et al. 2014b). However, no direct cytotoxicity was detected; thus, the authors concluded that the antitumour activity of WGOS may be related to their immunomodulatory effects. The study by Liu and Zhang (1996) suggested that one of the mechanisms by which ginsenoside Rg₁ enhanced immune function in old rats might be mediated by the increase of intracellular cAMP and cGMP contents, resulting in interleukin IL-2 gene expression and splenocyte proliferation. Kim et al. (1997) found that long-term oral administration of ginseng extract decreases serum γ -globulin and immunoglobulin IgG₁ isotypes in mice. Among the immunoglobulin Ig isotypes, including IgG₁, IgG_{2a}, IgG_{2b}, IgG₃, IgM and IgA, serum IgG₁ was dose dependently decreased to 68 % of control values at the dose of 150 mg/kg per day without significant changes in other Ig isotypes. However, the α_1 -globulin level increased by 24 % at the doses of 30 and 150 mg/kg per day.

Lymphocyte proliferation assays showed that both the neutral polysaccharides and acidic polysaccharides of ginseng roots were potent B and T cell stimulators (Zhang et al. 2009). Water-soluble ginseng oligosaccharides (designated as WGOS) were found to be potent B and T cell stimulators, and its fraction WGOS-1 exerted the highest immunostimulating effect on lymphocyte proliferation among those purified fractions, indicating WGOS potential to be developed into functional food or medicine (Wan et al. 2012). Studies showed that ginseng ginsenosides Rg₁ and Re had adjuvant activities in stimulating IgG, splenocyte proliferation and mRNA expression of cytokines IL-4, IL-10, IL-12 and IFN- γ as well as transcription factors GATA-3 and T-bet by splenocytes in C3H/HeB mice but not in C3H/HeJ mice carrying a defective

toll-like receptor-4 (TLR4) gene (Su et al. 2012). The results suggested that TLR4 signalling pathway was involved in the adjuvant activities of Rg₁ and Re. Nevertheless, pretreatment with anti-TLR4 antibody suppressed the Re- but not Rg₁-induced expression of NF-κB, indicating that Rg₁ may trigger both extracellular and intracellular TLR4 by passing through the cell membrane, while Re only activates extracellular TLR4 as it failed to enter inside of the cells to stimulate intracellular TLR4.

Sun et al. (2007) indicated that ovalbumin-specific antibody responses were significantly higher in mice immunised with ovalbumin co-administered with Rg₁, Re, Rg₂, Rg₃ and Rb₁ but not with Rd, Rc and Rb₂ when compared with the control (immunised with ovalbumin only). Significantly enhanced splenocyte proliferative responses to Con A, LPS and ovalbumin as well as the production of both IL-5 and IFN-γ stimulated by ovalbumin were also detected in mice immunised with ovalbumin co-administered with Rg₁ but not with Rb₁, Re and Rg₃. Of the ginsenosides studied, Rg₁, Re, Rg₂, Rg₃ and Rb₁ exhibited more potent adjuvant properties than the others, indicating that they are the major constituents contributing to the adjuvant activities of total ginseng saponins.

Three dammarane triterpenes from ginseng leaves significantly increased interleukin 12 expression in LPS-activated mouse peritoneal macrophage (Tran et al. 2014). Further, the new compound, 27-demethyl-(*E,E*)-20(22),23-dien-3β,6α,12β-trihydroxydammar-25-one, strongly increased the Th1 response-mediated cytokine IL-2 and decreased Th2 response-mediated cytokines IL-4 and IL-6 expression. Su et al. (2014) found that supplementation of ginseng ginsenoside (5.00 mg/kg) to 20 μl of inactivated rabies virus vaccine (RV) significantly amplified serum antibody responses and increased the CD4⁺:CD8⁺ ratio, interleukin IL-4, IL-10, IL-12 and IFN-γ secretions and Th1/Th2 responses inducing similar protection as did 100 μl of RV in ICR mice. This suggested that ginseng ginsenoside Re could be used to reduce the dose

and therefore the cost of the RV to achieve the same effective protection.

In a study of four normal healthy adult volunteers, increasing concentration of *P. ginseng* (0.16–1.6 µg/ml) caused a dose-related inhibition of phytohaemagglutinin (PHA-P)-induced transformation of peripheral blood lymphocytes (Chong et al. 1982). A combination of 500 µg/ml hydrocortisone and 0.80 µg/ml *P. ginseng* produced a greater suppression of PHA-P stimulation than either drug used alone. This suggested that *Panax ginseng* had a steroidlike effect in-vitro and may have a potentiating effect with hydrocortisone on T cell-mediated immunity. In a study of 10 young and 19 elderly persons, phytohaemagglutinin and Rg1 had stimulative effects on the phenotype of lymphocytes (Liu et al. 1995). Rg1 also increased the fluidity of lymphocyte membrane of the aged. The CD₂₅ and CD₄₅RA positive cells of lymphocytes in the elderly were lower than those of the young people. More CD₄₅RO-positive cells than CD45RA-positive cell lymphocyte populations were seen in the aged.

Anticomplementary Activity

Four anticomplementary polysaccharides, GL-PI to GL-PIV, and GL-PII, were isolated from ginseng leaves (Gao et al. 1988, 1990). Twelve ginsenosides were isolated from ginseng and exhibited definite anticomplement activity on complements C1q, C2, C3, C4 and C5, however, not C9 (Gao et al. 2013a). Sugar moiety was found to facilitate the anticomplement activity for oleanolic acid type ginsenosides. The targets researched partly explained the anti-inflammatory activity of some ginsenosides. *Panax ginseng* extract G-115 had anticomplementary and mitogenic activities (Yamada et al. 1995). Incubation with artificial gastric juice slightly decreased the anticomplementary activity, whereas incubation with artificial intestinal juice or with artificial gastric juice followed by artificial intestinal juice slightly increased the activity. The most potent anticomplementary activity was observed in the crude polysaccharide fraction, G-115G,

whereas the water-soluble dialysable fraction, G-115E, showed the most potent mitogenic activity.

Cardiovascular/Cardioprotective Activities

In-Vitro Studies

Ginsenosides and chikusetsusaponins present in the roots of *Panax ginseng* and rhizomes of *Panax japonicus* were identified as inhibitors of cyclic AMP phosphodiesterase (Nikaido et al. 1983). Saponins with a 20 (*S*)-protopanaxadiol or oleanolic acid moiety as the sapogenin were generally more inhibitory towards cyclic AMP phosphodiesterase than saponins with a 20 (*S*)-protopanaxatriol moiety as the sapogenin. The effects of various ginsenosides on corticosterone secretion and cyclic AMP phosphodiesterase activity appeared to be parallel. Ginsenosides from ginseng leaf and stem, Rb₁, Rb₂ or Rb₃ (30 µg/ml), restored the action potentials of xanthine–xanthine oxidase-induced free radical damaged myocardiocytes to normal, indicating their antioxidative action (Jiang et al. 1992). On normal myocardial cells, Rb₁, Rb₂ and Rb₃ (20 µg/ml) inhibited the action potential and spontaneous contractility. The degrees of their inhibitory effects were found to be Rb₁ > Rb₂ > Rb₃. Their effects against xanthine–xanthine oxidase were basically the same.

In an animal model in-vivo, ginseng ginsenosides (GS) were shown to protect against myocardial ischaemia–reperfusion damage with concomitant increased 6-keto-PGF1 alpha and decreased lipid peroxidation (Chen 1996). In perfused rabbit lung in situ and isolated rabbit aortic rings, GS protected the pulmonary and aortic endothelium against electrolysis-induced free radical injury. The results suggested that cardiovascular protection by GS may be partly mediated by the release of NO, a potent antioxidant, and that the GS-enhanced release of NO from endothelial cells, especially from perivascular nitric oxidergic nerves in rabbit corpus cavernosum, may partly account for the aphrodisiac effect of *Panax ginseng* used in traditional Chinese medicine.

Panax ginseng was found to promote the differentiation of mouse embryonic stem cells into cardiac-like cells (Sasaki et al. 2008). During a survey of 42 compounds from the database of *P. ginseng*, they found that vitamin B₁₂ (VB₁₂) and methionine were active.

Animal Studies

Administration of ginsenoside Rb₁ inhibited right ventricular hypertrophy (RVH) induced by monocrotaline in rats with some improvements of myocardial pathomorphology (Jiang et al. 2007). Rb₁ alleviated the high expressions of mRNA and/or proteins of CaN, NFAT₃ and GATA₄ from cardiocytes caused by monocrotaline. Ginseng saponins, protopanaxadiol and protopanaxatriol, significantly improved ischaemia–reperfusion injury-induced myocardial dysfunction by increasing left ventricular development pressure and time to contracture (Kim and Lee 2010). Moreover, the increases in the levels of lactate dehydrogenase (LDH), creatine kinase (CK), adenosine triphosphate (ATP) and malondialdehyde (MDA) and the decrease in the levels of GSH (reduced glutathione) were attenuated by total saponin and panaxatriol. Ginseng total saponins (GTS) inhibited endothelium cell damages induced by angiotensin II via AT1 receptor (Fang et al. 2011). The elevated plasma tumour necrosis factor- α (TNF- α) and lowered NO production induced by angiotensin II was reverted by GTS in rats. In in-vitro study, GTS reduced significantly the expressions of the NAD(P)H oxidase subunit P22phox, NF- κ B and intracellular ROS production induced by angiotensin II. Ginsenoside Rg₁ administration to male rats significantly ameliorated the histopathology of common carotid artery and decreases the protein expression of proliferating cell nuclear antigen induced by endothelial rubbing (Gao et al. 2011). Rg₁ could suppress the vascular neointimal hyperplasia induced by balloon injury; the mechanism may be involved in the suppression of ERK2 signalling and related, at least partly, to the increase in mitogen-activated protein kinase phosphatase-1 (MKP-1) expression.

Ginseng ginsenoside Rg₁ alleviated rat left ventricular hypertrophy induced by abdominal aorta coarctation, and the protection appeared to be attributed partly to its inhibitory effects on calcineurin and mitogen-activated protein (MAP) kinase signalling pathways (Deng et al. 2009). A standardised ginseng extract protected rodent hearts against acute myocardial ischaemia–reperfusion injury, and the infarct size reduction effect of ginseng was associated with glucocorticoid receptor (GR)/oestrogen receptor (ER)-mediated Akt and extracellular signal-regulated kinase (Erk) 1/2 activation in an endothelium NO synthase (NOS)-dependent manner (Zhou et al. 2011). Pretreatment of mice with compound K (20-O-D-glucopyranosyl-20(S)-protopanaxadiol), a novel ginseng ginsenoside metabolite, displayed protective effects on myocardial ischaemia–reperfusion injury, partly by mediating the activation of PI3K pathway and phosphorylation of protein kinase B (Akt) and endothelial nitric oxide synthase (eNOS) activity (Tsutsumi et al. 2011). Additionally, the hearts of compound K pretreated mice showed inhibition of mitochondrial swelling induced by Ca²⁺. Red ginseng saponin (RGS) protected rat cardiac myocytes against ischaemic injury in-vitro and in-vivo (Li et al. 2012b). RGS significantly attenuated myocardial ischaemic injury by improving cardiac systole function, partly by reducing cTnI secretion and improving cardiac diastolic function. Also, RGS attenuated the Ca²⁺ overload in cardiomyocytes and modulated the K_{ATP}, but not PI3K, signalling pathway; taken together, these mechanisms synergistically reduced infarct size.

Clinical Studies

In an 8-week, randomised, double-blind, placebo-controlled clinical trial with parallel design of 40 healthy subjects, administration of Korean red ginseng extract was found to improve blood circulation in the human body (Kang et al. 2013). Digital infrared thermal imaging showed that the temperature deviation in the whole body decreased safely in the Korean red ginseng group, which mitigated the body temperature imbalance.

Antihypertensive Activity

Kang et al. (1995) found that ginseng ginsenoside Rg₁ and ginsenoside Re from the protopanaxatriol group but not from the protopanaxadiol group enhanced the release of nitric oxide from endothelial cells and may contribute to the beneficial effect of ginseng on the cardiovascular system. The protopanaxatriol ginsenosides caused endothelium-dependent relaxation and production of cyclic GMP in the rat aorta. In subsequent study, they found that ginsenoside Rg₃ from the protopanaxatriol group caused a concentration-dependent relaxation of rat aortic rings (Kim et al. 1999c). Their results indicated ginsenoside Rg₃ to be a potent inhibitor of vascular smooth muscle tone and that this effect appeared to be due to an inhibition of Ca²⁺ influx and stimulation of K⁺ efflux, possibly via activation of tetraethylammonium-sensitive K⁺ channels. Ginsenoside Rg₃ was about 100-fold more potent than ginsenoside Rg₁ (Kim et al. 1999d). They further confirmed ginsenoside Rg₃ to be a major mediator of the endothelium-dependent nitric oxide-mediated relaxation in response to ginsenosides in isolated rat aorta, possibly via activation of tetraethylammonium-sensitive K⁺ channels. They also demonstrated that ginsenoside Rg₃ inhibited phenylephrine-induced vascular contraction through induction of nitric oxide synthase (iNOS) which was accompanied by NF-κB activation, involving phosphorylation and degradation of I-κBα and nuclear translocation of p65 (Kim et al. 2003b). Ginseng ginsenosides Rb₁ and Re decreased cardiac contraction in adult rat ventricular myocytes partly mediated by increased nitric oxide production (Scott et al. 2001). Ginseng extract (G115) inhibited angiotensin-converting enzyme (ACE) activity, but did not affect nitric oxide production in cultured human endothelial cells from umbilical veins (HUVEC) and bovine mesenteric arteries (Persson et al. 2006). Studies showed that 20(S)-ginsenoside Rg₃ prevented human endothelial cell apoptosis via Akt-dependent inhibition of the mitochondrial apoptotic signalling pathway suggesting

that it could help in controlling unwanted endothelial cell death at the site of vascular injury (Min et al. 2006).

Studies by Ahn et al. (2013) found that protopanaxatriol-enriched ginseng extract, TE, had the highest potency in nitric oxide production, followed by crude ginseng extract, protopanaxadiol-enriched ginseng extract and ginsenoside Rg1 in human umbilical vein endothelial cells. TE treatment resulted in rapid activation of intracellular signalling pathways, immediate linear rise of NO and increased eNOS activation. Further analysis revealed that TE, but not Rg1, resulted in AMPK phosphorylation at Thr¹⁷². The results supported the premise that the multiple components of extract rich in protopanaxatriol afforded combinatorial effects in NO production and vascular endothelium relaxation via multiple signalling pathways.

Animal Studies

Following the administration of ginseng ether extract (40 mg/kg) to dogs, the heart rate and the central venous pressure decreased significantly (Lee et al. 1981). The administration of ginseng ethanol extract (40 mg/kg) caused a significant decrease in the heart rate and the mean arterial pressure. After the administration of the aqueous extract (40 mg/kg), the cardiac output, stroke volume and central venous pressure were significantly decreased, while the total peripheral resistance was significantly increased. Ginsenoside (10–100 mg/kg, i.v.) lowered blood pressure in a dose-dependent manner in rats (Kim et al. 1994). The data suggested that vascular relaxations induced by ginsenoside were mediated by the release of endothelium-derived nitric oxide which enhanced the accumulation of cGMP. Crude saponin of Korean red ginseng (50, 100 mg/kg i.v.) induced a hypotensive effect and bradycardia in a dose-dependent manner in the anaesthetised rats but at 100 mg/kg induced a hypotensive effect and reflex tachycardia in the conscious rats (Jeon et al. 2000). Saponin-free fraction had no effect in the anaesthetised normotensive rats. It was found that the releasing effect of nitric oxide of Korean red ginseng, like NO donor, may be partly contributed to its hypotensive effect.

Intravenous administration of garlic, onion and ginkgo extracts produced dose-dependent and reversible hypotensive and bradycardic effects in anaesthetised normotensive rats (Brankovic et al. 2011). The most effective in reducing arterial blood pressure and heart rate was garlic extract.

Clinical Studies

In a study of 26 subjects with essential hypertension, 8 weeks medication with red ginseng decreased significantly 24 hour mean systolic blood pressure (Han et al. 1998). In eight subjects with white coat hypertension, no significant blood pressure change was observed. In eight subjects with white coat hypertension, no significant blood pressure change was observed. Studies by Sung et al. (2000) found that Korean red ginseng could improve vascular endothelial dysfunction in patients with hypertension possibly through increasing synthesis of nitric oxide. In a prospective, randomised, double-blind, placebo-controlled study of 30 healthy adults, therapy with *P. ginseng* extract at 200 mg extract daily increased QTc interval and decreased diastolic pressure 2 hours after ingestion in healthy adults on the first day of therapy (Caron et al. 2002).

In a double-blind, randomised, crossover design, involving 23 healthy individuals, administration of ginsenoside Rg3-enriched Korean red ginseng extract acutely lowered central and peripheral arterial pressures in healthy adults (Jovanovski et al. 2014).

Anti-inflammatory Activity

In-Vitro Studies

Panaxynol and linoleic acid were found to be major active anti-inflammatory components in ginseng root (Otsuka et al. 1981). 20(S)-Protopanaxatriol, one of ginsenoside metabolites, inhibited inducible nitric oxide synthase and cyclooxygenase-2 expressions through inactivation of nuclear factor- κ B in RAW 264.7 macrophages stimulated with lipopolysaccharide (Oh et al. 2004a). BST204, a fermented ginseng extract, suppressed

expression of cyclooxygenase-2 in murine RAW 264.7 cells by inhibition of p70 S6 kinase activation (Seo et al. 2005). The ginsenosides 20(*S*)-Rg₃, Rg₅ and Rk₁ from heat-processed ginseng selectively inhibited cyclooxygenase-2 activity (Yoo and Park 2012). Protopanaxatriol (PPT) moderately inhibited both cyclooxygenase-1 and cyclooxygenase-2. The ginsenosides 20(*R*)-Rg₃, Re and protopanaxadiol (PPD) were inactive. In the fertile egg method, ginseng chloroform extract exerted strong inhibitory activity against the formation of granulation tissue. A sterol glucoside, 3-*O*-β-d-glucopyranosyl-5,22,24-stigmastatrienol, and a known sterol, 5,22-stigmastadienol, isolated from ginseng seeds, inhibited NFκB-luciferase activity, with IC₅₀ values of 8.1 and 4.8 μM, respectively (Kim et al. 2013e). They also inhibited iNOS-luciferase activity in tumour necrosis factor (TNF)α-induced HepG2 cells, with IC₅₀ values of 2.2 and 2.9 μM, respectively. The dammarane triterpene saponin ginsenjilanol, ginsenoside Rf and ginsenoside Re₅ isolated from ginseng roots significantly inhibited nitric oxide production by lipopolysaccharide-activated RAW 264.7 cells in a concentration-dependent manner at concentrations of 60–200 μM with the half maximal inhibitory concentration (IC₅₀) values of 70.96 μM for ginsenjilanol, 74.14 μM for ginsenoside Rf and 79.83 μM for ginsenoside Re₅, whereas indomethacin had an IC₅₀ of 63.75 μM as a positive control drug (Wang et al. 2013a). Korean red ginseng extract inhibited the expression of MCP-1 and iNOS by suppressing the activation of NADPH oxidase, a source of reactive oxygen species (ROS), and the Jak2/Stat3 pathway, which mediates the expression of inflammatory mediators, in *Helicobacter pylori*-infected gastric epithelial cells (Cho et al. 2013c). Studies found that Korean red ginseng extract (RGE) inhibited interleukin IL-1β maturation resulting from NLRP3 inflammasome activation in both in-vitro and in-vivo models (Kim et al. 2014b). In addition, RGE strongly attenuated IL-1β secretion as well as pathogen clearance via pyroptotic cell death by macrophages through inhibition of AIM2

inflammasome activation. Ginsenosides Rg₁ and Rh₃ were suggested as inhibitors of the inflammasome activation.

Animal Studies

Orally administered KRGS Korean red ginseng saponin fraction (KRGS) and its genuine ginsenosides Rg₃, Rf and Rh₂ potently inhibited the mouse passive cutaneous anaphylaxis reaction induced by IgE (Bae et al. 2006). However, when these ginsenosides were intraperitoneally administered, ginsenoside Rh₂ showed the most potent inhibition. The ginsenoside Rh₂ also most potently inhibited the beta-hexosaminidase release from RBL-2H3 cells induced by IgE with antigen. KRGS administered topically at a dose of 0.1 % suppressed ear swelling in an oxazolone-induced mouse contact dermatitis model by 38.8 %. Its constituents ginsenosides Rg₃, Rf and Rh₂ at a concentration of 0.05 % also potently suppressed mouse ear swelling by 47.5 %, 34.8 % and 49.9 % at 16 days, respectively. These ginsenosides also significantly reduced mRNA expression levels of cyclooxygenase (COX)-2, interleukin (IL)-1beta, tumour necrosis factor-alpha and interferon-gamma induced by oxazolone applied to mouse ears. The ginsenoside Rh₂ also potently inhibited COX-2 and inducible NO synthase (iNOS) protein expression in lipopolysaccharide (LPS)-stimulated RAW 264.7 cells. *P. ginseng*-head part BuOH fraction reduced the carrageenan-induced paw oedema at 3 hours after oral administration and suppressed the production of serum interleukin IL-6 in CIA mice (Lee et al. 2008a). Ginseng extract (KRG) and total saponins (GTS) inhibited LPS-induced expression of iNOS, matrix metalloproteinase 9 (MMP-9) and proinflammatory cytokines in microglial cells (Park et al. 2009a). Suppression of microglial activation by ginseng was also observed in the mouse brain inflamed by LPS. Further, KRG and GTS significantly suppressed upstream signalling molecules, NF-κB and MAP kinase activities in inflammation.

When ginsenoside Rb₁ or compound K were orally administered to 2,4,6-trinitrobenzene sulfuric acid (TNBS)-induced colitic mice, these agents inhibited colon shortening, macroscopic score and colonic thickening (Joh et al. 2011). Also, treatment with ginsenoside Rb₁ or compound K at 20 mg/kg inhibited colonic myeloperoxidase activity by 84 % and 88 %, respectively, as compared with TNBS alone, and also potently inhibited the expression of tumour necrosis factor- α , interleukin (IL)-1 β and IL-6, but increased the expression of IL-10. Both ginsenoside Rb₁ and compound K obstructed the TNBS-induced expressions of COX-2 and iNOS and the activation of NF- κ B in mice. When ginsenoside Rb₁ or compound K was treated in LPS-induced murine peritoneal macrophages, these agents potently inhibited the expression of the proinflammatory cytokines. Ginsenoside Rb₁ and compound K also significantly inhibited the activation of interleukin 1 receptor-associated kinase-1 (IRAK-1), IKK- β , NF- κ B and MAP kinases (ERK, JNK and p38). Additionally, compound K inhibited the production of proinflammatory cytokines more potently than did those of ginsenoside Rb₁.

Korean red ginseng saponin fraction (KRGs) and ginsenosides Rh₂ and Rg₃ were found to exert an anti-inflammatory effect in-vivo and proved to be beneficial in atopic dermatitis-like skin lesions in NC/Nga mice (Kim et al. 2011a). Topical administration of 0.1 % KRGs, 0.1 % Rh₂ and 0.1 % Rh₂ + 0.1 % Rg₃ significantly reduced the clinical skin severity scores, ear thickness and mast cell infiltration in the 2-chloro-1,3,5-trinitrobenzene (TNCB)-induced atopic dermatitis-like skin lesions in NC/Nga mice. Topical application of KRGs and its constituents significantly reduced TNCB-induced increase in ear TNF- α and IL-4 mRNA expression, but not IFN- γ mRNA expression. Among the individual ginsenosides tested, Rh₂, Rh₃ and compound K significantly inhibited LPS-induced iNOS and cytokine expressions. Ginsenoside Re (from ginseng root) treatment decreased paw and ear thickness, elevated content and NO and MDA levels induced by carrageenan in BALB/C mice (Paul et al. 2012). Ginsenoside Re inhibited secretions of inflammatory

mediators such TNF α and IL-1 β in RAW 264.7 macrophage. Ginsenoside Re inhibited histamine-induced scratching behaviour in mice (Jang et al. 2012). However, its inhibitory effect was significantly attenuated in mice treated with COE (mixture of cefadroxil, oxytetracycline and erythromycin). Treatment with COE also significantly lowered faecal ginsenoside Re-metabolising β -glucosidase and α -rhamnosidase activities in mice, as well as faecal metabolic activity of ginsenoside Re to ginsenoside Rh₁. Ginsenoside Rh₁ had more superior anti-scratching behavioural effect than Re and potently inhibited the expression of IL-4 and TNF- α , as well as the activation of NF- κ B and c-jun activation in histamine-stimulated scratching behavioural mice.

Treatment with ginseng ginsenoside Rg₁ significantly improved survival of mice with caecal ligation and puncture-induced sepsis (Zou et al. 2013). Rg₁ administration suppressed the inflammatory response and enhanced bacterial clearance. Additionally, Rg₁ increased neutrophil counts in peritoneal cavity and inhibited lymphocyte apoptosis in the thymus and spleen.

Gastroprotective/Antiulcerogenic Activity

The 70 % methanol ginseng extracts exhibited inhibitory effects on the Shay ulcer in pylorus-ligated rats, serotonin-induced ulcer and endotoxin-induced ulcer (Matsuda and Kubo 1984). The extract also inhibited the decrease of gastric mucosal blood flow induced by serotonin and endotoxin. Ethanol extracts of the tissue-cultured ginseng and cultivated ginseng stimulated gastrointestinal propulsion in mice; the tissue-cultured ginseng also inhibited ulcer formation induced by water immersion and restraint stress and ligature of the pylorus (Suzuki et al. 1991a). In contrast, the cultivated ginseng showed no such inhibitory action. Fifty percent ethanol extracts of both cultured and cultivated ginsengs reduced gastric secretion and acid output in pylorus-ligated rats but did not affect pepsin activity (Suzuki et al. 1991b). The tissue-cultured ginseng inhibited histamine and pentagastrin-induced acid secretion in rats, but the cultivated

ginseng did not. They also suppressed acid secretion induced by 2-deoxy-d-glucose and baclofen [β -(*p*-chlorophenyl)- γ -aminobutyric acid], which had been reported to stimulate gastric acid secretion via the central nervous system. However, they had no effect on acid secretion induced by vagal stimulation. The results suggested that both tissue-cultured and cultivated ginsengs may have an inhibitory effect on gastric secretion via the central nervous system.

An acidic polysaccharide fraction, GRA-4, from ginseng root, when administered from 50 to 200 mg/kg orally, inhibited gastric lesions induced by HCl/ethanol or absolute ethanol in a dose-dependent manner (1991). The cytoprotective activity of GRA-4 decreased after its treatment with periodate but not after protein digestion, indicating that the carbohydrate moiety of this acidic polysaccharide contributed to this activity. The water-soluble crude polysaccharide fraction (GL-2) from ginseng leaves and the alkaline-soluble crude polysaccharide fraction (GRA-2) from ginseng roots prevented HCl/ethanol-induced ulcerogenesis in mice potently (Sun et al. 1992b). The most potent fraction, GL-2, was further fractionated into four polysaccharide fractions by precipitation with cetyltrimethylammonium bromide, and the weakly acidic polysaccharide fraction, GL-4, showed the most potent inhibition of gastric lesion formation. The activity of GL-4 decreased after treatment with periodate or digestion with endo-polygalacturonase, indicating that the carbohydrate moiety may contribute to the expression of the activity. Further purification of GL-4 yielded the most active purified polysaccharide, GL-4IIb1III, which prevented HCl/ethanol-induced ulcerogenesis in mice dose dependently. Oral administration of GL-4 at doses of 50–200 mg/kg inhibited the formation of the gastric lesions induced by necrotising agents such as HCl/ethanol and ethanol in a dose-dependent manner in mice and rats (Sun et al. 1992a). This protective effect was observed not only upon oral but also upon subcutaneous administration of GL-4 (50–100 mg/kg). GL-4 also inhibited the formation of gastric ulcers which were induced by water immersion stress, indomethacin or pylorus ligation. When GL-4 (100 mg/kg, p.o.) was administered into pylorus-ligated rats, both gastric acidity and pepsin activity in

the gastric juice decreased significantly. An antiulcer polysaccharide (GL-BIII) was purified from ginseng leaves (Kiyohara et al. 1994).

Among ginsenoside Rg3 and its metabolites, 20(S)-protopanaxadiol and 20(R)-protopanaxadiol potently inhibited the growth of *Helicobacter pylori*, and 20(S)-ginsenoside Rh₂ inhibited H⁺/K⁺ + ATPase of rat stomach (Bae et al. 2002b). Acid-treated ginseng (AG) extract, fermented AG extract and protopanaxadiol potently inhibited the growth of *Helicobacter pylori* (Bae et al. 2004). Korean red ginseng extract (RGE) inhibited *Helicobacter pylori*-induced gastric inflammation in Mongolian gerbils by suppressing induction of inflammatory mediators (keratinocyte chemoattractant factor, interleukin IL-1 β , iNOS), myeloperoxidase activity and lipid peroxide level in *H. pylori*-infected gastric mucosa (Bae et al. 2014).

Pretreatment of rats with ginseng extracts A and B attenuated the ethanol-induced gastric lesions compared to control group (Yeo et al. 2007). Significant induction of cytoprotective heat shock proteins HSP27 and HSP70 was found in the ginseng-administered rats, suggesting that the restoration of the proteins might contribute to the prevention of ethanol-induced gastric injuries. Ginsenoside Rd (protopanaxadiol 3,20-*O*-bidesmoside), isolated from the flower bud, exhibited inhibitory effects on ethanol- and indomethacin-induced gastric mucosal lesions in rats (Yoshikawa et al. 2007b). Ginseng ginsenoside Re treatment of rats dose dependently prevented gastric mucosal lesion development induced by compound C48/80 treatment (Lee et al. 2014b). Increases in the activities of myeloperoxidase (MPO; an index of neutrophil infiltration) and xanthine oxidase (XO) and the content of thiobarbituric acid reactive substances (TBARS; an index of lipid peroxidation) and decreases in the contents of hexosamine (a marker of gastric mucus) and adherent mucus, which occurred in gastric mucosal tissues after C48/80 treatment, were significantly attenuated by ginsenoside Re. The elevation of Bax expression and the decrease in Bcl-2 expression after C48/80 treatment were also attenuated by ginsenoside Re. Ginsenoside Re

significantly attenuated all these changes 3 hour after C48/80 treatment.

Neuroprotective/CNS Activity

Cho (2012) recently reviewed literature on the physiological and pharmacological effects of *P. ginseng* on neurodegenerative diseases and neurological disorders such as Parkinson's disease, Alzheimer's disease, Huntington's disease and amyotrophic lateral sclerosis and multiple sclerosis.

Ginseng- or ginsenosides-mediated neuroprotective mechanisms covered included maintaining homeostasis and anti-inflammatory, antioxidant, antiapoptotic and immune-stimulatory activities.

In-Vitro Studies

The total ginsenoside (N-butanol extract) fraction inhibited the uptake of radioactive gamma-aminobutyrate (GABA), glutamate (Glu), dopamine (DA), noradrenaline (NA) and serotonin (5-HT), but not the uptake of 2-deoxy- D-glucose (2-DG) and leucine (Leu) into rat brain synaptosomes (Tsang et al. 1985). Among the ginsenoside fractions investigated, fraction III which contained mainly ginsenoside Rd was the most effective in reducing the uptake of neurotransmitters. The inhibition was in the order of GABA = NA > DA > Glu > 5-HT, and this effect was concentration dependent. Similar studies indicated that ginsenoside Rc could affect neurotransmitter uptake specifically as well. Since the GABA uptake was most sensitive to the inhibitory action of these ginsenosides, it was postulated that ginseng may exert its action(s) in the central nervous system by affecting the removal of neurotransmitter substances in synaptic regions and that the GABAergic neurons may be one of the major sites of action.

Crude saponin extract of the ginseng root exerted a promoting effect on neurite extension of primary cultured neurons and also a protective effect on the distortion of neurites due to cytochalasin-B (Aiko et al. 1988). The lipophilic fraction of ginseng at a concentration of between 0.1

and 50 µg/ml induced neurite outgrowth of PC12 cells in a dose-dependent manner (Mizumaki et al. 2002). The lipophilic fraction of ginseng also induced neurite extension and promoted survival of rat cortical neurons at a concentration of between 0.025 and 1 µg/ml. It was found that ginseng lipophilic fraction exerted its neurotrophic effects via protein kinase C-dependent pathways. Liao et al. (2002) identified ginsenosides Rb₁ and Rg₁, extracted from ginseng root, as efficient neuroprotective agents for spinal cord neurons. These compounds dose dependently protected spinal neurons from excitotoxicity induced by glutamate and kainic acid, as well as oxidative stress induced by H₂O₂. *Panax ginseng* extract protected human neuronal SK-N-MC cells from the apoptosis induced by 2,2',5,5'-tetrachlorobiphenyl (PCB 52) and markedly attenuated lipid peroxidation, the generation of reactive oxygen species and DNA fragmentation and markedly reduced the PCB 52 induced proteolytic cleavage of β-catenin and PARP (Lee et al. 2004b).

Ginsenoside Rg₁ exerted a survival-promoting effect on both chick and rat cerebral cortex neurons in cell cultures (Himi et al. 1989). Ginsenoside Rb₁ (GRb₁) also had an effect in the rat and displayed some influence in the chick. Nerve growth factor (NGF) alone exerted no effect on both neurons, although it did potentiate the GRb₁ effect on chick embryonic cerebral cortex neurons, but did not alter the GRb₁ effect on rat embryonic cerebral cortex neurons. Ginsenoside Rg₃, extracted from ginseng attenuated NMDA (*N*-methyl-D-aspartate) receptor-mediated currents and NMDA-induced neurotoxicity in rat-cultured hippocampal neurons (Kim et al. 2004). Studies suggested that ginsenoside Rb₃, possibly as a non-competitive antagonist, could inhibit strychnine-sensitive glycine current at a dose-dependent manner in acutely dissociated hippocampal CA₁ neurons of young rats (Xu et al. 2005). The decrease of affinity of glycine to receptors and delay of receptor activation may be involved in Rb₃ inhibition.

Two ginseng aglycones, (20(*S*))protopanaxadiol and 20(*S*))protopanaxatriol) and ginsenoside Rh₂ (a monoglucoside of 20(*S*))protopanaxadiol), inhibited binding of

[³H]batrachotoxinin A-20 α -benzoate ([³H]BTX-B) in the mouse brain with IC₅₀ values of 42 μ M (20(*S*)protopanaxadiol), 79 μ M (20(*S*)protopanaxatriol) and 162 μ M (Rh₂) (Duan et al. 2006). It was found that 20(*S*)protopanaxadiol and the less potent inhibitor Rh₂ destabilised BTX-B-activated sodium channels through non-covalent allosteric modification of neurotoxin binding site 2. Among the nine ginsenosides tested, 20(*S*)-ginsenoside Rh₂ (20(*S*)-Rh₂) along with 20(*S*)-ginsenoside Rg₃ (20(*S*)-Rg₃) produced the highest inhibitory effect of NMDA receptors in cultured hippocampal neurons (Lee et al. 2006a). Although 20(*S*)-Rg₃ and 20(*S*)-Rh₂ selectively targeted NMDA receptors with similar potency, they produced additive effects and seemed to modulate different NMDA receptor regulatory sites. As a competitive antagonist, 20(*S*)-Rh₂ seems to inhibit the receptor via its interaction with polyamine-binding sites, and 20(*S*)-Rg₃ did so using glycine-binding sites. The data suggested that treatment of ginseng 20(*S*)-Rh₂ might be a novel preventive candidate in treating neurodegenerative disorders. Studies by Li et al. (2007) suggested that ginsenoside Rg₂ had a neuroprotective effect in PC12 cells against glutamate-induced neurotoxicity through mechanisms related to antioxidation and antiapoptosis. Further, the inhibitory effect of ginsenoside Rg₂ against the formation of β -amyloid A β 1-40 suggested that ginsenoside Rg₂ may also represent a potential treatment strategy for Alzheimer's disease.

López et al. (2007) found that ginsenosides from *P. ginseng* induced neuroprotection mainly through activation of antioxidant enzymes, namely, catalase, superoxide dismutase (SOD), glutathione peroxidases (GPx) and glutathione reductase (GR), and by decreasing ROS formation. Ginsenosides Rb₁, Rb₂, Re and Rg₁ were effective in reducing death of astrocytes, while Rb₁, Rb₂, Rd, Re and Rg₁ decreased ROS formation, ginsenoside Re being the most active. Exposure of astrocytes to H₂O₂ decreased the activities of antioxidant enzymes and increased ROS formation, but these

adverse effects were reversed by ginseng root extract (Naval et al. 2007). Roh et al. (2010) found that Rg₃ protected rat cortical neurons against 24-hydroxycholesterol-induced cytotoxicity by inhibiting NMDA receptors through a glycine modulatory site in the cortical neurons. Ginsenosides Rf and Rg₃ were found to be active components in ginseng-mediated neuroprotection via inhibition of L-type Ca²⁺ channels in cultured rat cortical neurons (Kim et al. 2008c).

Nie et al. (2008) found that panaxydol and panaxynol protected cultured cortical neurons against Abeta25–35-induced toxicity. The antiapoptotic action of panaxydol and panaxynol was mediated via inhibition of calcium influx and free radical generation. The findings suggested the possibility that panaxydol and panaxynol may reduce neurodegeneration in Alzheimer's disease. Neopanaxadiol, a new panaxadiol first obtained from the acid hydrolysate of the total ginsenosides of *Panax ginseng*, showed neuroprotective effect against glutamate-induced neurotoxicity in primary cultures of rat cortical cells (Tao et al. 2009). Yang et al. (2010) found that panaxynol pretreatment protected cortical neurons from ischaemia-like injury from oxygen-glucose deprivation (OGD)-induced neuronal apoptosis by upregulation of HIF-1 α expression and inhibition of apoptotic cascade. Ginseng water exhibited significant protective effects against 1-methyl-4-phenylpyridinium ion (MPP⁺)-induced cytotoxicity in SH-SY5Y human neuroblastoma cells possibly through the suppression of ROS generation and the inhibition of mitochondria-dependent apoptotic pathway (Hu et al. 2011). The approach may be used for screening therapeutic agents for degenerative disorders such as Parkinson's disease.

Gintonin was found to activate Ca²⁺-activated Cl-channel (CaCC) in *Xenopus* oocytes and to transiently increase intracellular free Ca²⁺ concentration ([Ca²⁺]_i) in mouse Ehrlich ascites tumour cells (Pyo et al. 2011; Hwang et al. 2012a; Nah 2012); gintonin activated G protein-coupled lysophosphatidic acid receptors with high affinity (Shin et al. 2012; Nah 2012). Gintonin induced [Ca²⁺]_i transients in B103 rat neuroblastoma cells transfected with human LPA receptors

with high affinity in the order of LPA2 > LPA5 > LPA1 > LPA3 > LPA4 (Hwang et al. 2012a). Shin et al. (2012) found that gintonin-mediated NMDA (N-methyl-D-aspartic acid) receptor-mediated ion current I (I_{NMDA}) potentiation and long-term potentiation induction in the hippocampus via the activation of LPA (lysophosphatidic acid) receptor might be responsible for ginseng-mediated improvement of memory-related brain functions. Studies by Karpagam et al. (2013) found ginseng ginsenosides CK, F1, Rh₁ and Rh₂ to be potential BACE1 inhibitors. BACE1, a β secretase candidate enzyme, had been reported to initiate the Alzheimer's disease pathogenesis via amyloid β (A β) peptide production serving as a potential therapeutic target. Pretreatment with ginseng ginsenoside Rb₁ activated Nrf2 (nuclear-factor-like2) pathway in cultured rat embryonic cortex-derived neural progenitor cells and led to an elevated expression of haem oxygenase-1 (Ni et al. 2014). The results demonstrated that Rb₁ displayed a potent antioxidative effect on cultured neural progenitor cells by activating Nrf2 pathway.

Animal Studies

Ginseng leaf crude saponin fraction (GF-DS-I) appeared to have CNS-depressive, neuroleptic, analgesic, hypertensive, cholinergic and histamine-like activities, while ginseng saponin GF-DS-II had CNS-depressive, neuroleptic, analgesic, hypotensive, atropine-like and papaverine-like activities in animals tested (Saito et al. 1973). These neuroleptic activities were examined and confirmed by tests on motor activity, exploratory movements, muscle tone, motor coordination, hypothermia and potentiation of CNS-depressant and pole climbing, anticonvulsant and analgesic tests. Similar effects were found for ginseng root neutral saponin fraction (Nabata et al. 1973).

Ginseng total saponin prevented the development of cocaine-induced reverse tolerance and dopamine receptor supersensitivity in mice (Kim et al. 1995b). The results suggested that ginseng total saponins may be useful for the prevention and therapy of the adverse action of cocaine. In a

separate study, Tokuyama et al. (1996) showed that ginseng extract may be useful clinically for the prevention of adverse actions of methamphetamine and cocaine. A concomitant i.p. injection of ginseng extract 200 mg/kg suppressed the development of reverse tolerance, the reappearance of locomotor sensitisation and conditioned place preference induced by methamphetamine and cocaine. Administration of ginseng total saponin (GTS) prior to and during the nicotine treatment in mice inhibited not only nicotine-induced hyperactivity and reverse tolerance but also postsynaptic dopamine receptor supersensitivity in nicotine-induced reverse tolerant mice (Kim and Kim 1999; Kim et al. 1999b). Intraperitoneal injection of ginseng total saponin (GTS) prior to and during the morphine treatment in mice inhibited morphine-induced hyperactivity and conditioned place preference (Kim et al. 1998a, 1999b). GTS inhibited the development of postsynaptic dopamine receptor supersensitivity. A single-dose administration of GTS also inhibited apomorphine-induced climbing behaviour, showing the antidopaminergic action of GTS at the postsynaptic dopamine receptor.

Intraperitoneal (i.p.) pretreatment administration of ginseng ginsenosides significantly suppressed kainic acid-induced induction of heat shock protein-70 (HSP-70) in both regions of the rat hippocampus (Lee et al. 2002b). Ginseng ginsenosides were effective in protecting hippocampal CA1 and CA3 cells against kainic acid-induced neurotoxicity. Oral administration of ginseng G115 afforded robust neuroprotection against neurotoxicity in rodent models of Parkinson's disease, namely, parkinsonism-inducing neurotoxin, 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP), in mice or its toxic metabolite, 1-methyl-4-phenylpyridinium (MPP(+)), in rats (van Kampen et al. 2003). Using a novel progressive model of Parkinson's disease (PD) by chronic exposure to the dietary phytosterol glucoside, β -sitosterol β -D-glucoside (BSSG), that triggered the progressive development of neurological deficits, with behavioural and cellular features that closely approximated those observed in PD, ginseng extract was found to be a potential neuroprotective therapy for the treatment of PD. Oral

administration of ginseng extract significantly reduced dopaminergic cell loss, microgliosis and accumulation of α -synuclein aggregates. Further, G115 administration fully prevented the development of locomotor deficits, in the form of reduced locomotor activity and coordination. Systemic administration of ginseng saponins (GS) produced significant protections against systemic 3-nitropropionic acid (3-NP)- and intrastriatal malonate-induced lesions in rat striatum with dose-dependent manner (Kim et al. 2005a). GS also improved significantly 3-NP-caused behavioural impairment and extended survival. GS inhibited 3-NP-induced intracellular Ca^{2+} elevations and restored 3-NP-caused mitochondrial transmembrane potential reduction in cultured rat striatal neurons. GS also prevented 3-NP-induced striatal neuronal cell deaths with dose-dependent manner; the EC_{50} was 12.6 $\mu\text{g/ml}$. Studies found that ginseng ginsenoside Rd could enhance the proliferation but not affect the differentiation of neural stem cells in rats and in-vitro (Lin et al. 2012). Ginsenoside Rd significantly increased the numbers of BrdU^+ and DCX^+ cells in the hippocampal dentate gyrus. In cultured neural stem cells, ginsenoside Rd promoted the size and number of neurospheres and increased the number of BrdU^+ and Ki67^+ cells but did not affect the differentiation of neural stem cells into neurons, astrocytes and oligodendrocytes.

Orally administered acid-treated ginseng (AG) extract and ginsenoside Rh_2 potently protected the rats against ischaemia–reperfusion brain injury (Park et al. 2004b). The ginsenoside Rh_2 also inhibited prostaglandin- E_2 synthesis in lipopolysaccharide-stimulated RAW 264.7 cells but showed no in-vitro antioxidant activity. Korean ginseng tea (KGT) protected rats against hypoperfusion-/reperfusion-induced brain injury; elevated lipid peroxidation (LPO) and decrease in glutathione (GSH), glutathione reductase (GR), catalase (CAT), glutathione-S-transferase (GST), glutathione peroxidase (GPx) and superoxide dismutase (SOD) were markedly reversed and restored to near normal levels in the groups pretreated with KGT (350 mg/kg given orally for 10 days) (Shah et al. 2005). The findings suggested Korean ginseng tea's therapeutic potential in cerebrovascular diseases

(CVD) including stroke. Chronically treating the rats with ginseng saponins (orally, 5 days before intracerebroventricular β -amyloid injection and 7 days afterward) resulted in a dose-related improvement against β -amyloid-induced amnesia; a significant reversion was observed at the highest GS dose (80 mg/kg/day) (Wang et al. 2006). Pretreatment with ginseng saponins completely protected the animal against β -amyloid-induced reduction of hippocampal acetylcholine release from hippocampal slices. The results indicated that ginseng saponins pretreatment could functionally prevent the β -amyloid-induced memory loss possibly by minimising the inhibitory effect of β -amyloid on hippocampal cholinergic transmission.

Ginseng ginsenoside Rg₂ protected rats against cerebral ischaemia–reperfusion-induced impairment of neurological responses, memory and caudate-putamen neuronal apoptosis in vascular dementia (VD) rat model (Zhang et al. 2008a). Neurological responses and memory ability of the ginsenoside Rg₂ or nimodipine groups improved significantly compared with the VD group, and this was associated with antiapoptosis mechanism. The expressions of BCL-2 and HSP70 proteins was increased while those of BAX and P53 decreased after ginsenoside Rg₂ and nimodipine treatment compared with the VD group. Ginsenoside Rg₃ exhibited neuroprotective effects on homocysteine-induced hippocampal excitotoxicity in-vitro and in-vivo (Kim et al. 2007b). In rat-cultured hippocampal neurons, ginsenoside Rg₃ treatment significantly and dose dependently inhibited homocysteine-induced hippocampal cell death, with an EC₅₀ value of 28.7 μ M, and attenuated homocysteine-induced caspase-3 activity. In-vivo studies revealed that intracerebroventricular (i.c.v.) pre-administration of Rg₃ significantly and dose dependently reduced i.c.v. homocysteine-induced hippocampal damage in rats. The results suggested that Rg₃-induced neuroprotection against HC in rat hippocampus might be achieved via inhibition of homocysteine-mediated NMDA receptor activation.

Ginsenoside Rb₁ infusion after cerebral ischaemia significantly promoted recoveries of neurological functions at

3 and 5 days after reperfusion compared to ischaemic rats (Gao et al. 2010). It was found that regulation of the expressions of brain-derived neurotrophic factor (BDNF) and caspase-3 may be involved in GRb1-induced neuroprotection against cerebral ischaemia. Ginsenoside Rd protected adult male Sprague-Dawley rats and cultured cortical neurons against okadaic acid-induced neurotoxicity and tau hyperphosphorylation by enhancing activities of protein phosphatase 2A (Li et al. 2011). In animal tests including tail suspension test, forced swimming test and rat olfactory bulbectomy depression model, it demonstrated antidepressant-like activity as potent as fluoxetine. It significantly reduced brain oxidative stress and downregulated serum corticosterone concentration in bulbectomy animals.

Studies by Shim et al. (2000) suggested that ginseng total saponin (GTS) may have an inhibitory action against nicotine-induced dopamine release in the brain nucleus accumbens (NA) of freely moving rats and tyrosine hydroxylase mRNA expression in the ventral tegmental area region. GTS may exert a potentiative effect on both c-fos and c-jun mRNA expressions at the nucleus accumbens region through inhibiting the release of dopamine in the nucleus accumbens. Studies suggested that intraperitoneal injections of ginseng total saponins could improve neurological deficits after focal cerebral ischaemia in rats by inducing endogenous neural stem cells activation and thereby enhancing adult central nervous system regeneration (Zheng et al. 2011). Hwang et al. (2012b) demonstrated that gintonin, a novel lysophosphatidic acid (LPA) receptor-activating ligand from ginseng, mediated the promotion of non-amyloidogenic processing to stimulate soluble sA β PP α (amyloid- β protein precursors alpha) release to restore brain function in mice with Alzheimer's disease. Gintonin promoted sA β PP α release in a concentration- and time-dependent manner. Moreover, in a transgenic mouse Alzheimer's disease D model, long-term oral administration of gintonin attenuated amyloid plaque deposition as well as short- and long-term memory impairment. Gintonin could be a useful agent for AD prevention or therapy.

Pre-administration of ginsenoside Rd protected mice against ischaemic brain damage induced by middle cerebral artery occlusion (MCAO) (Ye et al. 2011a). Rd at the doses of 10–50 mg/kg significantly reduced both cortical and striatal infarct volumes. This protection was associated with an improvement in neurological function and was sustained for at least 2 weeks after the insult. Rd significantly suppressed the accumulations of DNA, protein and lipid peroxidation products at 24 hour post-ischaemia. Rd also protected mitochondria at 4 and 24 hours after reperfusion. Furthermore, Rd partly enhanced endogenous antioxidant activities following MCAO. Ginsenoside Rd at the dose of 10–50 mg/kg significantly reduced the infarct volume and improved the long-term neurological outcome up to 6 weeks after focal cerebral ischaemia in rats (Ye et al. 2011b). Its neuroprotective activity may involve early free radicals scavenging pathway and a late anti-inflammatory effect.

Pretreatment of ginsenoside Rb₁ protected against cerebral ischaemic damage induced by middle cerebral artery occlusion and reperfusion in rats (Zhu et al. 2012). The results indicated that suppression of local inflammation after cerebral ischaemia might be one mechanism that contributed to the neuroprotection of ginsenoside Rb₁. In-vivo studies found that ginsenoside 20(R)-Rg₃ afforded significant neuroprotective effect in rats against focal cerebral ischaemic injury by markedly reducing cerebral infarct volumes and degrading infarct rate and improving behaviour of the animals (He et al. 2012). The results also suggested that 20(R)-Rg₃ (10 and 20 mg/kg) could significantly suppress the expressions of calpain I and caspase-3 mRNA.

Clinical Studies

Ginseng exhibited beneficial effects on γ -aminobutyric acid (GABA)_A receptor-related anxiety and sleep disorders (Lee et al. 2013a). Its ginsenoside Rg₃ also induced GABA_A receptor activation. The results indicated that Rg₃-induced GABA_A receptor activation via the γ_2 subunit and I_{GABA} enhancement

by Rg₃ might be one of the molecular bases of ginseng effects on GABA_A receptor. In a study of young male healthy volunteers (from 15 to 37 years old), ingestion of red ginseng extract three times daily for 7 days could improve the quality of sleep, thus having beneficial effects on sleep-disturbed subjects (Han et al. 2013). Total wake time was significantly reduced and sleep efficacy was increased, although slow-wave sleep stage 1 (N1) was reduced and non-rapid eye movement (REM) sleep was increased after ginseng administration.

Hepatoprotective Activity

Stem heat-processed ginseng containing ginsenosides Rg₃, Rk₁ and Rg₅ as its main ginsenoside components protected rats against lipopolysaccharide (LPS)-induced liver injury (Kang et al. 2007). LPS-elevated hepatic mitochondrial thiobarbituric acid reactive substance (TBA-RS) level was significantly lowered by 15 consecutive days of ginseng administrations. Additionally, upregulated hepatic inducible nitric oxide synthase and haem oxygenase 1 levels in LPS-treated control rats were significantly lowered and increased, respectively, by 100 mg/kg body weight/day of ginseng administration.

Wild ginseng was found to be efficacious in protecting rats against benzo[α]pyrene (BP)-induced hepatotoxicity (Gum et al. 2007). Pretreatment with wild ginseng for 4 weeks completely attenuated BP-induced increases in the alanine aminotransferase (ALT), aspartate aminotransferase (AST) and lipid peroxidation (LPO) levels and reversed BP-induced reduction of glutathione (GSH) content and glutathione S-transferase (GST) activity. Moreover, glutathione S-transferase alpha 2 (GSTA2), glutathione S-transferase alpha 3 (GSTA3) and glutathione S-transferase mu 2 (GSTM2) gene expressions were significantly increased by wild ginseng through the nuclear factor E2-related factor 2 (Nrf2)/antioxidant-responsive element pathway for enzyme induction. Wild ginseng moderately inhibited BP-induced CYP1A1 gene expression.

Spirulina platensis and *Panax ginseng* exhibited protective effect on cadmium-induced oxidative stress and hepatotoxicity in adult female Wistar albino rats (Karadeniz et al. 2009a). Both treatments markedly reduced lipid peroxidation and increased the endogenous antioxidants levels. *Panax ginseng* pretreatment of rats elicited protective effects against carbon tetrachloride toxicity as evidenced by decreases of tissue concentrations of oxidative stress markers (malondialdehyde and NO) and the reduction of CCL₄-induced antioxidant depletion and by histological attenuation of CCL₄-induced liver (cell degenerescence and fibrosis) injury (Karadeniz et al. 2009b). Ginseng treatment in combination with cadmium chloride in Swiss albino mice was protective against cadmium-induced hepatic injuries, significantly decreasing LPO, glutamic oxaloacetic transaminase (GOT) and glutamic pyruvic transaminase (GPT) and augmented GSH and serum alkaline phosphatase (Shukla and Kumar 2009). Ginsan effectively prevented carbon tetrachloride (CCl₄)-induced liver injury in BALB/c mice (Shim et al. 2010). The hepatoprotective effect of ginsan was attributed mainly through downregulation of oxidative stress induction of antioxidant protein contents, such as superoxide dismutase (SOD), catalase and glutathione peroxidase (GPX), as well as restoration of the hepatic GSH concentration and suppression of proinflammatory cytokines (IL-1 β , IFN- γ) and chemokines (MCP-1, MIP-2 β , KC). *Panax ginseng* treatment may play a protective role against carbon tetrachloride (CCl₄)-induced acute hepatotoxicity in rats (Karakus et al. 2011). Park et al. (2012) found that Korean red ginseng and its primary ginsenosides (Rg₃ and Rh₂) inhibited ethanol-induced oxidative injury by suppression of the mitogen-activated protein kinase (MAPK) pathway in mouse hepatocytes (TIB-73) cells. Pretreatment of rats with ginseng attenuated the elevated serum enzyme activities of liver and some biochemical parameters induced by CCL₄ challenge. Two months oral administration of Korean red ginseng or urushiol (*Rhus vernicifera*) treatment improved lipid profiles in rats with non-alcoholic fatty liver disease (NAFLD) (Hong et al. 2013). Both treatments significantly increased natural killer

cell activity in NAFLD rats and inhibited steatohepatitis in OLETF (Otsuka Long-Evans Tokushima Fatty) rats. Administration of ginseng essence (comprising *Panax quinquefolius*, *Panax ginseng*, *Nelumbo nucifera* and *Lilium longiflorum*) ameliorated oxidative stress and inflammation in CCL4-induced rats and improved liver function and abnormal metabolism of lipid (Weng et al. 2014). Additionally, ginseng essence could inhibit the activation of hepatic stellate cells by elevating the activities of antioxidative enzymes and the content of antioxidant, and also, it could ameliorate liver fibrosis.

Antiobesity Activity

The petroleum ether extract of *Panax ginseng* showed a significant inhibition of the diacylglycerol acyltransferase (DGAT) enzyme from rat liver microsomes (Lee et al. 2004d). DGAT is a key enzyme in the synthesis of triglycerides for the formation of adipose tissues. Bioactivity-guided fractionation led to the isolation of two new polyacetylenic compounds, (9*R*,10*S*)-epoxyheptadecan-4,6-diyn-3-one (1) and 1-methoxy-(9*R*,10*S*)-epoxyheptadecan-4,6-diyn-3-one (2), and the IC₅₀ values were 9 µg/mL for (1) and 32 µg/mL for (2). In-vitro studies showed that the less polar ginsenosides, particularly ginsenoside Rg₃, effectively reduced lipid accumulation in 3T3-L1 adipocytes, indicating that ginsenoside Rg₃ could be developed as an antiobesity treatment (Kim et al. 2009b). Hwang et al. (2009) found that the antiobesity effect of red ginseng rich constituent, ginsenoside Rg₃, involved the AMP-activated protein kinase (AMPK) signalling pathway and PPAR-gamma inhibition. Earlier, Hwang et al. (2007) found that ginsenoside Rh₂ was the most effective candidate for preventing metabolic disorders such as obesity and that it acted via the AMPK signalling pathway. Studies by Siraj et al. (2014) found that ginseng ginsenoside F₂ treatment with different doses reduced the level of lipid accumulated by obesity cell line 3T3-L1 adipocyte line during adipogenesis. There was a reduction in peroxisome proliferator-activated receptor gamma (PPAR γ) and perilipin gene expression levels

compared to that of differentiated adipocytes without any treatment.

Otsuka Long-Evans Tokushima Fatty rats, an obese insulin-resistant rat, treated with ginsan, a vinegar ginseng extract rich in ginsenoside Rg₃, had lower fasting and postprandial glucose concentrations and plasma insulin and improved glucose tolerance compared with vehicle-treated rats (Lim et al. 2009). These beneficial effects on body weight and glucose homeostasis were associated with alteration of expression of genes, glucose transporter 4, peroxisome proliferator-activated receptor γ and adenosine monophosphate-activated protein kinase, involved in glucose and fatty acid metabolism. Chronic administration of Korean red ginseng (KRG) reduced weight gain and visceral fat mass in the early period without altering food intake of Otsuka Long-Evans Tokushima fatty rats (Lee et al. 2009a). The KRG-treated fatty rats showed improved insulin sensitivity and significantly preserved glucose tolerance compared with untreated control animals up to 50 weeks of age, implying that KRG attenuated the development of overt diabetes. KRG promoted fatty acid oxidation by the activation of adenosine monophosphate-activated protein kinase (AMPK) and phosphorylation of acetyl-coenzyme A carboxylase in skeletal muscle and cultured C2C12 muscle cells. Increased expression of peroxisome proliferator-activated receptor- γ coactivator-1 α , nuclear respiratory factor-1, cytochrome *c*, cytochrome *c* oxidase-4 and glucose transporter 4 by KRG treatment indicated that activated AMPK also enhanced mitochondrial biogenesis and glucose utilisation in skeletal muscle. Ginseng was found to reduce body weight, adipose tissue mass and adipocyte size, but not food intake in high-fat diet-fed obese mice (Lee et al. 2013c). Ginseng decreased blood vessel density and MMP activities in adipose tissue. The expression of angiogenic factors (VEGF-A and FGF-2), (MMP-2 and MMP-9) and their inhibitors TSP-1, TIMP-1 and TIMP-2) in adipose tissue was markedly modulated by ginseng. The findings indicated that ginseng may prevent adipose tissue growth and obesity by inhibiting adipose tissue angiogenesis.

In the study of ten obese middle-aged Korean women, consumption of ginseng extract for 8 weeks exerted a weight loss effect and slight effects on gut microbiota in all participants (Song et al. 2014). The antiobesity effects of ginseng differed depending on the composition of gut microbiota prior to ginseng intake.

Analgesic/Antinociceptive Activity

Morphine-induced antinociception was prevented by pretreatment with ginseng total saponins in the tail-pinch and tail-flick tests carried out in mice (Kim et al. 1992). U-50,488H-induced antinociception was prevented by ginseng total saponins in the tail-flick but not in the tail-pinch test. It was found that antagonism of U-50,488H-induced antinociception by ginseng total saponins was dependent on serotonergic mechanisms. Later studies by Nemmani and Ramarao (2002) found that acute and chronic administration of ginseng total saponin (GTS) potentiated the U-50,488H (U50)-induced analgesia in U50-naïve mice. The potentiating effect of GTS on U50-induced analgesia may be partially responsible in the inhibition of tolerance to U50-induced analgesia in mice. Systemic administration of ginsenoside Rf (Rf) in mice elicited dose-dependent antinociception using two separate assays of tonic pain: in the acetic acid abdominal constriction test, the ED₅₀ was 56 mg/kg, a concentration similar to those reported for aspirin and acetaminophen in the same assay; in the tonic phase of the biphasic formalin test, the ED₅₀ was 129 mg/kg (Mogil et al. 1998). Rf failed to affect nociception measured in three assays of acute pain: the acute phase of the formalin test and the thermal (49 °C) tail-flick and increasing-temperature (3 °C/minute) hot-plate tests. Further it was found unlikely that Ca²⁺ channel inhibition on primary sensory neurons could fully explain the behavioural antinociception demonstrated for Rf.

Studies suggested that ginseng ginsenosides had antinociceptive activity in the formalin test, and this effect was due to blocking of SP-induced nociceptive information to postsynaptic site(s) at the spinal level (Yoon et al. 1998).

Pretreatment of mice with ginsenosides by intrathecal injection induced the inhibition of biting and licking of hind paw injected with 1 % formalin with dose-dependent manner. The ED₅₀ was 23 µg/mouse for acute phase and 15 µg/mouse for tonic phase. In subsequent animal studies, they found that ginsenosides produced antinociceptive effects through their action at the spinal and/or supraspinal site(s), not at nociceptors in the periphery (Nah et al. 2000). In addition, their results suggested that the antinociceptive effects were not mediated by opioid receptors.

Application of ginseng total saponins dose dependently suppressed Ca²⁺ channel currents in rat sensory neurons (Rhim et al. 2002). Also, ginseng total saponins could modulate L-, N- and P-type currents. The co-application of ginseng total saponins and the µ-opioid receptor agonist, d-Ala², N-MePhe⁴ and Gly⁵-ol-enkephalin (DAMGO), produced nonadditive effects in most cells tested, and each effect was significantly relieved by a depolarising prepulse. The results suggested that the modulation of Ca²⁺ channels by ginseng total saponins, in particular by ginsenoside Rg₃, could be part of the pharmacological basis of ginseng-mediated antinociception.

P. ginseng-head part BuOH fraction (PGHB) was safe in acute toxicity (LD₅₀ > 5,000 mg/kg) and inhibited the partially acetic acid-induced writhes (approximately 32 %) in mice (Lee et al. 2008a). Ginseng extract (500 mg/kg) inhibited the acetic acid-induced extravasation of Evan's blue dye in mice and was similar to the suppressive effect of ibuprofen as a positive control drug. A polyacetylenic compound, (9R,10S)-epoxyheptadecan-4,6-diyne-3-one (EHD), isolated from ginseng root extract inhibited Na⁺ currents in primary sensory neurons; EHD by inhibiting Na⁺ currents may contribute to the ginseng analgesia (Choi et al. 2008). Four glycoproteins isolated from ginseng root exhibited significant analgesic activities (Wang et al. 2013b). The glycoproteins in which protein content was the highest (73.04 %) displayed dose-dependent analgesic effect. In writhing test, the glycoproteins significantly inhibited writhes at the dose of 20 mg/kg by intraperitoneal injection. In hot-plate test, only the dose of 20

mg/kg prolonged the hot-plate latency. In the locomotor activity test, the glycoproteins significantly decreased motility counts at the dose of 20 and 40 mg/kg. Intraperitoneal administration of ginseng total saponins before or after surgery induced antihyperalgesic effects in a rat model of incisional pain (Kim et al. 2014d). The effects on mechanical hyperalgesia may be associated with anti-inflammatory cytokines and *N*-methyl-d-aspartate (NMDA) signalling.

In a 12-week, randomised, double-blind, controlled clinical trial of 38 patients with fibromyalgia, VAS (visual analogue scale) rating revealed a reduction in pain in the *P. ginseng* group, an improvement in fatigue and an improvement in sleep; with respect to baseline characteristics, there were no differences between the ginseng, amitriptyline and placebo groups (Braz et al. 2013). With respect to anxiety, improvements occurred in the *P. ginseng* group compared to baseline; however, amitriptyline treatment resulted in significantly greater improvements.

Antidepressant/Anxiolytic Activity

White and red varieties of ginseng (20 and 50 mg/kg) showed positive results when tested against several paradigms of experimental anxiety (Bhattacharya and Mitra 1991). Both were effective in the open-field and elevated plus maze tests and reduced conflict behaviour in thirsty rats and footshock-induced fighting in paired mice. Ginseng also attenuated pentylenetetrazole-induced decrease in rat brain MAO activity, confirming its anxiolytic activity since this has been proposed to be an endogenous marker for anxiety. Park et al. (2005b) found that the anxiolytic potential of sun ginseng (heat-processed ginseng at higher temperature) was stronger than that of red ginseng (steamed raw ginseng at 98–100 °C) by significantly increasing the number of open arms entries and the time spent on the open arms in the elevated plus maze model. Ginseng saponins were suggested to play an important role in the anxiolytic effects of ginseng.

The acidic polysaccharide portion of the plant (WGPA), containing arabinogalactan-, type-I rhamnogalacturonan (RG-

I)- and homogalacturonan (HG)-rich pectins exhibited antidepressant activity in mice (Wang et al. 2010a). At 100 mg/kg (but not the 200 mg/kg) it significantly reduced immobility time in the forced swim test, and both doses significantly increased social interactions and decreased aggressive behaviours in mice. It had no effects on spontaneous activity or behaviour in the elevated plus maze test.

Ginseng powder and crude saponin ginseng fraction significantly increased the frequency and duration of open arm entries of mice in the elevated plus maze test (Carr et al. 2006). Among the three types of pure ginsenoside (ginsenosides Rb₁, Rg₁ and Ro), only ginsenoside Rb₁ significantly increased both the frequency and duration of open arm entries. The results clearly implicated ginsenoside Rb₁ to be one of the active anxiolytic components of ginseng root.

Antiviral Activity

Panaxagin from ginseng root displayed an inhibitory activity against human immunodeficiency virus reverse transcriptase, and succinylation augmented this activity (Ng and Wang 2001). Polyacetyleneginsenoside Ro from ginseng root was found to inhibit the replication of human immunodeficiency virus type 1 (HIV-1) with an IC₅₀ value of 13.4 µg/mL (11.1 µM) (Zhang et al. 2002). Triterpenoids (20*R*)-20,25-epoxy-dammaran-2-en-6α,12β-diol; (20*R*)-20,25-epoxy-3-methyl-28-nordammaran-2-en-6α,12β-diol; isodehydroprotopanaxatriol; and oleanolic acid showed inhibitory activity against HIV-1 protease with IC₅₀ of 10.5, 10.3, 12.3 and 6.3 µM, respectively (Wei et al. 2009). Mice and ferrets fed with a 60-day diet containing red ginseng could be protected from lethal infections by highly pathogenic H5N1 influenza virus (survival rate of up to 45 % and 40 %, respectively) (Park et al. 2014). Interferon-α and interferon-γ antiviral cytokines were significantly induced in the lungs of mice fed with red ginseng, compared to mice fed with an unsupplemented diet.

Studies in human immunodeficiency virus (HIV)-1-infected patients showed that a combined therapy of Korean red ginseng and zidovudine for a prolonged period maintained CD4⁺ T cell counts from 239 to 234/ μ l, whereas in patients treated with zidovudine alone, CD4⁺ T cell counts decreased from 272 to 146/ μ l (Cho et al. 2001). This combined effect might be indirectly associated with delayed development of resistance mutation to zidovudine by red ginseng intake.

Two ginseng pectic polysaccharides, named as GP50-dHR and GP50-eHR, rescued cell viability from rotavirus infection dose dependently with IC₅₀ values of 15 and 10 μ g/mL, respectively, by inhibiting rotavirus attachment to cells (Baek et al. 2010). The results suggested ginseng polysaccharides to be viable therapeutic options for rotavirus diarrhoea.

Antibacterial and Antifungal Activity

Panaxagin from ginseng root exhibited ribonuclease activity towards yeast transfer RNA, translation-inhibitory activity in a rabbit reticulocyte lysate system and antifungal activity against fungi including *Coprinus comatus* and *Fusarium oxysporum*, but not against *Rhizoctonia solani* (Ng and Wang 2001). In-vitro and in-vivo studies found that ginseng polysaccharide (GP) possessed anti-septicaemic activity against sepsis caused by *Staphylococcus aureus* (Lim et al. 2002). In-vitro GP showed potent phagocytic activity and stimulated production of TNF- α by macrophage with 96 % lysis of murine fibrosarcoma L 929 cells. GP also stimulated production of IL-1 and IL-6 by stimulation of macrophage. The low mortality of GP-treated (0.025 mg/kg) infected mice was associated with decreased bacterial content in the blood. Nitric oxide production in *S. aureus*-infected mice whose macrophage was stimulated by GP increased approximately four times than the untreated *S. aureus*-infected group at 24 and 48 hours incubation. Combined treatment with GP (0.025 mg/kg body weight) and vancomycin (10 mg/kg B.W.) resulted in 100 % survival of the animals, whereas only 67 % or 50 % of the animals survived, respectively, when treated with GP or vancomycin alone.

Ginseng treatment of mouse with chronic *Pseudomonas aeruginosa* lung infection significantly lowered mortality (Song et al. 2003). The lung cells from the ginseng-treated group produced more interferon-gamma (IFN- γ) and tumour necrosis factor-alpha (TNF- α) but less interleukin 4 (IL-4). The ginseng-treated splenocytes produced more TNF- α and IFN- γ than the control spleen cells. Furthermore, a significantly milder lung pathology and faster bacterial clearance were observed. The results indicated a Th1-like immune response in the mice with *P. aeruginosa* lung infection after 7 days of ginseng treatment. Studies showed that administration of ginsenoside Rg₁ to mice intraperitoneally before intravenous challenge with live *Candida albicans* yeast cells protected them from experimental disseminated candidiasis (Lee and Han 2006). The protection was found to be mediated by Th1-type differentiation of CD4⁺ T cell. Also, ginsenoside Rg₁ inhibited in-vitro growth of *C. albicans* as tested by the agar diffusion susceptibility method. Ginsenoside Rd was found to have immunoadjuvant ability to induce *Candida albicans* surface mannan extract (CASM) to produce a protective antibody in mice (Han and Rhew 2013). This protected mice against disseminated candidiasis by eliciting higher titres of Th1-type antibody and a Th1-dominant immune response.

PG-F2, an acidic polysaccharide with high uronic acid content purified from the root of *Panax ginseng*, inhibited the adhesion of *Helicobacter pylori* to gastric epithelial cells and the ability of *Porphyromonas gingivalis* to agglutinate erythrocytes (Lee et al. 2004a). PG-F2 also exhibited its anti-adhesive effects against *Actinobacillus actinomycetemcomitans*, *Propionibacterium acnes* and *Staphylococcus aureus*. The minimum inhibitory concentrations (MIC) were found to be in a range of 0.25–0.5 mg/mL (Lee et al. 2006a). However, PG-F2 exhibited no inhibitory effects against *Lactobacillus acidophilus*, *Escherichia coli* or *Staphylococcus epidermidis*. Limited hydrolysis of PG-F2 via treatment with pectinase yielded an oligosaccharide fraction, with activity comparable to the precursor PG-F2 (the MIC of ca. 0.01 mg/mL against *H. pylori*

and *P. gingivalis*). Polysaccharides PG-F2, a pectin-type polysaccharide, and PG-HMW, an arabinogalactan from *Panax ginseng*, demonstrated strong anti-adhesive activities against oral and skin pathogens to host cell lines in a dose-dependent manner from 0.1 to 2.0 mg/ml (Lee et al. 2009b). PG-F2 and PG-HMW might have a selective anti-adhesive effect against certain pathogenic bacteria without adverse effects on commensal bacteria. Polyacetylene compounds, dihydropanaxacol, panaxacol 1-hydroxydihydropanaxacol and 17-hydroxypanaxacol, from ginseng hairy roots, exhibited antimicrobial activity in-vitro against *Staphylococcus aureus*, *Bacillus subtilis*, *Cryptococcus neoformans* and *Aspergillus fumigatus* (Fukuyama et al. 2012).

Radioprotective Activity

A single intraperitoneal injection of partially purified ginseng extract after X-irradiation of 650–675 R significantly increased the 30-day survival ratio in mice (Yonezawa 1976). Oral administration of a ginseng extract resulted in an increase of the number of mitotic cells both in myeloid and erythroid cells. Intraperitoneal injection of the extract also increased the rate of syntheses of serum albumin and gamma globulin as well as DNA, RNA, protein and lipid syntheses in bone marrow cells. Two fractions of ginseng extract, namely, CM-A and CM-B, were significantly efficacious at 5 % level and 0.1 % level, respectively, with the doses proportional to their yields (Yonezawa et al. 1981). CM-B (free of saponins) was separated into three fractions: G-I (0.44 mg per animal) and G-III (0.84 mg, calculated dose) were significantly efficacious, but G-II (0.47 mg) was not. Radiation protection from bone marrow death by a single injection (intraperitoneal and intravenous) of partially purified ginseng extract after whole-body X-irradiation was confirmed in JCL-ICR mice (Takeda et al. 1981). Stimulated recovery by the extract was also observed in thrombocyte and erythrocyte counts, while the extract did not markedly affect recovery of leucocyte counts. The extract also increased 30-day survival ratio of splenectomised mice. Recovery of thrombocyte counts after exposure was assumed one of the most important factors for

restoration of bone marrow death. A thermostable fraction of the ginseng extract protected mice (male) irradiated with 720 R of X-rays and rats (male) irradiated with 825 R with the dose about 6 mg per 100 g of body weight (Takeda et al. 1982). The fraction also protected guinea pigs, both female and male, irradiated with 325 R with the dose of about 80 mg per 300 g of body weight. Comparison of stimulated recovery by the thermostable fraction of the ginseng extract among the three blood cell counts showed that restoring action was the most marked on thrombocyte counts, commonly in the three species of the animals. A single postirradiation injection of the thermostable fraction of a ginseng extract enhanced the recoveries of the numbers of both blood-forming stem cells (10 days CFUs) and megakaryocytes in bone marrow of irradiated mice (Yonezawa et al. 1985). It also protected haemorrhaging tendency of X-irradiated mice determined by a quantitative measurement of occult blood appearance in daily faeces. The present study and their previous findings suggested that ginseng protected the irradiated animals from bone marrow death by stimulating thrombopoietic hematogenesis (CFUs, megakaryocytes and thrombocytes) and finally preventing haemorrhage. Zhang et al. (1987) found that water-soluble extract of whole ginseng gave the best protection against gamma radiation in C3H mice. The isolated protein and carbohydrate fractions gave less protection, while the saponin fraction did not. In further studies, they found that the water fraction and alkaloid fraction of *Panax ginseng* may reduce cell damage caused by gamma-rays, especially damage to DNA molecules, and play a role in the repair or regeneration process of damaged cells (Kim et al. 1993). Further, they found that ginseng administration before irradiation protected the jejunal crypts, increased the formation of endogenous spleen colony and reduced the frequency of radiation-induced apoptosis (Kim et al. 2001). Diethyldithiocarbamate (DCC) afforded similar radioprotective effects but showed no significant modifying effects on the formation of endogenous spleen colony. Also, they found that the lipophilic nonpolar compounds (fraction 1), lipophilic-acidic compounds (fraction 2), free sugars

(fraction 7) and saponin compounds (fraction 8) of ginseng extract might have a major radioprotective effect.

Ginsan, the polysaccharide extracted from ginseng roots, and amifostine did not alter the frequency of micronucleated polychromatic erythrocytes (MNPCE) of control mice, showing that they were non-mutagenic per se; gamma irradiation induced a statistically significant increase of MNPCE and decrease of PCE/NCE ratio compared to control group (Ivanova et al. 2006). However, ginsan applied 30 minutes before or 15 minutes after irradiation reduced MNPCE in a dose-dependent manner. Amifostine (200 mg/kg b.w.) did not reduce radiation-induced MNPCE, but stimulated erythropoiesis, when administered before irradiation. Based on the above results, the radioprotective effect of ginsan can be partially attributed to the reduction of radiation-induced genotoxicity.

Ginsan (acidic polysaccharide of *Panax ginseng* roots) pretreatment of bone marrow cells (BMs) significantly increased the viability of BMs against gamma radiation and increased production of interleukin IL-12, a major cytokine for immune responses (Kim et al. 2007a). Moreover, ginsan-treated mice had a larger number of BMs after gamma radiation than the control mice. The results suggested that ginsan may be a good candidate radioprotective agent for bone marrow cells. Ginsan protected mice from gamma radiation-induced damage of the small intestine (Park et al. 2011a). Ginsan treatment caused the lengthening of villi and a numerical increase of crypt cells in the small intestine at 3.5 days after 7 Gy irradiation compared to irradiated, non-treated controls. Additionally, ginsan significantly inhibited irradiation-induced apoptosis by decreasing the amount of pro-apoptotic p53 and Bax as well as augmenting that of antiapoptotic Bcl-2 at 24 hours after irradiation. Further they found that ginseng acidic polysaccharide (APG) protected mouse small intestine from irradiation-induced apoptosis through inhibition of the p53-dependent pathway and the mitochondria/caspase pathway (Bing et al. 2014).

Treatment with ginsenoside Rd before γ -irradiation inhibited irradiation-induced apoptosis in murine intestinal

epithelial IEC-6 cells (Tamura et al. 2008). Administration of Rd after irradiation also inhibited apoptosis in these cells. It was found that ginsenoside Rd protects and rescues rat intestinal epithelial cells from irradiation-induced apoptosis through a pathway requiring activation of PI3K/Akt, inactivation of MEK and also inhibition of a mitochondria/caspase pathway.

Studies suggested that red ginseng saponin fraction could be considered and developed for use as an effective radioprotective agent with minimal adverse effects (Lee et al. 2014c). Ginseng fraction strongly suppressed ionising radiation (IR)-enhanced and lipopolysaccharide (LPS)-induced proinflammatory responses such as nitric oxide (NO) production ($IC_{50} = 5.1 \mu M$) and interleukin 1β levels. It was found to exert its radioprotective effects by inhibition of a signalling cascade that activated checkpoint kinase 2-nuclear factor- κB . In addition, it strongly inhibited IR-enhanced LPS-induced expression of hemoxygenase-1.

Angiogenic Activity

Results of in-vitro studies in human umbilical vein endothelial cell (HUVEC) and in-vivo studies in mouse suggested that ginsenosides Rg_1 and Re could be a novel group of nonpeptide angiogenic agents with a superior stability and may be used for the management of tissue regeneration (Yu et al. 2007). It was found in-vitro that HUVEC proliferation, migration in a Transwell plate and tube formation on Matrigel were all significantly enhanced in the presence of basic fibroblast growth factor (bFGF), Rg_1 or Re. However, after being treated at different temperatures, pH or solvent species, the remaining activity of bFGF on HUVEC behaviours reduced significantly, but the activities of Rg_1 and Re remained unchanged throughout the entire course of the study. The in-vivo results observed on day 7 after implantation showed that the blank control (Matrigel alone) was slightly vascularised. In contrast, the density of neovessels in the Matrigel plug mixed with bFGF, Rg_1 or Re was significantly enhanced. However, after being treated, the density of neovessels was significantly

reduced in the Matrigel plug mixed with bFGF, while those of Rg₁ and Re remained unchanged. Lin et al. (2008) found that the stimulating effect of Rg₁ HUVECs proliferation remained unchanged after dissolved for 30 days in culture medium at 37 °C when compared with the effect of bFGF. One week after implantation in transgenic mice, bFGF or Rg₁ mixed in Matrigel plug significantly enhanced angiogenesis; however, at 6 weeks a significant decrease in angiogenic effect was observed in Matrigel with bFGF, but not in Matrigel with Rg₁. The results confirmed that Rg₁ could be used in tissue engineering.

Spasmolytic Activity

All ginseng saponins diminished acetylcholine-induced contraction of the isolated ileum of the guinea pig, but high concentrations of Rb₂ caused contraction of the ileum by itself (Kaku et al. 1975). Both ginseng total saponins (GTS) and its constituents, protopanaxatriol saponins (PT), inhibited the electrically evoked contractions of guinea pig ileum (GPI) in a concentration-dependent manner in a range of 1–100 µg/ml, and this effect was irreversible at high concentrations of the saponins (Watanabe et al. 1988). Protopanaxadiol saponins (PD) had a transient and weak effect. In contrast, in mouse vas deferens (MVD), the contractions were increased by PT and PD; however, GTS was almost without effect. The inhibitory effect of morphine was arithmetically increased by pretreatment with 100 µg/ml of these saponins in guinea pig ileum preparations, while the inhibitory effect of the contractions was potentiated in MVD preparations. Neither the inhibition of contractions in the guinea pig ileum preparation nor the facilitation of contractions in the MVD preparation by these ginseng saponins was reversed by naloxone, in contrast to naloxone antagonism of morphine-induced contractions in both preparations. GTS and PT caused a dose-dependent inhibition of BaCl₂-induced contraction of guinea pig ileum. It was concluded that the mechanism on the inhibitory or facilitated effect of ginseng saponins on electrically evoked contractions in guinea pig ileum and mouse vas deferens

preparations may be based on the direct action of the saponins on smooth muscles preparations and not on the effect of opioids.

Anti-glaucoma Activity

Ginseng was found to have parasympathomimetic activity (Takatori et al. 1963). In a prospective, randomised, placebo-controlled, double-masked crossover trial of 36 patients with open-angle glaucoma, Korean red ginseng treatment significantly improved retinal peripapillary blood flow in the temporal peripapillary region (Kim et al. 2010). Blood pressure, heart rate, intraocular pressure and visual field indices did not change after placebo or red ginseng treatment. No significant changes were found in retinal peripapillary blood flow in either the rim region or the nasal peripapillary region. The results implied that red ginseng may be helpful in glaucoma management.

Wound Healing Activity

Application of ginseng ginsenoside Rd, a main ingredient of ginseng leaf, to an excision wound in mice showed an effective healing process (Kim et al. 2013f). Ginsenoside Rd significantly increased the proliferation and migration level of keratinocyte progenitor cells and human dermal fibroblasts in a dose-dependent manner and effectively induced collagen type 1 and downregulated matrix metalloproteinase-1 (MMP-1) in a dose-dependent manner. All of these beneficial effects were associated with an induction of intracellular cAMP levels and phosphorylated cAMP response element-binding protein expression in the nucleus. The findings suggested that ginsenoside Rd can be used as a natural source for skin regeneration.

Hearing Loss Ameliorating Activity

Red ginseng and ginsenoside compound K promoted recovery from hearing threshold shifts caused by noise exposure resulting in noise-induced hearing loss in mice (Hong et al.

2011). Red ginseng, ginsenoside Rh₁ and ginsenoside compound K promoted recovery of central auditory function impairment, while red ginseng and ginsenoside compound K promoted recovery of hair cell functional damage in the cochlea. The results suggested that consumption of Korean red ginseng may facilitate recovery from noise-induced hearing loss. Administration of red ginseng ameliorated 3-nitropropionic acid (3-NP)-induced cochlear damage and 3-NP-induced hearing loss in BALB/c mice (Tian et al. 2013). Red ginseng treatment of C57BL/6 mice with inner ear disorder delayed age-related hearing loss and vestibular dysfunction (Tian et al. 2014). Vestibular dysfunction was observed in the tail-hanging and swimming tests, with significantly different severity scores and swimming times detected between the control and 150 mg/kg red ginseng-treated group at the age of 12 months. However, long-term and high-dose treatment with red ginseng may induce aggressive behaviour.

Antihypertrophic Activity

Ginseng root saponin (200 mg/kg, × 7 days, p.o.) attenuated the suppressive action of cortisone acetate (10 mg/kg, × 7 days, i.m.) on compensatory adrenal hypertrophy in rats after unilateral adrenalectomy (Tanizawa et al. 1981). Ginseng saponin was also found to be antagonistic to the decrease of thymus weight and serum K⁺ concentration induced by cortisone acetate in these rats. In histochemical studies, ginseng saponin showed no effect on the improvement of fatty metamorphosis induced by cortisone acetate in the liver of these rats.

Antidermatitis Activity

Korean red ginseng extract significantly reduced the total clinical severity score, ear thickness and the level of serum IgE in mouse with atopic dermatitis, whereas aprepitant reduced only the serum IgE level (Lee and Cho 2011). The extract not only decreased TNF- α , IFN- γ and substance P but also reduced the infiltration of FOXP3⁺ regulatory T (Treg) cells

and CD1a⁺ Langerhans cells in the lesions, whereas aprepitant decreased only substance P and the infiltration of Treg cells. Ginseng ameliorated 2,4-dinitrochlorobenzene (DNCB)-induced dermatitis severity, serum levels of IgE and TARC (activation-regulated chemokine) and mRNA expression of TARC, TNF- α , IFN- γ , IL-4, IL-5 and IL-13 in mice (Choi et al. 2013). CG attenuated the Th1 and Th2 responses and leucocyte infiltration and reduced thickness of epidermis/dermis in ear lesions in NC/Nga mice. Ginseng inhibited TARC expression via blockade of NF- κ B activation in HaCaT cells.

Oral administration of Korean red ginseng extract inhibited the development of atopic dermatitis-like skin lesions in trinitrochlorobenzene (TNCB)-treated NC/Nga mice by modifying thymic stromal lymphopoietin (TSLP), dendritic cells and, at least in part, the Th2 response (Cho and Cho 2013). Oral administration of 20-*O*- β -D-glucopyranosyl-20(*S*)-protopanaxadiol-fortified ginseng extract significantly attenuated *Dermatophagoides farinae* body extract-induced increases in atopic dermatitis score, ear thickness, scratching time and severity of skin lesions in NC/Nga mice (Kim et al. 2014a). Ginseng treatment also reduced the level of macrophage-derived chemokine in serum, infiltration of eosinophils and mast cells in skin and production of cytokines in splenocytes.

Antiemetic Activity

Pretreatment or post-treatment with Korean ginseng root extract significantly attenuated cisplatin-induced kaolin (pica) intake and markedly improved intake of normal food by rats (Raghavendran et al. 2011). Post-treatment with the lowest dose resulted in a significant anti-pica effect and improved food intake until 72 hours. The anti-pica effects of ginseng were further confirmed with haematological and histopathological findings. The findings indicated that ginseng improved the resistance of rats against emesis. They also reported that pretreatment with Korean ginseng protected rats against X-ray irradiation-induced acute pica to a moderate extent, leading to improved feeding behaviour (Raghavendran

et al. 2012). The antiemetic effect of Korean ginseng was further confirmed on the basis of serotonin release and histopathological findings.

Renoprotective Activity

Ginseng extract exerted a stimulating effect on rat renal nuclear RNA synthesis resulting in an increased incorporation of labelled leucine into rat renal protein, and maximum activity was observed at 12 hours after the intraperitoneal administration (Nagasawa et al. 1977). Intraperitoneal administration of ginseng saponin preparation lowered the elevated adrenal cyclic AMP in a dose-dependent manner and increased plasma 11-hydroxycorticosteroid in intact rats (Hiai et al. 1979). In hypophysectomised rats, saponin treatment did not increase adrenal cyclic AMP, whereas corticotropin treatment did. It was concluded that ginseng saponin indirectly stimulated the adrenocortical function in intact rats.

The free radical scavenging activity of ginsenoside Re-alanine mixture was increased by heat processing (Lee et al. 2012b). Ginsenoside Re was gradually changed into Rg₂, Rg₆ and F₄ by heat processing. The improved free radical scavenging activity by heat processing was mediated by the generation of antioxidant Maillard reaction products (MRPs). Antioxidant MRPs were generated from the reaction of glucose and alanine. Based on the viability results of LLC-PK1 renal epithelial cells, MRPs and less polar ginsenosides contributed to the combined renoprotective effect against oxidative renal damage. Maillard reaction was importantly involved in the increased antioxidant effect of ginsenoside by heat processing.

Kang et al. (2008) found that renal dysfunction of streptozotocin-induced diabetic rats was significantly ameliorated by ginseng 20(S)-ginsenoside Rg₃ administrations in a dose-dependent manner. The beneficial effects on diabetic renal damage were related to the inhibitory effect of 20(S)-Rg₃ against NMDA receptor-mediated nitrosative stress. Studies showed that ginsenosides from ginseng may be useful in enhancing the tolerance of the kidney against renal injury

associated with cantharidin (Xu et al. 2013). Pretreatment of ginsenosides reduced the increases of serum creatinine, urine protein, urea nitrogen and histological change in rats caused by cantharidin. Ginsenoside pretreatment also reduced NRK cell apoptosis caused by cantharidin and augmented the cantharidin-lowered Bcl-2 expression. Korean red ginseng extract prevented renal impairment and pharmacokinetic changes by metformin in rats with renal failure induced by gentamicin (Lee et al. 2013g).

Haemolytic/Antihaemolytic Activity

Some fractions of ginseng were haemolytic and some fractions were antihaemolytic, exhibiting protective activity against saponaria saponin haemolysis and lecithin haemolysis (Namba et al. 1973). By treatment with acid hydrolysis, haemolytic fractions afforded panaxatriol, and protective fractions gave panaxadiol. Saponins with genuine sapogenins 20-*S*-protopanaxatriol were found to be haemolytic and saponins with genuine sapogenins 20-*S*-protopanaxadiol were antihaemolytic. Among the seven ginseng saponins, Rd, Re and Rb₂ showed more potent haemolytic actions than those of the rest, and the potencies were proportional to their toxicities (Kaku et al. 1975). Ginseng ginsenosides inhibited 2,2'-azobis(2-amidinopropane hydrochloride) (AAPH)-induced haemolysis of the erythrocyte in the order of 50 % inhibitory concentration IC₅₀ values Rb₃ ~ Rb₁ ≪ Rg₂ < Re < Rg₁ ~ Rc < Rh₁ < R₁. Rb₁, Rc and Rg₂, as antioxidants, prolonged the lag time of haemolysis (Liu et al. 2002). Contrariwise, Rg₃, Rd and Rh₁, together with high concentration of Rb₃, Rg₁ and Rh₂, function as pro-oxidants to accelerate AAPH-induced haemolysis. The order of synergistic antioxidative properties with α-tocopherol was Rb₁ > Rc > Re > Rh₁ > R₁ > Rg₂ > Rb₃. Rg₃, Rd and Rh₂, however, act as synergistic pro-oxidants in the above experimental system. Rg₁ did not show any synergistic antioxidative property. In in-vitro studies it was found that the following ginseng ginsenosides protected human erythrocytes against hemin-induced haemolysis, and

the overall sequence was $R_c > R_d > R_e \sim R_{b_1} > R_{g_1} \sim R_{h_1} > R_{b_3} \sim R_{g_2} \sim R_1 \sim$ pseudoginsenoside $F_{11} \sim 20(S)$ -protopanaxatriol (PT) (Li and Liu 2008). Ginsenosides R_{h_2} and R_{g_3} intensified haemolysis in the presence of hemin and initiated haemolysis even in the absence of hemin. Further 20(*S*)-protopanaxadiol (PD) promoted haemolysis appreciably, whereas PT protected erythrocytes efficiently.

Intestinal Transit Activity

Ginseng root improved both carbachol-induced and $BaCl_2$ -induced hyperperistalsis of the small intestine in mice suggesting that both an inhibitory effect on the cholinergic nervous system and direct suppressive effect on muscles were involved in the ameliorative effect of ginseng root on the accelerated small intestinal transit (Hashimoto et al. 2003). Ginsenoside R_{b_1} and ginsenoside R_d , the major components of ginseng roots, also improved accelerated small intestine transit.

Metabolic Stimulating Activity

Ginseng extract stimulated RNA polymerase activity in rat liver nuclei (Hiai et al. 1971). The increase in the activity of the polymerase due to ginseng extract did not disappear even when the synthesis of bulk nuclear protein was greatly inhibited by puromycin.

Ginseng root extract increased the incorporation rate of labelled precursors into liver nuclear RNA at 4 hours and into cytoplasmic polysomal RNA at 5.5–6.0 hours after a single-dose intraperitoneal injection in rat (Oura et al. 1971). Intraperitoneal administration of ginseng extract (fraction 3 or 4) to rat was found to increase the rate of synthesis of serum proteins such as albumin and γ -globulin (Oura et al. 1972a). The incorporation rate of ^3H -leucine into serum proteins was significantly increased 4 hours after the injection of fraction 3. The increased rate of protein synthesis reached a maximum of about 8–12 hours after the administration, and 46–49 % increase in the rate of serum protein synthesis was observed. A

single intraperitoneal injection of ginseng root extract (fraction 4) increased the incorporation rate of labelled precursor into cytoplasmic polysomal ribonucleic acid (RNA) of the rat liver (Oura et al. 1972b). The content of heavy polysomes (over hexamer) in postmitochondrial supernatant from liver treated with fraction 4 was observed to increase at 6 and 10 hours after treatment. Particularly, 29S ribosomal and 9-10S messenger RNAs were stimulated significantly.

In an amino acid incorporation system in-vitro, stimulatory activities of microsomes and polysomes from ginseng-treated rat liver were more active by 85 and 67 % than those from normal liver, respectively. Ginseng saponin mixture (fraction 5) exhibited high activity for such incorporation of labelled leucine into serum protein at 6 hours after a single intraperitoneal injection in a mouse (Oura et al. 1975). Administration of ginseng root ginsenosides Rb₁ and Rc to rats stimulated biosynthesis of rat serum protein (Shibata et al. 1976). Intraperitoneal injection of ginsenoside Rb₁ increased while Rc decreased the incorporation of ³H-orotic acid into nuclear RNA of rat liver, and Rg₁ did not affect it (Iijima et al. 1976). Furthermore, intraperitoneal administration of Rb₁ enhanced and Rc repressed RNA polymerase activity. Both purified ginsenosides did not show any effect on RNA polymerase activity when added in-vitro. Apoproteins of chylomicrons and very low-density lipoprotein were stimulated. Fraction 4 of ginseng root stimulated DNA and protein syntheses in rat testes (Yamamoto et al. 1977a). Oral administration to rats of fraction 3 from ginseng root and addition of fraction 4 in-vitro stimulated DNA, protein and lipid synthesis in bone marrow cells (Yamamoto et al. 1977b). The numbers of mitosis were increased by oral administration of fraction 3. The numbers of total nucleated cells in bone marrow and reticulocytes in peripheral blood were significantly increased. Administration of seven ginseng saponins isolated (ginsenosides Rb₂, Rc, Rc₂, Rd, Re and Rg₁), except for ginsenoside Rb₁, caused an increase of leucine incorporation over that in control mice. Ginseng aqueous extracts inhibited intracellular protein degradation in

confluent cultures of IMR-90 human diploid fibroblasts and stimulated protein synthesis in human fibroblasts indicating that components of ginseng extract are capable of acting directly on human cells to promote protein accumulation (Lu and Dice 1985).

Results of in-vivo studies suggested that ginseng saponin decreased the glycogen stores, but the degree of its effect was regulated by the nutritional status of rats (Yokozawa et al. 1976). Administration of the ginseng root extract (fraction 5) increased the activity of hepatic pyruvate kinase in rats fed on a laboratory pellet chow (Yokozawa et al. 1979). However, rise of the enzyme activity due to ginseng treatment did not seem to involve de novo protein synthesis which required mRNA production. In contrast, when the diet contained an excess of carbohydrate, ginseng treatment resulted in a decreased enzyme level, and the elimination of food resulted in the loss of the effect of ginseng principle. Treatment of rats with saponin (fraction 5) from ginseng roots caused a decrease in the activity of hepatic serine dehydratase (Yokozawa and Oura 1979). Maximum decrease in the enzyme activity was observed 2 hours after the administration of the ginseng saponin. In contrast, when the animals were starved, ginseng treatment resulted in an increased level of the enzyme.

Administration of ginsenoside Rb₂ to streptozotocin-induced diabetic rats resulted in increases of total protein and lysine, glycine, glutamine, arginine, etc. in serum, while no significant change of serum albumin was observed (Yokozawa et al. 1987a). In the liver, the urea content was decreased with a concomitant increase of ribonucleic acid content. The increase in ribosomes caused by the administration of ginsenoside Rb₂ was mainly due to the increase in membrane-bound ribosomes. Ginsenoside Rb₂ exhibited a normalising action on the hepatic concentrations of glutamine, thymine, phenylalanine and tyrosine. Daily intraperitoneal administration of ginsenoside Rb₂ for 3 or 6 days to streptozotocin-induced diabetic rats resulted in an increase of RNA polymerase I activity, as well as an increment of RNA polymerase II activity (Yokozawa et al. 1993). The results

suggested that ginsenoside Rb₂ may promote the synthesis of rRNA and mRNA.

Gommori et al. (1976) observed an enhancement of cholesterol synthesis in liver slices incubated with ¹⁴C-acetate taken from rats treated with ginsenosides Rb₁, Rc and Rd thus confirming the in-vivo incorporation of ¹⁴C-acetate into liver and serum cholesterol. However the ginsenosides did not exhibit any effect on cholesterol synthesis by normal liver slices when added to the incubation mixture. Earlier Sakakibara et al. (1975) reported the enhancement of cholesterol biosynthesis from incorporation of ¹⁴C-acetate into serum and liver cholesterol by administered saponins ginsenosides Rb₁, Rc, Rd, Re and Rg₁, especially by ginsenoside RB₁.

A single intraperitoneal administration of ginseng root extract (fraction 4) increased the incorporation of labelled precursor into total lipid of liver and epididymal adipose tissue in rats (Yokozawa et al. 1975). In contrast, the concentration of serum triglycerides was slightly decreased after treatment with fraction 4. Further, reduction of blood sugar level and liver glycogen content by ginseng extract administration was observed. In further studies, incorporation of ¹⁴C-acetate into total lipid and the glycogen content in the liver were determined 4 hours after the intraperitoneal administration of ginseng extract (fraction 4) to rats (Yokozawa and Oura 1976). Treatment of rats with ginseng ginsenoside Rb₂ stimulated lipid and sugar metabolism (Yokozawa et al. 1984a). Hepatic glycogen content decreased 8 hours after the treatment but recovered 24 hours after treatment. There was also a dramatic increase in the phosphofructokinase activity, peaking at 12 hours. Accumulation of lipid in adipose tissue was observed 10–12 hours after the administration, but no significant changes in the total lipid, triglyceride, total cholesterol, phospholipid, glucose, pyruvate and lactate levels of the liver were observed throughout the experimental period. A transitory increase of hepatic glucose-6-phosphate dehydrogenase activity was observed 2–4 hours after the treatment. A stimulation of glucose-6-phosphate

dehydrogenase activity beginning 4 hours was observed after the administration of ginsenoside Rb₂ (Yokozawa et al. 1984b). At this time, a slight increase of acetyl-coenzyme A carboxylase activity was observed, and a significant increase was noted 16 hours after the treatment. The maximum increase in malic enzyme activity was observed at 12 hours. An increase in the lipolytic activity of lipoprotein lipase was observed 4 hours after the intraperitoneal administration of ginsenoside Rb₂, reaching a maximum (262 %) at 16 hours after the treatment, while a repressive effect was observed on hormone-sensitive lipase activity throughout the experimental period. Administration of ginsenoside Rb₂ to rats also increased the triglyceride content in adipose tissue. The results suggested that ginsenoside Rb₂ brought about the accumulation of triglyceride in adipose tissue as a result of its stimulating action on the lipogenic pathway.

Anti-ageing Activity

The results of studies by Lee et al. (2007b) suggested that ginseng root extract promoted collagen production in human dermal fibroblast cells. Additionally, the extract was found to induce the phosphorylation of Smad2, an important transcription factor in the production of type I procollagen. When applied topically in a human skin primary irritation test, ginseng extract did not induce any adverse reactions and thus may be considered as an attractive, wrinkle-reducing candidate for topical application.

Topical application of total ginseng saponins (10 pg or 100 ng/mouse) and ginsenoside Rb₁ (100 fg, 10 pg, or 1 ng/mouse) significantly inhibited increases in skin thickness and wrinkle formation and the reduction in skin elasticity induced by long-term UVB irradiation (Kim et al. 2009c). Topical application of total saponins and ginsenoside Rb₁ prevented increases in apoptotic, Ki-67- and 8-hydroxy-2'-deoxyguanosine-positive cells induced by UVB exposure. Further, total saponins and ginsenoside Rb₁ prevented the disruption of collagen fibres induced by the long-term UVB irradiation. Ginsenoside Rb₁ (100 fg, 10 pg and 1 ng/ml) increased the Bcl-2 expression

level in UVB-treated human keratinocytes. The protective effect of ginsenoside Rb₁ on UVB-mediated apoptosis may be due to the upregulation of Bcl-2 expression. The results suggested that the protective effect of ginsenoside Rb₁ on skin photoageing induced by chronic UVB exposure may be due to the increase in collagen synthesis and/or the inhibition of matrix metalloproteinase expression in dermal fibroblasts.

Animal studies showed that fermented *Panax ginseng* extract (GINST) had antioxidant and anti-ageing properties (Ramesh et al. 2012b). Treatment with GINST could improve the antioxidant status during ageing, thereby minimising the oxidative stress and occurrence of age-related disorders associated with free radicals. Increased levels of aspartate aminotransferase (AST), alanine aminotransferase (ALT), urea and creatinine were observed in the serum of aged rats. Increased levels of malondialdehyde (MDA) and significantly lowered activities of superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPx), glutathione reductase (GR) and glutathione-S-transferase (GST) were observed in the liver, kidneys, heart and lungs of aged rats, when compared with those in young rats. Quantitative analysis of the nonenzymatic antioxidants such as reduced glutathione (GSH), ascorbic acid and α -tocopherol levels showed significantly lower values in the liver, kidneys, heart and lungs of aged rats. In contrast, administration of GINST to aged rats resulted in increased activities of SOD, CAT, GPx, GR and GST, as well as elevation in GSH, ascorbic acid and α -tocopherol levels. Besides, the level of MDA, AST, ALT, urea and creatinine were reduced on the administration of GINST to aged rats.

Anti-infertility/Aphrodisiac Activity

Studies by Kim et al. (1976) found that ginseng facilitates mating behaviour of male albino rats. Under the influence of ginseng, male rats (a) began ejaculation earlier and repeated the action more often in a 45-minutes observation period and (b) deposited more copulation plugs in 10 days. Rats that received 5 % ginseng for 60 days experienced a significant

increase in blood testosterone level (Fahim et al. 1982). Prostate weight in the treated animals was significantly reduced as compared to the control animals. There was an increase in daily food consumption without an increase in body weight of treated animals. Pak et al. (2005) found that administration of Korean red ginseng total saponins to mature female Sprague-Dawley rats with oestradiol valerate-induced polycystic ovary attenuated the elevated expression of nerve growth factor (NGF) in the ovaries. Korean red ginseng extract was found to have a relaxing effect on rabbit vaginal smooth muscle tissue and to have potential as a therapeutic agent for female sexual dysfunction (Kim et al. 2008b). The relaxation effects might be mediated partly through the NO pathway and hyperpolarisation via Ca^{2+} -activated K^{+} channels.

Studies by Choi et al. (1999) confirmed that long-term administration (3 months) of Korean red ginseng in rabbits and rats enhanced penile erectile capacity both in in-vitro and in-vivo experiments. Its action was found to be mediated by endothelium-derived relaxing factor and peripheral neurophysiologic enhancement. Earlier in-vitro studies found that Korean red ginseng extract had a relaxing effect on the rabbit corpus cavernosal tissue in a dose-dependent manner (Choi et al. 1998). The relaxation action of EKG red ginseng was mediated by multiple action mechanisms that included increasing the release of NO from the corporal sinusoids, increasing intracellular calcium sequestration and a hyperpolarising action. Studies in streptozotocin-induced, non-insulin-dependent diabetes mellitus (NIDDM) rats found that oxidative stress to cavernous tissue may be a contributory factor in erectile dysfunction in diabetics (Ryu et al. 2005). Treatment with Korean red ginseng preserves potency in the NIDDM rats through its antioxidant activity. Both glutathione and malondialdehyde levels in diabetic rats treated with red ginseng were comparable to their age-matched controls while there were significantly reduced in untreated diabetic rats.

Korean ginseng berry extract GB0710 was found to have a greater relaxation effect on rabbit penile corpus cavernosum smooth muscle than did Korean red ginseng root extract (Cho

et al. 2013b). GB0710 increased intracavernosal pressure in a rat in-vivo model in both a dose- and duration-dependent manner. This relaxation effect appeared to be mediated by NO production.

Ginseng-treated rats exhibited significantly increased sperm count and motility with enhanced levels of cAMP-responsive element modulator messenger RNA and protein, suggesting that ginseng appeared to induce spermatogenesis via cAMP-responsive element modulator activation in rat testes (Park et al. 2007b).

The study of Lee et al. (2007a) demonstrated that 2,3,7,8-tetrachlorodibenzo-*p*-dioxin induced the pathological damage such as reduced seminiferous tubular diameter, an increased number of damaged tubules (maturation arrest, eosinophilic degeneration and spermatid giant cells) and genotoxic (DNA damage and elevated expression of CYP1A1 mRNA) damage in rat testes, while *P. ginseng* extract treatment exhibited a therapeutic capacity to reduce these effects via reduction of CYP1A1 mRNA. *Panax ginseng* root aqueous extract showed cytoprotective effect on gallic acid-induced toxicity in TM3 mouse Leydig cells by decreasing the intracellular production of hydrogen peroxide (Park et al. 2007a).

In a double-blind, placebo-controlled, crossover study of 45 patients with clinically diagnosed erectile dysfunction, administration of ginseng 90 mmg/day for a duration of 8 weeks on treatment and 2 weeks of washout was found to be effective in treating erectile dysfunction (Hong et al. 2002). The mean International Index of Erectile Function scores were significantly higher in patients treated with Korean red ginseng than in those who received placebo. Scores on questions 3 (penetration) and 4 (maintenance) were significantly higher in the ginseng than in the placebo group. Among other variables penile tip rigidity on RigiScan showed significant improvement for ginseng versus placebo. In a 12-week placebo-controlled study of 35 patients with erectile dysfunction (23 patients ginseng treated, 12 placebo), the International Index of Erectile Function (IIEF-5) score improved significantly in patients treated with mountain

ginseng, suggesting that mountain ginseng extract could be a treatment candidate for erectile dysfunction (Kim et al. 2006).

Antiosteoarthritic/Osteogenic Activity

Panax ginseng and its ginsenosides Rd and Rb₃ suppressed matrix metalloproteinase MMP3 secretion in S12 murine articular cartilage cell, and ginsenosides Rd and Rb₃ were the major elements involved in the suppression of MMP3 by ginseng (Shin et al. 2009). Further, the suppression of MMP3 by ginseng occurred via the inhibition of phospho-p38 activation. The results indicated that ginseng may exert a protective effect against the cartilage degradation of osteoarthritis.

Ginsenoside Rg₁ promoted the proliferation and odontogenic/osteogenic differentiation of human dental pulp stem cells through alteration of gene expression profiles (Wang et al. 2014b). Gene expressions of dentin sialophosphoprotein (DSPP), alkaline phosphatase (ALP), osteocalcin (OCN), bone morphogenetic protein-2 (BMP-2), fibroblast growth factor 2 (FGF2) and protein expressions of BMP-2 and FGF2 were increased compared with the untreated group. Several ginsenosides Rc, Rd, Rf, Rg₃ and F4 were found to inhibit matrix metalloproteinase MMP-13 expression in IL-1 β -treated human chondrocytes (Lee et al. 2014g). Ginsenosides F4 and Rg₃ blocked cartilage breakdown in rabbit cartilage tissue culture. Thus, it was suggested that certain ginsenosides may have therapeutic potential for preventing cartilage collagen matrix breakdown in diseased tissues such as those found in patients with arthritic disorders.

Hair Stimulating Activity

Ginseng fruit extract significantly increased the proliferation of human hair dermal papilla cells hair regeneration in C57BL6 mice in dose- and time-dependent manners through antiapoptotic activation (Park et al. 2011b). Topical administration of ginseng fruit extract might have hair regeneration activity for the treatment of hair loss.

Antitrypanosomal Activity

Hexane extracts of *Panax ginseng*, *Panax notoginseng* and the pure panaxynol were cytotoxic to and human cancer cell line HeLa to *Trypanosoma brucei brucei* and at the same time highly selective against *Trypanosoma brucei brucei*, whereas methanol extracts and 12 isolated ginsenosides were significantly less toxic and showed only weak selectivity (Herrmann et al. 2013). Panaxynol was cytotoxic against *Trypanosoma brucei brucei* at the concentration of 0.01 µg/mL with a selectivity index of 858, superior even to established antitrypanosomal drugs. The high selectivity together with a cytotoxic concentration in the range of the bioavailability suggested panaxynol and other polyacetylenes in general to be very promising lead compounds for the treatment of African trypanosomiasis.

Hematopoietic Activity

Studies by Chen et al. (2009) suggested that total saponins of *Panax ginseng* may enhance the erythroid differentiation of human CD34⁺ hematopoietic stem and progenitor cells via Epo/EpoR-mediated JAK₂/STAT₅ signalling pathway.

Anti-lipolytic Activity

A metal binding tetradecapeptide, isolated from ginseng root, displayed anti-lipolytic activity in an isolated rat fat cell assay (Kajiwara et al. 1996). The results suggested that the tetradecapeptide may perform its anti-lipolytic activities through an ability to modulate the level of free cellular Mg²⁺ and Mn²⁺ ions.

Drug Potentiating Activity

Co-administration of ginseng ginsenosides Rg₁, Rb₁ and schisandrin markedly increased the systemic exposure level of each compound in-vivo (Zhan et al. 2014). The mixture of ginsenosides Rg₁, Rb₁ and schisandrin administration exhibited synergistic effect of inducing NO release in

isoproterenol (ISO)-induced myocardial ischaemia rats, while administration of the individual compounds had no effect of inducing real-time NO release. Ginsenoside Rb₁ and/or schisandrin in mixture could significantly postpone the elimination of ginsenoside Rg₁ in rat serum.

Anticataract Activity

Intraperitoneal injection of sun ginseng extract and non-saponin fraction to rats with cataract induced by sodium selenite had significantly lower incidence and smaller mean cataract area compared with the saponin fraction (Lee et al. 2010b).

Steroid Hormone Modulating Activity

Ginseng ginsenosides Rb1, Rb2, Rc, Rd, Re and Rg1 (GRb1, GRb2, etc.) and their 20S- and 20R-prosapogenins (S-PS and R-PS), 20S- and 20R-protopanaxadiols (S-PPD and R-PPD) and a mixture of 20S- and 20R-panaxadiols (SR-PD) at various doses administered to rats intraperitoneally affected plasma corticosterone secretion activity (Hiai et al. 1983). Most of these 11 compounds did not significantly affect the plasma glucose level at 30 minutes after treatment. Eight potential biomarkers were found and identified in the urinary excretion of diabetic rats treated with water-soluble ginseng polysaccharide (WGP) (Niu et al. 2012). Significantly increased inosine, serotonin, phenylpropionylglycine and dodecanedioic acid showed the effect of WGP on purine metabolism, tryptophan metabolism, fatty acid metabolism and energy metabolism. 1-Methyladenine, 4-deoxyerythronic acid, 5-hydroxyhexanoic acid and tetrahydrocortisol were significantly decreased which indicated that WGP could regulate DNA metabolism, organic acids metabolism and steroid hormone metabolism. An end metabolite of the protopanaxatriol saponins in ginseng, 20(s)-protopanaxatriol (M4), strongly reduced adrenal corticotropic hormone - stimulated cortisol production in the adrenal fasciculata cells in-vivo (Hasegawa et al. 2013). Additionally, M4 significantly inhibited the production of pregnenolone, progesterone,

deoxycorticosterone, cortisol and corticosterone in a dose-dependent manner. The results also suggested that M4 inhibited the conversion from cholesterol to pregnenolone because the production of pregnenolone was reduced.

Pharmacokinetics and Metabolism Activities

Ginseng ginsenoside Rg₁ was absorbed rapidly from the upper parts of the digestive tract, accounting for 1.9–20.0 % of the dose of Rg₁ administered orally to rats (Odani et al. 1983a).

However, ginsenoside Rg₁ was not found in the brain.

Ginsenoside Rg₁ was excreted into rat urine and bile in a 2:5 ratio. It was also proved that ginsenoside Rg₁ was not significantly metabolised in the liver. However, the decomposition and/or metabolism of ginsenoside Rg₁ in rat stomach and large intestine were confirmed. Little ginsenoside Rb₁ was absorbed from the digestive tract after oral administration (100 mg/kg) to rats (Odani et al. 1983b). The serum level of Rb₁ in rats after intravenous injection (5 mg/kg) declined biexponentially, and the half-life of the β -phase was 14.5 hours. Rb₁ was gradually excreted into urine, but not bile. Unabsorbed Rb₁ in the digestive tract was rapidly decomposed and/or metabolised mainly in the large intestine. These results were quite different from our results on ginsenoside Rg₁ in rats.

Five decomposition products of ginsenoside Rb₂ were found in the rat large intestine after oral administration (Karikura et al. 1990). They were identified as ginsenoside Rd; 3-*O*- β -d-glucopyranosyl-20-*O*-[α -L-arabinopyranosyl(1 $\rightarrow$ 6)- β -D-glucopyranosyl]-20(*S*)-proto-panaxadiol; ginsenoside F₂; 20-*O*-[α -L-arabino-pyranosyl(1 $\rightarrow$ 6)- β -d-glucopyranosyl]-20(*S*)-protopanaxadiol; and compound K. After ingestion, ginsenoside Rb₂ was a little decomposed in the rat stomach, and a small quantity of an unidentified metabolite, which was different from the hydrolysed products (20(*R*, *S*)-ginsenoside Rg₃) in 0.1 N HCl, was observed

(Karikura et al. 1991a). The metabolite was separated into four compounds, which were determined to be 25-hydroxy-23-ene; 24-hydroxy-25-ene; 25-hydroperoxy-23-ene; and 24-hydroperoxy-25-ene derivative of Rb₂, respectively. As in the case of Rb₂ reported previously, Rb₁ was hydrolysed to 20(*R*, *S*)-ginsenoside Rg₃ in 0.1 N HCl (Karikura et al. 1991b). In contrast, hydroperoxidation of Rb₁ occurred in rat stomach; the major hydroperoxide was separated and identified as the 25-hydroperoxy-23-ene derivative of Rb₁. In rat large intestine, five decomposition products of Rb₁ were detected and identified as gypenoside XVII, ginsenoside Rd, ginsenoside F2, compound K and 25-hydroperoxy-23-ene derivative of Rb₁. Tetracycline-resistant bacteria decomposed both Rb₁ and Rb₂ to their respective prosapogenins, except for Rd, and their respective hydroperoxides, while Rd and hydroperoxides of Rb₁ and Rb₂ were produced by enteric enzymes.

Administration of ginseng in the rat resulted in a reduction of bile flow and bile secretion of total lipids and cholesterol, while it increased the secretion of proteins in a dose-dependent manner (Abdul Salam et al. 2002).

After oral dosing, ginsenoside Rh₂ was found to be distributed mainly to the liver and gastrointestinal tissues in rats (Gu et al. 2009). Systemic clearance of Rh₂, however, was low – around 2 and 20 ml/minute/kg in dogs and rats, respectively. Only 1 % of dosed Rh₂ was recovered in excreta of rats as the intact form after oral administration. Low membrane permeability, efflux transport, pre-systemic elimination (degradation in acidic condition; metabolism in intestine tissue and contents), as well as low solubility largely accounted for the low bioavailability of Rh₂. They found that micronisation of the dose almost doubled the rate of absorption in dogs. Eleven and nine metabolites together with ginsenoside Re were detected and identified in rat urine collected after intravenous and oral administration of ginsenoside Re, respectively (Yang et al. 2009). Metabolites of ginsenoside Re were characterised as three oxidation, two

combinative and six deglycosylated metabolites. Ginsenoside Re was rapidly cleared from the body with a short half-life, and oral absorption of ginsenoside Re was poor after intravenous and oral administration of pure Re or ginseng berry extract in mouse (Joo et al. 2010). Ginseng berry extract elicited greater absorption at equivalent dosage administered, indicating that it might be a good form for ginsenoside Re intake.

When ginsenosides Rb₁ and Rb₂ were anaerobically incubated with human intestinal microflora, these ginsenosides were metabolised to 20-*O*-β-D-glucopyranosyl-20(*S*)-protopanaxadiol (compound K) and 20(*S*)-protopanaxadiol (Bae et al. 2000). *Eubacterium* sp., *Streptococcus* sp. and *Bifidobacterium* sp., which more potently hydrolysed gentiobiose than sophorose, metabolised ginsenoside Rb₁ to compound K via ginsenoside Rd rather than gypenoside XVII. However, *Fusobacterium* K-60, which more potently hydrolysed sophorose than gentiobiose, metabolised to compound K via gypenoside XVII. Ginsenoside Rb₂ was also metabolised to compound K via ginsenoside Rd or compound O by human intestinal microflora. *Eubacterium* sp., *Streptococcus* sp. and *Bifidobacterium* sp. metabolised ginsenoside Rb₂ to compound K via ginsenoside Rd rather than compound O. *Fusobacterium* K-60 metabolised ginsenoside Rb₂ to compound K via compound O. *Bacteroides* sp., *Eubacterium* sp. and *Bifidobacterium* sp. metabolised ginsenoside Rg₃ to protopanaxadiol via ginsenoside Rh₂ (Bae et al. 2002b). However, *Fusobacterium* sp. metabolised ginsenoside Rg₃ to ginsenoside Rh₂ alone. 20(*S*)-Ginsenoside Rg₃ was quickly transformed to 20(*S*)-ginsenoside Rh₂ or 20(*S*)-protopanaxadiol in an amount 19-fold compared with the transformation of 20(*R*)-ginsenoside Rg₃ to 20(*R*)-ginsenoside Rh₂ or 20(*R*)-protopanaxadiol. When ginsenoside Rc was anaerobically incubated with human faecal microflora, all specimens metabolised ginsenoside Rc to the main metabolite compound K and protopanaxadiol (Bae et al. 2002a). *Bacteroides* sp., *Eubacterium* sp. and *Bifidobacterium* sp. potently transformed ginsenoside Rc to compound K.

Bifidobacterium K-103 and *Eubacterium* A-44 transformed Rc to compound K via ginsenoside Rd, and *Bacteroides* HJ-15 and *Bifidobacterium* K-506 metabolised it to compound K via ginsenoside Mb, which was isolated as a new metabolite.

Transformed ginsenoside Rg₃ and delta20-ginsenoside Rg₃ from acid-treated ginseng extract were metabolised to ginsenoside Rh₂ and delta20-ginsenoside Rh₂, respectively, by human faecal microflora (Bae et al. 2004). *Bacteroides* sp., *Bifidobacterium* sp. and *Fusobacterium* sp. potently transformed ginsenoside Rg₃ to ginsenoside Rh₂.

Toxicity Studies

Ginseng saponins showed weak toxicities in mice; especially, Rg₁, Rf and Rb₁, which contained glucose as a sugar component, were weaker in their toxicities than the rest, which contained arabinose and/or rhamnose (Kaku et al. 1975). It was also noted that the saponins containing protopanaxadiol as sapogenin were more toxic than those containing protopanaxatriol. There was neither abnormality nor mortality of the experimented mice found in the acute and cumulative toxicity tests (Ding et al. 1993). The Ames mutation test on *Salmonella typhimurium* test strains TA97, TA98, TA100 and TA102 was negative. The results of teratogenesis test showed that the ginseng cell cultures did not cause teratogenesis in both testis and chromosome of marrow cell in mice. The highest dose of cell cultures of *P. ginseng* was 2.5 g/kg. Two percent starch was taken as negative contrast and 50 mg/kg cyclophosphamide as positive contrast.

Ginsenoside Re, active ingredient of ginseng, was well tolerated up to a 375 mg/kg/day oral dosage level and nontoxic in both male and female rats. It did not induce death, adverse effects or dose-dependent changes in feed consumption or body weight gain (Lu et al. 2012). No abnormality of any organs was noted in both gross and histopathological examinations.

Drug Antagonistic Activity

In a randomised, open-label, controlled study of 25 ischaemic stroke patients, co-administration of *P. ginseng* and warfarin did not influence the pharmacologic action of warfarin (Lee et al. 2008b). In contrast, in a 4-week, randomised, double-blind, placebo-controlled trial of 20 healthy patients, administration of American ginseng reduced warfarin's anticoagulant effect. In a recent paper, Shao and Jia (2013) reported possible serious interactions between nutraceutical ginseng and warfarin in patients with ischaemic stroke.

Other Adverse Issues

The oral administration of *Panax ginseng* as powder caused leucocytosis in rabbits' action (Yamada 1955). In 1979, the term ginseng abuse syndrome was coined as a result of a study of 133 people who took ginseng for 1 month (Siegel 1979). Most subjects experienced central nervous system stimulation. At a dose of <15 g/day, subjects experienced depersonalisation and confusion. At a dose of >15 g/day, some subjects experienced depression. Fourteen patients experienced ginseng abuse syndrome, characterised by symptoms of hypertension, nervousness, sleeplessness, skin eruption and morning diarrhoea. Vaginal bleeding has been reported in cases of ginseng use (Greenspan 1983). Punnonen and Lukola (1980) reported oestrogen-like effect of ginseng on the vaginal epithelium and competition by saponins with 17 β -oestradiol and R5020 for binding to human myometrial receptor proteins. Hopkins et al. (1988) reported a case of postmenopausal bleeding attributed to the use of topical ginseng face cream. Ginseng appeared to have an oestrogen-like effect on genital tissues.

Jones and Runikis (1987) reported a case of interaction between Asian ginseng and the antidepressant medication phenelzine when taken concurrently, resulting in symptoms like insomnia, headache, irritability and visual hallucinations. An episode of Stevens–Johnson syndrome was reported in a 27-year-old man following ingestion of ginseng at a dose of two pills for 3 days; the patient recovered after 30 days (Dega et al. 1996).

The neuro-excitatory β -ODAP (β -*N*-oxalyl-L- α,β -diaminopropionic acid), suggested to be the cause of the crippling neurolathyrism, was the major component in ginseng seed extract (70 % of the total free amino acids detected) and showed the highest concentration (0.43 % by wt) compared to that in the different parts of young (1–3-year-old) ginseng plants (Kuo et al. 2003). β -ODAP concentration was higher in the shoots as compared to the roots and declined in older plants. Another neuroactive nonprotein amino acid, GABA (γ -aminobutyric acid), increased dramatically after germination and reached highest concentration in different parts of 3-year-old plants. Liao et al. reported a case of an 83-year-old woman with chronic kidney disease who developed atrial fibrillation with slow ventricular response possibly related to ginseng (Liao et al. 2010). The authors reasoned the bradyarrhythmia due to digitalis glycoside-like effects of ginseng in the condition of renal failure that had not been reported before.

A case of manic episode with psychotic symptoms without previous psychiatric background after consumption of Korean ginseng was reported by Vera-Barrios et al. (2013). Two cases of new-onset manic psychoses associated with high-dose, chronic ginseng use was reported by Norelli and Xu (2014). A 23-year-old man developed acute mania after 1 month of daily ginseng use and intermittent cannabis use. A 79-year-old man developed hypomania while using ginseng and yohimbine for erectile dysfunction and had a recurrence of mania after stopping yohimbine but increasing his daily intake of ginseng. Symptoms of mania fully remitted within days upon discontinuation of ginseng and supportive treatment.

Studies by Poindexter et al. (2006) found that fully developed rat cardiomyocytes were able to accommodate higher doses of ginseng than neonatal cells and that the effects of ginseng on newly formed, developing myocytes could be extremely deleterious to the fetus. However, for adults, ginseng might well be a “tonic” in its ability to increase beating and intramyocytic calcium levels. Cardiotoxic effects in adult cells (cardiotoxicity in neonatal cells) were most profound with Asian ginseng (2.6 times that of Siberian ginseng, 1.6 times that of Indian ginseng) probably due to the

active ingredients (ginsenosides in Asian, eleutherosides in Siberian and withanolides in Indian) being structurally different.

Traditional Medicinal Uses

Panax ginseng has been used in China, Korea Tibet and Indochina for thousands of years as a traditional medicine. Therapeutic properties of ginseng have been known by Chinese popular medicine since time immemorial. Ginseng has been used under various preparations such as teas, tinctures, wines, pill and unguents for the prevention of ageing, tiredness, headaches, amnesia, tuberculosis, diabetes, illness of the liver, heart, kidneys, nervous system, etc. (Popov and Goldwag 1973). It is said in Chinese medicine that Ginseng root has an antifatigue, anti-hypothermia, antidiabetic and sedative activities (Takagi et al. 1972b). It has been also utilised to develop physiological strength and to increases spontaneous movement of digestive system.

Ginseng has been used for several thousand years in the Orient as a tonic, prophylactic and “restorative” agent (Bahrke and Morgan 1994). In traditional Chinese medicine (TCM), ginseng is a highly valued herb and has been applied to a variety of pathological conditions and illnesses such as hypodynamia, anorexia, shortness of breath, palpitation, insomnia, impotence, haemorrhage, diabetes, cancer prevention and ageing process (Xiang et al. 2008; Ruan et al. 2010). *Panax ginseng* has been used in TCM to enhance stamina and capacity to deal with fatigue and physical stress (Li and Liu 2008). Ginseng radix (ginseng root) is prescribed in many Chinese medicines as a stomachic and for the purpose of antidiarrhoic effect, metabolic promotion and hematic effects and has been well known as one of the representative drugs of nutritious tonics (Otsuka et al. 1981). In TCM, ginseng is regarded as warm, sweet and slightly bitter, tones up energy, produces fluid, calms the nerves and affects the spleen and lungs (Lu 2005). Ginseng is prescribed for poor appetites, fatigue, upset stomach, diarrhoea, coughs, excessive perspiration, forgetfulness, impotence, frequent urination, diabetes, excessive menstruation, nervous disorders, shortness

of breath, tonic for general weakness and anaemia (Lu 2005; Wee and Keng 1990). Korean ginseng tea (KGT), prepared from the roots of *Panax ginseng*, is widely used by Korean people for antistress, antifatigue and endurance-promoting effects (Shah et al. 2005). *P. ginseng* is traditionally used as a remedy for cancer, inflammation, stress and ageing (Kim et al. 2013b). In Korea ginseng is regarded as antioxidant, antifatigue, immunostimulant and hypoglycaemic, increases HDL cholesterol, stimulates ADH enzyme and is used for weakness, diabetes, alcoholism and endometritis (NPRI 1998). The medical effects described in the related reference books categorise ginseng as a “mild” medication, a tonic that strengthens and invigorates a weakened body (Park et al. 2005b). The main physical ailments for which ginseng is said to be effective include headache, fatigue, dizziness, nausea, asthma, haemorrhage and impotence. It is further said to generally strengthen the viscera, improve resistance to external disease-causing agents and improve the general physical conditions and mental capacity. Ginseng is regarded as adaptogens, substances that strengthen and normalise body functions, helping the body deal with various forms of stress.

Other Uses

Ginseng contains saponins, polyphenols, polyacetylenes, alkaloids and polysaccharides and has recently been used by adding the leaf, stem and berry extracts to cosmetics and soaps and by adding the plant to feed (Choi et al. 2009). Studies found that extruded white ginseng extract had a good potential to be incorporated into alginate to make antioxidant biodegradable film or coating for various food applications (Norajit et al. 2010).

Comments

Two forms of ginseng are marketed – “white ginseng” and “red ginseng” White ginseng is harvested after 4–6 years and then peeled and dried to reduce the water content to 12 % or less. “Red” ginseng is harvested after 6 years, is not peeled and is steam cured and dried, thereby giving them a glossy reddish-brown colouring. Red ginseng contains all the saponins so far isolated from white ginseng and others which are probably formed during the steaming process.

The study of Liberti and Der Marderosian (1978) found a wide variation among commercial ginseng products and the need for more rigid control. Panaxoside patterns of slurry-filled capsules and root extracts most closely resembled those of whole ginseng roots. Tablets did not contain detectable panaxosides while teas and granules for infusion yielded only low concentrations.

Asparagus cochinchinensis

T. K. Lim¹✉

(1) Canberra, Aust Capital Terr, Australia

Scientific Name

***Asparagus cochinchinensis* (Lour.) Merr.**

Synonyms

Asparagus cochinchinensis (Lour.) Merr. var. *longifolius* F. T. Wang and T. Tang, *Asparagus dauricus* Link var. *elongatus* Pampanini, *Asparagus falcatus* (Benth.), *Asparagus gaudichaudianus* Kunth, *Asparagus insularis* Hance, *Asparagus lucidus* Lindl., *Asparagopsis sinica* Miquel, *Asparagus sinicus* (Miquel) C. H. Wright., *Melanthium cochinchinensis* Lour.

Family

Liliaceae (also in Amaryllidaceae)

Common/English Names

Chinese Asparagus, Cochinchinese Asparagus, Shiny Asparagus, Wild Asparagus.

Vernacular Names

Chinese: Tian Men Dong

Japanese: Kusa Sugi Kazura, Nangoku Kusa Sugi Kazura, Tachi-Tenmondo

Khmer: Tumpèang

Korean: Cheun Mun Dong

Portuguese: Espargo De Jardim

Russian: Sparzha Blestiashchaia

Taiwan: Tian Men Dong, Chōnmuntong

Vietnam: Thiên Môn Đông, Thiên Môn, Tút Thiên Nam, Tóc Tiên Leo, Dây Tóc Tiên, Mè Nắm, Nắm Sắm (Tay), Co Sin Sương (Thai), Sùa Sú Tùng (H'Mong), Dù Mào siam (Dao)

Origin/Distribution

Asia – China, Japan, Korea, Vietnam, Laos

Agroecology

The species occurs on thinly forested slopes, roadsides, waste fields and coastal areas, near sea level to 1,700 m. It thrives in full sun on well-drained, loamy soil but is partially shade tolerant and drought tolerant and can grow in dry, sandy soils.

Edible Plant Parts and Uses

The fusiform tubers are washed to remove the bitterness and the fibrous core removed, and the tubers are then boiled before being consumed (Uphof 1968; Usher 1974; Kunkel 1984). The root tastes like asparagus. Tubers are also eaten after preserving in sugar as sweet conserves (Facciola 1990). The fruit has also been reported to be edible.

Botany

A scandent herbaceous perennial, 1–1.5 m tall with tuberous roots in fascicles, rhombiform, straight or curved and long stalked. Stems slender, much branched, smooth. True leaves scalelike, subtending narrow, green leaflike branchlets (cladodes) (Plate 1). Cladodes 1–3 in a fascicle, linear, flat, 1–2 cm long, 1–1.2 mm wide, falcate, acuminate apex and lustrous. Flowers are bisexual, yellowish-white, 6–7 mm long, 1–3, arising from axils of cladodes; pedicels 7–8 mm long, jointed in the middle or above; male and female flowers separate with perianth in six segments; stamens six, filaments arising from base of perianth segments, anthers versatile and the ovary is oblong. Fruit a globose berry, 5–6 mm in diameter, whitish, ripening to red. Seed one, small and black.

Plate 1 Leaflike cladodes of Chinese Asparagus

Nutritive/Medicinal Properties

Studies reported that *Asparagus cochinchinensis* tuberous roots contained free amino acids saponins, phenols, steroids, phytosterols and polysaccharides as the main constituents with an array of pharmacological properties as elaborated below.

The roots were reported to contain many amino acids: asparagine, citrulline, serine, threonine, proline, glycine, alanine, valine, methionine, leucine, isoleucine, phenylalanine, tyrosine, aspartic acid, glutamic acid, arginine, histidine and lysine (Le and Nguyen 1999). Zeng et al. (2011) reported the content of main chemical groups in *A. cochinchinensis* samples from different producing areas in Guizhou as follows: water 8.17–14.03 %, alcohol 63.49–92.67 %, total ash 4.41–4.82 %, total saponin 2.65–4.36 % and amino acid 3.14–6.83 %.

Seven oligosaccharides, a trisaccharide, a tetrasaccharide, a pentasaccharide, a hexasaccharide, an octasaccharide, a nonasaccharide and a decasaccharide, were isolated from *A. cochinchinensis* tuberous roots (Tomoda and Satoh 1974). Determination of components, periodate oxidation, methylation and partial degradation studies provided the evidences that they were neokestose; they possessed nonreducing linear structure made up of 2→1 linked β-D-fructofuranose residues having a neokestose unit on the end of the molecule. Four new polysaccharides, named as *Asparagus* polysaccharides A, B, C, D, with antitumour activities, were isolated from the tuberous roots (Du and Guo 1990). A polysaccharide, ACP 1, was isolated from the tuberous roots (Li et al. 2000). It was found to be a galactoglucan, containing backbone of 8β-(1→4) linked D-GALACTOPYRANOSIDIC and 6α (1→6) linked D-GLUCOPYRANOSIDIC linkages, with a glucosyl branch attached to 3 O of a galactosyl residues of the main chain.

Asp-IV, V, VI and VII, the major furostanol oligosides, were isolated from the methanol extract of *Asparagus cochinchinensis* (Konishi and Shoji 1979). The structures of Asp-IV, V, VI and VII were respectively established as 26-O-

β -D-glucopyranosyl-22-methoxyfurostane-3 β , 26-diol 3-*O*- β -D-xylopyranosyl (1 $\rightarrow$ 4)- β -D-glucopyranoside (1); 26-*O*- β -D-glucopyranosyl-22-methoxyfurostane-3 β , 26-diol 3-*O*- α -L-rhamnopyranosyl (1 $\rightarrow$ 6)- β -D-glucopyranoside (2); 26-*O*- β -D-glucopyranosyl-22-methoxyfurostane-3 β , 26-diol 3-*O*- β -D-xylopyranosyl (1 $\rightarrow$ 4)-[α -L-rhamnopyranosyl (1 $\rightarrow$ 6)]- β -D-glucopyranoside (3); and 26-*O*- β -D-glucopyranosyl-22-methoxyfurostane-3 β , 26-diol 3-*O*-[β -D-glucopyranosyl (1 $\rightarrow$ 2)] [β -D-xylopyranosyl (1 $\rightarrow$ 4)] [α -L-rhamnopyranosyl (1 $\rightarrow$ 6)]- β -D-glucopyranoside (4). The aqueous extract of *A. cochinchinensis* yielded a new oligofurostanoside 3-*O*-[α -L-rhamnopyranosyl-(1 $\rightarrow$ 4)- β -D-glucopyranosyl]-26-*O*-(β -D-GLUCOPYRANOSYL)-(25R)-furosta-5,20-diene,-3 β ,26-diol as well as two known furostanosides, methylprotodioscin and pseudoprotodioscin (Liang et al. 1988). A novel compound, (+)-nyasol, was isolated from *A. cochinchinensis* tubers (Tsui and Brown 1996).

The following compounds were isolated from dried roots of *Asparagus cochinchinensis*: new spirostanol saponin, asparacoside, two new C-27 spirosteroids, asparacosins A and B, a new acetylenic derivative, 3'-methoxyasparennydiol and a new polyphenol, 3'-hydroxy-4'-methoxy-4'-dehydroxynyasol, as well as five known phenolic compounds, asparennydiol, nyasol, 3'-methoxynyasol, 1, 3-bis-di-*p*-hydroxyphenyl-4-penten-1-one and *trans*-coniferyl alcohol (Zhang et al. 2004). Three new furostanol oligoglycosides, named aspacochioside A, B and C, together with the known compound 3-*O*-[(α -L-rhamnopyranosyl-(1 $\rightarrow$ 4))(β -D-glucopyranosyl)]-26-*O*-[β -D-glucopyranosyl]-(25S)-5 β -spirostane-3 β -ol were isolated from *Asparagus cochinchinensis* roots (Shi et al. 2004). The structures of the new aspacochiosides were elucidated as 3-*O*-[(α -L-rhamnopyranosyl-(1 $\rightarrow$ 4))(β -D-glucopyranosyl)]-26-*O*-[β -D-glucopyranosyl]-(25S)-5 β -furostane-3 β ,22 α ,26-triol (1), 3-*O*-[(α -L-rhamnopyranosyl-(1 $\rightarrow$ 4))(β -D-glucopyranosyl)]-26-*O*-[β -D-glucopyranosyl]-22 α -methoxy-(25S)-5 β -furostane-3 β ,26-diol (2) and 3-*O*-[(α -L-rhamnopyranosyl-(1 $\rightarrow$ 4))(β -D-glucopyranosyl)]-26-*O*-[β -D-glucopyranosyl]-(25S)-5 β -furost-20(22)-en-3 β ,26-diol (3). Eight compounds were isolated from the chloroform extract of *Asparagi Radix*, the root of *Asparagus cochinchinensis*, and identified as β -sitosterol;

daucosterol; n-ethatriacontanoic acid, palmitic acid; 9-heptacosylene; sarsapogenin; diosgenin; and 3-*O*-[α -L-rhamnopyranosyl(1–4)]- β -D-glucopyranoside-(25S)-5 β -spirostan-3 β -ol (XU et al. 2005). The last compound was found to have antifungal and antitumour activities.

A new furostanol saponin, (25S)-26-*O*- β -D-GLUCOPYRANOSYL-5-furost-20(22)-en-3 β , 15 β ,26-triol-3-*O*-[α -L-rhamnopyranosyl-(1–4)]- β -D-glucopyranoside, named aspachioside D along with three known saponins, aspachioside C, (25S)-5 β -spirostan-3 β -yl-*O*-[*O*- α -L-RHAMNOPYRANOSYL-(1–4)]- β -D-glucopyranoside and pseudoprotoneodioscin, were isolated from *A. cochinchinensis* (Shen et al. 2011). A new norlignan glycoside, named iso-agatharesinoside and its aglycone, iso-agatharesinol, were isolated from *A. cochinchinensis* tuberous roots (Li et al. 2012). Two new furostanol glycosides, aspachiosides L and M, were isolated from *Asparagus cochinchinensis* roots (Jian et al. 2013a). Three new pregnane glycosides, aspachiosides N, O, and P, were isolated from *A. cochinchinensis* roots, together with four known furostanol glycosides (Jian et al. 2013b). Five compounds including quercetin, asparagines, sucrose, β -sitosterol-3-*O*- β -D-glucopyranoside and β -sitosterol were isolated from the methanol extract of *A. cochinchinensis* tuber (Hoang and Nguyen 2013).

Antioxidant Activity

ACP 1, a galactoglucan polysaccharide, isolated from the tuberous roots, was found to scavenge superoxide anion($O^{\cdot 2}$) produced by PMS-NADH-NBT (phenazine methosulfate – reduced nicotinamide adenine dinucleotide – nitro blue tetrazolium) system, to inhibit lipid peroxidation induced by Fe^{2+} ascorbic acid in mouse liver microsome and to antagonise the haemolysis of rat RBC (red blood cells) induced by H_2O_2 (Li et al. 2000). Quercetin, from *A. cochinchinensis* tuber, exhibited strong antioxidant activity with $IC_{50} = 14.52 \mu g/mL$ in the 2,2-diphenyl-1-picrylhydrazyl 1,1-diphenyl-2-picrylhydrazyl (DPPH), radical scavenging

assay as compared to standard vitamin C with $IC_{50} = 10.49$ $\mu\text{g/mL}$ (Hoang and Nguyen 2013). *A. cochinchinensis* tuber aqueous extract showed DPPH, nitrite and hydroxyl radicals scavenging activity in a dose-dependent manner (Samad et al. 2014). It also inhibited linoleic acid peroxidation and Ferric³⁺ reducing ability. The levels of phenolic and flavonoid compounds from *A. cochinchinensis* were found to be 459 μg gallic acid equivalent/g (GAE/g) dry mass and 642 μg catechin equivalent/g (CE/g) dry mass, respectively.

Anticancer Activity

Compounds asparacocide, 3'-hydroxy-4'-methoxy-4'-dehydroxynyasol and 3'-methoxynyasol isolated from the roots demonstrated moderate cytotoxicities in a panel comprised of KB (HeLa contaminated carcinoma/papilloma cells), Col-2 (human colon carcinoma cells), LNCaP (androgen-sensitive prostate adenocarcinoma cells), Lu-1 (lung adenocarcinoma cells lung adenocarcinoma cells) and HUVEC (human umbilical vein endothelial cells), with IC_{50} values ranging from 4 to 12 $\mu\text{g/mL}$ (Zhang et al. 2004). Aspacochioside C exhibited moderate cytotoxicity against human tumor cell line, A549, with an IC_{50} value of 3.87 $\mu\text{g/mL}$ (Shen et al. 2011). Ethyl acetate fraction from *A. cochinchinensis* extract was more effective than other fractions; it induced apoptosis of human hepatocellular carcinoma HepG2 ($IC_{50} = 72.33$ $\mu\text{g/mL}$), as revealed by apoptotic feature observation, increased capase-3 activity and Poly ADP ribose polymerase cleavage and decreased expression of X-linked inhibitor of apoptosis protein in a dose-dependent manner (Park et al. 2011). Protein levels of autophagy-related molecules, microtubule-associated protein 1 light chain 3 α and beclin 1, appeared to be induced by the fraction, suggesting *A. cochinchinensis* extract exhibited anticancer activity with induction via both apoptosis and autophagy signalling pathways in HepG2 cells. Chun et al. (2011) reported that the ethyl acetate fraction of *A. cochinchinensis* extract exhibited antitumour activity in nude mice xenografted with human hepatocellular carcinoma

(HepG2) cells. Treatment with the *A. cochinchinensis* extract significantly reduced tumour growth. The extract significantly increased the number of apoptotic cells in tumours in a dose-dependent manner, whereas cisplatin treatment significantly decreased tumour volumes and increased the number of apoptotic cells and exhibited hepatotoxicity and nephrotoxicity, in contrast to *A. cochinchinensis* treatment. *A. cochinchinensis* was found to possess antitumor activities without associated hepatotoxicity and nephrotoxicity. Quercetin, from *A. cochinchinensis* tuber, exhibited strong cytotoxicity against the HeLa, human cervical cancer cell line with $IC_{50} = 5.78 \mu\text{g/mL}$, followed by lung cancer cell line (NCI-H460) with $IC_{50} = 12.57 \mu\text{g/mL}$ and liver cancer cell line (Hep-G2) with $IC_{50} = 20.58 \mu\text{g/mL}$ (Hoang and Nguyen 2013). The anticancer activity of quercetin against breast cancer cell line (MCF-7) was recorded with $IC_{50} = 31.04 \mu\text{g/mL}$.

Hepatoprotective Activity

Aqueous extract of *Asparagus cochinchinensis* roots ameliorated ethanol-induced cytotoxicity in human hepatoma Hep G2 cells (Koo et al. 2000). The extract (1–100 $\mu\text{g/mL}$) dose dependently inhibited the ethanol-induced tumor necrosis factor-alpha (TNF-alpha) secretion. It (1–100 $\mu\text{g/mL}$) also inhibited the ethanol and TNF-alpha-induced cytotoxicity. In addition, the extract inhibited the TNF-alpha-induced apoptosis of Hep G2 cells. The results suggested that *A. cochinchinensis* roots may prevent the ethanol-induced cytotoxicity through inhibition of the apoptosis of Hep G2 cells.

Anti-inflammatory Activity

Aqueous extract of *Asparagus cochinchinensis* roots inhibited secretion of tumor necrosis factor-alpha (TNF-alpha) from primary cultures of mouse astrocytes (Kim et al. 1998). The extract dose dependently inhibited the TNF-alpha secretion by astrocytes stimulated with substance P (SP) and lipopolysaccharide (LPS). Administration of the extract to

astrocytes stimulated with both LPS and SP decreased interleukin 1 (IL-1) secretion. The results suggested that the extract may inhibit TNF- α secretion by inhibiting IL-1 secretion and that it had an anti-inflammatory activity in the central nervous system.

Separate studies showed that ethanolic extract of *A. cochinchinensis* roots (ACE) inhibited topical oedema in the mouse ear, following administration at 200 mg/kg (i.p.), leading to substantial reductions in skin thickness and tissue weight, inflammatory cytokine production, neutrophil-mediated myeloperoxidase activity and various histopathological indicators (Lee et al. 2009). Additionally, ACE was effective at reducing inflammatory damage induced by chronic TPA (12-*O*-tetradecanoyl-phorbol-13-acetate) exposure and evoked a significant inhibition of vascular permeability induced by acetic acid in mice. The results demonstrated ACE to be an effective anti-inflammatory agent in murine phorbol ester-induced dermatitis and suggested that the compound may have therapeutic potential in a variety of immune-related cutaneous diseases. Aspacochinoside M, from the roots, showed moderate inhibitory effect on NO production in LPS-induced BV-2 microglial cells with IC₅₀ value of 32.26 μ M (Jian et al. 2013a). Aspacochinosides O and P and a known furostanol glycoside showed significant inhibition on NO production in LPS-induced BV-2 microglial cells with IC₅₀ values of 13.51, 4.72 and 63.57 μ M, respectively (Jian et al. 2013b).

A. cochinchinensis tuber aqueous extract enhanced the viability of RAW 246.7 cells and reduced the number of lipopolysaccharide (LPS)-induced cell death (Samad et al. 2014). Only 50.8 % of RAW 246.7 cells were viable after being treated with LPS. After treatment with Asparagus extract (0.2, 0.3, 0.4 and 0.5 mg/mL), the viability of the RAW cells increased to 51.8, 71.1, 80.0 and 92.7 %, respectively. The results indicated that *A. cochinchinensis* tuber had anti-inflammatory activity.

Anti-aging Activity

Polysaccharides and aqueous extracts of *A. cochinchinensis* roots significantly increased the spleen index and the superoxide dismutase (SOD) activity but reduced the malondialdehyde (MDA) content and slowed down the aging process (Xiong et al. 2011). In contrast, feeding with the stem extracts significantly reduced the SOD activity and increased the MDA accumulation in the brain and liver of mice, suggesting that the stem extracts may not be appropriate for treating aging-related diseases.

Antisteoporotic Activity

The ethanol extract of *A. cochinchinensis* was found to have the potential to prevent bone-related diseases such as osteoporosis by increasing the differentiation of osteoblasts and reducing both the number and activity of osteoclasts (Lee et al. 2008). The extract increased the differentiation and alkaline phosphatase activity of osteoblasts and decreased the number of tartrate-resistant acid phosphatase (TRAP)-positive multinucleated osteoclasts cells and TRAP activity.

Drug Metabolism Activity

Asparagus cochinchinensis, *Rehmannia glutinosa*, *Scrophularia ningpoensis* and *Ophiopogon japonicus* are components of the Chinese herbal drug Tianwang Buxin Wan, and each component was found to have varying effect on CYP450 enzyme in the rat liver (Wu et al. 2011). It was found that *R. glutinosa* and *S. ningpoensis* aqueous extracts decreased the contents of CYP450 and significantly increased the activity of CYP3A and CYP1A2. *A. cochinchinensis* increased content of Cytb5 and increased the activity of CYP2E1 and CYP1A2. *O. japonicus* had no significant difference on the contents of CYP450 and Cytb5 but increased the activities of CYP3A, CYP2E1 and CYP1A2. They found that by inhibiting CYP450 activity to decrease the metabolism of other drugs, the effect of other functional groups in the compatibility of Tianwang Buxin Wan could be enhanced.

Traditional Medicinal Uses

This plant has been used in traditional Chinese medicine for over 2,000 years (Duke and Ayensu 1985; Samad et al. 2014). The root is harvested when the plant is dormant and is dried for medicinal use. The dried root is antibacterial, antihelminthic, anti-inflammatory, antipyretic, antiseptic, antitussive, diuretic, expectorant, nervine, sialagogue, stomachic, nervous stimulant and tonic (Duke and Ayensu 1985; NPRI-SNU 1998; Le and Nguyen 1999; Samad et al. 2014). *Asparagus cochinchinensis* is a traditional Chinese medicine used for treating lung- and spleen-related diseases (Xiong et al. 2011). Dried root is a tonic with antifebrile, antitussive and diuretic activity (Konishi and Shoji 1979). *A. cochinchinensis* is often used for the treatment of fever, cough, haemoptysis, diabetes, constipation, swollen and throat pain (Jiang et al. 2010). Prolonged usage is recommended for the treatment of impotence. The plant also has a folk history for the treatment of cancer. *Asparagus cochinchinensis* has been traditionally used for the treatment of cancer in Korea and China (Park et al. 2011).

It also has anti-inflammatory activity and may have therapeutic potential in a variety of immune-related cutaneous diseases.

Asparagus cochinchinensis is often decocted with other herbs (*Rehmannia glutinosa*, *Scrophularia ningpoensis*, *Stemona tuberosa*, *Trichosanthes kirilowii*, *Schisandra sinensis*, *Adenophora verticillata*, *Angelica sinensis*, *Panax ginseng* and *Ophiopogon japonicus*) in various medicinal formulations and used in the treatment of a wide range of ailments including pulmonary diseases; impairment of the body fluid; consumptive ailments such as cough, haematemesis, sore throats and constipation; and diabetes mellitus (NPRI-SNU 1998; Le and Nguyen 1999; Wu et al. 2011).

Other Uses

In China, the plant is used as biological pest control against maggots and mosquito larvae (Yang and Tang 1988).

Comments

The plant is usually propagated by removing foot bud clumps from the mother plant and planting them out.

Origin/Distribution

The species is believed to have originated in Southeast Asia and Papua New Guinea, but was carried throughout much of the Pacific by early Polynesians. It is now widely cultivated and sometimes naturalised in these areas including northeastern Australia, New Zealand and the Pacific Islands.

Agroecology

Being a tropical species, the plant thrives in a warm and humid environment from the lowlands to the mountainous areas with mean annual temperatures of 18–30 °C. It grows well in well-drained, fertile sandy loams. It grows in full sun or partial shade. Ti plants have been reported to develop best foliage colour in full sun or bright light. Ti plant responds well to regular watering and fertilisers.

Edible Plant Parts and Uses

The rhizomes, leaves, young shoots and seeds are eaten (Hedrick 1972; Ochse and van den Brink 1980; Facciola 1990). The fleshy rhizome contains up to 20 % sugar, mainly fructose, and is used as a natural sweetener in New Zealand and for the production of an alcoholic beverage *okolehao* in Hawaii. The large, sweet, white rhizome of some cultivars are cooked, roasted or baked for up to four days in earthen ovens to be consumed as food, sweets, refreshment or confectionery in Fiji, Papua New Guinea and the Pacific Islands. In Java, the young shoots are cooked and eaten as *lalap* with rice. In the Hawaiian kitchens, food is wrapped into the leaves for cooking. The Maoris in New Zealand eat both the leaves and seeds.

Botany

Plants erect, evergreen shrub growing to 1–3 m high and spread of 1 m, with a strong usually unbranched, slender, woody stem with rings of leaf scars and enlarged tuber-like subterranean rhizomes (Plate 1). Leaves green or variously coloured; variegated with various combinations of red, pink, purple, maroon, yellow, rose, orange, glossy, oblong-lanceolate, elliptic-lanceolate or narrowly oblong; 25–50 × 5–10 cm, with distinct mid-vein which is raised abaxially; leaf apex is aristate. Petiole 10–30 cm, channelled abaxially, with dilated base clasping stem and other petiole bases (Plates 1, 2, 3). The leaves are clustered in tufts at the top of the woody stems in mature plants and well spaced along the stems in younger plants. Panicle 30–60 cm; branches spreading, 6–13 cm, and many flowered. Flowers are sweetly scented, subsessile or shortly pedicellate; subtended by three bracteoles; bracteoles ovate, 2–3 mm, margin broadly membranous, apex cuspidate. Perianth six, reddish, yellowish or bluish purple; tube 5–6 mm; and lobes erect or recurved, nearly as long as tube. Stamens six, yellow, inserted in the throat of the perianth. Fruit reddish, round, three-parted, 1 cm diameter berries, several to many seeded.

Plate 3 Ti plant with variegated red leaves

Nutritive/Medicinal Properties

Plant Phytochemicals

The constitution of the glucofructan in Ti plant tuber was found to compose of 1 unit of D-GLUCOSE and about 13 of D-fructose (Boggs and Smith 1956). The methylated polysaccharide upon hydrolysis yielded 1,3,4,6-tetra-*O*-methyl-D-fructose (4 moles), 1,3,4-tri-*O*-methyl-D-FRUCTOSE (2 moles), 3,4,6-tri-*O*-methyl-D-fructose (5 moles), 0, 3,4 di-*O*-methyl-D-fructose and 2,3,4-tri-*O*-methyl-D-fructose (1 mole).

Leaves were reported to contain tyramine (Hegnauer 1964), and shikimic and quinic acids (Yoshida et al. 1975). Thymidine was isolated from the plant (Ooi et al. 1993). Steroidal sapogenins of smilagenin {(25*R*)-5 β -spirostan-3 β -ol}, sarsasapogenin {(25*S*)-5 β -spirostan-3 β -ol} and 5 β -spirostanes were isolated from *C. terminalis* var. *petiolaris* (Blunden et al. 1981). Four cholestane glycosides were isolated from Ti leaves and characterised as (22*S*)-3 β ,7 β ,16 β ,22-tetrahydroxycholest-5-en-1 β -yl β D-GLUCOPYRANOSIDE (1); (22*S*)-3 β , 16 β ,22,25-tetrahydroxycholest-5-en-1 β -yl β -*d*-glucopyranoside (2); (22*S*)-3 β , 16 β ,22,25-tetrahydroxy-5 α -cholestan-1 β -yl β -D-gluco-pyranoside (3); and (22*S*)-16 β ,22,25-trihydro-xcholest-5-en-3 β -yl *O*- α -L-RHAMNO-PYRANSOYL-(1 $\rightarrow$ 2)- β -D-glucopyranoside (4) and the aglycone of (1) (22*S*)-cholest-5-ene-1 β , 3 β ,7 β ,16 β ,22-pentol.

Antioxidant Activity

Total phenol contents of the methanol leaf extract was determined as 106.2 mg gallic acid equivalent (GAE), and the DPPH radical scavenging activity of the methanol leaf extract was determined as EC50 value of 0.135 mg/g ascorbic acid equivalent (Reddy et al. 2011). Encapsulation of the leaf polyphenol extract of 68.1 mg/g in sodium caseinate beads was achieved. The encapsulated extract showed a stable polyphenol content of 72.35 mg/g GAE (mean) for 6 months, decreasing to 60.02 mg/g of GAE at the end of 6 months and

to 52.18 mg/g of GAE after 1 year. The encapsulate polyphenol extract showed significant antioxidant activity compared to non-encapsulated extracts. Sodium-caseinate beads were found to be a promising technique for food supplementation with natural antioxidants.

Antimicrobial Activity

Studies reported that the plant possessed antibacterial activity (Ahmed et al. 2003). The methanolic plant extract showed moderate antibacterial activity against *Escherichia coli*, *Shigella boydii*, *Streptococcus pyogenes* and *Staphylococcus epidermis*. The n-hexane soluble fraction showed mild antibacterial activity against *Salmonella typhi*, *Shigella boydii* and *Shigella dysenteriae*, whereas the acetone and chloroform fraction did not show any activity.

Anticancer Activity

An aqueous extract of Cordyline was found to contain thymidine which exhibited antiproliferative activity (Ooi et al. 1993). 10–5M of thymidine inhibited EL4 cell replication and decreased cell viability after 12–24 hours. The effect was highly specific for this nucleoside. Treated cell cultures showed a significant increase in S phase cells and a corresponding decrease in G1 phase cells. A human breast cancer cell line (MCF7) was also growth-inhibited by 10–5M thymidine, but a murine lymphoma cell line (K36) was not. The aglycone of cholestane glycoside (1), i.e. (22*S*)-cholest-5-ene-1 β , 3 β , 7 β , 16 β , 22-pentol, isolated from the leaves, exhibited weak cytotoxic activity against HL-60 leukaemia cells with an IC₅₀ value of 15.6 μ g/ml compared to etoposide the positive control with IC₅₀ of 0.26 μ g/ml (Yokosuka et al. 2012). The four cholestane glycosides and aglycone of cholestane glycoside (2) were not cytotoxic to HL-60 cells at sample concentrations of 20 μ g/ml.

Traditional Medicinal Uses

In Hawaiian traditional medicine, Ki flowers are combined with other herbal preparations for treatment of nasal growth, for shortness of breath/asthma, for phlegm in the chest and for vomiting. For fever with absence of perspiration, Ki leaves are wrapped about the head and chest. Ki leaves are used as healing apparatus, not as medicines themselves: they were wrapped around warm stones to serve as hot packs, used in poultices and applied to fevered brows. In Hawaii, a hot leaf infusion was used to induce abortion. In Polynesia and Thailand, Ti plant is used for fever, headache and diarrhoea and as disinfectant for wounds in tropical West Africa. In New Guinea, this species is a stimulant and magic plant used to stimulate fierceness of young warriors. The leaf heart and stem have been reported to be efficacious for abortion in Fiji, and the leaves are used as abortifacient in New Caledonia and Vanuatu and as a contraceptive in New Guinea. In Buka, the Solomon Islands, Ti plant is used in a menstrual ceremony.

In the Philippines, it is used for haemoptysis due to pulmonary tuberculosis, premature abortion, excessive menstruation and blood in urine, bleeding due to piles, enteritis-bacillary dysentery and rheumatic bone pains and swelling pain due to sprains. In Peninsula Malaysia, the heated oiled leaves had been prescribed as application to the abdomen for ague and the medicinal bath of the roots prescribed for the same ailment. Leaves and ashes of leaves had been used in various preparations to treat small pox, madness, skin eruptions and joint pains. A leaf prescription, alone and combined with *Lasia*, had been used for treating coughs.

Other Uses

Ti plant is frequently cultivated as hedge plant and ornamental shrub and indoor foliage potted plant with numerous cultivars available in the tropics, many of them selected for green or reddish or purple foliage. It is used as food, medicinal plant, fibre crop and for magical purposes. Ti foliage is extensively used for flower arrangement and decorative displays and used as food wrappings. Its leaves are used to thatch the roofs of houses and to wrap and store food. The leaves are used as thatch, rain capes and symbols of status, plates, instruments and cups; the stem is used in divining. Leaves are knotted together as measure for houses building. Ti leaves are also used to make items of clothing including skirts worn in dance performances. The Hawaiian hula skirt is a dense skirt, an opaque layer of at least 50 green leaves with the bottom (top of the leaves) shaved flat. The Tongan dance dress, the *sisi*, is an apron of about 20 leaves, worn over a tupenu and decorated with some yellow or red leaves. Ti leaves are also used to make lei and to outline borders between properties. To this day, some Hawaiians plant Ti near their houses to bring good luck. The leaves are also used for lava sledding. A number of leaves are lashed together and people ride down hills on them.

Ti plant represents a symbol of purity and spiritual power in ancient (and modern) Hawai'i. In ancient Hawaii, Ti was thought to have great spiritual power; only high priests and chiefs were able to wear leaves around their necks (healer's leis) during certain ritual activities and used in ceremonial blessings. It was often grown at temples of the medicine god Lono and the hula goddess Laka. Temples to Lono were thatched with lā'ī leaves and those to Kū (the war god) were thatched with other plants. In Malaysia, green and red Ti plants had been used in occult and magic to keep away evil spirits. Red-leaved Ti plants had been hung over the head of women during confinement to keep away evil spirits. A sick man may be stroked with a bunch of Ti leaves to purge out mischievous spirits from him and may be carried when elephant hunting as a protection. Among the dayaks in East

Malaysia, Ti plants were planted where propitiatory offerings were placed to attract good spirits. Also shoots had been placed in water in a spirit-summoning ceremony in Kelantan.

Comments

Ti plant is really propagated from stem sections, terminal stem cuttings and seeds and by air layering. Ray et al. (2013) described an efficient and rapid micropropagation method for large-scale multiplication of *Cordyline terminalis* in a cost-effective manner. Thousands of micropropagated plants were produced within 4–5 months using this protocol.

Desv., *Tricoryne acaulis* D.Dietr., *Tricoryne caulescens* D.Dietr.

Family

Asparagaceae

Common/English Names

Dragon's Beard, Dwarf Lily turf, Fountain Plant, Mondo Grass, Japanese Lily Turf, Japanese Snake's Beard, Liriopogon, Monkey Grass, Ophiopogon, Snake's Beard

Vernacular Names

Brazil: Grama Preta

Chinese: Mai Dong, Mai Men Dong

Czech: Sedoulek Japonský

Danish: Japansk Slangeskæg

Dutch: Japanse Slangenbaard, Ophiopogonus

French: Herbe Aux Turquoises, Muguet Du Japon, Ophiopogon

German: Japanischer Schlangenbart

Japanese: Ja-No-Hige, Ryu-No-Hige

Korean: Jobnipmaekmundongajaebi

Philippines: Langigit

Portuguese: Grama-Preta, Ofiopógão-Do-Japão, Pêlo-De-Urso

Russian: Ofiopogon Japonskij

Swedish: Ormskäg

Vietnamese: Mạch Đông, Mach Món, Mach Môn Đông, Tóc Tiên, Lan Tiên, Xà Thảo, Duyên Giới Thảo, Phiếc Kép Phạ (Tay.)

Origin/Distribution

The plant is native to East Asia – China (Anhui, Fujian, Guangdong, Guangxi, Guizhou, Hebei, Henan, Hubei, Hunan, Jiangsu, Jiangxi, Shaanxi, Shandong, Sichuan, Yunnan, Zhejiang), Japan (Hokkaido, Honshu, Kyushu, Shikoku), Korea, Taiwan and the Philippines – Luzon (Benguet Province) and Mindanao (Mt. Apo).

Agroecology

In its natural habitat, it occurs in shady places in lowland and foothills, forests, dense scrub in ravines, moist and shady places on slopes and along streams, cliffs at elevations of 200–2,800 m in East Asia. It grows well in full sun or partial shade in well-drained, moist sandy or sandy-loam soils with a pH between 6.5 and 7.5.

Edible Plant Parts and Uses

The plant is more widely known as a medicinal herb than a food plant. Tuberous root is edible (Usher 1974) and eaten as a famine food (Read 1946). The root is used as food ingredient in Taiwan and as functional food in China often as a substitute for ginseng. *O. japonicus* is a traditional medicine, admitted as one of functional food ingredient by the Ministry of Health of the People's Republic of China (Liang et al. 2012). The root is considered aromatic, sweet (Stuart 1979) and mucilaginous (Duke and Ayensu 1985), but other reports say that the bitterness has to be removed before consumption (Tanaka 1976; Kunkel 1984).

Botany

An evergreen, tuft-forming stoloniferous perennial. Stolons creeping, slender, roots moderately thick, usually with tuberos part near middle or tip. Leaves basal, sessile, fasciculate, linear, generally 15–50 cm long by 2–4 mm, 3–7 parallel veined, margin serrulate, dark green above, pale glaucous beneath (Plate 1). Scape 6–15 (–27) cm, much shorter than leaves. Inflorescence in axillary racemes, 1–20 cm long, several to more than 10 flowered with lanceolate white bracts. Flowers solitary or paired, usually pendant; pedicel 34 mm. Tepals 6-lobed, white or pale lilac, lanceolate, 5 × 2 mm. Filaments very short; anthers 2.53 mm, lanceolate. Style narrowly conical, 4 mm, moderately thick, basally widened. Berry subglobose to ellipsoid–globose, blue violet, 5–9 mm in diameter. Seeds globose 6–8 mm.

Plate 1 A dense clump of *Ophiopogon japonicus*

Nutritive/Medicinal Properties

Tuberous Root Nutrient/Phytochemicals

The root was reported to contain about 1.6 % protein, 0.5 % fat, 80 % carbohydrate, 2.3 % ash (Read 1946), mucilage, sugars, β -sitosterol, ophiopogonin A, ophiopogonin B and ophiogonone A (Le and Nguyen 1999), minerals N, P, K (Chen et al. 2005); Ni, Zn, Mn, Cu, Mg, Fe, Ca and Pb (Lou and Xu 2007).

Steroidal Saponins and Glycosides

Four steroidal glycosides, named ophiopogonins A, B, C and D, were isolated from the rhizome (Kato et al. 1968). The structure of ophiopogonin B from the tubers was established as ruscogenin (1)- α -L-rhamnopyranosyl (1_{rham}→2_{fuc})- β -D-fucopyranoside (Tada and Shoji 1972). The chemical structure of ophiopogonin D, a glycoside isolated from *O. japonicus* tuber, was established as ruscogenin (1)-[α -L-rhamnopyranosyl(1_{rham}→2_{fuc})]-[D-xylopyranosyl(1_{xy}→3_{fuc})]- β -D-fucopyranoside (Tada et al. 1973). The following minor oligosides were isolated from the tubers: ophiopogonin A = ruscogenin 1-O-[(3-O-acetyl)- α -L-rhamno-pyranosyl (1→2)]- β -D-fucopyranoside; ophiopogonin B' = diosgenin 3-O-[(4-O-acetyl)- α -L-rhamnopyranosyl (1→2)] [β -D-xylopyranosyl (1→3)]- β -D-glucopyranoside; ophiopogonin C = mono-O-acetylophiopogonin D; ophiopogonin C' = diosgenin 3-O- α -L-rhamnopyranosyl (1→2)- β -D-glucopyranoside (=prosapogenin A of dioscin); and ophiopogonin D' = diosgenin 3-O-[α -L-rhamnopyranosyl-(1→2)] [β -D-xylopyranosyl (1→3)]- β -D-glucopyranoside (Watanabe et al. 1977). Two borneol glycosides, L-borneol- β -D-glucoside and L-borneol 6-O- β -D-apiosyl- β -D-glucoside, were isolated from the roots (Kaneda et al. 1983). A steroidal sapogenin named ophiogenin with the structure 25R-spirost-5-en-3 β , 14 α , 17 α -triol was isolated (Nakanishi and Kameda 1987). The following compounds were isolated from *O. japonicus*: diosgenin 3-O-[(2-O-acetyl)- α -L-rhamnopyranosyl (1→2)] β -D-xylopyranosyl

(1→3)]-β-D-glucopyranosyl, ruscogenin 1-*O* -[α-L-rhamnopyranosyl(1→3)][β-D-xylopyranosyl (1→3)] β-D-glucopyranosyl, L-borneol 6-*O*-β-D-apifuranosyl (1→6)β-D-glucopyranosyl, diosgenin 3-*O*-[α-L-rhamnopyranosyl (1→2)][β-D-xylopyranosyl (1→3)]-β-D-glucopyranosyl and diosgenin-3-*O*-[α-L-rhamnopyranosyl (1→3)]β-D-glucopyranosyl (Yang et al. 1987b). Two terpenoid glycosides ophiogenin 3-*O*-α-L-rhamnopyranosyl-(1→2)-β-D-glucopyranoside and bornyl 7-*O*-α-L-arabinofuranosyl(1→6)-β-D-glucopyranoside were isolated from *O. japonicus* roots (Adinolfi et al. 1990). Two monoterpene glycosides L-BORNEOL *O*-β-D-glucopyranoside and L-borneol *O*-β-D-apiofuranosyl (1→6)-β-D-glucopyranoside and eight steroidal glycosides ophiopogonin B, (25*S*)-ruscogenin 1-*O*-α-L-rhamnopyranosyl(1→2)-β-D-fucopyranoside = glycoside C, ophiopogonin D, (25*S*)-ruscogenin 1-*O*-[α-L-rhamnopyranosyl(1→2)][β-D-xylopyranosyl(1→3)]-β-D-fucopyranoside = Ls-10, ruscogenin 1-*O*-sulfate, (23*S*,24*S*,25*S*)-23,24-dihydroxyruscogenin 1-*O*-[α-L-rhamnopyranosyl(1→2)][β-D-xylopyranosyl (1→3)]-α-L-arabinopyranoside 24-*O*-β-D-fucopyranoside, (23*S*, 24*S*, 25*S*)-23,24-dihydroxyruscogenin I-*O*-[α-L-2,3,4-tri-*O*-acetylramnopyranosyl(1→2)][β-D-xylopyranosyl(1→3)]-α-L-arabinopyranoside 24-*O*-β-D-fucopyranoside and (23*S*,24*S*,25*S*)-23,24-dihydroxyruscogenin 1-*O*-[α-L-2,3,4-tri-*O*-acetylramnopyranosyl(1→2)][β-D-xylopyranosyl(1→3)]-α-L-arabinopyranoside 24-*O*-β-D-fucopyranoside (Asano et al. 1993b).

A steroidal saponin with the following structure (25*S*)-1-*O*-β-D-fucopyranosyl-3-*O*-α-L-RHAMNOPYRANOSYLRUSCOGENIN was isolated from *Ophiopogon japonicus tuber* (Branke and Hashilinger 1995). Two new C27 steroidal glycosides designated cixi-ophiopogons A and B with respective structures 3-*O*-α-L-rhamno-pyranosyl (1→2) [β-D-xylopyranosyl (1→3)]-β-D-glucopyranoside and ophiogenin 3-*O*-α-L-rhamno-pyranosyl (1→2) [β-D-xylopyranosyl (1→3)][β-D-glucopyranosyl (1→4)]-β-D-glucopyranoside together with a known ophiogenin 3-*O*-α-L-rhamnopyranosyl (1→2)-β-D-glucopyranoside were isolated from the tubers (Chen et al. 2000). Four known glycosides, L-borneol-*O*-β-D-

glucopyranoside, (1), L-borneol-*O*-[β -D-apiofuranosyl(1 $\rightarrow$ 6)]-*O*- β -D-GLUCOPYRANOSIDE, 4-allyl-1,2-benzenediol-1-*O*-L-rhamno-pyranosyl(1 $\rightarrow$ 6)-*O*- β -D-GLUCOPYRANOSIDE and (22*S*)-cholest-ene-1 β ,3 β ,16 β ,22-tetrol-1-*O*- α -L-rhamnopyranosyl-16-*O* β -D-glucopyranoside, were isolated from *Ophiopogon japonicus* tubers (Dai et al. 2000a). Two new C₂₇ steroidal glycosides, named ophiopojaponins A and B were isolated from the tubers, and their structures elucidated, respectively, as pennogenin 3-*O*-[2'-*O*-acetyl- α -L-rhamnopyranosyl (1 $\rightarrow$ 2)]- β -D-xylopyranosyl (1 $\rightarrow$ 3)- β -D-glucopyranoside and (25*R*)-3 β ,14 α ,22 ξ ,26-tetrahydroxyfurost-5-ene-3-*O*-[α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)- β -D-glucopyranoside]-26-*O*- β -D-glucopyranoside (Dai et al. 2000b). A new steroidal glycoside, named ophiopojaponin C with the structure ophiopogenin 3-*O*-[α -L-rhamnopyranosyl (1 $\rightarrow$ 2)]- β -D-xylopyranosyl(1 $\rightarrow$ 4)- β -D-glucopyranoside, and two known ones, diosgenin 3-*O*-[2-*O*-acetyl- α -L-RHAMNOPYRANOSYL(1 $\rightarrow$ 2)]- β -D-xylopyranosyl(1 $\rightarrow$ 3)- β -D-glucopyranoside and ruscogenin 1-*O*-[2-*O*-acetyl- α -L-rhamnopyranosyl(1 $\rightarrow$ 2)]- β -D-xylopyranosyl(1 $\rightarrow$ 3)- β -D-fucopyranoside, were isolated from *O. japonicus* (Dai et al. 2005). A new steroidal saponin, named ophiopogonin E with the structure pennogenin 3-*O*- β -D-xylopyranosyl (1 $\rightarrow$ 4)- β -D-glucopyranoside, was isolated from the tubers along with five known steroidal saponins: pennogenin 3-*O*-[2'-*O*-acetyl- α -L-rhamnopyranosyl (1 $\rightarrow$ 2)]- β -D-xylopyranosyl(1 $\rightarrow$ 3)- β -D-glucopyranoside, 25(*R*)-ruscogenin 1-*O*-[α -L-rhamnopyranosyl (1 $\rightarrow$ 2)][β -D-xylopyranosyl(1 $\rightarrow$ 3)]- β -D-fucopyranoside, 25-(*R*)-ruscogenin, diosgenin 3-*O*-[2-*O*-acetyl- α -L-rhamnopyranosyl (1 $\rightarrow$ 2)] [β -D-xylopyranosyl(1 $\rightarrow$ 3)]- β -D-glucopyranoside and diosgenin 3-*O*-[α -L-rhamnopyranosyl(1 $\rightarrow$ 2)][β -D-xylopyranosyl(1 $\rightarrow$ 3)]- β -D-glucopyranoside (Cheng et al. 2006). A new furospirostanol saponin, ophiofurospiside B, was isolated from *O. japonicus* (Xu et al. 2007). A new furospirostanol saponin, ophiofurospiside A with the structure 26-*O*- β -D-glucopyranosyl-(22*S*, 25*R*)-furospirost-5-ene-3 β , 17 α , 26-triol-3-*O*-[α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)]-[β -D-xylopyranosyl-(1 $\rightarrow$ 4)]-glucopyranoside, was isolated together with three known steroidal glycosides 2–4 from the tubers (Xu et al. 2008a). A new C₂₇-steroidal glycoside, pennogenin-3-*O*- α -l-

rhamnopyranosyl-(1→2)-β-D-xylopyranosyl-(1→4)-β-D-glucopyranoside, along with three known compounds pennogenin-3-*O*-α-L-rhamnopyranosyl-(1→2)-β-D-glucopyranoside, ophiopogonin C and ophiopogonin D, was isolated from the tuber (Wang et al. 2008). Two new steroidal glucosides, 26-*O*-β-D-glucopyranosyl (25*S*)-furost-5-ene-1β,3β,22α,26-tetraol 1-*O*-β-D-xylopyranosyl-(1→3)-[α-L-rhamnopyranosyl-(1→2)]-β-D-fucopyranoside and (25*R*) spirost-5-ene-3β,14α-diol-3-β-*O*-β-L-RHAMNOPYRANOSYL(1→2)-[β-D-xylopyranosyl(1→4)]-β-D-glucopyranoside, were isolated from the *Ophiopogon japonicus* (Xu et al. 2008b).

Two novel furostanol saponins, ophiopogonin F and ophiopogonin G, were isolated from the fresh tubers and their chemical structures assigned as (25*R*)-26-[(*O*-β-D-glucopyranosyl-(1→2)-β-D-glucopyranosyl)]-22α-hydroxyfurost-5-ene-3-*O*-β-D-xylopyranosyl-(1→4)-*O*-[α-L-rhamnopyranosyl-(1→2)]-β-D-glucopyranoside and (25*R*)-26-[(*O*-β-D-glucopyranosyl-(1→6)-β-D-glucopyranosyl)]-22α-hydroxyfurost-5-ene-3-*O*-β-D-xylopyranosyl-(1→4)-*O*-[α-L-rhamnopyranosyl-(1→2)]-β-D-glucopyranoside respectively (Zhang et al. 2009). Three steroidal saponins, (25*R*)-ruscogenin-3-yl α-L-rhamnopyranosyl-(1→2)-[β-D-xylopyranosyl-(1→4)]-β-D-glucopyranoside, diosgenin-3-yl 2-*O*-acetyl-α-L-rhamnopyranosyl-(1→2)-[β-D-xylopyranosyl-(1→4)]-β-D-glucopyranoside and pennogenin-3-yl 2-*O*-acetyl-α-L-rhamnopyranosyl -(1→2)-[β-D-xylopyranosyl-(1→4)]-β-D-glucopyranoside (Duan et al. 2010a), and two new furostanol glycosides, ophiopogonins H and I, with respective structures (25*R*)-26-[(*O*-β-D-glucopyranosyl-(1→2)-β-D-glucopyranosyl)]-22α-hydroxyfurost-5-ene-3-*O*-[α-L-rhamnopyranosyl-(1→2)]-β-D-glucopyranoside and (25*R*)-26-[(*O*-β-D-glucopyranosyl-(1→2)-β-D-glucopyranosyl)]-20α-hydroxyfurost-5,22-diene-3-*O*-[α-L-rhamnopyranosyl-(1→2)]-β-D-glucopyranoside (Duan et al. 2010b), were isolated from the fibrous roots. A new steroidal glycoside, (25*R*)-14α, 17α-hydroxyspirost-5-en-3β-yl 3-*O*-α-L-rhamnopyranosyl-(1→2)-β-D-glucopyranosyl-(1→3)-β-D-glucopyranoside, together with three known steroidal glycosides, (25*R*)-3β-hydroxyspirost-5-en-1β-yl-3-*O*-α-L-rhamnopyranosyl-(1→2)-*O*-β-D-xylopyranosyl-(1→3)-α-L-arabinopyranoside, cixi-ophiopogon

B and cixi-ophiopogon A, were obtained from the tuberous roots (Wang et al. 2011a). The average recoveries of diosgenin and ruscogenin from *O. japonicus* root using nonaqueous capillary electrophoresis were 102 % and 99.2 %, respectively (Huang et al. 2011). The content of diosgenin in the root was 0.018 mg/g and ruscogenin 0.008 mg/g.

Eight novel steroidal saponins, ophiopogonins H–O, along with seven known steroidal saponins were isolated from the tubers (Zhang et al. 2012). Two new furostanol saponins ophiopogonins J and K were isolated from the fibrous roots (Kang et al. 2013). Their structures were established, respectively, as (25*R*)-26-*O*-[(β -d-glucopyranosyl-(1 $\rightarrow$ 2)- β -D-glucopyranosyl)]-14-hydroxyfurost-5,20(22)-diene 3-*O*-[α -L-rhamnopyranosyl-($\rightarrow$ 2)]- β -d-glucopyranoside (1) and (25*R*)-26-*O*-[(β -d-glucopyranosyl-(1 $\rightarrow$ 2)- β -D-glucopyranosyl)]-furost-5,20(22)-diene 3-*O*- α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)[(β -d-xylopyranosyl-(1 $\rightarrow$ 4)- β -D-glucopyranoside)]. A new furostanol glycoside, named ophiopogonin J, was isolated from the fibrous root, and its structure was established as (25*R*)-26-[(*O*- β -D-GLUCOPYRANOSYL-(1 $\rightarrow$ 2)- β -D-glucopyranosyl)]-20 α -hydroxyfurost-5, 22-diene-3-*O*- α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)-[β -d-xylopyranosyl(1 $\rightarrow$ 4)]- β -D-glucopyranoside (Duan et al. 2012).

Four new steroidal saponins, named ophiopogonin P–S (1–4), together with 11 known ones, pennogenin-3-*O*-[2-*O*-acetyl- α -l-rhamnopyranosyl-(1 $\rightarrow$ 2)] [β -D-xylopyransoyl-(1 $\rightarrow$ 4)]- β -D-glucopyranoside, diosgenin 3-*O*-[2-*O*-acetyl- α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)] [β -D-xylopyransoyl-(1 $\rightarrow$ 4)]- β -D-glucopyranoside, sprengerinin A, sprengerin C, pennogenin-3-*O*- α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)-[β -D-xylopyransoyl-(1 $\rightarrow$ 4)]- β -d-glucopyranoside, 14-hydroxy diosgenin 3-*O*- α -rhamnopyranosyl-(1 $\rightarrow$ 2)- β -d-glucopyranoside, (25*R*)-spirost-5-,14-dien-3 β -yl-*O*- α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)- [β -d-xylopyransoyl-(1 $\rightarrow$ 4)]- β -D-glucopyranoside, ophiogenin 3-*O*- α -rhamnopyranosyl-(1 $\rightarrow$ 2)- β -d-glucopyranoside, ophiopojaponin C, 14-hydroxydiosgenin 3-*O*- α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)- β -D-glucopyranoside and ophiopogonin D, were isolated from the tuberous roots (Li et

al. 2013). Two new furostanol saponins elucidated as (25R)-26-O-[[β -d-glucopyranosyl-(1 $\rightarrow$ 2)- β -d-glucopyranosyl]-5-ene-furost-1 β ,3 β ,22 α ,26-tetraol-3-O- α -l-rhamnopyranosyl-(1 $\rightarrow$ 2)-[[β -d-xylopyranosyl-(1 $\rightarrow$ 4)]- β -d-glucopyranoside (ophiopogonin P) and (25R)-26-O-[[β -d-glucopyranosyl-(1 $\rightarrow$ 6)- β -d-glucopyranosyl]-5-ene-furost-1 β ,3 β ,22 α ,26-tetraol-3-O- α -l-rhamnopyranosyl-(1 $\rightarrow$ 2)-[[β -d-xylopyranosyl-(1 $\rightarrow$ 4)]- β -d-glucopyranoside (ophiopogonin Q) were isolated from the tubers (Guo et al. 2013). Nolinospinoside F, a steroidal saponin, was isolated from *O. japonicus* (Sun et al. 2013).

Homoisoflavonoids

Four new homoisoflavonoids were isolated from the tubers: methylophiogonanone A, methylophiogonanone B, methylophiogononone A and methylophiogononone B (Tada et al. 1980). Their structures were established as 5,7-dihydroxy-6,-8-dimethyl-3-(3,4-methylenedioxybenzyl)-chroman-4-one; 5,7-dihydroxy-6,-8-dimethyl-3-(3,4-methoxybenzyl)-chroman-4-one; 5,7-dihydroxy-6,-8-dimethyl-3-(3,4-methylenedioxybenzyl)-chromane; and 5,7-dihydroxy-6,-8-dimethyl-3-(4-methoxybenzyl)-chromane, respectively. Eight compounds were isolated from the roots including the known homoisoflavanoids (methylophiopogonanone A, methylophiopogonanone B, ophiopogonanone A), two other homoisoflavonoids, an amide compound and two borneol glycosides (Kaneda et al. 1983). Two homoisoflavones 6-aldehydo-isoophiopogonone A and 6-aldehydo-isoophiopogonone B were isolated from the roots (Zhu et al. 1987b). Five homoisoflavonoids: 6-aldehydo-isoophiopogonanone A, methylophiopogonanone A and methylophiopogonanone B and two new homoisoflavones, named 6-aldehydo-isoophiopogonone A and 6-aldehydo-isoophiopogonone B, were isolated from tubers (Zhu et al. 1987a). The following compounds were isolated from the tuber: homoisoflavonoids methylophiopogonone A, ophiopogonone A, methylophiopogonanone A, ophiopogonanone A, [5,7-dihydroxy-3-(4'-hydroxybenzyl)-6-methylchromone] = JE-III, desmethylisoophiopogonone B, 5,

7, 2'-trihydroxy-6-methyl-3-(3', 4'-methylenedioxybenzyl)chromone, 5, 7, 2'-trihydroxy-8-methyl-3-(3', 4'-methylenedioxybenzyl)chromone and a racemate of 5-hydroxy-7, 8-dimethoxy-6-methyl-3-(3', 4'-dihydroxybenzyl)chroman-4-one (Asano et al. 1993a). Five new homoisoflavonoids, ophiopogonanone C, ophiopogonanone D, ophiopogonone C, ophiopogonanone E and ophiopogonanone F and six known compounds were isolated from an ethanol extract of the tubers (Chang et al. 2002). From the ethyl acetate extract of the tuberous roots of *O. japonicus*, eight known and five new homoisoflavonoid compounds were isolated (Nguyen et al. 2003). The new compounds were 5,7-dihydroxy-8-methoxy-6-methyl-3-(2'-hydroxy-4'-methoxybenzyl)chroman-4-one, 7-hydroxy-5,8-dimethoxy-6-methyl-3-(2'-hydroxy-4'-methoxybenzyl)chroman-4-one, 5,7-dihydroxy-6,8-dimethyl-3-(4'-hydroxy-3'-methoxybenzyl)chroman-4-one, 2,5,7-trihydroxy-6,8-dimethyl-3-(3',4'-methylenedioxybenzyl)chroman-4-one and 2,5,7-trihydroxy-6,8-dimethyl-3-(4'-methoxybenzyl)chroman-4-one. Twenty-five homoisoflavonoids were isolated from the tubers, and 18 were characterised: 5,3',4'-trihydroxy-7-methoxy-8-methyl homoisoflavanone, 5,2'-dihydroxy-7,8,4'-trimethoxy-6-methyl homoisoflavanone, 5-hydroxy-7,4'-dimethoxy-6,8-dimethyl homoisoflavone, 5,7,4'-trihydroxy-3',5'-dimethoxy-6,8-dimethyl homoisoflavanone, 5-hydroxy-3',4'-dimethoxy-6,8-dimethyl homoisoflavanone, 5,4'-dihydroxy-7,3'-dimethoxy-8-methyl homoisoflavanone, ophiopogonanone E, 5-hydroxy-7-methoxy-3',4'-methylenedioxy-6,8-dimethyl homoisoflavanone, ophiopogonanone A, 5,7-dihydroxy-4'-methoxy-6-methyl homoisoflavanone, methylophiopogonone A, methylophiopogonanone A, ophiopogonanone F, methylophiopogonanone B, 6-aldehydo-isoophiopogonone A, 6-aldehydo-isoophiopogonone B and 5,7-dihydroxy-4'-methoxy-6-aldehydo-8-methyl homoisoflavanone (Ye et al. 2005b). Ye et al. (2005a) found that the homoisoflavonoid content of 3 principal homoisoflavonoids, methylophiopogonanone A, methylophiopogonanone B and 6-aldehydo-isoophiopogonanone A, of *O. japonicus* varied significantly from species to species and from locality to

locality. Seven homoisoflavones, namely, methylophiopogonanone A, methylophiopogonanone B, methylophiopogonone A, methylophiopogonone B, 2'-hydroxy-methylophiopogonone A, 6-aldehydo-isoophiopogonanone A and 5,7-dihydroxy-8-methoxy-6-methyl-3-(2' hydroxyl- 4'- methoxybenzyl)chroman- 4-one, were isolated from the tubers (Cheng et al. 2005a). Two new homoisoflavonoids ophiopogonone D and ophiopogonanone G were isolated from the fibrous roots (Duan et al. 2009). Three homoisoflavonoid compounds including methylophiopogonanone A, 6-aldehydo-isoophiopogonone A and 6-formyl-isoophiopogonanone A, were successfully isolated from *O. japonicus* and purified using combination of supercritical fluid extraction and high-speed countercurrent chromatography (Ma et al. 2009). In the operation, 140 mg crude extracts was separated and yielded 15.3 mg of methylophiopogonanone A (96.9 % purity), 4.1 mg of 6-aldehydo-isoophiopogonone A (98.3 % purity) and 13.5 mg of 6-formyl-isoophiopogonanone A (97.3 % purity). The mean recoveries of three homoisoflavonoids, 6-aldehydo-3-ophiopogonanone A, methyl ophiopogonanone A and ophiopogonanone A from *Ophiopogon japonicus* by HPLC were 99.41–99.86 % (RSD 0.82–1.05 %) (Zeng et al. 2012). The linear response ranges of 6-aldehydo-3-ophiopogonanone A, methyl ophiopogonanone A and ophiopogonanone A were 0.165–0.990 μg ($R^2 = 0.9999$), 0.153–0.918 μg ($r = 0.9999$) and 0.270–1.620 μg ($R^2 = 0.9999$), respectively.

Ten homoisoflavonoids isolated from *O. japonicus* extracts were identified as methylophiopogonanone A (1), methylophiopogonanone B (2), ophiopogonanone A (3), ophiopogonanone E (4), 5, 7-dihydroxy-6, 8-dimethyl-3-(4'-hydroxy-3', 5'-methoxybenzyl) chroman-4-one (5), methylophiopogonone A (6), methylophiopogonone B (7), desmethylophiopogonone B (8), 5, 7, 2'-trihydroxy-8-methyl-3-(3', 4'-methylenedioxybenzyl) chromone (9) and 5, 7, 2'-trihydroxy-6, 8-dimethyl-3-(3', 4'-methylenedioxybenzyl) chromone (Zhou et al. 2008a). Homoisoflavonoids isolated from the tuberous roots were identified as (3*R*)-2,3-dihydro-7-hydroxy-5-methoxy-3-(4-methoxybenzyl)-6,8-dimethyl-4*H*-

chromen-4-one, (3*R*)-3-(1,3-benzodioxol-5-ylmethyl)-2,3-dihydro-7-hydroxy-5-methoxy-6,8-dimethyl-4*H*-chromen-4-one, (3*R*)-3-(1,3-benzodioxol-5-ylmethyl)-2,3-dihydro-7-hydroxy-5-methoxy-6-methyl-4*H*-chromen-4-one and ophiopogonanone A (Wang et al. 2010b). Two new homoisoflavonoids, named ophiopogonone E and ophiopogonanone H, together with 13 known ones, namely, 5,7,2'-trihydroxy-3',4'-methylenedioxy-6,8-dimethyl homoisoflavone, 5,7,4'-trihydroxy-3'-methoxy-6,8-dimethyl homoisoflavanone, 5,7-dihydroxy-4'-methoxy-6-methyl homoisoflavanone, methylophiopogonanone B, 5,7,2'-trihydroxy-4'-methoxy-6,8-dimethyl homoisoflavanone ophiopogonanone A, methylophiopogonanone A, methylophiopogonone A, ophiopogonanone E, 5,7,2'-trihydroxy-3',4'-methylenedioxy-8-methyl homoisoflavone, 7,2'-dihydroxy-5,8,4'-trimethoxy-6-methyl homoisoflavanone, 5,7,4'-trihydroxyhomoisoflavone and 5,7,4'-trihydroxy-6-methyl homoisoflavanone, were isolated from the tuberous roots (Li et al. 2012a). One novel spirostan, named ophiogenin, together with six known spirostans, and one new sesquiterpene glycoside, named ophioside A together with one known monoterpene glycoside, were isolated from the active fractions of *Ophiopogon japonicus* roots (Lan et al. 2013). The aglycone of ophioside A named ophiopogonol was obtained from acid hydrolysis of ophioside A. Thirteen homoisoflavonoids, including three new ones 8-formyl-7-hydroxy-5,4'-dimethoxy-6-methylhomoisoflavone, 6-formylisoophiopogonone B and 8-formylophiopogonanone B, were isolated (Zhou et al. 2013). The structure of the formerly reported “6-aldehydo-isoophiopogonone B” was revised to 8-formylophiopogonone B. Two homoisoflavonoids (methylophiopogonanones A and B) were used as markers in the quality control of Radix Ophiopogonis in Shengmai injection (Wang et al. 2013).

Polysaccharides/Lectins

Md-1 and Md-2 polysaccharides from *O. japonicus* were found to be glucosans, consisting of D-glucose units joined by alpha-(1→4) glucosidic linkages and with molecular weight of

27,064 and 48,651, respectively (She and Shi 2003). Radix *Ophiopogonis* polysaccharide (ROP or MDG-1), a natural graminan-type fructan with weight average molecular weight (M_w) of ~5 kDa, was isolated (Lin et al. 2005; Zheng et al. 2007, 2009; Wang et al. 2010a). The water-soluble β -D-fructan (MDG-1) was isolated from *O. japonicus* (Xu et al. 2005; Wang et al. 2010a, 2012a; Zhu et al. 2014). A fructan, Opaw-2, with molecular mass of about 14 kDa, was isolated from the tuberous roots of *O. japonicus* (Wu et al. 2006). Opaw-2 comprised of fructose and glucose with a molar ratio of 30:1. Opaw-2 possessed a backbone structure of beta-(1 $\rightarrow$ 2)-Fruf and beta-(2 $\rightarrow$ 6)-Fruf residues that branched at O-6 of beta-(1 $\rightarrow$ 2)-Fruf residues with alpha-1-linkage to the Glcp residues and terminated with Fruf residues. Four sulfated heteropolysaccharide fractions (OJP-1, OJP-2, OJP-3 and OJP-4) were isolated and purified from the tuber of *Ophiopogon japonicus* (Xiong et al. 2011). The content of hexuronic acid and sulfate in the four sulfated heteropolysaccharide fractions were in decreasing order OJP-4 > OJP-3 > OJP-2 > OJP-1 and OJP-1S > OJP-4 > OJP-3 > OJP-2 > OJP-1, respectively. OJP-1, a water-soluble polysaccharide isolated from the roots, was found to compose of Ara, Glc and Gal in a relative molar ratio of 1:16:8 and with average molecular weight of 35.2 kDa (Chen et al. 2011). POJ-U1a polysaccharide with molecular weight of 4.02×10^3 Da isolated from *O. japonicus* was an α -configuration an α -configuration polysaccharide with a highly branched structure and consisted of pyranoside and funanside (Wang et al. 2012c). The backbone of POJ-U1a consisted of 1,6- α -D-glucopyranose and 1,3,6- α -D-glucofuranose in the molar ratio of 7:3, while the branched chains were mainly composed of 1,3- α -D-glucopyranose and 1- α -D-GLUCOPYRANOSE in the molar ratio of 1:3.

A novel mannose-binding lectin (designated OJL) was purified from *O. japonicus* rhizomes (Tian et al. 2008; Zhang et al. 2010b). This novel lectin was a homodimer consisting of approximately 12 kDa subunits linked by non-covalent bonds. The haemagglutination activity was stable in the pH range of 5.0–9.0 and at temperatures below 60 °C. The

haemagglutination activity of OJL was inhibited by Man- α (1,3:1,6)-mannotriose, Man- α (1,3)-Man, Man- α (1,6)-Man, Man- α (1,2)-Man, Me α -D-man and D-mannose.

Miscellaneous Phytochemicals

β -sitosterol, stigmasterol and β -sitosterol- β -D-glucoside were isolated from the ether-soluble fraction of the rhizome (Kato et al. 1968). A borneol derivative, calcium bornyl sulfate, glycerol and α -humulene were isolated from the tubers (Nakanishi and Kameda 1987). Six allelopathic chemicals were isolated from the methanol extracts of dwarf lilyturf roots: *O*-hydroxybenzoic acid, 4-hydroxy-3-methoxybenzoic acid, 4-hydroxy-3,5-dimethoxy benzoic acid, 3,5-dimethoxy-4-hydroxycinnamic acid, syringaldehyde and *p*-hydroxybenzoic acid (Lin et al. 2003b). Salicylic acid and *p*-hydroxybenzoic acid were isolated from the root methanolic extract (Iqbal et al. 2004). A *cis*-eudesmane sesquiterpene glycoside, ophiopogonoside A, with the structure 1 β ,4 β ,6 β -trihydroxy-*cis*-eudesmane-6-*O*- β -D-glucopyranoside, was isolated from the tubers (Cheng et al. 2004). Two anthraquinones, chrysophenol and emodin; 3 phenolic acids, vanillic acid, *p*-hydroxybenzaldehyde and *trans*-*p*-coumaric acid; two terpenes, L-borneol- β -D- glucopyranoside and oleanolic acid; and two fatty acids, azelaic acid and *n*-tricosanoic acid were isolated from the tubers (Cheng et al. 2005a). Two cyclodipeptides cyclo-(Phe-Tyr) and cyclo-(Leu-Ile), N-(2-(4-hydroxyphenyl) ethyl)-4-hydroxycinnamide and tianshonic acid were isolated from the tubers (Cheng et al. 2005b). A phenolic glycoside, ophiopojaponin D, with the structure 3-tetradecyloxy-4-hydroxy-allylbenzene-4-*O*- α -L-rhamnopyranosyl (1 $\rightarrow$ 6)- β -D-glucopyranoside was isolated from the tubers together with 3, 4-dihydroxy-allylbenzene-4-*O*- α -L-rhamnopyranosyl (1 $\rightarrow$ 6)- β -D-glucopyranoside (2) and L-PYROGLUTAMIC acid (Dai and Mei 2005). (*E*)-3-(4-Hydroxy-3-methoxybenzyl-idene)-4-(4-hydroxy-phen-yl)pyrrolidin-2-one was isolated from an ethanol extract of *Ophiopogon japonicus* (Zhou et al. 2008b).

Forty-one fat-soluble components were identified from *O. japonicus*, accounting for 81.72 % of the total fat-soluble

components with 46.133 % of fatty acids (Shen et al. 2008). 9,12-octadecadienoic acid, hexadecanoic acid, 6-octadecenoic acid and guaiol were the chief components, and their relative contents were 24.648 %, 10.829 %, 6.367 % and 6.757 %, respectively.

Other Plant Part Phytochemicals

The glycoside ophioside was isolated from the fruit (Arisawa and Nakaoki 1969). Eleven compounds were isolated from *O. japonicus* flowers and identified as β -sitosterol, diosgenin, daucosterol, ophiopogonin C', dioscin, 7-dihydroxy-6-methyl-3-(4'-hydroxybenzyl) chroman-4-one, luteolin, kaempferol-3-*O*- β -D-glucopyranoside, kaempferol-3-*O*-(6"-tigloyl)- β -D-glucopyranoside, kaempferol-3-*O*-(6"-acetyl)- β -D-glucopyranosides and glucose (Zhu et al. 2011).

Antioxidant Activity

Homoisoflavonoids isolated from *O. japonicus* extracts scavenged hydroxyl radical ($\cdot$ OH) and hydrogen peroxide (H_2O_2) into a certain extent, and their bioactivities should be related with the respective structures (Zhou et al. 2008a). Four sulfated heteropolysaccharide fractions (OJP-1, OJP-2, OJP-3 and OJP-4) isolated from the tubers exhibited antioxidant activity (Xiong et al. 2011). In comparison with OJP-1, other polysaccharides showed stronger 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical and hydroxyl radical scavenging activity. POJ-U1 polysaccharide from *O. japonicus* possessed strong antioxidant activity as shown by its DPPH radical scavenging, hydrogen radical scavenging and superoxide anion scavenging activities (Wang et al. 2012b).

Antidiabetic Activity

Many studies found that *O. japonicus* possessed antidiabetic effects supporting the traditional medicinal use of the plant in treating diabetes mellitus. The water-soluble β -D-fructan (MDG- 1) from *O. japonicus* exhibited antidiabetic effects in the *ob/ob* mouse model of type 2 diabetes mellitus (Xu et al.

2011). MDG-1 (300 mg/kg) exerted acute and long-term hypoglycaemic effects on fed blood glucose in *ob/ob* mice. However, only a marginal hypoglycaemic effect on fasting blood glucose levels was observed. MDG-1 (300 mg/kg) improved oral glucose tolerance and reduced serum insulin levels and triglyceride content in the liver in *ob/ob* mice. Additionally, a reduction in body weight gain and the weight of subcutaneous fat were observed following treatment with MDG-1 (150 mg/kg) compared with the control group. MDG-1 had no significant effects on the total cholesterol and triglyceride levels, food intake and other adipose and organ tissues. The data suggested that MDG-1 exhibited hypoglycaemic activity and reduced insulin resistance. Chen et al. (2011) reported that OJP-1, a water-soluble polysaccharide isolated from the roots, was found to have antidiabetic activity. OJP-1 significantly reduced blood glucose level, increased the insulin level and remediated destruction of pancreatic islets in streptozotocin -induced diabetic rats compared with the diabetic control group. The water-soluble β -D-fructan (MDG-1) from *O. japonicus* reduced the hyperglycaemia, hyperinsulinaemia and hyperlipidaemia in the KKAY mice (Wang et al. 2012a). The oral glucose tolerance test (OGTT) and the level of insulin in the serum showed that insulin resistance in KKAY mice was ameliorated after MDG-1 treated. After 8 weeks treatment with 300 mg/kg MDG-1, the content of triglycerides (TG) and low-density lipoprotein cholesterol (LDL-C) in the serum decreased significantly, and high-density lipoprotein cholesterol (HDL-C) content increased notably. The authors stated that MDG-1 could be a promising antidiabetic compound that will be helpful for the treatment of type 2 diabetes mellitus.

Studies found that OJP1OJP1, a polysaccharide isolated from *O. japonicus* roots, possessed potent antioxidant activity and could protect the liver and kidneys from the injurious effects of diabetes (Chen et al. 2013b). OJP1 significantly reduced the MDA (malondialdehyde) concentration and increased the activity of both GPx (glutathione peroxidase) and SOD (superoxide dismutase) in the serum, liver and kidneys of streptozotocin-induced diabetic rats. Moreover, the values of TG (triglyceride), TC (total cholesterol), LDL-C

(low-density lipoprotein cholesterol) and HDL-C in diabetic rats were significantly reversed by OJP1 treatment. The mRNA expression of transforming growth factor- β 1 (TGF- β 1) and connective tissue growth factor (CTGF) in diabetic rats decreased significantly after administration of OJP1. Oligosaccharides extracted from *O. japonicus* vinegar (OOV) by alcoholic and acetic acid fermentation with water extracts from the root exhibited stronger inhibition against α -glucosidase than oligosaccharides extracted from the root (OOJ) without fermentation (Lin et al. 2011a). The hypoglycaemic effect of OOV on alloxan-induced diabetic mice was stronger than that of OOJ. More importantly, the ability of OOV to reduce damage on islets in diabetic mice was stronger than that of OOJ. The data suggested that alcoholic and acetic acid fermentation improved the hypoglycaemic activity of *O. japonicus* oligosaccharides. Wang (2013) reported that intragastric administration of *Ophiopogon* polysaccharide for 14 days could decrease the fasting blood glucose level and serum insulin level and improve APN mRNA in fat tissue and placenta of streptozotocin-induced diabetic rats.

MDG-1, a water-soluble β -D-fructan polysaccharide from *O. japonicus*, could treat type 2 diabetes mellitus (T2DM) experimentally (Zhu et al. 2014). To elucidate the antidiabetic mechanism of MDG-1, a faecal metabonomic study was conducted in female diabetic KK mice. After 8 weeks of treatment with MDG-1, faeces samples were collected for gas chromatography/time-of-flight mass spectrometry analysis. Consequently, 12 potential biomarkers were identified, including monosugars (D-tagatose, D-lyxose, D-ERYTHROSE, xylo-hexos-5-ulose, 2-deoxy-galactose), butanedioic acid, amino acids (phenylalanine, L-lysine, L-methionine, L-aspartic acid) and purine derivatives (7H-purine, 2'-deoxyinosine). They assumed that the monosugars and butanedioic acid were the fermentation products of MDG-1 by intestinal microbes, and MDG-1 actions against diabetes might be accomplished through the absorbable monosugars and butanedioic acid via suppressing intestinal glucose absorption, enhancing liver glycogenesis, inhibiting glycogenolysis and promoting glucagon-like peptide-1 (GLP-1) secretion. Besides, MDG-1

might alleviate diabetes and diabetic nephropathy by reducing 7H-purine and 2'-deoxyinosine.

Anticancer Activity

Two homoisoflavonoids ophiopogonone D and ophiopogonanone G isolated from the roots exhibited cytotoxic activities against Hela and Hep2 cells (Duan et al. 2009). *Ophiopogon japonicus* lectin (OJL), a mannose-binding lectin, was found to markedly inhibit growth of MCF-7 cells by induction of apoptosis via a caspase-dependent pathway (Liu et al. 2009). There was an association among the haemagglutinating activity, antiproliferative activity and mannose-binding activity. *Ophiopogon japonicus* lectin (OJL) was found to induce murine fibrosarcoma L929 cell apoptosis (Zhang et al. 2010b). The mechanism of lectin-induced apoptosis was a caspase-dependent pathway.

Three new steroidal saponins, (25*R*)-ruscogenin-3-yl α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)-[β -D-xylopyranosyl-(1 $\rightarrow$ 4)]- β -D-glucopyranoside, diosgenin-3-yl 2-*O*-acetyl- α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)-[β -D-xylopyranosyl-(1 $\rightarrow$ 4)]- β -D-glucopyranoside and pennogenin-3-yl 2-*O*-acetyl- α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)-[β -D-xylopyranosyl-(1 $\rightarrow$ 4)]- β -D-glucopyranoside, were isolated from the fibrous roots exhibited weak cytotoxicities against Hela and Hep2 cell lines (Duan et al. 2010a). Homoisoflavanones isolated from the tuberous roots, (3*R*)-2,3-dihydro-7-hydroxy-5-methoxy-3-(4-methoxybenzyl)-6,8-dimethyl-4H-chromen-4-one and (3*R*)-3-(1,3-benzodioxol-5-ylmethyl)-2,3-dihydro-7-hydroxy-5-methoxy-6,8-dimethyl-4H-chromen-4-one, showed weak cytotoxicity against the HepG2 (human hepatoma G2), KB (human oral epidermoid carcinoma) and MCF-7 (human breast adenocarcinoma) cell lines (Wang et al. 2010b). Homoisoflavanone (3*R*)-3-(1,3-benzodioxol-5-ylmethyl)-2,3-dihydro-7-hydroxy-5-methoxy-6-methyl-4*H*-chromen-4-one exhibited weak cytotoxicity against HepG2 and MCF-7, and moderate cytotoxicity against KB cell lines while ophiopogonanone A showed moderate cytotoxicity against HepG2, KB and MCF-7 cell lines. Ophiopogonin B (OP-B), a bioactive component of the root, reduced growth of non-small

cell lung cancer (NSCLC) cell lines NCI-H157 and NCI-H460 by cell cycle arrest at the G0/G1 phase and autophagy, and not by induction of apoptosis (Chen et al. 2013a). This was associated with its inhibition of PI3K/Akt/mTOR signalling pathway in both cancer cells. Several homoisoflavonoids exhibited promising in-vitro antiproliferative activities against the human lung tumour A549 cell line with IC₅₀ values of 0.84–10.01 µM (Zhou et al. 2013).

DT-13, a saponin from *Ophiopogon japonicus*, inhibited MDA-MB-435 lung cancer cell proliferation, adhesion and migration in-vitro and lung metastasis in nude mice by suppressing vascular endothelial growth factor (VEGF), C-C chemokine receptor type 5 (CCR5) and hypoxia-inducible factor 1α (HIF-1α) expression (Zhao et al. 2014).

Anti-inflammatory Activity

O. japonicus root extract significantly inhibited xylene-induced ear swelling and carrageenan-induced paw oedema in mice when given orally at doses of 25 and 50 mg/kg (Kou et al. 2005a). The extract also markedly suppressed carrageenan-induced pleural leucocyte migration in rats and zymosan A-evoked peritoneal total leucocyte and neutrophil migration in mice, while had no obvious effect on pleural prostaglandin E2 level. Further, its two active compounds ruscogenin and ophiopogonin D dose-dependently reduced phorbol-12-myristate-13-acetate (PMA)-induced adhesion of HL-60 cells to ECV304 cells, with IC₅₀ of 42.85 µg/mL, 7.76 nmol/L and 1.38 nmol/L, respectively. However, they showed no inhibitory effect on PMA-induced cyclooxygenase-2 (COX-2) mRNA expression in ECV304 cells. Ruscogenin and ophiopogonin D also markedly decreased zymosan A-induced peritoneal leucocyte migration. These results demonstrated that *O. japonicus* root extract possessed notable anti-inflammatory activity and supported its traditional use in the treatment of various diseases associated with inflammation. Separate studies showed that ruscogenin, a major steroidal sapogenin of *O. japonicus* root, significantly suppressed zymosan A-evoked peritoneal total leucocyte migration in

mice in a dose-dependent manner, while it had no obvious effect on celiac prostaglandin E₂ content in peritoneal exudant (Huang et al. 2008). Ruscogenin also inhibited TNF- α induced over expression of ICAM-1 both at the mRNA and protein levels and suppressed NF-kappaB activation considerably by decreasing NF-kappaB p65 translocation and DNA-binding activity. The findings elucidated the possible molecular mechanism of ruscogenin and Radix *Ophiopogon japonicus* for the inhibition of endothelial responses to cytokines during inflammatory and vascular disorders.

Tran et al. (2010) reported that homoisoflavonoids isolated from the roots exhibited anti-inflammatory activity in-vitro. They inhibited the release of the inflammatory chemokine eotaxin, stimulated by interleukin IL-4 and the combination of IL-4 and TNF- α in BEAS-2B cells. Li et al. (2012a) found six homoisoflavonoids, ophiopogonanone H, 5,7,4'-trihydroxy-3'-methoxy-6,8-dimethyl homoisoflavanone, methylophiopogonanone B, 5,7,2'-trihydroxy-4'-methoxy-6,8-dimethyl homoisoflavanone, methylophiopogonone A and ophiopogonanone E, isolated from the tuberous roots that exhibited potent inhibitory effects on NO production induced by lipopolysaccharide in the murine microglial cell line BV-2 with IC₅₀ values of 20.1, 17.0, 7.8, 5.1, 19.2 and 14.4 μ M, respectively.

Cardioprotective Activity

Studies had shown that *O. japonicus* possessed cardioprotective activity supporting its use in traditional medicine in treating cardiovascular disorders.

The saponin monomer 13 of dwarf lilyturf tuber (DT-13) was found to have potent cardioprotective effects (Tao et al. 2005). It dose-dependently reduced L-type calcium currents during hypoxia in adult rat ventricular myocytes.

Radix *Ophiopogonis* polysaccharide (ROP), a natural graminan-type fructan with weight average molecular weight (M_w) of ~ 5 kDa (Lin et al. 2005), had been found to be very effective against myocardial ischaemia (Zheng et al. 2007,

2009; Wang et al. 2010a). Ophiopogonis polysaccharide protected isolated Langendorff guinea pig heart from myocardium ischaemia–reperfusion injury (IRI) and from subcutaneous injection of isoprenaline induced acute myocardial ischaemia in rats (Zheng et al. 2007). In further studies, they found that sulfation of the polysaccharide significantly enhanced its antimyocardial ischaemic activity (Zheng et al. 2009). Lin et al. (2009a) found the enhanced permeability and retention effect caused by ischaemia could overcome the negative effect of the reduction of blood flow on the distribution of *O. japonicus* polysaccharide (OJP) from blood into myocardial ischaemic zones and actually help OJP target myocardial ischaemic zones where it could exert its pharmacological effect directly.

Wang et al. (2010a) found that MDG-1, the water-soluble β -D-fructan from *O. japonicus*, protected cardiomyocyte and microvascular endothelial cells (HMEC-1) against oxygen glucose deprivation (OGD)-induced cell death, as well as protected myocardial cells from ischaemia-induced death occurring after coronary artery ligation in rats. Their data indicated that MDG-1 presented remarkable anti-ischaemic activity and protected cardiomyocyte and HMEC-1 cells from ischaemia-induced cell damage by inducing sphingosine 1-phosphate (S1P) and basic fibroblast growth factor (bFGF) cytoprotective and proangiogenic effects via the S1P/bFGF/Akt (protein kinase B)/ERK (extracellular signal-regulated kinase)/eNOS (endothelial nitric oxide synthase) signalling pathway. Ophiopogonin D (OP-D), bioactive component of *O. japonicus* root, prevented H₂O₂-induced injury primary human umbilical vein endothelial cells (HUVECs) (Qian et al. 2010). It inhibited mRNA levels of antioxidant, inflammatory and apoptotic genes in a dose-dependent manner in HUVECs. H₂O₂-induced lipid peroxidation, protein carbonylation, mitochondrial ROS generation and cell apoptosis were reduced by OP-D pretreatment. Further, OP-D restored cellular total antioxidative capacity and inhibited the release of inflammatory cytokines. Additionally, OP-D suppressed the enzymatic activity of catalase, HO-1 and caspases. Finally,

OP-D blocked activation of NF- κ B and ERK signalling cascades. The results indicated that ophiopogonin D could be developed as a novel drug for the therapy of cardiovascular disorders. *Ophiopogon japonicus*, water-soluble β -D-fructan polysaccharide(MDG-1), augments survival in the ischaemic heart by inducing S1P release and sphingosine 1-phosphate receptor 1 (S1P₁) expression by activation of the sphingosine kinase enzyme activity coupled with the autocrine and paracrine stimulation of cell surface S1P receptors (Wang et al. 2012b). Oral administration of oligosaccharides of *Ophiopogonis japonicus* (OOJ) in doses of 225 and 450 mg/kg body weight to high-fat diet and low-dose streptozotocin-induced type 2 diabetic rats for 3 weeks increased body weight decreased organ-related weights of liver and kidney, reduced fasting blood glucose level and improved oral glucose tolerance in diabetic rats (Li et al. 2012b). Studies found that two spirostan compounds 4 and 8 from *O. japonicus* significantly improved on tube formation in human myocardial microvascular endothelial cells, and ophioside A showed moderate increasing effect, while spirostan compound 5 exhibited potent inhibitory effect (Lan et al. 2013).

Studies showed that Shengmai (herbal preparation of ginseng and *Ophiopogon* root) had protective effects on cardiogenic shock (Ding et al. 2007). In the dogs treated with Shengmai, the mean arterial pressure, heart rate, left ventricular pressure, the maximum of its first derivative (+/- dp/dtmax), the cardiac output and the cardiac index were increased significantly. The left ventricular end diastolic pressure and the peripheral vascular resistance were decreased significantly; the myocardial infarct size was reduced markedly. Additionally, the activity of lactate dehydrogenase and creatine kinase and level of malondialdehyde in serum were decreased significantly; however, the activity of superoxide dismutase was increased markedly.

Neuritogenic Activity

Several steroidal saponins and a saponin, isolated from *O. japonicus*, were found to be potent inducers of neuritogenesis

on PC12 cells (Qu et al. 2011; Ye et al. 2013). In both studies, the aglycone was found to be more important for the neuritogenic activity of the compounds rather than the sugar moieties and acylation. Also, specific inhibitor experiments and Western blot analysis suggested that the steroidal saponin-induced neuritogenic activity depended on the activation of mitogen-activated protein kinase (MEK)/extracellular signal-regulated kinase (ERK) signalling pathway on PC12 cells (Ye et al. 2013). Compounds with neuritogenic activity could be important in the treatment of neurodegenerative diseases.

Neuroprotective Activity

Shengmai (containing active principles of ginseng and *Ophiopogon* root) injection increased mRNA expression of hypoxia-inducible factor 1-alpha (HIF-1alpha) in neonatal SD rat brain and reduced the apoptosis of hippocampus neurons after hypoxic–ischaemic brain damage (Wang et al. 2009). Guan et al. (2013) found that pretreatment of adult male mice (C57BL/6 strain) with ruscogenin, a major steroid sapogenin from *O. japonicus*, before transient middle cerebral artery occlusion (MCAO)/reperfusion, markedly decreased the infarct size, improved neurological deficits and reduced brain water content after MCAO. NF- κ B DNA-binding activity and the expression of NF- κ B target genes, including ICAM-1, inducible nitric oxide synthase (iNOS), cyclooxygenase (COX-2), tumour necrosis factor- α (TNF- α) and interleukin-1 β (IL-1 β), were also suppressed by ruscogenin pretreatment after 1-hour MCAO and 24-hours reperfusion. The results indicated that ruscogenin protected the brain against ischaemic damage caused by MCAO, and this effect may be through downregulation of NF- κ B-mediated inflammatory responses.

Intravenous injection of Shengmai (*Panax ginseng*, *Ophiopogon japonicus* and *Schisandra chinensis*) ameliorated the adverse effects of glomerulosclerosis induced by Adriamycin in SD rats (Peng et al. 1999). Rats treated with Shengmai had lower levels of BUN (blood urea nitrogen), cholesterol and protein urine; also 1 V collagen and laminin content in the renal cortex and mesangial area were reduced significantly compared to glomerulosclerosis rats.

Anti-ageing Activity

Nolinospinoside F, a steroidal saponin, isolated from *O. japonicus* was found to significantly extend the replicative lifespan of K6001 yeast at doses of 1, 3 and 10 μM , indicating that it had an anti-ageing effect (Sun et al. 2013). This may be attributed to its antioxidative effect, as nolinospinoside F could increase yeast survival under oxidative stress conditions and decrease the level of malondialdehyde (MDA), an oxidative stress biomarker. It could also increase antioxidative stress genes, *SOD1* and *SOD2*, expression and the activity of superoxide dismutase (SOD). It increased the activity of SIRT1, an upstream inducer of *SOD2* expression. Further, nolinospinoside F inhibited the expression of *UTH1*, a yeast-ageing gene involved in the oxidative stress of yeast.

Immunomodulatory Activity

Studies showed that the aqueous extract *Ophiopogon japonicus* could increase obviously the spleen weight (immunity organ) of mice, enhance the clearance rate of i.v. charcoal particles in mice and antagonise markedly the leukopenia caused by cyclophosphamide (Yu et al. 1991).

A fructan, Opaw-2, isolated from the roots, significantly stimulated the proliferation of cultured lymphocytes in a dose-dependent manner (Wu et al. 2006). Four sulfated heteropolysaccharide fractions (OJP-1, OJP-2, OJP-3 and OJP-4) isolated from the tubers exhibited immunomodulatory activity (Xiong et al. 2011). They and OJP-1S exhibited remarkable macrophage-activating capability by the promotion of phagocytic capacity, energy metabolism rate, NO and interleukin-1 production. It was significantly different between five polysaccharides and decreased in the order OJP-1S > OJP-4 > OJP-3 > OJP-2 > OJP-1. Studies showed that sulfated *Ophiopogon* polysaccharide could significantly promote lymphocyte proliferation and enhance serum antibody titre in chicken vaccinated with Newcastle disease vaccine (Zhang et al. 2013). The action was significantly or numerically stronger than those of corresponding unmodified polysaccharides. The

results indicated that sulfation modification could enhance the immune-enhancing activity of *Ophiopogon* polysaccharides.

Antithrombotic Activity

In-vivo studies showed that once oral administration of ethanol extract of *O. japonicus* root at doses of 12.5 and 25 mg/kg significantly inhibited venous thrombosis induced by tight ligation of the inferior vena cava for 6 hours in mice and for 24 hours in rats (Kou et al. 2005b). This was associated with its endothelial cell-protective and anti-adhesive activities. This afforded scientific support to the therapeutic use of the plant for thrombotic disease. In further studies, they showed that aqueous extract of Radix *Ophiopogon japonicus* (ROJ-ext) markedly decreased length of tail thrombus in mice at 48 and 72 hours after carrageenan injection at doses of 12.5 and 25.0 mg/kg (Kou et al. 2006). Also, ROJ-ext markedly inhibited thrombosis induced by arterial-venous (AV) shunt (silk thread) in rats at doses of 6.25 and 12.5 mg/kg. Further, ROJ-ext and one of its components, ruscogenin, significantly inhibited platelet aggregation induced by adenosine diphosphate (ADP) in rats by oral administration of 12.5 mg/kg or 0.7 mg/kg for three times; however, ophiopogonin D 1.4 mg/kg only showed slight inhibition. In contrast, ophiopogonin D (0.5–2.0 mg/kg, p.o.) and ruscogenin (0.25–1.00 mg/kg, p.o.) produced dose-related inhibition of venous thrombosis induced by tight ligation of the inferior vena cava for 6 hours in mice by once oral administration.

Cognitive-Enhancing Activity

Ophiopogon japonicus extract ameliorated MK-801-induced amnesia in rats in the avoidance task (Lin et al. 2003c). The extract at 0.1 and 0.3 g/kg prolonged the step-through latency (STL) of the retention trial and reversed the STL shortened by MK-801. The results suggested that the extract possessed cognition-enhancing activities and anti-amnesic effects.

Antihyperlipidaemic Activity

A furostanol glycoside, named ophiopogonin J, isolated from the fibrous root, was found to have fatty acid synthase inhibitory activity (Duan et al. 2012).

Results of studies showed that rats fed with Shengmai San (herbal preparation of *Panax ginseng*, *Schisandra chinensis* and *Ophiopogon japonicus* (2:1:2)) (SMS)-containing diet had reduced the H₂O₂-induced erythrocytes susceptibility to haemolysis, and 4 % SMS feeding rats had higher plasma glutathione concentration compared to the animals fed with high-cholesterol control diet (Yao et al. 2008). However, SMS had no effect on plasma lipids (total cholesterol, triglyceride and high-density lipoprotein cholesterol) and TBARS (thiobarbituric acid reactive substances) concentration. In contrast, rats fed with the 4 % SMS diet had reduced hepatic cholesterol and triglyceride contents. Faecal bile acid excretion was significantly increased in rats fed with the SMS-containing diet. Higher hepatic glutathione and lower TBARS concentrations were observed in rats fed with the 4 % SMS diet compared with the rats fed with the high-cholesterol control diet. No significant difference in activities of glutathione peroxidase, glutathione-S-transferase and superoxide dismutase was found in the liver and heart after the SMS treatment. Results from the study suggested that the SMS may reduce hepatic lipids and lipid peroxidation in rats.

Anti-arrhythmic Activity

The arrhythmias induced by chloroform-epinephrine, BaCl₂ and aconitine were prevented and antagonised by *Ophiopogon japonicus* root total saponins (OTS) (Chen et al. 1990). The incidence of ventricular arrhythmia produced by ligation of the left anterior descending coronary artery was effectively decreased without any changes in the haemodynamic indices of dogs. OTS shortened action potential duration APD₁₀, APD₅₀ and APD₉₀ decreased amplitude (APA) and maximum rate of depolarisation (V_{max}) of both monophasic and transmembrane action potentials. OTS also increased the effective refractory period (ERP)/APD ratio and prevented or

abolished the arrhythmikinesis provoked by ouabain and aconitine.

Anti-allergic Activity

(Wang et al. 2007) found that immunisation of C57BL/6 mouse with submandibular gland (SMG) autoantigen decreased salivary flow and body weight and increased water intake, SMG index, spleen index, IFN- γ level and IFN- γ /IL-4 ratio compared with the normal group (Wang et al. 2007). Administration of *Ophiopogon japonicus* polysaccharides at the high dose ameliorated these parameters the pathological changes of SMG with respect to the autoallergic model mice. The results suggested a basis for the use of *O. japonicus* in Sjogren's syndrome, an autoimmune disorder characterised by lymphocytic infiltration of salivary and lacrimal glands leading to xerostomia and keratoconjunctivitis sicca.

Antimicrobial Activity

25S-ruscogenin and a mixture of ruscogenin and 25S-ruscogenin from the tubers showed antimicrobial activities in-vitro against Gram-positive bacteria, namely, *Bacillus subtilis*, *Staphylococcus aureus*, *Sarcina lutea*, *Streptococcus faecalis* and *Micrococcus lysodeikticus* (Nakanishi and Kameda 1987). A mannose-binding lectin (designated OJL) purified from *O. japonicus* rhizome inhibited herpes simplex virus type II (HSV-II) with an EC₅₀ of 3.93 μ g/mL and showed antifungal activity against *Gibberella saubinetii* and *Rhizoctonia solani* (Tian et al. 2008).

Skin-Lightening Activity

Methylophiopogonanone B (5,7-dihydroxy-6,8-dimethyl-3-(4-methoxybenzyl)chroman-4-one) had been reported to activate Rho, inducing cytoskeleton disorganisation, and to reduce melanosome transfer by determining a reversible dendrite retraction (Ito et al. 2006). The compound did not influence melanin synthesis or the expression of melanogenic enzymes

and could be considered as a promising skin-lightening compound.

Mucociliary Transport-Enhancing Activity

Studies showed that treatment with *O. japonicus* root (OR) extract was found to have beneficial effects on mucociliary transport following injury to the palate induced by sodium metabisulphite (MB) which releases SO₂ on contact with water (O'Brien et al. 2004). The loss of cilia or ciliated cells prevented full recovery of mucociliary clearance time after MB in untreated bull frog palates. In OR-incubated palates, mucociliary transport was completely restored within 20 minutes after topical application of MB, possibly through a protective action on the extracellular matrix.

Herbal Drug–Drug Interaction Activity

Twenty-two traditional Chinese medicines (TCMs) ethanol extracts including that of *O. japonicus* and eight bioactive compounds could activate pregnane X receptor (PXR) signalling pathway and induce CYP3A4 reporter gene in HepG2 cells (Yu et al. 2011). Therefore, caution should be taken when these PXR activators are used in combination with prescribed drugs metabolised by CYP3A4.

Xia et al. (2009) demonstrated that Shengmai (herbal preparation of ginseng and *Ophiopogon* root) injection could significantly inhibit midazolam 4-hydroxylation but activated its 1'-hydroxylation in human liver microsomes (HLMs), rat liver microsomes (RLM) and recombinant human CYP3A4 and CYP3A5. Among the major components in Shengmai, total ginsenoside, *Ophiopogon* total saponins, *Ophiopogon* total flavone, ginsenoside Rd, ophiopogonin D and ophiopogonone A exhibited significant inhibition on both 4-hydroxylation and 1'-hydroxylation of midazolam in HLM and RLM, while no activation on midazolam metabolism was observed in the presence of these major constituents alone or together.

Pharmacokinetic Studies

Studies showed that oral administration of ophiopogonin saponin D' could be metabolised by intestinal bacteria in the intestine of rat, and its metabolite, diosgenin, was absorbed in blood of rat (Shen et al. 2005). The clearance of FOJ-5, a graminan-type fructan polysaccharide of *O. japonicus* from the bodies of rats following intravenous injection displayed a complex type of kinetics involving at least two compartments, and the half-life of the elimination of FOJ-5 from plasma administered at 15 mg/kg (18.1 minutes) was quicker than that administered at 50 mg/kg (28.9 minutes) (Lin et al. 2005). Lin et al. (2006) found that the sodium caprate containing formulations could significantly improve fluorescein isothiocyanate (FITC)- *O. japonicus* polysaccharide (OJP) bioavailability in rats. Compared with the formulations not containing sodium caprate, the increase varied from 5.6- to 20.8-fold for the worst and best sodium caprate containing formulations studied, respectively. The absorption enhancement effects were 2.1- to 3.6-fold higher than those of faster and slower release formulations studied. In further studies, they found that *Ophiopogon japonicus* polysaccharides (OJP) alone was poorly absorbed from all the rat intestinal segments but was rapidly absorbed when co-administered with sodium caprate (Lin et al. 2009b). The absorption increase was significant, and the best absorption enhancing site of sodium caprate for OJP was the colon.

Radix *Ophiopogonis* polysaccharide (ROP) had been found to have an excellent antimyocardial ischaemic activity; however, its rapid renal excretion following administration remarkably limits its efficacy and clinical use (Lin et al. 2010a, 2011b). They demonstrated that PEGylation using a moderate coupling reaction between the hydroxyl-activated ROP and the amino-terminated mPEG to prepare different mPEG-ROP conjugates to be a promising approach for improving the clinical efficacy of ROP by prolonged retention in plasma. The conjugates were found to be well absorbed after subcutaneous administration, with absolute bioavailability being 75.4 % and 43.9 %, respectively (Lin et al. 2011b). Wang et al. (2011b) found that the half-life of

PEGylated ROP conjugate following subcutaneous (sc) administration was basically identical to that after intravenous (i.v.) administration. The absolute bioavailability of the conjugate following sc administration was approximately 56 %, and the mean in-vivo residence time was 52.1 hours, increased 2.4 times compared to those of i.v. administration. A simple HPGPC-FD (high-performance gel permeation chromatography–fluorescence detection) method was developed for the sensitive and specific determination of FITC-ROP (fluorescein isothiocyanate-labelled ROP) in plasma and rat tissues (heart, liver, spleen, lung, kidney, brain and stomach) (Lin et al. 2010b). PEGylation was found to be a promising approach to improve the antimyocardial ischaemic activity of Radix Ophiopogonis polysaccharide (ROP) by prolonging its retention in plasma (Lin et al. 2011a). Using a long-circulating and bioactive PEGylated ROP with 1.04 mol 20-kDa mPEG per mol ROP ((1.04)P(20 k)-R), they found that the AUC of (1.04)P(20 k)-R in ischaemic hearts was approximately 1.6-fold greater than in normal hearts owing to enhanced permeability and retention effect caused by ischaemia. Compared with ROP in rats, the distribution tendency of (1.04)P(20 k)-R in the mouse kidney, brain and lung was reduced by approximately 42, 1.6 and 1.3 times, respectively, whereas it was increased by approximately 1.3-fold in the liver.

Toxicity Studies

Toxicity studies demonstrated that Radix Ophiopogonis decoction (26.9 g/kg) had no detectable adverse effects in either the treated F0 female SD rats or the foetuses (Zhang et al. 2010a). No deaths, premature deliveries or dose-related clinical signs were attributed to Radix Ophiopogonis decoction. Maternal body weight and body weight gain were not affected. There were no effects on foetus weight and viability, incidences of foetal malformation and variation.

Traditional Medicinal Uses

Mai men dong is the cardinal herb for Yin deficiency. According to the Chinese Herbal Medicine Materia Medica, the herb is sweet, slightly bitter and slightly cold; enters the heart, lung and stomach; channels and nourishes the yin of the stomach, spleen, heart and lungs; and clears heat and quiets irritability (Bensky et al. 2004). The tuber is antitussive, aphrodisiac, expectorant, pectoral, sedative, sialogogue, stomachic, mucolytic, emollient, demulcent, anti-pyretic, anti-angina, anti-inflammatory, diuretic, cardiotonic, antibacterial, haemostatic, laxative calming, antiscrofulatic and tonic (Yeung 1985; Duke and Ayensu 1985; Bown 1995). It is said to have anticancer activity. *Ophiopogon japonicus* is a traditional Chinese medicine used to treat diabetes for thousands of years (Xu et al. 2011; Zhu et al. 2014) and a traditional Chinese medicine used to treat cardiovascular disease (Wang et al. 2010a). Shengmai San (SMS), which is comprised of the medicinal herbs of *Panax ginseng* root, *Schisandra chinensis* fruit and *Ophiopogon japonicus* root (2:1:2), is a traditional Chinese medicine being used for treatment of coronary heart disease (Yao et al. 2008). Shengmai injection (SMI), one of the most popular herbal preparations, is widely used for the treatment of coronary atherosclerotic cardiopathy and viral myocarditis (Xia et al. 2009). It has been used to relieve coughing, phlegm and heat in the lungs caused by bacterial infection (Liang et al. 2012). It is used internally in the treatment of dry coughs, fevers, thirst, dry constipation, insomnia, anxiety, fearfulness and palpitations (Bown 1995). It is also frequently used to lower blood pressure (Yeung 1985).

Other Uses

In many countries, it is used as ornamental for borders and lawns. Several cultivars have been selected, including “Albus” (white flowers), “Compactus” and “Kyoto Dwarf” (dwarf forms, not over 4–5 cm tall) and “Silver Dragon” (variegated, with white-striped leaves). It is often sold as a decorative plant for freshwater aquaria, but does not last long in water. It forms a good carpeting plant, spreading rapidly and is commonly planted as a ground cover or as a low-maintenance grass substitute. It is particularly valuable for preventing soil erosion.

The methanolic extract of *O. japonicus* roots exhibited allelopathic activity; it strongly inhibited root and hypocotyls growth of lettuce (Iqbal et al. 2004). Allelopathic constituents of the diethyl ether extract were isolated and identified as salicylic acid and *p*-hydroxybenzoic acid. Among the pair, salicylic acid was found to be the most active one. Six allelopathic chemicals were isolated from the methanol extracts of dwarf lilyturf tuberous roots: *O*-hydroxybenzoic acid, 4-hydroxy-3-methoxybenzoic acid, 4-hydroxy-3,5-dimethoxy benzoic acid, 3,5-dimethoxy-4-hydroxycinnamic acid, syringaldehyde and *p*-hydroxybenzoic acid (Lin et al. 2003b). Dwarf lilyturf has been known to be both a cover crop with weed suppression for gardening in Japan and a medicinal plant (Lin et al. 2003a). They found that all aqueous extracts (1 %, 2 %, 4 %, 8 %, w/v) from the dried powders of underground parts of *Ophiopogon japonicus* inhibited the germination and seedling growth for three weed species, viz. monochoria (*Monochoria vaginalis*), smallflower umbrella (*Cyperus difformis*) and bur-Marigold (*Bidens biternata*). In addition, application of dwarf lilyturf dried powders (50, 100, 150 g/m²) significantly inhibited emergence and dry weights of weeds existed in paddy field, and had no adverse effects on growth of transplanted rice. From these results, the dwarf lilyturf plants might be used as a natural herbicide to control weeds in rice fields.

The results of studies suggested that the dwarf lilyturf plants have inhibitory potential and could use as a biological fungicide to control rice blast (Lin et al. 2003b). The methanol extract of dried powdered roots inhibited growth of *Pyricularia grisea* in-vitro. Methanol extract of dwarf lilyturf roots significantly inhibited the in-vitro mycelial growth rate of three plant pathogens, *Thanatephorus cucumeris*, *Taphrina deformans* and *Fusarium solani* (Lin et al. 2009a).

Comments

The plant is readily propagated either through seeds or by division of the existing plant.

Greek: Lappa

Hungarian: Bojtorján, Keseru Lapu, Keserulapu Bojtorján, Közönséges Bojtorján

Icelandic: Króklappa

India: Pichawag (Lahaul)

Indonesian: Gobo

Italian: Bardana, Bardana Maggiore, Rfariaccio, Lappa Bardana, Lappola, Lappola Bardana

Japanese: Gobo (Root), Goboshi, Akujitsu, Dairikishi (Fruit)

Korean: Ueong, Uang

Norwegian: Storborre, Klengjegras, Klåteblom, Lungegras

Polish: Lopian, Lopian Wiekszy, Łopian Wiekszy

Portuguese: Bardana-Maior, Erva Dos Tinhosos, Pergamasso, Carrapicho Grande ***Spanish:*** Bardana Mayor, Lampazo, Bardana, Lampazo Mayor, Lapa

Swedish: Kardborrerot, Stor Kardborre, Rodkardborre, Rotkardborre

Vietnamese: Ngu Bang

Origin/Distribution

Burdock is reported to be native to northern Europe to northeast Asia including northern India. It has become naturalised in many parts of the world, growing wild throughout Europe and North America where it is used as folk medicine. The Japanese developed it as an edible vegetable when it was introduced into Japan a thousand years ago. Today, burdock is widely cultivated in Japan, Taiwan and China and also some Southeast Asian countries (in the highlands) mainly for export to Japan.

Agroecology

Burdock is a cool climate, temperate crop flourishing best at temperatures of 18–28 °C in full sun and is frost sensitive. For quality burdock roots, deep profiled and well-drained sandy loam or fresh, worked soil and well-drained soil rich in humus or nitrogen are preferred. Burdock is responsive to nitrogen fertilisers.

Edible Plant Parts and Uses

Burdock root is eaten raw or cooked in a variety of food preparations, and petiole, young leaves and sprouts are also eaten.

The root is very crisp and has a sweet, mild and pungent flavour. It is popularly used in the following Japanese cuisine: burdock in combination with pork in miso soup (*Tinjiro*, *tonjiru*); Japanese-style pilaf (*Takikomi gohan*); *Kinpira gobo* which comprises shredded burdock root and carrot, braised with soy sauce, sugar, mirin and/or sake and sesame oil; and burdock *Makizushi* (sushi filled with pickled burdock root rather than fish; the burdock root is often artificially coloured orange to resemble a carrot). In Kyoto, gobo is also processed as snack similar to potato chips, and the roots are eaten cooked and the young sprouts can be eaten just like bean sprouts.

Botany

A biennial herb growing to 100–300 cm high (Plate 1) with slender, fleshy, tapering roots, which can grow up to 120 cm long and 3–4 cm across. Roots usually have a brown skin with white flesh that oxidises (discolours) quickly when exposed to air. Leaves with 15–35 cm solid, glabrous green or red petioles (Plate 3a, b). Lamina – large, 25–80 × 20–70 cm, coarsely dentate to subentire, cordate, lower surface thinly grey tomentose, upper green, sparsely short hairy to nearly glabrous. Inflorescence heads usually in long-pedunculate corymbiform clusters (Plate 2). Involucres 25–45 mm diameter. Phyllaries linear to linear–lanceolate, glabrous, margins with minute spreading or reflexed hairs. Florets more than 40 with purple, glabrous corollas 10–15 mm. Cypselae light brown, 6.2–7.5 mm and with short pappus bristles 2–5 mm.

Plate 1 Young burdock plant

Plate 2 Burdock inflorescences and leaves

Plate 3 (a, b) Burdock root, whole and halved

Nutritive/Medicinal Properties

Root Nutrients/Phytochemicals

Analyses carried out in the United States reported raw burdock root to have the following proximate composition (per 100 g edible portion): water 80.09 g; energy 72 kcal (302 kJ); protein 1.53; total lipid 0.15 g; ash 0.89 g; carbohydrates 17.34 g; total dietary fibre 3.3 g; total sugars 2.90 g; Ca 41 mg, Fe 0.8 mg, Mg 38 mg, P 51 mg, K 308 mg, Na 5 mg, Zn 0.33 mg, Cu 0.077 mg, Mn 0.232 mg, Se 0.7 µg, vitamin C 3.0 mg, thiamine 0.010 mg, riboflavin 0.030 mg, niacin 0.300 mg, pantothenic acid 0.321 mg, vitamin B6 0.240 mg, total folate 23 µg, choline 11.7 mg, betaine 0.2 mg, vitamin A 0 IU, vitamin E (α-tocopherol) 0.30 mg and vitamin K (phylloquinone) 1.6 mcg; total saturated fatty acids 0.025 g and 16:0 (palmitic acid) 0.025 g; total monounsaturated fatty acids 0.037 g and 18:1 undifferentiated (oleic acid) 0.037 g; total polyunsaturated fatty acids 0.059 g, 18:2 undifferentiated (linoleic acid) 0.056 g and 18:3 undifferentiated (linolenic acid) 0.002 g; and tryptophan 0.006 g, threonine 0.026 g, isoleucine 0.030 g, leucine 0.032 g, lysine 0.067 g, methionine 0.009 g, cystine 0.006 g, phenylalanine 0.033 g, tyrosine 0.018 g, valine 0.033 g, arginine 0.105 g, histidine 0.031 g, alanine 0.025 g, aspartic acid 0.177 g, glutamic acid 0.157 g, glycine 0.031 g, proline 0.052 g and serine 0.025 g (USDA-ARS [2014](#)). Dry burdock root extract contained (mg/g) 0.011 mg Cu, 0.5520 mg Na, 7.47 mg K, 0.0035 mg Mn, 0.0239 mg Pb, 0.0270 mg Fe, 0.391 mg Mg and 0.0128 mg Cd and 12.1 % protein and 15 amino acids (wt%), namely, asparagine 2.5 %, threonine 0.8 %, serine 1.1 %, glutamine 6.7 %, proline 0.9 %, glycine 1 %, alanine 1 %, valine 1 %, isoleucine 0.8 %, leucine 1.6 %, tyrosine 0.8 %, phenylalanine 1.2 %, histidine 0.7 %, lysine 0.9 % and arginine 2.5 % (Azizov et al. [2012](#)). The dry extract of burdock roots contained 40.5 % inulin; mineral elements (mg/g), Cu 0.0112 mg, Na 0.55 mg, K 7.47 mg, Mn 0.0035 mg, Pb 0.0239 mg, Cd 0.0128 mg, Fe 0.027 mg and Mg 0.391 mg (Azizov et al. [2012](#)); and 12.1 % protein comprising asparagines 2.5 %, threonine 0.8 %, serine 1.1 %, glutamine 6.7 %, proline 0.9 %, glycine 1 %, alanine 1 %, valine 1 %, isoleucine 0.8 %, leucine 1.6 %, tyrosine 0.8 %, phenylalanine 1.2 %, histidine 0.7 %, lysine 0.9 % and arginine 2.5 %. Khamidova et al. ([2009](#)) reported burdock to contain up to 45 % of the polysaccharide inulin, 12.3 % protein, up to 0.2 % essential oil, up to 3.9 % fatty oil, organic acids, 13.2 % carotenoids, 0.7 % flavonoids and tanning agents and bitter principles. Yamada et al. ([1975](#)) isolated γ-

guanidino-*n*-butyric acid from burdock root. Kuo et al. (2012) identified α -linolenic acid, methyl α -linolenate and methyl oleate in the *n*-hexane fraction of burdock root.

From burdock roots the following compounds were isolated: sulfur-containing acetylenic acid named arctic acid with the structure 5'-(1-propynyl)-5-carbomethoxy-2, 2'-bithienyl; volatile acids, acetic, propionic, *n*-butyric, isobutyric, isovaleric, tiglic and *trans*-2-hexenoic acids; non-hydroxy acids, lauric, myristic, stearic, palmitic, oleic, linoleic and linolenic acids; aldehydes, acetaldehyde, propionaldehyde, butanal isobutyraldehyde, *n*-valeraldehyde, isovaleraldehyde, *n*-caproic aldehyde, *n*-caprylic aldehyde and benzaldehyde; and 2,4-dinitrophenylhydrazones of carbonyl compounds (Obata et al. 1970).

Schulte et al. (1967) identified 14 polyacetylenes in fresh burdock roots of different samples with 1,11-tridecadien-3,5,7,9-tetrayne (up to 1.5 mg%), 1-tridecene-3,5,7,9,11-pentayne (up to 1.1 mg%) and 1,3,11-tridecatriene-5,7,9-triayne (up to 0.2 mg%) as major components. Treatment of sliced burdock root tissue with copper sulfate stimulated the formation of two phytoalexins, isolated and characterised as (S)-12,13-epoxy-2,4,6,8,10-tridecapentayne and 1-tridecene-3,5,7,9,11-pentayne (Takasugi et al. 1987). Burdock also contained baicalin (Uchiyama et al. 2005); lappaphen-a and lappaphen-b, two guaianolides linked with a sulfur-containing acetylenic compound (Washino et al. 1987); polyacetylenic compounds, namely, 1,11(*E*)-tridecadien-3,5,7,9-tetrayne; (3*E*,11*E*)-1,3,11-tridecatriene-5,7,9-triayne; (3*E*)-3-tridecen-5,7,9,11-tetrayn-1,2-epoxide as C₁₃ polyynes; (8*Z*,15*Z*)-heptadeca-1,8,15-heptadecatriene-11,13-diyne as C₁₇ polyyne; and (4*E*,6*E*,12*E*)-4,6,12-tetradecadien-8,10,12-triyn-1,3-diyl diacetate; (4*E*,6*Z*,12*E*)-4,6,12-tetradecadien-8,10,12-triyn-1,3-diyl diacetate; (4*E*,6*E*)-4,6-tetradecadien-8,10,12-triyn-1,3-diyl diacetate and (4*E*,6*Z*)-4,6-tetra-decadien-8,10,12-triyn-1,3-diyl diacetate (Washino et al. 1986b). Nine sulfur-containing acetylenic compounds and derivatives 5'-(1-propynyl)-2,2'-bithienyl-5-yl were isolated and identified as arctinone-a and arctinone-b, arctinol-a and arctinol-b, arctinal, arctic acid-b and arctic acid-c, methyl arctate-b and arctinone-a acetate (Washino et al. 1986a). Arctic acid, arctinone-a, arctinone-b and methyl arctate-b, minor components of *Arctium lappa* were synthesised via 5-(1-propynyl)-2,2'-bithienyl starting from 2,2'-bithienyl (Washino et al. 1986c). From burdock methanol extract, the following compounds were isolated sitosterol- β -D-glucopyranoside, methyl palmitate, methyl linoleate, methyl

linolenate, methyl stearate, methyl oleate, palmitic acid, linoleic acid, linolenic acid, stearic acid and oleic acid (Miyazawa et al. 2005). Seventeen compounds were isolated from burdock root ethanol solution: three from petroleum ether extract (β -sitosterol, oleanolic acid, ursolic acid), four from chloroform extract (β -sitosterol, daucosterol, syringaresinol, ethyl- β -D-pyran fruit glycoside), one from ethyl acetate extract (1,5-di-*O*-caffeoylquinic acid) and two from *n*-butanol extract (succinic acid and 5-hydroxymaltol). Oleanolic acid, ursolic acid, clove lignans, ethyl- β -D-pyran fruit glycoside, succinic acid and 5-hydroxymaltol were also isolated (Han et al. 2013).

The presence of flavonoids, saponins, lignans and alkaloids was reported in burdock (Cao et al. 2012). A xyloglucan isolated from burdock KOH extract was found to comprise predominantly of repeating oligosaccharide units of hepta-(Glc–Xyl = 4:3), nona-(Glc–Xyl–Gal–Fuc = 4:3:1:1) and deca-(Glc–Xyl–Gal–Fuc = 4:3:2:1) saccharides in an approximate molar ratio of 14:12:5 (Kato and Watanabe 1993). A low molecular weight fructofuranan of the inulin type was isolated from the roots (Kardosová et al. 2003). Burdock root was reported to contain 45 % of the polysaccharide inulin, 12.3 % protein, up to 0.2 % essential oil, up to 3.9 % fatty oil, organic acids, 13.2 % carotenoids, 0.7 % flavonoids and tanning agents and bitter principles (Azizov et al. 2012). Inulin and oligofructose are soluble, fermentable, dietary fibres, of low net caloric value having many of the possible health benefits attributed to fibre (Carabin and Flamm 1999). Such fibre was reported to comprise of polymers and oligomers of fructose joined by $\beta(2\rightarrow1)$ fructosyl–fructose bonds. Optimum ultrasound extraction condition for inulin from burdock roots was found to have a sonication time of 25 minutes, sonication amplitude of 83.22 % and temperature of 36.76 °C (Milani et al. 2011). Seven fructooligosaccharides with degrees of polymerisation (DP) between 3 and 9, as well as fructose, glucose and sucrose, were simultaneously determined in burdock from different regions (Li et al. 2013). The recoveries ranged from 99.2 to 102.6 %.

The cell walls of gobo consisted of pectic substances (rhamnogalacturonan with neutral sugars), hemicellulose (arabinan, xylan, galactan, arabinogalactan and xyloglucan) and cellulose in the ratio of 53.6:8 and 0:38.4, respectively (Yato et al. 1991). The approximate ratio of fructan and cell wall polysaccharides was 47:53 for gobo. An acidic xylan with a backbone chain of $\beta(1\rightarrow4)$ -xylopyranosidic residues, about 8.3 % of which were substituted at the 2-position with 4-*O*-ethyl- α -D-glucopyransoyl-uronic acid residues, was isolated from gobo (Watanabe et al. 1991). A

xyloglucan was isolated from the 24 % KOH extract of gobo (Kato and Watanabe 1993). It consisted of repeating oligosaccharide units of hepta-(Glc–Xyl=4:3), nona-(Glc–Xyl–Gal–Fuc=4:3:1:1) and deca-(Glc–Xyl–Gal–Fuc=4:3:2:1) saccharides. A fructan–fructan 1-fructosyltransferase (1-FFT) was purified from edible burdock, and a cDNA encoding 1-FFT was isolated from the plant (Abe et al. 2009). Two 1-FFTs named 1-FFTa and 1-FFTb were purified from extract of edible burdock, and FFT cDNA named *alft1* was found to be involved in the elongation of fructosyl chains of fructooligosaccharides in edible burdock. Three fructooligosaccharide derivatives without a terminal glucose residue were generated in burdock roots stored underground from November to May (Ishiguro et al. 2009). They were determined to be inulobiose [β -D-fructofuranosyl-(2 $\rightarrow$ 1)- β -D-fructopyranose], inulotriose [β -D-fructofuranosyl-(2 $\rightarrow$ 1)- β -D-fructofuranosyl-(2 $\rightarrow$ 1)- β -D-fructopyranose] and inulotetraose [β -D-fructofuranosyl-(2 $\rightarrow$ 1)- β -D-fructofuranosyl-(2 $\rightarrow$ 1)- β -D-fructofuranosyl-(2 $\rightarrow$ 1)- β -D-fructopyranose]. Seventy to eighty percent of the terminal fructose residue of the three saccharides was in pyranosyl form, while 20–30 % in furanosyl form. Variation of total FOS, total IOS, inulin and their related-metabolising enzymes, sucrose hydrolase (SH), 1-kestose hydrolase (1-KH), inulin hydrolase (InH), sucrose–sucrose 1-fructosyltransferase (1-SST) and fructan–fructan 1-fructosyltransferase (1-FFT) in burdock stored under different temperatures, was found to be dependent partly on temperature and other physiological factors (Ishiguro et al. 2010a). SH showed an irregular variation at 15 and 20 °C and was significantly higher at 0 °C showing a continuous increase during the storage period. 1-KH decreased progressively at 15 and 20 °C, but had a sharp rise at 0 °C after 2 weeks and decreased thereafter. InH decreased gradually at 0, 15 and 20 °C. However, the decrease was more significant at 15 and 20 °C during the first 2 weeks, while at 0 °C the decrease was significant after 4-week storage. 1-SST and 1-FFT activities decreased progressively and showed similar patterns. At 15 and 20 °C, total FOS increased during the first 3 weeks and then decreased, while at 0 °C FOS increased progressively during storage. Total IOS increased during storage; however, this increase was much higher at 0 °C than that observed at 15 and 20 °C. Inulin content decreased during storage and final content was lower at 20 °C. Further, they found that low temperature induced strongly the hydrolysis of inulin and formation of IOSs in burdock root suggesting that this reaction would not be the result of a putative endo-inulinase but resulted from the activity of fructan–fructan 1-fructosyltransferase (1-FFT)

(Ishiguro et al. 2010b). At 15 and 20 °C, inulobiose appeared after 3-day storage, and then, it increased gradually to 2.03 and 2.72 mg/g dry weight (DW) after 42 days, while inulotriose, inulotetraose, inulopentaose, inulohexaose and inuloheptaose appeared after 1 week and increased also progressively. At 0 °C, the different inulooligosaccharides (IOSs) increased sharply after the second week, but inulobiose and inulotriose decreased slightly after 5 weeks. However, their contents were much higher than those observed at 15 and 20 °C. A water-soluble polysaccharide (ALP1) purified from burdock root was characterised as a fructan composed of fructose and glucose in the ratio of 13.0:1.0, with an average molecular weight of 4,600 Da. The linkages in ALP1 were $\rightarrow$ 1)-Fruf-(2 $\rightarrow$, Fruf-(2 $\rightarrow$ and Glcp-(1 $\rightarrow$ (Liu et al. 2014).

Ferredoxin from *Arctium lappa* was found to consist of a single polypeptide chain of 97 residues, four of which were cysteine (Takruri et al. 1982). Ueno et al. (2011) isolated a gene cDNA, named *aleh1*, encoding for fructan 1-exohydrolase (1-FEH) in edible burdock. *Aleh1* encoded a polypeptide of 581 amino acids. The purified recombinant protein showed hydrolysing activity against β -2, 1 type fructans such as 1-kestose, nystose, fructosyl-nystose and inulin. In contrast, sucrose, neokestose, 6-kestose and high DP levan were poor substrates.

Five caffeoylquinic acid derivatives were isolated from the roots: 1-*O*-,5-*O*-dicaffeoyl-quinic acid; 1-*O*-,5-*O*-dicaffeoyl-3-*O*-succinyl-quinic acid; 1-*O*-,5-*O*-dicaffeoyl-4-*O*-succinyl-quinic acid; 1-*O*-,5-*O*-dicaffeoyl-3-*O*-,4-*O*-disuccinylquinic acid; and 1-*O*-,3-*O*-, 5-*O*-tricaffeoyl-4-*O*-succinylquinic acid (Maruta et al. 1995).

Hydroxycinnamoylquinic acids identified in burdock roots included 1-caffeoyl-quinic acid, 3-caffeoylquinic acid and 4-caffeoylquinic acid, chlorogenic acid, 1,3-dicaffeoylquinic acid, caffeoylquinic acid glycoside, 3,4-dicaffeoylquinic acid, 1,4-dicaffeoylquinic acid, 3,5-dicaffeoylquinic acid, 1,5-dicaffeoylquinic acid, 4,5-dicaffeoylquinic acid, 1,5-dicaffeoyl-3-succinoylquinic acid, 1,5-dicaffeoyl-4-succinoyl-quinic acid, 1,3,5-tri-caffeoylquinic acid, 1,5-dicaffeoyl-3,4-disuccinoylquinic acid, 1,3,5-dicaffeoyl-4-succinoylquinic acid and 3,4,5-tricaffeoylquinic acid (Lin and Harnly 2008).

Hydroxycinnamoylquinic acids, 5-*O*-caffeoyl-quinic acid, 1,4-di-*O*-caffeoylquinic acid, 1,5-di-*O*-caffeoylquinic acid and 3,5-di-*O*-caffeoylquinic acid, and 15 quantitatively minor fumaric, succinic and malic acid-containing chlorogenic acids were identified in burdock roots (Jaiswal and Kuhnert 2011). These were 3-*O*-succinoyl-4,5-dicaffeoyl or 1-*O*-succinoyl-3,4-dicaffeoylquinic acid, 1,5-di-*O*-caffeoyl-3-succinoylquinic acid, 1,5-di-*O*-caffeoyl-4-

succinoylquinic acid, 3,4-di-*O*-caffeoyl-5-succinoylquinic acid, 1,3-di-*O*-caffeoyl-5-fumaroylquinic acid, 1,5-di-*O*-caffeoyl-4-fumaroylquinic acid, 1,5-di-*O*-caffeoyl-3-maloylquinic acid, 1,4-di-*O*-caffeoyl-3-maloyl-quinic acid, 1,5-di-*O*-caffeoyl-4-maloylquinic acid, 1,3,5-tri-*O*-caffeoyl-4-succinoylquinic acid, 1,5-di-*O*-caffeoyl-3,4-disuccinoylquinic acid, 1,5-di-*O*-caffeoyl-3-fumaroyl-4-succinoylquinic acid, 1-fumaroyl-3,5-di-*O*-caffeoyl-4-succinoylquinic acid, dicaffeoyl-dimaloylquinic acid and 1,5-di-*O*-caffeoyl-3-succinoyl-4-dimaloylquinic acid. Phenolic compounds found in the hydroethanolic extract of burdock root extracts included artigenin, quercetin, chlorogenic acid and caffeic acid (Predes et al. 2011). Arctiin, luteolin and quercetin rhamnoside were identified in burdock roots (Ferracane et al. 2010). The total phenolic content of burdock roots and leaves ranged from 3.93 to 14.13 g of chlorogenic acid (5-CQA) equivalent/100 g dry weight (DW) (Haghi et al. 2013). There was a significant variability from 89 to 571 mg/100 g for 5-CQA and 48–486 mg/100 g for 11,5-dicaffeoylquinic acid in dry material. Chlorogenic acid, used as a chemical marker for HPTLC analysis, was estimated to be 0.107–0.140 % in *A. lappa* root (Pandey et al. 2004, 2007). The mean values of total contents of biofunctional components (chlorogenic acid, 1-*O*-,5-*O*-dicaffeoylquinic acid and 1-*O*-,5-*O*-dicaffeoyl-3-*O*-succinylquinic acid) in burdock roots varied from 1.7 to 7.9 mg/g dry weight (Wang et al. 2001).

Nine hydrocarbons (cyperene, 1-pentadecene, β -elemene, caryophyllene, clovene, α -guaiene, 1-heptadecene, dihydroaplotaxene and aplotaxene); 19 aldehydes (propanal, 2-methylpropanal, butanal, 3-methylbutanal, pentanal, hexanal, heptanal, (*Z*)-3-hexenal, (*E*)-2-hexenal, octanal, nonanal, (*E*)-2-octanal, decanal, benzaldehyde, undecanal, phenylacetaldehyde, dodecanal, tridecanal and 4-methoxybenzaldehyde); seven 2-alkyl-3-methoxypyrazines, namely, 2-methoxy-3-methylpyrazine, 2-isopropyl-3-methoxypyrazine, 2-methoxy-3-propylpyrazine, 2-sec-butyl-3-methoxypyrazine, 2-isobutyl-3-methoxypyrazine, 2-butyl-3-methoxypyrazine and 2-isoamyl-3-methoxypyrazine; 32 acids, namely, acetic acid, propionic acid, 2-methylpropionic acid, butyric acid, 2-methylbutyric acid, 2,3-methylbutyric acid, pentanoic acid, hexanoic acid, (*E*)-3-hexenoic acid, heptanoic acid, (*E*)-3-heptenoic acid, octanoic acid, (*E*)-3-octenoic acid, nonanoic acid, (*E*)-3-nonenoic acid, decanoic acid, benzoic acid, undecanoic acid, phenylacetic acid, salicylic acid, dodecanoic acid, 2-phenylpropionic acid, 3-hydroxyoctanoic acid, cinnamic acid, tridecanoic acid, tetradecanoic acid, 3-methoxybenzoic acid, pentadecanoic acid, nonanedioic acid, hexadecanoic acid, costic acid and octadecanoic

acid; and two sesquiterpenoids, dehydrocostus lactone and dehydrodihydrocostus lactone, were isolated and identified in the volatile components of burdock roots (Washino et al. 1985). Aplotaxene, dehydrocostus lactone, dehydrodihydrocostus lactone and costic acid were identified as major components. The volatile oil from burdock roots yielded 14 compounds, representing 85.4 % of the total composition (Aboutabl et al. 2013). The major compound was caryophyllene oxide (51.1 %), followed by aromadendrene (16 %) and isoaromadendrene epoxide (6.4 %). Other components were γ -cadinene 2.79 %, β -costol 1.98 %, β -copaen-4 α -ol 1.69 %, hexacosane 1.41 %, α -pinene 0.5 %, eicosane 0.35 %, pentacosane 0.19 %, heptacosane 0.19 %, *trans*- β -farnesene 0.11 %, tetracosane 0.09 % and carvomenthone 0.03 %. Sixty-three compounds were identified representing 87.67 % of the total contents of burdock essential oil (Wang et al. 2004). The major constituents were methyl linolenate, linoleic acid, 2-naphthalenemethanol, decahydro- and benzaldehyde.

Polyphenol oxidase purified from burdock had a molecular weight of 31,000 estimated by SDS-PAGE and 25,000 by gel filtration (Murao et al. 1993). The enzyme had properties different from those of polyphenol oxidases from other sources such as mandarin orange and soybean. Polyphenol oxidase purified from burdock was estimated to have a molecular weight of about 41,000 and 40,000 by gel filtration and SDS-PAGE, respectively (Han et al. 2006). The purified enzyme quickly oxidised chlorogenic acid and (–)-epicatechin. The optimum pHs were 5.0 for chlorogenic acid oxidase (ChO) and 8.0 for (–)-epicatechin oxidase (EpO).

The weight loss of burdock was as high as 60 % of fresh weight when corrugated cardboard cartons were used for storage at 20 °C (Ishimaru et al. 2004). However, polyethylene bag packaging or low-temperature storage resulted in lower levels of weight loss (less than 30 %). There was a significant decline in sugar content during storage at 8 and 20 °C, corresponding to an increased production of white solids. The fructan composition of raw burdock roots decreased faster to about 60 % after storage for 30 days at 2 °C than at other storage temperatures (to about 30 %). Inulinase activity in burdock roots stored at 2 °C was higher than those stored at 8 and 20 °C. The storage of burdock roots in polyethylene film packaging for 30 days at 2 °C was suitable to prevent the formation of muddy precipitate in processed burdock sticks.

Leaf Phytochemicals

Nutritional composition of burdock leaves was more superior in the leaves than in the petioles (Itabashi and Takamura 1985).

Ten compounds, namely, eremophilene, fukinone, petasitolone, fukinanolide, β -eudesmol, taraxasterol and its esters, acetate and palmitate, including two new sesquiterpenes dehydrofukinone and arctiol, were isolated from burdock leaves (Naya et al. 1972). Dehydrofukinone and arctiol were confirmed to be $\Delta^{9(10)}$ -fukinone and 8 α -hydroxyeudesmol, respectively. Burdock leaves contained triterpene alcohols α -amyrin, β -amyrin, lupeol, phytol, taraxasterol and ω -taraxasterol in free and esterified state as well as sterols stigmasterol and sitosterol (Yochkova et al. 1989). A sesquiterpene lactone onopordopicrin was isolated from burdock leaves (Barbosa-Filho et al. 1993). Two sesquiterpene lactones arctiopocrin and onopordopicrin were isolated from the juice of fresh burdock leaves (Savina et al. 2006). Compounds isolated from burdock leaves were onopordopicrin, dehydromelitensin-8-(4'-hydroxymethacrylate), dehydromelitensin, melitensin, dehydrovomifoliol and loliolide (Machado et al. 2012).

Lignans, arctiin and artigenin were isolated from the leaves (Liu et al. 2005a). Phenolic acids, quercetin, quercitrin and luteolin in burdock leaves were reported for the first time (Ferracane et al. 2010). The phenolic compounds identified in various burdock leaf fractions were chlorogenic acid, *o*-hydrobenzoic acid, caffeic acid, *p*-coumaric acid and rutin (Lou et al. 2010a); benzoic acid and *p*-coumaric acid (Lou et al. 2010c). Two triterpenoids, characterised as 3 α -hydroxylanosta-5,15-diene and 3 α -acetoxy-hop-22(29)-ene. 3 α -hydroxylanosta-5,15-diene, were isolated from the leaves (Jeelani and Khuroo 2012). High amount of pectic substances about 1.9 % per wet mass (about 21 % of dry mass) was detected in the leaf stems of burdock (Mkrtchian et al. 1998). The uronide component of burdock pectin was 66 %, esterification rate 47 %, methoxyl component 9 %, equivalent weight 343 and free carboxyl group content 16 %.

The volatile constituents from the leaves showed 19 identified compounds, the major being caryophyllene oxide (54.2 %), followed by β -elemene (6.2 %) and β -costol (4.03 %) (Aboutabl et al. 2013). Other components included hexacosane 2.67 %, β -copaen-4 α -ol 2.06 %, nonadecane 1.77 %, γ -cadinene 1.70 %, eicosane 1.48 %, pentadecane 1.43 %, tetracosane 1.27 %, tetradecane 0.75 %, nonanal 0.72 %, docosane 0.64 %, α -pinene 0.50 %, heptacosane 0.46 %, limonene 0.23 %, carvomenthone 0.11 %, *trans*- β -farnesene 0.1 % and pentacosane 0.09 %.

The enzyme preparation from burdock petioles catalysed the enantioselective formation of (+)-secoisolariciresinol from coniferyl alcohol in the presence of NADPH and H₂O₂ (Umezawa and Shimada 1996). The (+)-enantiomer of secoisolariciresinol was the predominant antipode of secoisolariciresinol isolated from burdock petioles.

Boldizsár et al. (2010) reported that upon acidic hydrolysis the dibenzylbutyrolactone-type lignans (arctiin, arctigenin, methylarctigenin, matairesinoside, matairesinol) were stable, while the diphenylperhydrofurotetrahydrofurane-type lignans (phylligenin, pinoresinol) decomposed. The fragment species of the derivatised lignan glycosides, in the presence of excess hexamethyldisilazane, led to their in situ derivatisation. The distribution of the lignan constituents was presented for five *Arctium*, for eight *Centaurea* and for four *Forsythia* plant extracts: the total of lignan contents varied between 0.42 and 87.9 mg/g, respectively.

Fruit/Seed Phytochemicals

The following lignans were isolated from burdock seeds: lappaols A and B (Ichihara et al. 1976); lappaols C, D and E (Ichihara et al. 1977); lappaols F and H (Ichihara et al. 1978); and lappaols A and F (Ichihara et al. 1979). Five compounds identified as daucosterol, arctigenin, arctiin, matairesinol and lappaol F and a new lignan named neoarctin were isolated from burdock seeds (Wang and Yang 1993). Neoarctin A (Wang and Yang 1995) and six compounds daucosterol, arctigenin, arctiin, matairesinol, lappaol F including a new lignan named neoarctin B were isolated from burdock seeds (Wang and Yang 1993). Cell-free extracts from ripening seeds of *Arctium lappa* catalysed the enantioselective formation of (–)-pinoresinol, (–)-lariciresinol and (–)-secoisolariciresinol from achiral coniferyl alcohol in the presence of NADPH and H₂O₂ (Suzuki et al. 1998, 1999). The enantioselectivity of the lignan formation was opposite to that of the (+)-secoisolariciresinol formation catalysed by cell-free extracts from petioles of the same plant species. The petiole enzyme preparation catalysed the formation of (+)-pinoresinol (33 % e.e.), (+)-lariciresinol (30 % e.e.), and (+)-secoisolariciresinol (20 % e.e.) from achiral coniferyl alcohol in the presence of NADPH and H₂O₂, whereas that from ripening seeds catalysed the formation of (–)-pinoresinol (22 % e.e.), (–)-lariciresinol (>99 % e.e.) and (–)-secoisolariciresinol (38 % e.e.) under the same conditions (Suzuki et al. 2002). In addition, the ripening seed enzyme preparation mediated the selective formation of the optically pure (>99 % e.e.) (–)-

enantiomer of matairesinol from racemic (+/-)-secoisolariciresinols in the presence of NADP.

A novel lignan, diartigenin, with the structure bis-5',5'-arctigenin, together with the known butyrolactone derivatives, arctigenin and arctiin, was isolated from burdock seeds (Han et al. 1994). Arctigenin, major burdock lignin, with the systematic name (3*R-trans*)-4-[(3,4-dimethoxyphenyl) methyl]-3-[(4-hydroxy-3-methoxyphenyl) methyl]-4,5-dihydrofuran-2(3*H*)-one, was found to have dibenzylbutyrolactone skeleton (Gao et al. 2008).

Seven compounds, β -sitosterol, daucosterol, lappaol C, lappaol A, arctignan E, lappaol F and arctiin, were isolated from burdock seed methanol extract (Dong et al. 2004). The occurrence of some phenolic acids (caffeic acid, chlorogenic acid and cynarin) was detected in burdock seeds (Ferracane et al. 2010). A new lignan neoarctin A, together with nine known compounds, matairesinol; arctiin; lappaols A, E, F and H; and arctignans A, G and H, was obtained from the ethanolic extract of burdock seeds (Yong et al. 2007). The contents of arctiin and arctigenin in burdock seed samples were 53.7 and 9.7 mg/g (0.5 and 0.1 %) of dry sample, respectively (Kravtsova and Khasanov 2011). The fatty acid esters determined as normalised per cent of the total of all identified esters were (% GC-MS) 14:0, tr.; 16:1, tr.; 16:0, 6.8; 18:0, 3.5; 18:1(9), 26.7; 18:1(12), 1.6; 18:2, 60.3; 20:0, 0.7; 22:0, 0.3; and 24:0, 0.2 %. Linoleic acid (18:2) had the greatest per cent content. Small amounts of myristic (14:0) and palmitoleic (16:1) acids were also observed. 12-Octadecenoic acid (18:1) and the three acids 20:0, 22:0 and 24:0 were detected for the first time in burdock seed.

Three lignan compounds, namely, 3'-demethyl arctigenin, arctigenin and arctigenin glucoside, were isolated from the seed (Kamkaen et al. 2006). A new butyrolactone sesquilignan, isolappaol C, together with two known sesquilignans lappaol C and lappaol D and two known dilignans lappaol F and diartigenin, was isolated from the methanolic extract of the seeds (Park et al. 2007). Seeds (dry samples) were found to contain mainly arctiin 53.7 mg/g and arctigenin mg/g and also fatty acid esters determined as 14:0 (myristic acid) traces, 16:0 (palmitic acid) 6.8 %, 18:0 (stearic acid) 3.5 %, 16:1 (palmitoleic acid) traces, 18:1 (n9) (9-octadecenoic acid) 26.7 %, 18:1 (n12) (12-octadecenoic acid) 1.6 %, 18: 2 (linoleic acid) 60.3 %, 20:0 (arachidic acid) 0.7 %, 22:0 (behenic acid) 0.3 % and 24:0 (lignoceric acid) 0.2 % (Kravtsova and Khasanov 2011). Phenolic compounds arctigenin; arctiin; chlorogenic acid; 4,5-dicaffeoylquinic acid; 3,5-dicaffeoylquinic acid; 3,4-dicaffeoylquinic

acid; matairesinol; isolappaol A; lappaol F; and lappaol B, together with 1:1 mixtures of isolappaol C and lappaol C, arctignan E and arctignan D and isolappaol A and lappaol A, were isolated from burdock seeds, while 3,3',4'-tri-*O*-demethylarctigenin, 3,3'-di-*O*-demethyl-4'-dehydroxyarctigenin and 3-*O*-demethylarctigenin were obtained by anaerobic microbiological metabolism of arctigenin (Tezuka et al. 2013). A total of 14 lignans were identified in burdock seeds and 12 caffeoylquinic acids in burdock roots (Liu et al. 2012). High levels of caffeoylquinic acids were also detected in burdock seeds, but only trace amounts of lignans were found in burdock roots. Burdock seeds contained higher concentrations of lignans and caffeoylquinic acids than burdock roots.

After anaerobic incubation of arctiin from burdock seeds with a human faecal suspension, six metabolites were formed, and their structures were identified as (–)-arctigenin, (2*R*,3*R*)-2-(3',4'-dihydroxybenzyl)-3-(3'',4''-dimethoxybenzyl) butyrolactone, (2*R*,3*R*)-2-(3'-hydroxybenzyl)-3-(3'',4''-dimethoxybenzyl) butyrolactone, (2*R*,3*R*)-2-(3'-hydroxybenzyl)-3-(3''-hydroxy-4''-methoxybenzyl) butyrolactone, (2*R*,3*R*)-2-(3'-hydroxybenzyl)-3-(3'',4''-dihydroxybenzyl) butyrolactone and (2*R*,3*R*)-2-(3'-hydroxybenzyl)-3-(3''-hydroxybenzyl)butyrolactone or (–)-enterolactone (Xie et al. 2003).

The volatile oil from burdock seeds yielded 22 compounds, representing 80.4 % of the total composition (Aboutabl et al. 2013). The major compound was *E*-citral (28.8 %), followed by geraniol (20.3 %) and *Z*-citral (9.5 %). Other components were β-elemene 3.02 %, β-myrcene 2.82 %, methyl oleate 2.58 %, octadecanoic acid methyl ester 2.23 %, hexacosane 2.36 %, squalene 1.50 %, linalool 1.12 %, aromadendrene 0.76 %, eicosane 0.34 %, γ-cadinene 0.33 %, ethyl oleate 0.27 %, thymol 0.26 %, nonanal 0.23 %, methyl palmitate 1.59 %, β-costol 1.36 %, β-copaen-4α-ol 0.43 %, caryophyllene oxide 0.15 %, pentacosane 0.09 % and limonene 0.03 %.

Burdock fruit contained fatty oil, lappaurin (a yellow compound), arctiin (bitter glycosidic principle) and lappanaesthin (an anaesthetic substance) (List and Hörhammer 1972; Hoppe 1975). Two new sesquilignan derivatives, AL-D and AL-F, along with arctiin, arctigenin and matairesinol, were isolated from burdock fruit (Yamanouchi et al. 1976). AL-D was elucidated as 2-[2-(3-methoxy-4-hydroxy) phenyl-3-hydroxy-methyl-7-methoxy-2,3-dihydrobenzofuran-5-yl] methyl-3-(3-methoxy-4-hydroxy)-benzyl-butyrolactone or 2-(3-methoxy-4-hydroxy) benzyl-3-[2-(3-

methoxy-4-hydroxy)-phenyl-3-hydroxymethyl-7-methoxy-2,3-dihydro-benzofuran-5-yl] methyl-buthyrolactone. AL-F was found to be a stereoisomer of AL-D. Arctiin was isolated from the burdock fruit and then enzymolyzed into arctigenin (Sun et al. 1992). From the fruit, (+)-7,8-didehydroarctigenin, together with the known lignans (–)-arctigenin and (–)-matairesinol, was isolated (Matsumoto et al. 2006). The concentration range of 0.010–5.0 µg/mL for arctiin and 0.025–7.5 µg/mL for arctigenin was determined in burdock fruit (Liu et al. 2010). The recoveries were between 74.4 and 100 %. Two new neolignan glucosides named (7*S*,8*R*)-4,7,9,9'-tetrahydroxy-3,3'-dimethoxyl-7'-oxo-8-4'-oxyneolignan-4-*O*-β-d-glucopyranoside and (7'*S*,8'*R*,8*S*)-4,4',9'-trihydroxy-3,3'-dimethoxy-7',9-epoxylignan-7-oxo-4-*O*-β-d-glucopyranosyl-4'-*O*-β-D-glucopyranoside, together with two small molecular peptides named 3-benzyl-6-(1-hydroxyethyl)-2,5-piperazinedione and 3-benzyl-2,5-piperazinedione, were isolated from the burdock fruit extract (Yang et al. 2012).

Antioxidant Activity

The hydroethanolic extracts of burdock roots exhibited the strongest free radical scavenging activity, while the highest phenolic content was observed in Soxhlet extraction (Predes et al. 2011). The 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical scavenging activity and inhibition of Fe²⁺-induced lipid peroxidation of burdock ethanol extract significantly increased in a dose-dependent manner (Lee 2011). For DPPH, its IC₅₀ was 296 µg/assay (1.29 mg of dry sample) and Fe-induced lipid peroxidation inhibition IC₅₀ was 1,759 µg/assay (7.65 mg of dry sample). Burdock extract also significantly inhibited the MDA-BSA conjugation reaction with an IC₅₀ of 57.58 mg/assay (250 mg of dry sample). It exerted no inhibitory effects against the direct and indirect mutagenicities in *Salmonella typhimurium* TA98 and TA100.

Studies showed that *A. lappa* root extract possessed free radical scavenging activity (Lin et al. 1996). The IC₅₀ of *A. lappa* extract on superoxide and hydroxyl radical scavenger activity was 2.06 and 11.8 mg/mL, respectively. Another in-vitro study confirmed that burdock roots possessed significant antioxidant activities both free radical and active oxygen scavenging activities (Duh 1998). Of the solvents used for extraction, water yielded the greatest amount of extract that exhibited the strongest antioxidant activity. Results revealed that water extracts of burdock (WEB) and hot water extracts

of burdock (HWEB) were also active as oxygen scavengers and as secondary antioxidants. WEB and HWEB exhibited an 80 % scavenging effect on 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical and marked reducing power, indicating that WEB and HWEB act as primary antioxidants. Both extracts at a dose of 1.0 mg exhibited a 60.4–65.0 % scavenging effect on superoxide and an 80.5 % scavenging effect on hydrogen peroxide. They also showed a marked scavenging effect on the hydroxyl radical. Another study showed that burdock root possessed significant DPPH free radical scavenging activity, which was mainly attributed to chlorogenic acid, whose free radical scavenging activity was similar to that of caffeic acid and higher than that of vitamin E (Chen et al. 2004). Peeling of the root greatly decreased the free radical scavenging activity and the concentrations of these two active phenolic components, due to elimination of the components in the discarded skin. Heat treatment slightly decreased the free radical scavenging activity, which was partially due to the degradation of chlorogenic acid. Dos et al. (2008) reported that the chloroform burdock root extract (250 µg/mL) and an active fraction B (100 and 250 µg/mL) exhibited free radical scavenging ability, inhibiting DPPH radical activity by 50 %, 20 % and 55 %, respectively. The DPPH radical scavenging activity of the burdock ethanol and hot water extracts after gamma irradiation were 54.56 and 59.21 % at 500 ppm, respectively, and the lipid oxidation of oil emulsion was delayed by the addition of the extracts (Lee et al. 2010).

In-vitro antioxidant assays demonstrated that a water-soluble polysaccharide (ALP1) from burdock root possessed moderate ABTS(+) scavenging activity, strong hydroxyl radical scavenging activity and strong ferrous ion-chelating activity (Liu et al. 2014). In in-vivo antioxidant assays, ALP1 administration significantly enhanced antioxidant enzyme activities and total antioxidant capacity, as well as decreased the levels of malondialdehyde (MDA) in both the serum and liver of ageing mice.

The metabolite 3'-desmethyларctigenin (3'-DMAG) transformed from arctiin or arctigenin by human intestinal bacterium named *Blautia* sp. AUH-JLD56 showed significantly higher 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical scavenging activity than that of the substrate arctigenin at the concentrations tested (Liu et al. 2013).

Five caffeoylquinic acid derivatives, 1-*O*-,5-*O*-dicaffeoylquinic acid (1), 1-*O*-,5-*O*-dicaffeoyl-3-*O*-succinylquinic acid (2), 1-*O*-,5-*O*-dicaffeoyl-4-*O*-succinylquinic acid (3), 1-*O*-,5-*O*-dicaffeoyl-3-*O*-,4-*O*-disuccinylquinic acid (4) and 1-*O*-,3-*O*-, 5-*O*-tricaffeoyl-4-*O*-

succinylquinic acid (5) isolated from the root, showed antioxidant activity as measured in a hexane/2-propanol solution of methyl linoleate in the presence of a radical initiator (Maruta et al. 1995). The antioxidative efficiency was in the order of α -tocopherol < chlorogenic acid < caffeic acid < (1) = (2) = (3) = (4) < 5.

Polysaccharides isolated from *Arctium lappa* var. *Herkules* were reported to inhibit peroxidation of soybean lecithin liposomes by OH radicals (Kardosová and Machová 2006). Of all the fractions of burdock leaf, the ethyl acetate fraction (EAF) exhibited the highest antioxidant activity (Lou et al. 2010a). Although tertiary butylhydroquinone (TBHQ) exhibited higher lipid peroxidation inhibitory activity than EAF, the reducing power, superoxide anion scavenging capability and DPPH radical and hydroxyl radical scavenging ability of EAF were higher than those of synthetic antioxidant (TBHQ). Furthermore, a synergistic antioxidant effect between EAF and TBHQ was first demonstrated by isobolographic analysis, indicating that EAF markedly enhanced the antioxidant efficiency of TBHQ.

TEAC values and total phenolic content for hydroalcoholic extracts of burdock seeds, leaves and roots ranged from 67.39 to 1.63 μ mol Trolox equivalent/100 g dry weight (DW) and from 2.87 to 45 g of gallic acid equivalent/100 g DW, respectively (Ferracane et al. 2010). The main compounds of burdock extracts were caffeoylquinic acid derivatives, lignans (mainly arctiin) and various flavonoids.

Anticancer Activity

The dichloromethane extracts of burdock roots showed selective antiproliferative activity against K562, MCF-7 and 786-0 human cancer cell lines (Predes et al. 2011). In an earlier study, dichloromethane-soluble extract of *Arctium lappa* exhibited 100 % preferential cytotoxicity under the nutrient-deprived condition at a concentration of 50 μ g/mL with virtually no cytotoxicity under nutrient-rich condition, and the active principle isolated arctigenin (Awale et al. 2006). The human colon cancer HT29 cell viability was inhibited by burdock ethanol extract after gamma irradiation with up to 52.45 % at a 250 ppm level (Lee et al. 2010). Burdock root ethanol extract exhibited antileukaemic properties, inducing cell death of J-45.01 human acute T-cell leukaemia via apoptosis (Wegiera et al. 2012). Burdock root extract exhibited marked cytotoxic effect on the human erythroleukaemia cell line (K562) cell line and lymphocyte cells (Khakdan et al. 2013). Burdock root extract exhibited marked cytotoxic effect on the human

erythroleukaemia (K562) cell line and lymphocyte cells (Khakdan et al. 2013).

Artigenin, from burdock fruit, was the most active lignin showing differentiation inducing activity against mouse myeloid leukaemia M1 cells at a concentration of 0.5 μM (Umehara et al. 1996a, b). Its aliphatic esters were more effective in inducing the differentiation of M1 cells than its aromatic esters. Especially, n-decanoate, which was the most active derivative, induced more than half of the M1 cells into phagocytic cells at a concentration of 2 μM . Of the three new dilignans isolated, arctignans G and H showed activities at 50–100 μM , whereas arctignan F showed only slight activity at these concentrations. Two active sesquilignans, lappaol E and arctignan A (an isolated of lappaol E), were found to possess the highest differentiation activities among the sesquilignans tested. Sesquilignans were less effective than lignans and dilignans showed even weaker activity. These lignoids were inactive towards a human acute promyelocytic leukaemia cell line (HL-60).

Arctigenin was found to be a potent inducer of apoptosis of human leukaemia HL-60 and K562 cells, modulated via caspase-3 activation and upregulation of Bax/Bcl-2 (Wang et al. 2008). Arctigenin significantly suppressed both constitutively activated and IL-6-induced STAT3 phosphorylation and subsequent nuclear translocation in cancer cells (Yao et al. 2011). Arctigenin dramatically promoted cisplatin-induced cell death in cancer cells, indicating that arctigenin enhanced the sensitivity of cancer cells to cisplatin mainly via STAT3 suppression.

The (–)-arctigenin, from burdock fruit, and its synthesised derivatives showed anticancer activity (Chen et al. 2012). A series of new (–)-arctigenin derivatives with variably modified O-alkyl groups exhibited were synthesised and their preferential cytotoxicity against human pancreatic cancer cell line PANC-1 under nutrient-deprived conditions (Kudou et al. 2013). The results showed that monoethoxy derivative 4i, diethoxy derivative 4 hours and triethoxy derivative 4 m showed the preferential cytotoxicities under nutrient-deprived conditions, which were identical to or more potent than (–)-arctigenin. In a mouse xenograft model, triethoxy derivative 4 m exhibited antitumour activity with the potency identical to or slightly more than (–)-arctigenin.

Arctigenin from burdock fruit appeared to be a new suppressive regulator of heat shock response (the activation of heat shock transcription factor, the induction of mRNA and the synthesis and accumulation of heat shock proteins) in mammalian cells and may be

useful for hyperthermia cancer therapy (Ishihara et al. 2006). Arctigenin exhibited 100 % preferential cytotoxicity against nutrient-deprived cells at a concentration of 0.01 µg/mL. Arctigenin was also found to strongly suppress the PANC-1 tumour growth in nude mice, as well as the growth of several of the tested pancreatic cancer cell lines. Arctigenin blocked the activation of Akt induced by glucose starvation, a key process in the tolerance exhibited by cancer cells to glucose starvation. Purification of the selective cytotoxicity in burdock extract resulted in the identification of arctigenin as tumour-specific agent that showed cytotoxicity to human lung adenocarcinoma (A549), liver cancer (HepG2) and stomach cancer (KATO III) cells, with no cytotoxicity to several normal cell lines (Susanti et al. 2012). Arctigenin specifically inhibited the proliferation of cancer cells, which might consequently lead to the induction of apoptosis. Ethanol (70 %) burdock fruit extract showed potent antiproliferative activity against B-cell hybridoma cell line, MH60 (Matsumoto et al. 2006). Of its active components, (–)-arctigenin showed the most potent antiproliferative activity against MH60 cells via apoptosis (IC₅₀, 1.0 µM). The anaerobic metabolite of arctiin, (2R,3R)-2-(3'-hydroxybenzyl)-3-(3'',4''-dihydroxybenzyl) butyrolactone, showed the most potent proliferative effect on the growth of MCF-7 human breast cancer cells in culture among 1 and 6 metabolites, while it showed inhibitory activity on estradiol-mediated proliferation of MCF-7 cells at a concentration of 10 µM (Xie et al. 2003). A retrospective cohort study in 510 women was conducted by Zick et al. (2006) to ascertain the effect of Essiac (a medicinal blend of burdock root, *Arctium lappa*, Indian rhubarb *Rheum palmatum*, sheep sorrel *Rumex acetosella* and the inner bark of slippery elm *Ulmus fulva* or *Ulmus rubra*) in women with breast cancer. Essiac has become one of the most popular herbal remedies for breast cancer treatment, secondary prevention, improving quality of life and controlling negative side effects of conventional breast cancer treatment. The study showed that Essiac did not appear to improve health-related quality of life (HRQOL) or mood states.

Studies demonstrated that arctigenin selectively promoted glucose-starved A549 tumour cells to undergo necrosis by inhibiting mitochondrial respiration (Gu et al. 2012a). In doing so, arctigenin elevated cellular level of reactive oxygen species (ROS) and blocked cellular energy metabolism in the glucose-starved tumour cells. It was also demonstrated that cellular ROS generation was caused by intracellular ATP depletion and played an essential role in the arctigenin-induced tumour cell death under the glucose-limiting condition. Further, the combination of arctigenin with the glucose

analogue 2-deoxyglucose (2-DG) displayed preferential cell death-inducing activity against tumour cells compared to normal cells. Among the compounds isolated from burdock seeds and anaerobic metabolites, arctigenin and 3-*O*-demethylarctigenin (a metabolite) showed potent activity against human pancreatic cancer PANC-1 cells, with PC₅₀ values of 1.75 and 4.38 μ M, respectively, while matairesinol, lappaol B and 3,3'-di-*O*-demethyl-4'-dehydroxyarctigenin (metabolite) showed mild activity with PC₅₀ values of 31.1, 30.9 and 38.7 μ M, respectively (Tezuka et al. 2013). The proliferation of human gastric cancer cell line SNU-1 and AGS cells was significantly inhibited by arctigenin in a time- and dose-dependent manner (Jeong et al. 2011). Inhibition of cell proliferation by arctigenin was in part associated with apoptotic cell death. Also, arctigenin blocked cell cycle arrest from G₁ to S phase by regulating the expression of cell cycle regulatory proteins such as Rb, cyclin D1, cyclin E, CDK4, CDK2, p21Waf1/Cip1 and p15INK4b.

Arctigenin from burdock selectively arrested the proliferation of lung adenocarcinoma cells at the G₀/G₁ phase through the downregulation of NPAT protein expression (Susanti et al. 2013). This downregulation occurred via the suppression of either cyclin E/CDK2 or cyclin H/CDK7, while apoptosis was induced through the modulation of the Akt-1-related signalling pathway. Furthermore, a glutathione synthetase inhibitor specifically enhanced the cytotoxicity of arctigenin against the cancer cells. Arctigenin induced apoptosis of oestrogen receptor-negative human breast cancer MDA-MB-231 cells via the ROS/p38 MAPK pathway and epigenetic regulation of Bcl-2 by the upregulation of histone H3K9 trimethylation (Hsieh et al. 2014). Arctigenin treatment resulted in a significant and dose-dependent inhibition of human ovarian cancer OVCAR-3 and SKOV3 cell proliferation (Huang et al. 2014). Arctigenin-treated cells showed a four- to sixfold increase in the percentage of caspase-3-dependent apoptosis, compared to control cells. Arctigenin treatment significantly inhibited STAT3 phosphorylation and survivin and iNOS expression.

The methanolic extract of burdock seeds exhibited inhibitory activity against prostate cancer cell lines (Ming et al. 2004). Some of its bioactive compounds lappaol C, lappaol A and lappaol F also exhibited inhibitory activity against the LNCaP prostate cancer cell line with IC₅₀ values of 8, 16 and 40 μ g/mL, respectively. However, Zeng et al. (2005) found that arctiin may not exert significant modifying effect on prostate carcinogenesis in probasin/SV40 T antigen transgenic rats.

Arctiin from burdock seeds, exerted a protective effect on 2-amino-1-methyl-6-phenylimidazo [4,5-b] pyridine (PhIP)-induced mammary carcinogenesis in female Sprague-Dawley rats in the promotion period (Hirose et al. 2000). Contrariwise, arctiin may have a weak cocarcinogenic influence on 2-amino-3,8-dimethylimidazo [4,5-f] quinoxaline (MeIQx)-associated hepatocarcinogenesis in male rats. In addition, the results suggested that PhIP was a weak pancreatic carcinogen in female SD rats, targeting acinar cells. Matsuzaki et al. (2008) found that arctiin induced growth inhibition and dephosphorylated the tumour-suppressor retinoblastoma protein in human immortalised keratinocyte (HaCaT) cells by downregulation of cyclin D1 protein expression. The arctiin-induced suppression of cyclin D1 protein expression also occurred in various types of human tumour cells, including osteosarcoma; lung, colorectal, cervical and breast cancer; melanoma, transformed renal cells; and prostate cancer.

Lappaol F from burdock suppressed cancer cell growth in a time- and dose-dependent manner in human cancer cell lines of various tissue types by inducing G1 and G2 cell cycle arrest which was associated with strong induction of p21 and p27 and reduction of cyclin B1 and CDK1 (Sun et al. 2014). In contrast to its strong growth-inhibitory effects on tumour cells, lappaol F had minimal cytotoxic effects on non-tumorigenic epithelial cells tested. Also, it was demonstrated that lappaol F exhibited strong growth inhibition of xenograft tumours in nude mice. Lappaol F was well tolerated in treated animals without significant toxicity.

Crude extract (CE), ethyl acetate fraction (EAF) of burdock leaves and onopordopicrin compound isolated from burdock leaves exhibited in-vitro antiproliferative activity in human tumour cell line Caco-2 (Mello et al. 2010). The results of CC₅₀ in Caco-2 cells were 347.6 µg/mL, 24.7 µg/mL and 19.8 µg/mL for CE, EAF and onopordopicrin, respectively. Burdock leaf compounds tested in Caco-2 tumour cells showed antiproliferative activity with the following CC₅₀ (µg/mL) values: onopordopicrin, 19.7 µg/mL; onopordopicrin with dehydromelitensin-8-(4'-hydroxymethacrylate), 24.6 µg/mL; dehydromelitensin-8-(4'-hydroxymethacrylate) with dehydromelitensin, 27 µg/mL; onopordopicrin with melitensin, 42 µg/mL; and loliolide 30 µg/mL (Machado et al. 2012). Compound dehydrovomifoliol showed no activity.

Antimutagenic Activity

A desmutagenic factor with molecular weight of >300,000 and polyanionic characteristics, isolated from burdock, reduced the mutagenicity of mutagens that were active without metabolic activation, such as 4-NO₂-1,2-DAB and 2-NO₂-1,4-DAB, as well as mutagens such as ethidium bromide, 2-aminoanthracene, Trp-P-1 and Trp-P-2 requiring S9 for metabolic activation (Morita et al. 1984). It is resistant to heat and proteolytic enzymes and sensitive to treatment with MnCl₂. The antimutagenicity against 3-amino-1,4-dimethyl-5H-pyrido[4,3-b]indole and 2-nitrofluorene was also found for burdock ethanol extract after gamma irradiation (Lee et al. 2010).

Antimicrobial Activity

The ethyl acetate fraction of *A. lappa* inhibited the growth of endodontic microorganisms *Pseudomonas aeruginosa*, *Escherichia coli*, *Lactobacillus acidophilus*, *Streptococcus mutans* and *Candida albicans* in-vitro (Gentil et al. 2006). Antimicrobial activity of extracts from leaves of burdock exhibited a great microbial inhibition potential against the tested endodontic pathogens: *Enterococcus faecalis*, *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Bacillus subtilis* and *Candida albicans* (Pereira et al. 2005). The data from minimum inhibitory concentration (MIC) values showed that ethyl acetate (EF), *n*-butanol (BF) and water (WF) fractions of burdock leaves effectively inhibited the growth of all test food-borne bacterial pathogens (*Staphylococcus aureus*, *Streptococcus pneumoniae*, *Bacillus subtilis*, *Escherichia coli*, *Shigella dysenteriae* and *Salmonella typhimurium*), the antibacterial activity of EF being much greater than BF and WF. The time–kill study indicated that EF exhibited significant bactericidal activity against all the six pathogens. For all the fractions, the antibacterial capacity had a significant correlation with total phenolic content, suggesting that the activities were probably due to the combined action of phenolic compounds. Two purified active phenolic compounds (chlorogenic acid, rutin) were obtained and identified.

Burdock extract was microbicidal for *Staphylococcus aureus*, *Staphylococcus epidermidis*, *Streptococcus mutans*, *Candida albicans*, *Candida tropicalis* and *Candida glabrata* in planktonic cultures, microbiostatic for biofilms and not cytotoxic to the macrophages (RAW 264.7) (de Oliveira et al. 2014).

The volatile constituents of burdock leaves and roots showed weak to moderate antimicrobial activity against bacteria (*Escherichia coli* and *Bacillus subtilis*) and higher antifungal activity (*Candida albicans* and *Aspergillus niger*) in comparison with the standards

used (Aboutabl et al. 2013). The volatile constituents of the seeds showed moderate antimicrobial activity against bacteria and weak activity against fungi. The volatile constituents of the leaves and the roots show a minimum inhibitory concentration of 250 $\mu\text{L/mL}$ against the two fungi which were lower than that of the standard, Flucoral 1,000 $\mu\text{L/mL}$.

Antiviral Activity

Arctigenin at the concentration of 100 $\mu\text{g/kg}$ and 10 $\mu\text{g/kg}$ for the intranasal treatment markedly inhibited the lung consolidation of mice pneumonia caused by the infection of influenza virus (Yang et al. 2005). Arctigenin at the concentration of 100 $\mu\text{g/kg}$ prolonged the survival time of mice infected with influenza virus. Arctiin and its aglucone, arctigenin from burdock fruits, exhibited potent in-vitro antiviral activities against influenza A virus (IFV) (Hayashi et al. 2010). Arctiin was orally effective against either IFV-inoculated normal or 5-fluorouracil (5-FU)-treated mice, being less effective as compared with oseltamivir. Arctiin produced a larger amount of virus-specific antibody than those of control and oseltamivir in sera collected from 5-FU-treated mice. Further, oral treatment of 5-FU-treated mice with arctiin did not induce any resistant viruses, although the same treatment with oseltamivir induced resistant viruses at a 50 % frequency. When the combination of arctiin and oseltamivir was administered to normal mice infected with IFV, the virus yields in both bronchoalveolar lavage fluids and lungs were significantly reduced relative to those in the mice treated with arctiin or oseltamivir alone.

Prebiotic Activity

Burdock inulin (B-INU) significantly stimulated the growth of Bifidobacteria in Man–Rogosa–Sharp medium, anaerobically (Li et al. 2008). Compared with chicory inulin (C-INU), long-chain inulin (L-INU) and fructooligosaccharides (FOS), 1 % (w/v) B-INU promoted the specific growth rate of beneficial bacteria. In-vivo, B-INU significantly increased the number of lactobacilli and bifidobacteria in caecal content. Mice fed with B-INU, C-INU and FOS for 14 days had greater number of caecal beneficial bacterial population than those fed with L-INU for 14 days. Additionally, all fructans did not cause any side effects, such as eructation and bloating. Results indicated that inulin extracted from edible burdock showed prebiotic properties that could promote health.

Anti-inflammatory Activity

Subcutaneous administration of *A. lappa* root crude extract significantly decreased carrageenin-induced rat paw oedema. When simultaneously treated with CCl₄, it produced pronounced activities against CCl₄-induced acute liver damage (Lin et al. 1996). Cho et al. (2004) reported that arctigenin inhibited phosphorylation of MAP kinases ERK1/ERK2, p38 kinase and JNK and their activities in RAW 264.7 cells treated with lipopolysaccharide (LPS). Arctigenin potently inhibited the activity of MKK1 in-vitro with the IC₅₀ value of 1 nM. Additionally, arctigenin blocked TNF- α production and decreased the level of TNF- α mRNA in the cells exposed to LPS. The results showed that arctigenin inhibited the activation of MAP kinases including ERK1/ERK2, p38 kinase and JNK through the inhibition of MKK activities, leading to AP-1 inactivation, thus partially contributing to the inhibition of TNF- α production. Kim et al. (2008) demonstrated that diartctigenin from burdock seeds inhibited the production of NO, prostaglandin E₂, tumour necrosis factor-alpha and interleukin (IL)-1beta and IL-6 with IC₅₀ values of 6–12 μ M in zymosan- or lipopolysaccharide (LPS)-activated macrophages. Diartctigenin attenuated zymosan-induced mRNA synthesis of inducible NO synthase (iNOS) and also inhibited promoter activities of iNOS and cytokine genes in the cells. The results showed that diartctigenin downregulated zymosan- or LPS-induced inflammatory gene transcription in macrophages by direct inhibition of the DNA-binding ability of NF- κ B. Lignans lappaol F and diartctigenin, from burdock seeds, strongly inhibited NO production in the LPS-stimulated RAW 264.7 cells with IC₅₀ values of 9.5 and 9.6 μ M, respectively (Park et al. 2007).

In-vitro studies showed that methanolic extracts of burdock (MEB) and their major components, chlorogenic acid and caffeic acid, exhibited marked antioxidant activity against oxidative damage of liposome, deoxyribose and protein (Wang et al. 2007). At a concentration of 500 μ g/mL, the inhibitory effect of MEB on low-density lipoprotein oxidation was 66.9 % compared to the control. MEB, at 200 μ g/mL, not only enhanced glutathione (GSH) levels but also increased the activity of GSH reductase, GSH peroxidase, GSH transferase and catalase. MEB directly scavenged nitric oxide in a concentration-dependent fashion. Moreover, MEB showed a reducing effect on nitric oxide production of lipopolysaccharide (LPS)-induced RAW 264.7 cells and inhibited the expression of inducible nitric oxide synthase (iNOS) and cyclooxygenase-2 (COX-

2). The expression of iNOS and COX-2 mRNA in activated macrophages was suppressed by a high concentration (500 µg/mL) of MEB by downregulating NF-κB activation. The results suggested that MEB attenuated excessive NO generation at inflammatory sites as well as in cardiovascular disease.

Arctigenin, a lignan from *Arctium lappa* seeds, potently inhibited lipopolysaccharide (LPS)-stimulated NO production and proinflammatory cytokine secretion, including TNF-α and IL-6 in a dose-dependent manner in cultured macrophage RAW 264.7 cells and THP-1 cells (Zhao et al. 2009). Arctigenin also strongly suppressed the expression of iNOS and iNOS enzymatic activity, whereas the expression of COX-2 and COX-2 enzymatic activity was not affected by arctigenin. Arctigenin was found to inhibit type I–IV allergic inflammation and proinflammatory enzymes in-vitro and in-vivo (Lee and Kim 2010). Arctigenin significantly inhibited the heterologous passive cutaneous anaphylaxis induced by ovalbumin in mice and compound 48/80-induced histamine release from rat peritoneal mast cells. Arctigenin significantly inhibited reversed cutaneous anaphylaxis and the Arthus reaction to sheep's red blood cells, decreasing the haemolysis titre, the haemagglutination titre and the plaque-forming cell number for SRBCs. Additionally, arctigenin significantly inhibited delayed-type hypersensitivity and the formation of rosette-forming cells. Contact dermatitis induced by picryl chloride and dinitrofluorobenzene was significantly inhibited by surface treatment with arctigenin (0.3 mg/ear). Furthermore, arctigenin dose dependently inhibited proinflammatory enzymes, such as cyclooxygenase-1 and cyclooxygenase-2, 5-lipoxygenase, phospholipase A2 and phosphodiesterase.

Arctium lappa extract significantly reduced degranulation and biosynthesis of cys-leukotrienes of human basophils in peripheral blood mononuclear cells (PBMCs) with IC₅₀ of 8.3 and 11.4 µg/mL, respectively (Knipping et al. 2008). A fraction from the extract inhibited beta-hexosaminidase release (IC₅₀ = 22.2 µg/mL). Topical administration of an aqueous burdock extract (5 mg/ear) on the ear of whey-sensitised mice 4 hours before challenge with whey in the ear inhibited acute ear swelling by 50 % in an in-vivo cow's milk allergic model. Burdock seed ethanol extract ameliorated high-fat/high-cholesterol diet-induced vascular dysfunction in rats through protection of vascular relaxation and suppression of vascular inflammation (Lee et al. 2012). Treatment with low or high doses of burdock extract markedly attenuated plasma levels of triglycerides

and augmented plasma levels of high-density lipoprotein (HDL) in HFCD-fed rats. Chronic treatment with the extract markedly reduced impairments of acetylcholine (ACh)-induced relaxation of aortic rings, significantly lowered systolic blood pressure (SBP) and maintained smooth and flexible intimal endothelial layers in HFCD-fed rats. Chronic treatment with the extract suppressed upregulation of intercellular adhesion molecule (ICAM)-1, vascular cell adhesion molecule (VCAM)-1 and E-selectin in the aorta and also suppressed increases in matrix metalloproteinase (MMP)-2 expression.

Oral administration of lactone sesquiterpene onopordopicrin-enriched fraction (ONP fraction) from *Arctium lappa* exerted marked protective effects in acute experimental colitis induced by 2,4,6-trinitrobenzene sulfonic acid (de Almeida et al. 2013). ONP fraction (25 and 50 mg/kg) treatment significantly reduced the macroscopic inflammation scores and morphological alterations associated with an increase in the mucus secretion. Similarly, the degree of neutrophil infiltration and the cytokine levels were significantly ameliorated and COX-2 overexpression was reduced by ONP fraction. Arctigenin ameliorated inflammation in-vitro in lipopolysaccharide (LPS)-induced peritoneal macrophages and in-vivo in LPS-induced systemic inflammation as well as 2,4,6-trinitrobenzene sulfonic acid (TNBS)-induced colitis in mice by inhibiting the PI3K/AKT pathway and polarising M1 macrophages to M2-like macrophages (Hyam et al. 2013).

Intragastric administration of the herbal preparation comprising *Arctium lappa* roots, *Sophora japonica* fruits, *Acorus calamus* roots, *Urtica dioica* leaves and *Humulus lupulus* fruits reduced severity of the exudation phase of inflammation in the limbs of animals (37.3 %) and inhibited pulmonary oedema (21.0 %) (Galkin et al. 2013). The phytopreparation reduced the weight of the granulation–fibrous tissue by 50.6 %.

Anti-allergic Activity

Burdock treatment showed significant improvement in itching behaviour in NC/Nga mice induced by 2,4-dinitrofluorobenzene (DNFB) (Kim et al. 2010a). However, burdock treatment showed neither significant improvement on allergic dermatitis lesions nor in IL-4 and INF- γ measurement. Butanol burdock extract significantly inhibited β -hexosaminidase release in RBL-2H3 cells and suppressed mRNA expression and protein secretion of IL-4 and IL-5 induced by ConA-treated primary murine splenocytes (Sohn et al. 2011). Additionally, the extract (100 μ g/mL) suppressed not only the

transcriptional activation of NF- κ B but also the phosphorylation of MAPKs in ConA-treated primary splenocytes. The results supported the hypothesis that burdock extract may have beneficial effects in the treatment of allergic diseases, including atopic dermatitis.

Antihyperglycaemic/Antidiabetic Activity

Burdock methanol and ethyl acetate extracts exhibited an inhibitory activity of α -glucosidase (Miyazawa et al. 2005). The inhibitory compound isolated from the ethyl acetate extract was identified as sitosterol- β -D-glucopyranoside. It inhibited 97.3 % of α -glucosidase activity at a concentration of 200.0 μ mol/mL, and the ID₅₀ (50 % inhibition dose) value was 30 μ mol/mL. In addition, the inhibitory compounds from the ethyl acetate extract were also identified as methyl palmitate (2), methyl linoleate (3) and methyl linolenate (4) by GC-MS analysis. Compounds 2–4 inhibited 73.4 %, 66.5 % and 68.5 % of α -glucosidase activity at a concentration of 200 μ mol/mL, and the ID₅₀ values were 52.8, 47.5 and 46.7 μ mol/mL.

Arctigenin from burdock was found to be an effective endoplasmic reticulum (ER) alleviator, which protected cells against ER stress through activating AMPK, thus attenuating protein translation and reducing ER load (Gu et al. 2012b). ER stress had been linked to obesity and to be a central feature of peripheral insulin resistance and type 2 diabetes at the molecular, cellular and organismal levels (Ozcan et al. 2004).

Administration of total lignans from burdock fruit to alloxan-diabetic rats and mice for 10 days elicited significant reductions in plasma glucose, triglycerides and total cholesterol, and glucose tolerance, serum insulin level and HDL cholesterol were elevated without the risk of hypoglycaemia (Xu et al. 2008). Burdock is considered to be a source of inulin that is converted into fructose and short fructose chains that penetrate into the circulatory system upon entering the gastrointestinal tract (Azizov et al. 2012). The remaining uncleaved part of inulin and cellulose is capable of absorbing a significant amount of dietary glucose and preventing it from being assimilated into the blood. This helps to reduce the sugar level in the blood after meals. Study showed that total lignans from *Fructus Arctii* (TLFA) exerted significant hypoglycaemic potential in Goto-Kakizaki rats, a spontaneous type 2 diabetes animal model, via stimulation of insulin secretion, promoting the release of serum glucagon-like peptide-1 (GLP-1) and decreasing intestinal absorption of glucose (Xu et al. 2014).

Arctiin treatment of male Sprague-Dawley rats with streptozotocin-induced diabetic retinopathy significantly decreased glycosylated haemoglobin (HbA1c) level, and the serum glucose level was also decreased in the rats treated with the highest dose of arctiin (Lu et al. 2012). Further, treatment with arctiin ameliorated retinal oedema, detachment of the retina and VEGF expression in the retina. Also, arctiin increased the viability of retinal microvascular endothelial cells in-vitro.

Huang et al. (2012) reported that arctigenin activated muscle uptake of glucose and inhibited hepatocyte gluconeogenesis and lipogenesis by reducing mitochondrial respiration and inducing AMP-activated protein kinase (AMPK) activity. AMPK, a major regulator of energy homeostasis, had been known to be activated by different glucose-lowering agents. They found that arctigenin improved glucose and lipid metabolism in ob/ob mice. They thus suggested that arctigenin may represent a valuable lead compound for developing innovative glucose-lowering molecules.

Treatment with arctiin significantly decreased the levels of 24 hour urinary albumin, prevented the sclerosis of glomeruli and effectively restored the glomerular filtration barrier damage by upregulating the expression of nephrin and podocin and downregulating heparanase level in streptozotocin (STZ)-induced diabetic nephropathic rats (Ma et al. 2013).

Antiobesity Activity

Kuo et al. (2012) found that burdock root treatment significantly reduced body weight in rats. The active n-hexane root fraction contained components with the most effective hypolipidaemic potential in human hepatoma HepG2 cells. The fraction decreased the expression of fatty acid synthase (FASN) and inhibited the activity of acetyl-coenzyme A carboxylase (ACC) by stimulating AMP-activated protein kinase (AMPK) through the LKB1 pathway.

Consumption of the burdock and *Aspergillus awamori*-fermented burdock diets significantly elevated faecal IgA and mucins (indices of intestinal immune and barrier functions) and reduced faecal lithocholic acid (a risk factor for colon cancer) in rats fed a high-fat (HF) diet (Okazaki et al. 2013). The fermented burdock diet markedly elevated caecal *Bifidobacterium* and organic acids, including lactate, acetate, propionate and butyrate, and reduced faecal deoxycholic acid (a risk factor for colon cancer) and perirenal adipose tissue weight, but the burdock diet did not. The results

suggested that consumption of fermented burdock improved the intestinal luminal environment and suppressed obesity in rats fed a high-fat diet.

Nephroprotective Activity

In-vivo studies found that the combined use of *Astragalus* and *Arctium* may ameliorate the condition of diabetic nephropathy in streptozotocin (STZ)-induced rats by inhibiting the activation of the reactive oxygen species (ROS) content and nuclear transcription factor-kappaB expression (NF- κ B) in renal tissue (Wang and Chen 2008).

Wu et al. (2009) found that arctiin from *Arctium lappa* exerted ameliorative effect on rat glomerulonephritis induced by cationic bovine serum albumin. After oral administration of arctiin (30, 60, 120 mg/kg/d) for 3 weeks, the levels of serum creatinine (Scr) and blood urea nitrogen (BUN) and 24 hour urine protein content markedly decreased, while endogenous creatinine clearance rate (ECcr) significantly increased. The parameters of renal lesion, hypercellularity, infiltration of polymorphonuclear leukocyte (PMN), fibrinoid necrosis, focal and segmental proliferation and interstitial infiltration, were reversed. Additionally, arctiin markedly reduced the levels of malondialdehyde (MDA) and proinflammatory cytokines including interleukin 6 (IL-6) and tumour necrosis factor (TNF- α), suppressed nuclear factor-kappaB p65 (NF- κ B) DNA-binding activity and enhanced superoxide dismutase (SOD) activity.

Gastroprotective Activity

Oral administration of burdock root chloroform extract (100 mg/kg) per day for 7 days reduced the chronic gastric ulceration induced by acetic acid by 52 % in animals (Dos Santos et al. 2008).

Intraduodenal administration of the extract (100, 300 and 600 mg/kg) reduced the total acidity of gastric secretion by 22 %, 22 % and 33 %, respectively, while IP administration (10, 30 and 100 mg/kg) inhibited total acidity by 50 %, 60 % and 67 %, respectively. In-vitro studies confirmed that the extract protected animals from gastric lesions by reducing gastric acid secretion via inhibition of gastric H⁺, K⁺-ATPase. In another study, oral administration of burdock powder for 7 days exerted a protective effect against dextran sulfate sodium-induced colitis in BALB/c mice (Huang et al. 2010).

Burdock treatment could prevent mucosal oedema, submucosal erosions, ulceration, inflammatory cell infiltration and colon damage.

Furthermore, immunohistochemistry analysis showed that the levels of the inflammatory cytokines, interleukin 6 (IL-6) and tumour necrosis factor- α (TNF- α) in colonic sections, were also decreased in burdock-treated groups.

Oral administration of burdock root ethanol extract (1, 3, 10 and 30 mg/kg) reduced the gastric lesion area in 29.2 %, 41.4 %, 59.3 % and 38.5 %, respectively, and at 10 mg/kg promoted significant regeneration of the gastric mucosa in rats (da Silva et al. 2013). Burdock extract did not increase the gastric mucus content but restored the superoxide dismutase activity, prevented the reduction of glutathione levels, reduced lipid hydroperoxide levels, inhibited the myeloperoxidase activity and reduced the microvascular permeability. Additionally, burdock extract reduced the free radical generation and increased scavenging of 2,2-diphenyl-1-picrylhydrazyl (DPPH) free radicals in-vitro. The main compound in the extract was found to be a series of hydroxycinnamoylquinic acid isomers. Onopordopicrin (ONP)-enriched fraction from burdock leaves (50 mg/kg, p.o.) significantly inhibited the mucosal injury induced by ethanol/HCl solution (75 %), indomethacin/bethanechol (68.9 %) and stress (58.3 %) in rodents (de Almeida et al. 2012). ONP fraction significantly increased serum somatostatin levels (82.1 vs. control group 12.7 pmol/L) and decreased serum gastrin levels (62.6 vs. control group 361.5 μ g/mL). Mucus production was not significantly altered by the ONP fraction. The results suggested an antisecretory mechanism involved with the antiulcerogenic effect of the ONP fraction.

Crude burdock seed extracts and isolated compounds showed a strong antibacterial activity against a clarithromycin-resistant *Helicobacter pylori* strain (Kamkaen et al. 2006). Specifically, at a concentration of 50 μ g/mL, 3'-demethyl arctigenin and arctigenin each exerted a 100 % inhibition against *H. pylori* compared to a standard amoxicillin (5 μ g/mL) and clarithromycin (1 μ g/mL), while arctigenin glucoside and crude extract showed a 95 % and 86 % inhibition, respectively. In clinical trials of 27 patients with peptic ulcers, of 20 patients that took burdock essence, 17 (85 %) recovered completely and 3 (15 %) did not (Wu et al. 2010). In the experimental group, the ulcer wounds of the three patients who had taken burdock essence did not completely heal, but wounds were reduced in size by 30, 75 and 33 %. Moreover, 10 out of 11 patients who originally were positive for *Helicobacter pylori* infections no longer had the pathogen by the end of the trial. These results indicate that burdock essence has an inhibitory effect on *H. pylori*. The study confirmed that two tablets (500 mg/tablet) of burdock essence taken

orally three times a day after meals could help eliminate *H. pylori* infection and promote the therapeutic effect of conventional medication on gastric mucosal repair in gastrointestinal ulcer patients. Clinical trial has proved that greater burdock can function as an adjuvant therapy for patients with gastric ulcer caused by *Helicobacter pylori* (Ku et al. 2013). The concentration of chlorogenic acids in the essence degraded from 29.29 to 28.29 µg/g during the accelerated storage tests conducted for up to 6 months. Further, the concentration of chlorogenic acids degraded from 29.29 to 28.57 µg/g during the long-term storage tests conducted for a period of up to 12 months. In both these tests, no changes were observed in trait, scent and colour of the great burdock essence compounds.

Hepatoprotective Activity

Studies showed that burdock root extract could protect the liver cells from CCl₄ or acetaminophen-induced liver damages, perhaps by its antioxidative effect on hepatocyte (Lin et al. 2000). Burdock suppressed the SGOT and SGPT elevations induced by CCl₄ or acetaminophen in a dose-dependent manner and alleviated the severity of liver damage based on histopathological observations. Also, burdock decreased the malondialdehyde (MDA) content in CCl₄ or acetaminophen-intoxicated mice. Lin et al. (2002) also found that *A. lappa* significantly improved various pathological and biochemical parameters in rats which were exacerbated by ethanol plus CCl₄-induced liver damage, such as the ethanol plus CCl₄-induced decreases in total cytochrome P450 content and NADPH-cytochrome c reductase activity, increases in serum triglyceride levels and lipid peroxidation (the deleterious peroxidative and toxic malondialdehyde metabolite may be produced in quantity) and elevation of serum transaminase levels. The results suggested that the hepatotoxicity induced by ethanol and potentiated by CCl₄ could be alleviated with 1 and 7 days of burdock treatment.

Neuroprotective Activity

Pretreatment of rats with arctigenin for 7 days before transient occlusion of the middle cerebral artery and reperfusion significantly reduced cerebral infarction and improved neurological outcome by suppressing the activation of microglia and decreased the expression of interleukin (IL)-1β and tumour necrosis factor (TNF)-α (Fan et al. 2012).

Antihypertensive Activity

Ca²⁺ antagonists had been used as therapeutic agents to treat coronary heart diseases and hypertension. Potent Ca²⁺ antagonist activity was found in hot aqueous burdock fruit extract in the methanol fraction (Ichikawa et al. 1986). Of the lignans tested the order of inhibitory potencies was butanolides > bis-tetrahydrofurans = steganes. Other lignans tested, tetrahydrofuran and aryltetrahydronaphthalene, had no significant activity. The most potent activity occurred in trachelogenin, a typical butanolide; the calculated IC₅₀ and pA₂ were 1.1×10^{-6} M and 6.60, respectively. Trachelogenin had a potent and long-lasting antihypertensive effect on spontaneously hypertensive rats. Arctigenin was less potent. Lappaols C, E, F and H had lower inhibitory activity.

Antiatherosclerotic Activity

Studies found that arctigenin promoted cholesterol efflux in oxidised low-density lipoprotein (oxLDL)-loaded THP-1 macrophages through upregulation of ATP-binding cassette transporter A1 (ABCA1), ABCG1 and apoE, which was dependent on the enhanced expression of peroxisome proliferator-activated receptor gamma (PPAR- γ) and liver X receptor alpha (LXR- α) (Xu et al. 2013). Cholesterol efflux from macrophages is a critical mechanism to prevent the development of atherosclerosis.

Antiplatelet Activity

The hot aqueous extract of *A. lappa* seeds including its active constituents arctigenin and arctigenin methyl ether showed significant inhibitory activity on binding of platelet-activating factor (PAF) to rabbit platelets (Iwakami et al. 1992). Burdock seed extract inhibited PAF binding to 74 % at 200 μ g/mL concentration. IC₅₀ for PAF binding was 2.9 μ M for arctigenin and 0.56 μ M for arctigenin methyl ether.

Antitussive Activity

A fructofuranan of the inulin type, isolated from burdock roots, exhibited antitussive activity in cats (Kardosová et al. 2003). The fructan was found to be equally active as some non-narcotic, synthetic preparations used in clinical practice to treat coughing, and in mitogenic and comitogenic tests, its biological response was

comparable to that of the commercial zymosan immunomodulator. A polysaccharide from *Arctium lappa* L., var. *Herkules* was reported to have antitussive activity (Sutovska et al. 2007).

Antiuro lithiatic Activity

Studies by Grases et al. (1994) reported that *Arctium lappa* was one of the seven plants found to have antiuro lithiatic activity in female Wistar rats and that the beneficial effect could be attributable to the presence of saponins.

Anti-ageing Activity

Animal studies showed that the anti-ageing effect of Niubangen (burdock root) decoction was mainly attributed to the enhancement of superoxide dismutase activity in liver tissues and blood serum of decoction-fed rats and reduction in malondialdehyde in brain tissue and blood serum and lipofuscin contents (Liu et al. 2005b). Studies by Knott et al. (2008) showed that topical treatment with a natural *A. lappa* fruit extract significantly improved the metabolism of the dermal extracellular matrix and led to a visible wrinkle reduction in-vivo. In-vitro studies on human dermal fibroblasts and monocyte-derived dendritic cells supplemented with pure arctiin showed relative to untreated control cells a stimulation of collagen synthesis and a decrease in interleukin 6 and tumour necrosis factor- α concentration, respectively.

Anti-tyrosinase Activity

Water extracts of Fructus Arctii (burdock seeds) were shown to inhibit tyrosinase activity in-vitro and melanin content in α -melanocyte stimulating hormone-stimulated cells to similar levels as the well-known kojic acid and arbutin, respectively (Park et al. 2013). Melanogenic inhibitory activity was also identified in-vivo with zebrafish embryo. It was found that arctigenin, the active constituent, downregulated cAMP and the tyrosinase enzyme through its gene promoter and subsequently upregulated extracellular signal-regulated kinase activity by increasing phosphorylation in the melanogenesis signalling pathway, leading to a lower melanin content.

Memory Enhancement Activity

Arctigenin from burdock seeds at doses of 30 and 60 mg/kg (p.o.) potently reversed scopolamine-induced memory deficits in mice by 62 % and 73 %, respectively, in a passive avoidance test (Lee et al. 2011). Arctigenin more potently inhibited AChE activity than arctiin. Arctigenin also significantly reversed scopolamine-induced memory deficits of mice in the Y-maze and Morris water maze tests indicating that arctigenin may ameliorate memory deficits by inhibiting acetylcholinesterase (AChE) activity.

Treatment of arctigenin in mice highly decreased β -amyloid (A β)-induced neurodegeneration by decreasing A β formation and senile plaques and efficiently ameliorated Alzheimer's disease mouse memory impairment (Zhu et al. 2013). The results strongly highlighted the potential of arctigenin in anti- Alzheimer's disease.

Adaptogenic Activity

Administration of arctigenin efficiently improved mouse endurance on the treadmill as reflected by the increased fatigue time and distance, and potently enhanced mitochondrial biogenesis and fatty acid oxidation (FAO)-related gene expression in muscle tissues (Tang et al. 2011). Arctigenin strongly increased AMP-activated protein kinase (AMPK) phosphorylation via calmodulin-dependent protein kinasekinase (CaMKK) and serine/threonine kinase 11(LKB1)-dependent pathways and subsequently upregulated its downstream pathway in both H9C2 and C2C12 cells. The results suggested that arctigenin might be used as a potential lead compound for the discovery of the agents with mimic exercise training effects to treat metabolic diseases.

Antiparasitic Activity

Studies in mice showed that betamethasone and burdock treatments were found to be ineffective in protecting against intestinal lesions induced by the parasite *Angiostrongylus costaricensis*, a parasite that causes abdominal angiostrongyliasis in humans (Fante et al. 2008).

Photoprotective Activity

Burdock fruit fermented with the basidiomycetous fungus *Grifola frondosa* (G-FAE) exhibited photoprotective potential when tested in human dermal fibroblasts (HDF) exposed to ultraviolet A (UVA) (Kim et al. 2010b). G-FAE had an inhibitory effect on human interstitial collagenase (matrix metalloproteinase, MMP-1)

expression in UVA-irradiated HDF. The treatment of UVA-irradiated HDF with fermented burdock fruit resulted in a dose-dependent decrease in the expression level of MMP-1 mRNA. G-FAE also showed notable stimulation of collagen biosynthetic activity for fibroblasts. Pretreatment with arctiin prior to UVB irradiation reduced UVB-induced apoptosis, cell migration defects and DNA damage in normal human dermal fibroblast (NHDF) cells (Lee et al. 2014). It was also found that arctiin-induced UVB protection was associated with altered miRNA expression profiles in HNDF cells.

Burn/Wound Healing Activity

In a pilot study of five Amish with first- and second-degree burns, burns and wounds, burdock leaf dressing changes caused minimal or no pain; none of the burns became infected, and healing times averaged less than 14 days (Amish Burn Study Group et al. 2014). The use of this herbal remedy appeared to be an acceptable alternative to conventional burn care for these types of burns.

Enhancement of Sexual Behaviour Activity

Oral administration of burdock root extract at 600 and 1,200 mg/kg body weight to male albino rats significantly increased the frequencies of mount, intromission and ejaculation frequency (Cao et al. 2012). The latencies of mount and intromission were significantly reduced and ejaculation latency was prolonged. Administration of the extract also reduced the post-ejaculatory interval. The extract significantly increased the frequencies of all components of penile reflexes as well as serum testosterone levels, compared with the distilled water controls. The results thus supported the traditional use of burdock root extract for treating impotence and sterility.

Immunomodulatory Activity

Arctigenin inhibited the primary human T lymphocyte proliferation activated by anti-CD3/anti-CD28 Ab and decreased the gene expression interleukin 2 (IL-2) and interferon- γ (IFN- γ) production in a concentration-dependent manner (Tsai et al. 2011). Baicalin, a natural compound from burdock, and its derivative genistin, selectively inhibited the activities of terminal deoxyribonucleotidyltransferase (TdT) and truncated TdT (the so-called pol beta core domain) in which the BRCT motif was deleted in its N-terminal region (Uchiyama et al. 2005). The IC₅₀ value of baicalin to TdT was 18.6 μ M. The activity of genistin was higher

than baicalin although its IC₅₀ value was weaker (28.7 μM). Baicalin had previously been reported as an anti-inflammatory or antipyretic agent; terminal deoxyribonucleotidyltransferase had been suggested to play a role in immunological diversity (Coleman et al. 1974).

The phytopreparation comprising *Arctium lappa* roots, *Sophora japonica* fruits, *Acorus calamus* roots, *Urtica dioica* leaves and *Humulus lupulus* fruits activated macrophages (50–400 μg/mL), decreased the number of flattened cells, increased the number of rounded cells and increased the production of oxidative metabolites (by 26 % compared with intact cells) (Galkin et al. 2013). The herbal drug (0–300 μg/mL) increased cytokine secretion by human blood cells (interleukin 2 and interferon-γ).

Ocular Protective Activity

Total lignan from burdock fruit exhibited aldose reductase, suggesting its preventive potential on diabetic complications upon long-term administration (Xu et al. 2010).

Antiarthritic/Antiosteoporotic Activity

Studies by Kim et al. (2012) found that arctigenin may be useful for treating rheumatoid arthritis and osteoporosis. Arctigenin inhibited receptor activator of nuclear factor-κB ligand (RANKL)-mediated osteoclast differentiation in bone marrow macrophages in a dose-dependent manner and suppressed RANKL-mediated bone resorption. Additionally, the expression of typical marker proteins, such as NFATc1, c-Fos, TRAF6, c-Src and cathepsin K, was significantly inhibited. Arctigenin inhibited the phosphorylation of ERK1/ERK2, but not p38 and JNK, in a dose-dependent manner. Arctigenin also dramatically suppressed immunoreceptor tyrosine-based activation motif-mediated costimulatory signalling molecules, including Syk and PLCγ2, and Gab2. Arctigenin strongly inhibited the activation of Syk through RANKL stimulation. Furthermore, arctigenin prevented osteoclast differentiation in the calvarial bone of mice following stimulation with lipopolysaccharide.

Arctigenin strongly inhibited receptor activator of nuclear factor-κB ligand (RANKL)-induced osteoclast-like cell formation, differentiation and function by suppressing both calcineurin-dependent pathway and osteoblastic cell-dependent nuclear factor of activated T cells, cytoplasmic 1 (NFATc1) pathway, a key transcription factor for osteoclastogenesis (Yamashita et al. 2014).

Pharmacokinetic Studies

Nose et al. (1992) found that the lignins arctiin and tracheloside, from burdock seeds, were stable in gastric juice, and arctiin was rapidly transformed to arctigenin in rat large intestinal flora, followed by conversion to the major metabolite, 2-(3'',4''-dihydroxybenzyl)-3-(3',4'-dimethoxybenzyl)-butyrolactone. Tracheloside also decreased dependently with time and was converted to trachelogenin and its major metabolite, 2-(3'',4''-dihydroxybenzyl)-3-(3',4'-dimethoxybenzyl)-2-hydroxybutyrolactone. Further, they found that arctiin or tracheloside was transformed to at least two metabolites in the rat gastrointestinal tract, and after absorption from the intestine, metabolite 2 was converted into metabolite 1 through methylation by catechol-O-methyltransferase (COMT) in the liver, and arctiin and tracheloside existed as metabolite 1, the genuine genin, in the bloodstream (Nose et al. 1993). Three novel metabolites of arctigenin, namely, arctigenic acid, arctigenin-4'-*O*-glucuronide and 4-*O*-demethylarctigenin, were identified after oral administration of arctigenin in rats (Gao et al. 2013). Another potential metabolite of arctigenin, arctigenin-4'-*O*-sulfate, was identified in-vitro but not in-vivo. Rapid hydrolysis in plasma was identified as the major metabolic pathway of arctigenin after its oral administration and paraoxonase 1 was confirmed to be the enzyme responsible for arctigenin hydrolysis.

Three metabolites of arctiin were isolated and identified in rat faeces as (–)-enterolactone, (–)-arctigenin and [(2*R*,3*R*)-2-(3'-hydroxybenzyl)-3-(3'',4''-dimethoxybenzyl)-butyrolactone] (Wang et al. 2013). Arctiin was excreted 19.84 % in urine and 1.80 % in faeces, respectively; enterolactone, the abundant main metabolite, was excreted 35.80 % in faeces.

Toxicity Studies/Issues

A case of a 26-year-old woman complaining of blurred vision, inability to void, a dry mouth and a history of bizarre behaviour after ingestion of a commercial preparation of burdock tea was reported by Bryson et al. (1978). A case of anticholinergic poisoning associated with the consumption of a commercial burdock root tea preparation was confirmed by laboratory analysis in Arizona (Rhoads et al. 1984). The patient experienced mild anticholinergic symptoms which were caused by an atropine contaminant in the commercial preparation.

Studies had demonstrated that inulin-type fructans, when administered in the diet at high levels, do not result in mortality, morbidity, target organ toxicity, reproductive or developmental toxicity or carcinogenicity (Carabin and Flamm 1999). Several in-vitro studies had also shown the absence of mutagenic or genotoxic potential. A series of clinical studies had been reported showing that up to 20 g/day of inulin and/or oligofructose to be well tolerated.

Treatment for 28 days with preparations of burdock did not affect the parameters of glucose homeostasis examined in normal mice (basal plasma glucose and insulin, glucose tolerance, insulin-induced hypoglycaemia and glycated haemoglobin) (Swanston-Flatt et al. 1989). Administration of burdock to streptozotocin-diabetic mice aggravated the diabetic condition.

Allergy and Burdock Ophthalmia Issues

Sasaki et al. (2003) reported a case of a 53-year-old Japanese man, with a history of developing urticaria (once after consuming mackerel and 10 times after consuming boiled burdock, carrot, curry and rice), who presented with redness over his entire body and dyspnea 1 hour after eating boiled burdock. The results of the skin prick tests were positive for raw and boiled burdock. Also, contact with the burdock plant could cause allergic contact dermatitis reaction (Rodriquez et al. 1995). Allergic skin reactions had also been reported with the use of burdock plasters on the skin.

Burdock burr contains minute pointed, barbed bracts that can cause painful and severe ocular discomfort, foreign body sensation, photophobia, marked conjunctival hyperaemia, stringy mucus or even pseudomembranous, conjunctival exudation, eyelid oedema, blepharospasm and pathognomonic abrasions of the corneal epithelium (Havener et al. 1955). They reported that a water-soluble glycoside irritant in burdock plant when injected caused severe conjunctival irritations similar to that caused by the embedded bract. Breed and Kuwabara (1966) reported that burdock bristles when embedded in the conjunctiva, or rarely in the cornea, may evoke a characteristic clinical picture of burdock ophthalmia as described by Havener et al. (1955).

Traditional Medicinal Uses

Burdock has been used therapeutically in Europe, North America and Asia for hundreds of years (Grieve 1971; Foster and Duke 1998; Duke and Ayensu 1985; Chan et al. 2011; Chevallier 1996). Burdock

has been employed in traditional medicine to treat abscesses, joint pain, urinary complaints and respiratory ailments (congestion, fever caused by colds, flu and pneumonia) and to surmount serious health challenges by stimulating cellular regeneration, detoxification and cleansing. Burdock is one of the foremost detoxifying herbs in both Chinese and Western herbal medicines (Chevallier 1996). The herbal drug is listed in the German Pharmacopoeia for treating gastrointestinal disorders, as well as joint and bone ailments. The roots, seeds and leaves of burdock have been investigated in view of its popular uses in traditional Chinese medicine (TCM). The plant is antibacterial, antifungal and carminative (Launert 1981; Yeung 1985); has soothing, mucilaginous properties; and is employed for therapeutic treatment of many types of skin diseases, burns, bruises, herpes, eczema, acne, impetigo, ringworm, boils and bites (Grieve 1971; Phillip and Foy 1992). *Arctium lappa* has been reported to relieve gastrointestinal symptoms (de Almeida et al. 2013) and used as a diuretic, depurative and digestive stimulant and in dermatological conditions (Dos Santos et al. 2008). Burdock is a traditional medicinal plant that is popularly used for treating hypertension, gout, hepatitis and other inflammatory disorders (Lee et al. 2012).

Dried burdock root of 1-year-old plants is the official medicinal herb, but the leaves and fruits have also been used (Grieve 1971). The roots are considered to be alterative, aperient, blood purifier, cholagogue, depurative, diaphoretic, diuretic and stomachic (Duke and Ayensu 1985; Foster and Duke 1998). Roots of burdock are used in folk medicine as a tincture, a decoction, an extract, an infusion and an oil for gout, rheumatism and several skin diseases and as a diuretic and pathogenic agent and are used topically for eczema, ulcers, skin eruptions, festering wounds, furunculosis, sciatica and radiculitis (Azizov et al. 2012). Burdock root has traditionally been recommended as an aphrodisiac agent (Cao et al. 2012). It is used to treat impotence and sterility in China, and Native Americans included the root in herbal preparations for women in labour. Dried burdock roots and burdock tea are considered to be a traditional blood purifier, a diaphoretic, an alterative and a diuretic. Burdock root is used to treat conditions caused by an 'overload' of toxins, such as throat and other infections, boils, rashes and other skin problems, and is thought to be particularly good at helping to eliminate heavy metals from the body (Chevallier 1996). Medicinal herbs (*Arctium lappa* roots, *Sophora japonica* fruits, *Acorus calamus* roots, *Urtica dioica* leaves, *Humulus lupulus* fruits) are promising remedies for the prevention and treatment of alopecia (Galkin et al.

2013). Burdock fruit is an often-used herbal drug in traditional Chinese medicine for the treatment of common cold caused by wind and heat (Sun et al. 1992). Burdock seed is alterative, antiphlogistic, depurative, diaphoretic and diuretic (Duke and Ayensu 1985). Burdock seeds, containing arctigenin and its glycoside arctiin as main constituents, have been used as a diuretic, an anti-inflammatory and a detoxifying agent in traditional Chinese medicine (Hyam et al. 2013) and are widely used as a TCM for dispelling wind and heat and are included in the Chinese Pharmacopoeia (Zhao et al. 2009). Burdock seed is used as an alternative medicine for the treatment of inflammatory disorders (Kim et al. 2008). The pulverised seed and leaves are poulticed onto bruises, burns, ulcers and sores (Foster and Duke 1998).

Other Uses

Zhang et al. (2013) found that burdock fructooligosaccharide (BFO) enhanced the biocontrol efficacy of *Rhodotorula mucilaginosa* in controlling postharvest decay of peaches.

Burdock has potential application for biogas production. The average biogas yield of 480 L/kg_{vos}, 520 L/kg_{vos} and 296 L/kg_{vos} was obtained from greater burdock, large-leaf lupin and Sosnovsky cow parsnip biomass, respectively (Dubrovskis et al. 2011). The average methane yield of 276, 322 and 226 was obtained from greater burdock, large-leaf lupin and Sosnovsky cow parsnip biomass, respectively. The estimated average energy potential per unit of area is 87 GJ/ha and 82 GJ/ha for greater burdock and large-leaf lupin biomass cultivated on unused agricultural land area, respectively, and the energy potential was 38 GJ/ha for Sosnovsky cow parsnip.

Comments

Flor-Essence – a proprietary natural health product – is a compound herbal product of eight herbs including burdock (Saleem et al. 2009). Sixteen markers could be identified in Flor-Essence originating from four contributing herbs including four caffeoylquinic acids; three dicaffeoylquinic acids; two caffeic acid derivatives from *Arctium lappa*, luteolin-7-*O*-glucoside and luteolin; five apigenin glycosides; and apigenin from *Rumex acetosella* and *Nasturtium officinale* and sissotrin from *Trifolium pratense*.

A North American herbal formula called Essiac is a proper treatment for cancer and consists of *Arctium lappa*, *Rumex acetosella*, *Ulmus rubra* and *Rheum palmatum* (Chevallier 1996).

Helianthus tuberosus

T. K. Lim¹✉

(1) Canberra, Aust Capital Terr, Australia

Scientific Name

Helianthus tuberosus L.

Synonyms

Helianthus esculentus Warsz., *Helianthus serotinus* Tausch,
Helianthus tomentosus Michaux, *Helianthus tuberosus* var.
subcanescens A. Gray

Family

Asteraceae

Common/English Names

Earth Apple, Canada Potato, Girasole, Jerusalem Artichoke,
Jerusalem sunflower, Sunchoke, Sunflower Artichoke,
Sunroot, Topinambur, Woodland Sunflower

Vernacular/Local Names

Arabic: Tartúf, Tuffâhh El Ard

Brazil: Batata-Tupinambá, Girassol-De-Batata, Tupinambá, Tupinambor

Origin/Distribution

Jerusalem artichoke is an ancient Amerindian native to eastern North America from Maine west to Dakota and southwards to northern Florida and Texas. It is now widely cultivated in many places around the world, including North America, France, Italy, Germany, East European countries, China and also (in spite of low suitability) in some tropical countries in the cooler highlands (India, Indonesia, Malaysia, Kenya, Zaire and Nigeria).

Agroecology

Although a temperate species, *H. tuberosus* tolerates sub-zero to hot temperatures (Duke 1983). Most Jerusalem artichoke cultivars require average annual temperatures of between 6 and 26 °C, within a growing season of at least 125 frost-free days (Cosgrove et al. 2000; Duke 1983). Jerusalem artichoke grows under different pedoclimatic conditions and shows good tolerance to frost, drought and other adverse conditions, as well as resistance to pests and diseases (Slimestad et al. 2010). *H. tuberosus* tubers can withstand freezing for months even if the frost kills the stems and leaves (Duke 1983).

Jerusalem artichoke tolerates annual precipitation in the range of 310–2,820 mm (Duke 1983). However, an evenly distributed rainfall of up to 1,250 mm is preferred for optimal growth. The crop is tolerant of drought and survives short periods of flooding. Its water use efficiency is estimated to be between 1.1 and 1.9 g dm/L of water transpired (Conde et al. 1991). When only 50 % of the water requirement was available, tuber yield of Jerusalem artichoke was reduced by 20 % (Conde et al. 1991). Severe or mild water stress was reported to cause significant tuber yield losses of Jerusalem artichoke grown on a sandy loam soil (Schittenhelm 1999). Monti et al. (2005) found that the time course of Jerusalem artichoke plant growth and biomass partitioning was significantly affected by water availability especially during the period of the two first irrigations. *H. tuberosus* is generally considered to be moderately tolerant to salinity and to exhibit genotypic variability in salinity tolerance (Long et al. 2008; Newton et al. 1991), so they could be safely grown in salt-affected land with 25 and 50 % seawater irrigation (Zhao et al. 2008). Studies by Zhao et al (2008) showed that Jerusalem artichoke could be safely grown in salt-affected land of Laizhou area in North China Plain with 25 and 50 % seawater irrigation. Irrigation treatment with 75 %, 25 % and 50 % seawater increased the yields of Jerusalem artichoke compared to nonirrigated control. Long et al. (2008) found that 10 % seawater stress treatment had the least effect on Jerusalem

artichoke plant growth, while at 25 % seawater growth was significantly inhibited. Addition of nitrogen ameliorated the toxicity of seawater by improving the antioxidative enzymes, enhancing leaf proline and soluble sugars and altering the distribution of inorganic ions in *H. tuberosus*. Studies by Long et al. (2010) found great variability for seawater tolerance among *H. tuberosus* varieties and that greater photosynthesis capacity, higher relative growth rate and relatively higher tissue Na⁺ accumulation at high seawater concentrations appear to be associated with seawater tolerance in *H. tuberosus* varieties.

Jerusalem artichoke thrives in a wide range of soil types and pH levels, but production is favoured by slightly alkaline soils with optimal pH in the range of 4.5–8.6 (Duke 1983; Kosaric et al. 1984). It does best in friable, moderately well-drained soil in full sun to partial shade. Clay soils that are prone to waterlogging, for instance, may become too acid for optimum tuber growth. Greenhouse and field trials on heavy clay loam conducted by Newton et al. (1991) found that soil salinity reduced growth (plant biomass) and tuber biomass of Jerusalem artichoke.

Substantial genetic variation in the date and the duration of flowering were found with the onset of flowering ranging from 69 to 174 days after planting (DAP). Flowering duration ranged from 21 to 126 days (Kays and Kulture 2005). The onset of flowering was substantially affected by the planting date and to a lesser extent by the location. Studies have established critical day lengths for Jerusalem artichoke, although a wide variation has been observed between different clones. *H. tuberosus* requires short days for flowering, and the critical day length for a range of clones was found to be between 13 and 13.5 hours (Allard and Garner 1940; Zhao et al. 1984). *H. tuberosus* requires longer periods of light from seedling to maturation and shorter periods for tuber formation in late summer, as they are sensitive to day length hours (Huxley et al. 1992). But they do not grow where day lengths vary little (Duke 1983).

Edible Plant Parts and Uses

The edible artichoke tuber has a sweet nutty taste and is used as a vegetable that could be baked, steamed and mashed, or made into soups, sauces or pickles or eaten raw in salads. They are especially good grated into fresh salads and are a perfect snack for dieters. Boiled and mashed, they are rather similar to potatoes and can be used like potatoes in most recipes and can be made into a delicious and nutritious soup. Jerusalem artichokes also make delicious French fries. They are excellent pickled. Jerusalem artichokes can be roasted like potatoes with fowl or meat or bake with cream and cheese for a delicious scalloped/au gratin. The roasted tubers are used as a coffee substitute (Facciola 1990). The tubers can also be used for the production of alcohol and fructans.

H. tuberosus tubers being rich in inulin are an important source of fructose for industry. They can be used to make sweetening and inulin-rich floury products (Izsaki 2006). Due to the presence of inulin, starch which cannot be digested by the human enzyme system and being a good source of dietary fibres, the tubers provide food bulk without the associated calories. Compared to standard and substituted bread, Jerusalem artichoke bread prepared from tuber powder showed a high quality in organoleptic evaluation (grade I with 36.5 and 37.5 scores) (Praznik et al. 2002). Cakes made with 5–10 % Jerusalem artichoke tuber powder (JAP) contained 10.4 and 23.7 mg inulin/g dm, respectively (Celik et al. 2013). Panellists liked the crumb cell structure, flavour, chewiness, softness and sweetness of cakes with Jerusalem artichoke powder equally. Thus, with JAP can be used as a natural source of inulin in many bakery products such as breads, pastas, biscuits and cakes. The consumption of the bakery products containing JAP may help to increase the daily intake of inulin, a health-beneficial constituent for human nutrition. Studies by Kronberga et al. (2013) found that it was possible to substitute 40 % of total amount of sugar with Jerusalem artichoke syrup and so increase the nutritional value of marmalades and cakes and prolong their shelf life. Dried chips

containing inulin, other dietary fibres and a small amount of polyphenol can be prepared from Jerusalem artichoke tuber (Takeuchi and Nagashima 2011). Dried tubers had considerable water-holding capacity at low temperatures and viscosity-lowering activity on potato starch paste while heating. Their results suggested that Jerusalem artichoke tubers could be more widely utilised in the food industry as a functional modifier of other materials.

Gedrovica et al. (2011) reported that increasing the content of Jerusalem artichoke powder in pastry products like cakes, honey biscuits and butter biscuits substantially increased the content of non-starch polysaccharides. Non-starch polysaccharides (soluble and insoluble) constitute the main part of dietary fibre. They reported Jerusalem artichoke to be a good source of non-starch polysaccharides/dietary fibre as it is rich in fibre, vitamins, minerals and fructans.

Knowledge on the quality of raw and boiled Jerusalem artichoke tubers can be used to inform consumers on the right choice of raw material and thereby increase the consumption of the vegetable (Bach et al. 2013). The appropriateness of raw Jerusalem artichoke tubers was related to Jerusalem artichoke flavour, green nut flavour, sweetness and colour intensity, whereas the appropriateness of boiled tubers was related to celeriac aroma, sweet aroma, sweetness and colour intensity. Earlier Bach et al. (2012) found significant differences between harvest times and Jerusalem artichoke varieties for sensory scores and concentrations of tuber aroma volatiles. The total concentration of sampled volatiles was low with an average of 25.4 ng/g fresh weight and consisted mainly of terpenes. The sensory quality was determined by quantitative descriptive analysis of 19 sensory attributes. The sensory and aroma results separated the red-skinned variety Rema from the white-skinned Mari and Draga. Rema had a higher content of terpenes and was more associated with the unpleasant attributes iron flavour, fungus/earthy aroma and dried nut flavour compared to Mari and Draga.

A high-quality fructose syrup can be produced from Jerusalem artichoke tubers (Fleming and GrootWassink 1979).

They reported that Jerusalem artichoke had the potential to produce more sugar per acre than corn or sugar beets.

Botany

A multibranched herbaceous perennial growing to 1.5–3 m high and producing rhizomatous subterranean stem tubers and fibrous roots. Tubers knobby, uneven, white, red or purple skinned, ranging in size from 7.5 to 10 cm long, 3–5 cm thick, with nodes, internodes and eyes, the flesh is white (Plates 1, 2 and 3). The stems are erect, scabro-hispid to hirsute. Leaves mostly cauline opposite or alternate proximally. Lower leaves are larger, broadly ovoid–acute, up to 30 cm long, upper ones smaller and narrower, alternate and borne on winged petioles, 2–8 cm. Lamina 3-nerved from near bases, lanceolate to ovate, 10–23 × 7–15 cm, bases broadly to narrowly cuneate, margins entire or serrate, abaxial faces finely hairy and gland-dotted, adaxial scabrous. Flowering heads 5–7.5 cm across, 5–15, terminal on the branches. Involucres hemispheric. Phyllaries dark green, 22–35, bases appressed, apices more or less spreading, sometimes reflexed in fruit, lanceolate. Ray florets 10–20; laminae 25–40 mm. Disc florets 60 or more; corollas 6–7 mm, lobes yellow; anthers dark brown or black, appendages dark or yellowish. Cypselae 5–7 mm, glabrous or distally hairy; pappi with 2 aristate scales and 0–1 deltoid scales.

Nutritive/Medicinal Properties

Tuber Nutrients/Phytochemicals

Wild and cultivated Jerusalem artichoke genotypes appear to contain adequate protein and macro- and micro-minerals to contribute significantly towards a nutritionally balanced diet (Seiler 1990).

Jerusalem artichoke tubers were reported to contain mainly water-soluble polysaccharides (WSPS) (12.3 %), pectic substances (PS) (1.6 %), hemicelluloses (HMC)-A (1.2 %), HMC-B (0.8 %) and proteins (Rakhimov et al. 2003, 2011). WSPS comprised of glucose, fructose, saccharose, kestose and a homologous series of D-fructofuranosides (9.3 %), each member of which corresponded to the empirical formula $\text{Glcp } 1 \rightarrow 2\text{Fruf1-[2Fruf1]}_n$. The homologous series of fructosans starts at the saccharose of the lowest homolog (for $n = 0$) followed by the trisaccharide kestose and then tetrasaccharide w. Each oligofructoside differs from the previous one by a fructose unit. The highest homolog of this series is inulin. Pectin was found to consist of galactose, glucose, rhamnose, arabinose and galacturonic acid units forming the main chain. Glucose, galactose, xylose, arabinose and traces of rhamnose and galacturonic acid were detected in the hemicellulose hydrolysate. The tuber contained 0.86 % (per dry mass) nitrogen or 5.45 % protein content calculated by the Kjeldahl method. The amino acid composition of the protein determined after acid hydrolysis included asparagine 1.41 %, threonine 1.26 %, serine 1.27 %, glutamine 2.94 %, proline 2.01 %, glycine 0.96 %, alanine 0.97 %, 1/2 cysteine 1.63 %, valine 1.30 %, methionine 1.80 %, isoleucine 1.83 %, leucine 2.91 %, tyrosine 3.07 %, phenylalanine 2.18 %, histidine 1.34 %, lysine 2.51 % and arginine 1.8 %. Thus the chemical composition of Jerusalem artichoke tubers included monosaccharides, fructooligosaccharides, inulin, hemicelluloses, pectinic substance and proteins. Syrup prepared from tuber juice contained at least 71 % dry solids, protein content 5.45 % and inulin content 26 % with pH 3–4.5 and density 1.35–1.36 (Rakhimov et al. 2011). Total nitrogen

of 114 Jerusalem artichoke populations varied from 0.695 to 2.179 % dry weight (mean 1.23 %), alpha amino nitrogen content 0.012–0.118 % fresh weight (mean 0.07 %), potassium 0.231–0.452 % fresh weight (mean 0.403 %) and sodium 0.0003–0.0143 % fresh weight (mean 0.007 %) (Terzic and Atlagic 2009). The following attributes of Jerusalem artichoke tubers impart nutritional and health benefits: presence of alpha amino nitrogen, an essential nutrient for animals; a protein content similar to potato; high K/Na ratio that can positively affect the reduction of Na/K ratio and lower systolic blood pressure by a significant amount in adults with mild hypertension, high inulin content up to 80 % of the total sugar content as a dietary fibre and a fructose polymer that positively influences digestion and sugar blood levels (Terzic and Atlagic 2009).

In another analysis, proximate nutrient value of raw Jerusalem artichoke per 100 g edible portion was reported as water 78.01 g, energy 73kcal (304 kJ), protein 2 g, fat 0.01 g, ash 2.54 g, carbohydrate 17.44 g, total dietary fibre 1.6 g, total sugars 9.60 g, Ca 14 mg, Fe 3.40 mg, Mg 17 mg, P 78 mg, K 429 mg, Na 4 mg, Zn 0.12 mg, Cu 0.140 mg, Mn 10.0 mg, Se 0.7 µg, vitamin C 4 mg, thiamine 0.2 mg, riboflavin 0.06 mg, niacin 1.3 mg, pantothenic acid 0.397 mg, vitamin B6 0.077 mg, total folate 13 µg, total choline 30 mg, vitamin A (RAE) 1 µg, vitamin A 20 IU, β-carotene 12 µg, vitamin E (α-tocopherol 0.19 mg), vitamin K (phylloquinone) 0.1 µg, total monounsaturated fatty acids 0.004 g, 18:1 undifferentiated 0.004 g, total polyunsaturated fatty acids 0.001 g and 18:2 undifferentiated 0.001 g (USDA-ARS 2014). Jerusalem artichoke tubers, on a dry basis, yielded approximately 76 % soluble sugars (combined fractions from the drain liquor and hot water extract of skinless tubers and skins) and the remaining 24 % as an insoluble residue (Mullin et al. 1994). On a dry weight basis, the residues contained 20–25 % protein which was double the concentration in the soluble extract; the residues also contained up to 43 % total dietary fibre. Soluble sugars ranged over 75–85 % of the dry matter in the hot water extracts, which was double the amount retained in the residue. The lowest ash content (3.2–4.9 %) was found in the skinless tubers residue, and the highest (5.9–7.5) was in the skin

total unsaturated fatty acids 67.6 %, 18:1 (oleic acid) 1.2 %, 18:2 (linoleic acid) 54.5 % and 18:3 (linolenic acid) 32.4 % (Talipova 2001).

The amount of lipids extracted from the tubers were as follows: total lipids (0.56 %), free lipids (0.39 %) and bound lipids (0.36 %) (Chernenko et al. 2008). Total lipid was light yellow and contained carotenoid pigments (34.7 mg %). Bound lipids comprised neutral lipids (29.9 %), glucolipids (46.9 %) and phospholipids (23.2 %). Free lipids comprised mainly of neutral lipids. The following classes of neutral lipids were found: paraffinic and olefinic hydrocarbons, isoprenoid hydrocarbon squalene, tocopherols, triacylglycerides, free fatty acids, isoprenoid alcohols, triterpenols and sterols. Among the phospholipids, phosphatidylinositols (PI), phosphatidylcholines (PC), phosphatidylethanolamines (PE), phosphatidylglycerines (PG) and phosphatidic acid were identified. The main glucolipids were sterolglycosides and digalactosyldiglycerides; others included sulfolipids, cerebrosides and monogalactosyldiglycerides. The qualitative composition of the fatty acids in all lipid classes was the same and consisted of ten acids. However, they differed significantly quantitatively. The 18:0 and 16:0 acids dominated the saturated acids from polar lipids. The neutral lipids isolated from bound lipids contained a large amount of linoleic acid (53.0 %) and small amounts of 12:0, 13:0, and 14:0 acids. The total amount of unsaturated fatty acids in them was greater than 70 %. From total lipids, 5.2 % of unsaponified substances were isolated containing 46.9 mg% carotenoids. The unsaponified component comprised 17.9 % isoprenols and triterpenols, 13.2 % sterols, 8.2 % hydrocarbons, 9.6 % triterpenols, 19.4 % unidentified component I and 31.5 % unidentified component II.

Many studies had reported Jerusalem artichoke tubers to be rich in inulin. The nutritional energy value of inulin was reported to be lower than that of sucrose, being in the range 4.2–6.3 kJ/g (Roberfroid et al. 1993). Jerusalem artichoke tubers were reported to have 162.4 mg/g dm inulin content (Celik et al. 2013). Inulin is a generic term to cover all β (2 $\rightarrow$ 1) linear fructans including native inulin (DP 2–60, DP

(av) = 12), oligofructose (DP 2–8, DP (av) = 4) and inulin HP (DP 10–60, DP (av) = 25) as well as Synergy 1, a specific combination of oligofructose and inulin HP (Roberfroid 2005, 2007). Inulin-type fructans are prebiotic dietary fibres and classified as ‘non-digestible’ carbohydrates as they resist hydrolysis by intestinal digestive enzymes and are also functional food ingredients. They are also low-calorie carbohydrates [6.3 kJ/g (1.5 kcal/g)]. By increasing faecal biomass and water content of the stools, they improve bowel habits. They affect gastrointestinal functions not because of their physicochemical properties but rather because of their biochemical and physiological attributes. Fermentation of inulin-type fructans in the large bowel preferentially stimulate the proliferation of *Bifidobacteria* (and possibly a few other genera), thus causing significant changes in the composition of the gut microflora by increasing the number of potentially health-promoting bacteria and reducing the number of potentially harmful species. They also induce changes in colonic epithelium stimulating proliferation in the crypts, increasing the concentration of polyamines, changing the profile of mucins and modulating endocrine as well as immune functions. The claim ‘inulin-type fructans enhance calcium and magnesium absorption’ had been scientifically substantiated, and the most active product was oligofructose-enriched inulin (Synergy 1) (Roberfroid 2007). A series of studies had demonstrated that inulin-type fructans modulated the secretion of gastrointestinal peptides involved in appetite regulation as well as lipid metabolism. Studies had also been reported that inulin-type fructans reduced the risk of colon carcinogenesis and improved the management of inflammatory bowel diseases.

All the fructans (inulin) with a $DP \geq 3$ (i.e. the trisaccharide isokestose and larger polymers of fructose) were found to be located exclusively in the vacuoles of protoplast of *H. tuberosus* tubers, while sucrose, glucose and fructose were located only partially there (Frehner et al. 1984). The vacuoles were also found to be the sole cell compartments containing fructan-synthesising enzyme activities (sucrose–sucrose–fructosyltransferase and fructan–fructan–fructosyltransferase) and fructan-degrading enzyme activity (fructan exohydrolase),

depending on the stage of development of the tubers. Two key enzymes in inulin metabolism identified in *H. tuberosus* were sucrose–sucrose 1-fructosyltransferase (SST), the enzyme for initiating inulin synthesis leading to 1-kestose, and fructan-1-fructosyl-transferase (FFT) leading to higher inulin polymers (Edelman and Jefford 1968). The enzyme sucrose–sucrose 1F- β -D-fructosyl-transferase involved in fructan synthesis was isolated from *H. tuberosus* tubers (Praznik et al. 1990). Sucrose–sucrose 1-fructosyltransferase (1-SST), an enzyme involved in fructan biosynthesis, was purified to homogeneity from *Helianthus tuberosus* tubers (Koops and Jonker 1994). 1-SST preferentially catalysed the conversion of sucrose into the trisaccharide 1-kestose (GF2). Other reactions catalysed by 1-SST at a lower rate were self-transfructosylations with GF2 and 1,1-nystose (GF3) as substrates yielding GF3 and 1,1,1-fructosylnystose (GF4), respectively, as products. 1-SST also catalysed the removal of the terminal fructosyl unit from both GF2 and GF3, which resulted in the release of sucrose and GF2, respectively, and free fructose. Sucrose–sucrose 1-fructosyltransferase (1-SST) was purified 100-fold from tubers of *Helianthus tuberosus* L. and could be separated by isoelectric focusing into five isoforms which all were composed of two subunits (59 and 26 kDa) (Lüscher et al. 1996). When a combination of 1-SST and with fructan–fructan 1-fructosyltransferase (1-FFT) was incubated with sucrose, a series of oligofructosides with a degree of polymerisation of up to 20 was formed. Amino acid sequences of tryptic peptide fragments from both 1-SST and 1-FFT indicated these enzymes to be highly homologous with plant invertases.

The fructan- β -fructosidase activity (1-FEH) that degrades inulin in tubers of *Helianthus tuberosus* L. appeared to be developmentally regulated; it was low in growing tubers but increased during dormancy and sprouting (Marx et al. 1997). The enzyme exhibited a high substrate specificity, hydrolysing terminal β -(2–1)-fructosyl-fructose linkages in linear and branched fructan oligomers; β -(2–6) linkages were hardly hydrolysed. Hydrolysis of inulin oligomers followed normal saturation kinetics: K_m values for 1,1-kestotetraose and 1,1,1-kestopentaose were 8–3 mM and 12 mM, respectively.

Fructosyl residues were hydrolysed from inulin oligomers by a multichain mechanism. The fructan- β -fructosidase showed optimal enzyme activity at pH 5–2, and it retained its full activity after preincubation for 1 hour at up to 40 °C.

Spring-harvested Jerusalem artichoke tubers containing low molecular weight inulin were found to be well suited for fermentations or for the isolation of inulooligosaccharides. Tubers not exposed to frost and containing high molecular weight inulin were better sources for the production of high-fructose syrup (Praznik and Beck 1987). Inulin content in *H. tuberosus* tubers decreased during storage (Cabezas et al. 2002). The fructan fraction having molecular weight between 800 and 1,200 increased after sucrose reached its maximum content [$1.3\text{--}10^{-1}$ g/g DW] in tubers stored at 4 °C. Tuber maturity contributed to changes in inulin characteristics (Saengthongpinit and Sajjaanantakul 2005). A decrease in the more polymerised fractions (degree of polymerisation, DP >10) with an increase in fructose and sucrose composition was observed for late-harvested (20 weeks) tubers. For inulin DP 11–20, there was a decrease from 29.19 % at 16 weeks maturity to 26.71 % at 20 weeks maturity. For inulin DP 21–30, there was a decrease from 10.24 % at 16 weeks maturity to 9.52 % at 20 weeks maturity. For inulin DP >30, there was a decrease from 4.79 % at 16 weeks maturity to 4.48 % at 20 weeks maturity. There was no significant difference in inulin DP 3–10 when tubers were harvested at 16 weeks (47.01 %), 18 weeks (47.15 %) or 20 weeks (47.28 %) maturity. Sucrose increased from 7.51 % at 16 weeks maturity to 8.76 % at 20 weeks, while fructose increased from 7.51 to 8.76 % at 20 weeks maturity. Conversely, glucose decreased from 0.96 % at 16 weeks to 0.26 % at 20 weeks maturity. The inulin DP distribution profile from tubers, stored at 2 and 5 °C, significantly changed with increased storage time and temperature. Sucrose and DP 3–10 fractions increased, while DP >10 decreased, particularly after 4–6 weeks of storage. Changes in inulin composition were reflected by formation of a second fructan series DP 2'–DP 5' during cold storage but not under frozen storage at –18 °C. These second fructan series had been found in trace amounts in fresh tubers by Ernst

et al. (1996). They were characterised as inulo-*n*-ose that contained only β (2 $\rightarrow$ 1)-linked fructose molecules without an end glucose moiety (Ernst et al. 1996). These inulo-*n*-ose products, for example, 2' for inulo-*bi*-ose and 3' for inulo-*tri*-ose, might be derived from large inulin molecules by hydrolysis of terminal glucose or fructose molecules. Saengthongpinit and Sajjaanantakul (2005) obtained peaks that corresponded to inulo-*n*-ose fructan, where inulo-*tri*-ose (3') and inulo-*tetra*-ose (4') were predominantly found after 2 weeks of tuber storage at 2 and 5 °C. Inulo-*n*-ose (5') up to DP 17' increased as a percentage with longer storage time. Tubers in frozen storage at -18 °C maintained their inulin DP distribution profiles.

Of the harvesting methods (i.e. stalk, tuber and 'integral crop'), the integral crop (stalks and tubers) of Jerusalem artichoke at flowering time showed the highest yield potential of total sugars (fructose+glucose) and inulin (18.6 and 17.9 t/ha, respectively) (Baldini et al. 2004). This was obtained by the clone *Violette de Rennes*, which also had the greatest inulin chain (DP) length. The average inulin chain length (DP) was highest at flowering time in both stalks and tubers with a range of 7.5–11.2 in the genotypes studied, while, at the final harvest of tubers, it significantly decreased reaching values ranging from 4.8 to 6.7. Among the organs analysed, the tubers at stalk harvest showed both the highest inulin content and the longest inulin chain, expressed as DP. As a result of overwintering, the amount of inulin was found to decrease in Jerusalem artichoke tubers due to its conversion to sucrose and the formation of inulin with a lower degree of polymerisation (Clausen et al. 2012). Major effects on the concentration of citric acid, malic acid, γ -aminobutyric acid (GABA) and adenosine were also found. Malic acid concentration increased and citric acid concentration decreased. These changes, together with an increase in sucrose and GABA concentrations, were ascribed to mobilisation of nutrients prior to sprouting, suggesting that malic acid and GABA serve as carbon and nitrogen sources during sprouting of Jerusalem artichokes.

For the ten genetic variants of *H. tuberosus* collected and tested from different locations in Norway, 30–54 % of total carbohydrates were fructooligosaccharides, and the rest were sugars (mainly sucrose and low levels of fructose) (Seljåsen and Slimestad 2007). The level of total fructooligosaccharides varied from 20 mg/g (FW) for the variety ‘Bergly’ to 40 mg/g for ‘Kirkeøy’. Kestose and Nystose were the abundant fructooligosaccharides in all cultivars. Tuber peels contained relatively high levels of total phenolics (39–129 mg GAE/100 g FW). Early Jerusalem artichoke variants gave the highest tuber yield (28.7 t/hour) and 1.72 kg tubers/plant (e.g. white Tysnes) under Norwegian growing conditions. Late variants gave highest above-ground biomass (Slimestad et al. 2010). The content of soluble carbohydrates was found to be highest in stalks in August (sucrose and fructooligosaccharides).

Jerusalem artichoke samples contained one major component (β -bisabolene, 2.62 μ g/kg, 51 %) and a range of saturated long-chain hydrocarbons (22 %) (Macleod et al. 1982). B-farnesene (0.13 μ g/kg) was also identified. β -Bisabolene because of its high concentration may contribute appreciably to the characteristic flavour of Jerusalem artichoke, although it did not possess an aroma characteristic of Jerusalem artichoke. Twenty-two phenolic compounds were identified and quantified (100 g tuber or skin DW) from different Jerusalem artichoke varieties (Tchoué et al. 2007): gallic acid (1–140 mg), protocatechuic acid (5–200 mg), esculin (4–270 mg), gentisic acid (30 mg–3 g), catechin (1–300 mg), 4-hydroxybenzoic acid (1–90 mg), chlorogenic acid (20 mg–5 g), vanillic acid (1–520 mg), syringic acid (1–40 mg), caffeic acid (1–240 mg), epicatechin (4–800 mg), 2-hydroxy-3-5-dinitrobenzoic acid (2–140 mg), umbelliferone (2–110 mg), scopoletin (1–80 mg), *p*-coumaric acid (1–40 mg), coumaric-3-carboxylic acid (1–40 mg), ferulic acid (1–40 mg), sinapic acid (1–60 mg), 3-hydroxycinnamic acid (trace), ellagic acid (2–40 mg), 4-hydroxycoumarin (4–300 mg) and salicylic acid (30 mg–7 g).

Seven phenolic compounds, namely, 3-*O*-caffeoylquinic acid (chlorogenic acid), 5-*O*-caffeoylquinic acid (neochlorogenic acid), 4-*O*-caffeoylquinic acid (cryptochlorogenic

acid), 3,5-*O*-dicafeoylquinic acid, 3,4-*O*-dicafeoylquinic acid, 4,5-*O*-dicafeoylquinic acid and 1,3-*O*-dicafeoylquinic acid were identified from two polish cultivars of Jerusalem artichoke tubers: Rubik and Albik (Kapusta et al. 2013). Albik had a phenolic acids content 18 % lower than Rubik. In relation to the dry matter, Rubik contained 1.7 g/kg and Albik 1.4 g/kg of total phenolics. The following phenolic compounds were quantified in the tubers of two cultivars Rubik and Albik (mg/kg DM), respectively: 3-*O*-cafeoylquinic acid (471.85 mg; 368.15 mg); 5-*O*-cafeoylquinic acid (59.05 mg; 30.36 mg); 4-*O*-cafeoylquinic acid (61.09 mg; 61.65 mg); 3,5-*O*-dicafeoylquinic acid (102.28 mg; 170.94 mg); 3,4-*O*-dicafeoylquinic acid (630.39 mg; 513.38 mg); 4,5-*O*-dicafeoylquinic acid (68.98 mg; 37.75 mg) and 1,3-*O*-dicafeoylquinic acid (274.40 mg; 270.23 mg). The 3,4-*O*-dicafeoylquinic acid was most abundant in both cultivars followed by 3-*O*-cafeoylquinic acid (chlorogenic acid) and then 1,3-*O*-dicafeoylquinic acid.

Phytosterols were isolated and purified from Jerusalem artichoke tissues grown in-vitro in the presence of sodium acetate 1-¹⁴C in the dark and under far red light (Hartmann et al. 1972). A reproducible increase of the specific radioactivity of sterols was observed for tissues subjected to far red light. Solubilisation of chromatin from Jerusalem artichoke tubers in 2,4-dichlorophenoxyacetic acid (2,4-D) solution was associated with dissociation of the DNA and associated histone and nonhistone proteins (Yajima et al. 1975). Injection of d-[U-¹⁴C] fructose into developing Jerusalem artichoke tubers produced labelled glucose 6-phosphate, fructose 6-phosphate, fructose 1,6-bisphosphate, fructans and fructose 1-phosphate (Morgan and Pridham 1985). The latter ester was not produced on loading tubers with [U-¹⁴C] sucrose. In contrast to the other hexose phosphates, fructose 1-phosphate did not appear to be metabolised.

Solubilisation of acid invertase associated with cell wall preparations from aged slices of Jerusalem artichoke tuber tissue was achieved with buffer of high ionic strength (Little and Edelman 1973). Wounding induced cinnamic acid hydroxylase (CAH) in Jerusalem artichoke tuber (Benveniste

et al. 1977). CAH, a multienzyme system localised on the endoplasmic reticulum, catalyses transformation of *trans*-cinnamic acid into *p*-hydroxy-cinnamic acid. The content of cytochrome b₅, already present in the dormant tuber, was markedly enhanced by wounding. Proteins that were able to stimulate the exchange of phospholipids between natural membranes (mitochondria and microsomal fractions) or between artificial (e.g. liposomes) and natural membranes were isolated from cytosols of Jerusalem artichoke plant tissues (Douady et al. 1978). A cyclic AMP phosphodiesterase was isolated from dormant tubers of Jerusalem artichoke (Giannattasio et al. 1974). The enzyme hydrolysed 3',5'-cyclic AMP to 3'-AMP and 5'-AMP. A cyclic AMP-binding protein with molecular weight of circa 240,000 was purified from Jerusalem artichoke rhizome tissue (Giannattasio et al. 1979). The binding protein was devoid of the following activities: cyclic AMP phosphodiesterase, 5'-nucleotidase, adenosine deaminase and ATPase. Arginase [l-arginine amidinohydrolase] from Jerusalem artichoke tubers was shown to be more substrate specific than other plant and animal arginases and found to be very sensitive to competitive inhibition by indospicine, ornithine and citrulline (Wright et al. 1981). The AMP aminohydrolase enzyme was purified from particulate extracts of Jerusalem artichoke tubers (Le Floch and Lafleur 1983). Fractionation of phenolase enzyme from Jerusalem artichoke resulted in fractions with various specific activities, with an increase in activity of 160-fold for the first unbound enzymatic fraction and 18-fold for a fraction eluted with glycine buffer (Zawistowski et al. 1987). Polyphenol oxidase was purified from Jerusalem artichoke tubers and was found to be primarily an o-dihydroxyphenol oxidase with apparent K_m values of 1.9, 3.5 and 3.9 mM for chlorogenic acid, 4-methylcatechol and catechol, respectively (Zawistowski et al. 1988b). An acidic fraction of polyphenol oxidase was isolated purified from Jerusalem artichoke tubers (Zawistowski et al. 1988a). The pH optimum for its oxidation of chlorogenic acid, 4-methylcatechol and catechol was 6.0. Sucrose synthase (UDP-D-glucose–D-fructose 2- α -D-GLUCOSYLTRANSFERASE) occurred as an extravacuolar enzyme in *Helianthus tuberosus* tubers and as active sucrose transporter

in the tonoplast and was reported to play an important role towards sucrose synthesis in the tissue (Keller et al. 1988). Also found was the vacuolar marker β -N-acetylglucosaminidase and extravacuolar marker NAD-malate dehydrogenase in the protoplast lysate. Diamine oxidase activity was found to be associated with protoplasts and mitochondria in *H. tuberosus* tuber (Scoccianti et al. 1991). Polyphenol oxidase (PPO) was purified from Jerusalem artichoke tuber skin and flesh and characterised (Ziyan and Pekyardimci 2003). Optimum pH values were 7.5 for skin PPO and 8.0 for flesh PPO with 50 mM catechol. The optimum temperatures for skin and flesh PPO were 25 °C and 30 °C, respectively, with catechol. Thermal inactivation data indicated that apparent activation energies with catechol substrate were 29.34 kcal/mol for skin PPO and 42.56 kcal/mol for flesh PPO.

Ketodiene oxylipin biosynthesis in Jerusalem artichoke tubers was found to be mediated by the lipoxygenase pathway (Chechetkin et al. 2004). Through this pathway (9Z,11E,13S)-13-hydroperoxy-9,11-octadecadienoic acid (13-HPOD) was reduced to corresponding 13-hydroxy acid (13-HOD), which was then dehydrogenated into ketodiene (9Z,11E,13S)-13-oxo-9,11-octadecadienoic acid (13-KOD). Dehydrogenation of 13-HOD into 13-KOD was not dependent on the presence of either NAD or NADP, but was strongly dependent on the presence of oxygen. The enzyme flavin dehydrogenase catalysed the dehydrogenation of (9S,10E,12Z)-9-hydroxy-10,12-octadecadienoic acid (9-HOD) as effectively as 13-HOD, while α -ketol, (9Z)-12-oxo-13-hydroxy-9-octadecenoic acid and ricinoleic acid did not act as substrates for the dehydrogenase.

9Z- and 9E-dodecenoic acids were epoxidised by a microsome preparation from Jerusalem artichoke tuber to form *cis*- and *trans*-epoxydodecanoic acids, respectively (Fahlstadius 1991). Kauralexins A3, B2 and B3, 4-epicommunic acid and unknown C₁₅-acetylenic compound were found in *H. tuberosus* (Bohlmann et al. 1980). 7-hydroxylated coumarin phytoalexins like ayapin and scopoletin were excreted from sliced *H. tuberosus* tuber

tissues (Cabello-Hurtado et al. 1998). They accumulated in response to treatment with chemical elicitors like CuCl₂ or sucrose, but not in response to MnCl₂.

Two mannose-/glucose-binding lectins designated HTA 1 (a monodimer 17 KDa) and HTA 11 (a heterodimer, 17 KDa and 18 KDa) were purified from *H. tuberosus* callus (Nakagawa et al. 1996). They exhibited strong hemagglutinating activity. Heltuba A, a mannose-binding lectin, was isolated from *H. tuberosus* tubers (Bourne et al. 1999). It shared the carbohydrate-binding site and beta-prism topology of its galactose-binding counterparts: jacalin and *Maclura pomifera* lectin. Heltuba was found to be a cytosolic, tetrameric protein composed of four identical subunits of 15.5 kDa and exhibited a preferential specificity towards oligomannosides (Van Damme et al. 1999). Another lectin (HTTL) with native molecular mass of 72 kDa and subunit molecular masses of 17 and 18.5 kDa was isolated from *Helianthus tuberosus* tubers (Suseelan et al. 2002). The lectin agglutinated both untreated and trypsin-treated rabbit erythrocytes and did not agglutinate human blood cells of groups A, B and O. The HTTL was mitogenic to mouse spleen (total) cells at 25 µg/ml concentration. The lectin showed characteristics different from those of the earlier reported *H. tuberosus* tuber lectins. *Helianthus tuberosus* agglutinin (HTA) was found to be predominantly expressed in tubers and very weakly expressed in stems, but not expressed at all in other tissues (Chang et al. 2006). Southern blotting analysis indicated that HTA was encoded by a multigene family. HTA showed haemagglutination ability and a higher carbohydrate-binding ability for mannose than other tested sugars. Trypsin inhibitory activity was detected in the crude extracts of induced *Escherichia coli* BL21 (DE3) expressing HTA and was further verified by trypsin inhibitory activity staining on native polyacrylamide gel.

A total of 195 constituents were identified in the hydrodistilled essential oil of Jerusalem artichoke tubers, representing 88.2 and 93.6 % of the oil compositions for Samples A and B, respectively (Radulović and Đorđević 2014). The main constituents identified were β-bisabolene

(22.9–30.5 %), undecanal (0–12.7 %), α -pinene (7.6–0.8 %), kauran-16-ol (6.9–9.8 %), 2-pentylfuran (0.0–5.7 %) and (*E*)-tetradec-2-enal (0.0–4.9 %). Several rare compounds characteristic for *Helianthus* ssp. were also detected: helianthol A (2.1–1.9 %), dihydroeuparin (0.0–2.3 %), euparin (0.0–0.4 %), desmethoxyencecalin (traces – 0.2 %), desmethylenecalin (0.0–0.4 %) and an isomer of desmethylenecalin (0.0 %-traces).

Leaf Phytochemicals

The leaf protein extraction residue contained 12 % crude protein and 28 % crude fibre (Rawate et al. 1985). Leaves were reported to contain water-soluble polysaccharides (WSPS) 3.3 %, pectinic substances 9.1 %, soluble sugars in alcohol 11.4 % and hemicelluloses 14.7 % (Rakhimov et al. 2011). Lipid composition of Jerusalem artichoke leaves was reported as lipids 2.7 %, moisture and volatiles 70.5 %, acid number 7.5 mg KOH, chlorophyll a 28.6 mg/g, chlorophyll b 9.6 mg/g, total carotenoids 1.8 mg/g, fatty acids after saponification 37.1 %, unsaponifiable substances 19.9 %, neutral lipids 51.4 %, glucolipids 37.6 % and phospholipids 11.0 % (Talipova 2001). Neutral lipids comprised hydrocarbons, carotenoids, fatty acid esters with phytosterols and triterpenols, triacylglycerines, free fatty acids, triterpenols, 4-monomethylsterols, sterols and chlorophylls. Glucolipids contained mono- and digalactosyldiacylglycerines, sterolglycosides and their fatty acid esters. Phospholipids comprised phosphatidylethanolamines, phosphatidylcholines, phosphatidylinositols and phosphatide acids. Leaves had higher content of phospholipids, while tuber had higher contents of glucolipids. The fatty composition of the leaves was reported as total saturated fatty acids 44.9 %, 12:0 (lauric acid) 0.71 %, 14:0 (myristic acid) 0.70 %, 16:0 (palmitic acid) 42.2 %, 18:0 (stearic acid) 1.3 %, total unsaturated fatty acids 55.1 %, 18:1 (oleic acid) 4.7 %, 18:2 (linoleic acid) 30.8 % and 18:3 (linolenic acid) 19.6 % (Talipova 2001). *Helianthus tuberosus* leaves were found to contain protein, amino acid, reducing sugar, organic acids, phenols and tannins, flavonoids, lactones, cardiac glycoside and lipids (Liu et al. 2007). Feruloylquinic

acids, *p*-coumaroylquinic acids, chlorogenic acids, caffeoylquinic acids, diferuloylquinic acids and caffeoylshikimic acids were found in the leaves of *Rudbeckia hirta*, *Helianthus tuberosus*, *Carlina acaulis* and *Symphotrichum novae-angliae* (Jaiswal et al. 2011).

Heliangen, a sesquiterpene lactone and plant growth regulator was isolated from the leaves (Morimoto et al. 1966). Two heliangolides, deacetylviغيستنin (tagitinin E) and erioflorin, were also isolated from the leaves (Morimoto and Oshio 1981). Yoshihara et al. (1992) isolated the following tuber-forming substances from the leaves: tuberonic acid, methyl tuberona glucoside, jasmonic acid, β -D-glucopyranosyltuberonic acid and six acetylene compounds including methyl 3-hydroxy-10, β -D-glucopyranosyloxy-11-dodecen-6,8-diynoate, methyl- β -D-GLUCOPY-RANOSYL helianthenate A and B.

Four tuber-forming substances were isolated from the leaves: jasmonic acid, methyl β -D-glucopyranosyl tuberona and two new polyacetylene compounds, methyl 10-*O*-glucopyranosyl helianthenate A and methyl 8-*O*-glucopyranosyl helianthenate B (Matsuura et al. 1993b); four polyacetylenic glucosides were characterised as methyl 10- β -D-GLUCOPYRANOSYLOXY-3-hydroxy-11-dodecene-6,8-dynoate, the aglycone part named helianthenic acid C; methyl 9- β -D-glucopyranosyloxy-10-undecen-5,7-diynoate, the aglycone part named helianthenic acid D; (4*E*) methyl 10- β -D-GLUCOPYRANOSYLOXY-3-hydroxy-4,11-dodecadiene-6,8-diynoate, the aglycone part named helianthenic acid E and (8*Z*) 10- β -D-GLUCOPYRANOSYLOXY-8-decene-4,6-diynoate the aglycone part named helianthenic F (Matsuura et al. 1993a); six sesquiterpenoids, α -acetoxypinnatifidin; α -hydroxypinnatifidin; budlein A; 17, 18-dehydroviغيپinin; 4,15-isoatriplicolide angelate and 4,15-isoatriplicolide methacrylate (Baba et al. 2005) were isolated from the leaves. Two Jerusalem artichoke chemotypes were found: one was characterised by dominance of 1,10-epoxidised heliangolides and the other by 1-keto-2,3-unsaturated-furanoheliangolides; a total of 19 such sesquiterpene lactones were found in the leaf capitate glandular trichomes (Spring 1991); 7 chlorogenic

acids comprise three caffeoylquinic acids, one feruloylquinic acid and three dicaffeoylquinic acids (Yuan et al. 2008c). Four cytotoxic sesquiterpene lactones, $\Delta^{4,15}$ -isoatripliciolide tiglate, $\Delta^{4,15}$ -isoatripliciolide methacrylates, budlein A isobutylate and budlein A tiglate, were isolated from the CH_2Cl_2 leaf extract (Choi et al. 2012). Eleven sesquiterpene lactones including a new sesquiterpene lactone of 3-hydroxy-8 β -tigloyloxy-1, 10-dehydroariglovin and two known flavones were isolated from the leaves (Yuan et al. 2013).

Two new epoxy steroids, 5 α ,8 α -epidioxy-22 β ,23 β -epoxyergosta-6-en-3 β -ol and 5 α ,8 α -epidioxy-22 α ,23 α -epoxyergosta-6-en-3 β -ol, and ten known steroids including (24*R*)-5 α ,8 α -epidioxyergosta-6-en-3 β -ol; (22*E*,24*R*)-5 α ,8 α -epidioxyergosta-6,22-dien-3 β -ol; (22*E*,24*R*)-5 α ,8 α -epidioxyergosta-6,9(11),22-trien-3 β -ol; β -sitosterol; sitost-5-en-3 β -ol acetate; 7 α -hydroxysitosterol; schleicheol 2; (24*R*)-24-ethyl-5 α -cholestane-3 β ,5 α ,6 β -triol; 7 α -hydroxystigmasterol and stigmasterol were isolated from the leaves of *Helianthus tuberosus* grown in Laizhou salinised land (Li et al. 2011).

Other Aerial Part Phytochemicals

Stems were reported to contain water-soluble polysaccharides (WSPS) 1.4 %, pectinic substances 4.0 %, soluble sugars in alcohol 20.0 % and hemicelluloses 8.0 % (Rakhimov et al. 2011). Lipid composition of Jerusalem artichoke stems was reported as lipids 1.2 %, moisture and volatiles 56.8 %, acid number 5.8 mg KOH, chlorophyll a 11.2 mg/g, chlorophyll b 4.6 mg/g, total carotenoids 1.6 mg/g, fatty acids after saponification 30.3 %, unsaponifiable substances 16.1 %, neutral lipids 58.3 %, glucolipids 35.2 % and phospholipids 6.5 % (Talipova 2001). The fatty composition of the stems was reported as total saturated fatty acids 47.4 %, 12:0 (lauric acid) 0 %, 14:0 (myristic acid) 1.5 %, 16:0 (palmitic acid) 45 %, 18:0 (stearic acid) 0.9 %, total unsaturated fatty acids 52.6 %, 18:1(oleic acid) 2.3 %, 18:2 (linoleic acid) 9.8 % and 18:3 (linolenic acid) 40.5 % (Talipova 2001).

Nine diterpenoid and sesquiterpene lactone were isolated from the chloroform-soluble fraction of the methanol extract of the whole plant: *ent*-17-oxokaur-15(16)-*en*-19-oic acid; *ent*-17-hydroxykaur-15(16)-*en*-19-oic acid; *ent*-15 β -hydroxykaur-16(17)-*en*-19-oic acid methyl ester; *ent*-15-*nor*-14-oxolabda-8(17),12*E*-dien-18-oic acid; 4,15-isoatriplicolide angelate; 4,15-isoatriplicolide methacrylate; (+)-pinoresinol; (–)-loliolide and vanillin (Pan et al. 2008, 2009).

Allelochemical salicylic acid (*o*-hydroxybenzoic acid) and the closely related compound *p*-hydroxybenzaldehyde, as well as minor quantities of *o*-coumarinic acid and coumarin, were found in the diethyl ether shoot extract (Tesio et al. 2011).

Studies using explants of the stem of *Coleus blumei* and the storage tissue of *Helianthus tuberosus* found the pentose phosphate pathway as a source of NADPH for lignin synthesis (Pyrke and ap Rees 1977). Significant amounts of ^3H and ^{14}C were recovered in syringaldehyde, vanillin, *p*-hydroxybenzaldehyde and ligothio-glycollic acid from the explants of *Coleus* and *Helianthus*. The $^3\text{H}/^{14}\text{C}$ ratios in these derivatives and preparations of lignin indicated that much of the reducing power for lignin synthesis comes from the pentose phosphate pathway. An extract from Jerusalem artichoke shoots exhibited important adenine phosphoribosyltransferase activity (Le Floc'h and Lafleuriel 1978). The results suggested that adenine phosphoribosyltransferase of *Helianthus tuberosus* had a key role in the purine salvage pathway. The presence of adenosine and inosine–guanosine nucleosidases (Le Floc'h and Lafleuriel 1981) and hypoxanthine–guanine and adenine phosphoribosyltransferase (Le Floc'h et al. 1982) were found in the shoots. Jerusalem artichoke had been reported to contain low levels of polyamines (putrescine, spermidine or spermine) and explants from its dormant tuber afford a natural polyamine-deficient model for polyamine research in plants (Tassoni et al. 2010).

Transglutaminase activity was found in the crude extract of sprout apices of *Helianthus tuberosus* tubers (Serafini-Fracassini et al. 1988) and in activated slices of medullary

parenchyma tuber tissues (Serafini-Fracassini et al. 1989). Transglutaminase was able to covalently bind polyamines (spermidine, spermine, putrescine) to endogenous substrates of different molecular weights in-vitro. The main bound polyamine was putrescine. Plant transglutaminases displayed characteristics which were different from those of animal transglutaminases. Transglutaminase activity was also demonstrated in green (leaves) and nongreen tissues (flower buds) (Falcone et al. 1993) and during greening and growth of *Helianthus tuberosus* explants developed from dormant tubers in-vitro (Del Duca et al. 1993). This enzyme activity, low in dormant tubers, increased in both explants; considerably in untreated greening explants but much less in 2,4-D-treated growing ones. They also found that light activated transglutaminase conjugation of polyamines to thylakoid proteins in *H. tuberosus* chloroplasts (Dondini et al. 2003). The protective effect on chloroplasts under photo-damage, stress or senescence conditions attributed to free polyamines was elucidated with respect to the occurrence of polyamine conjugates catalysed by transglutaminases. In a recent study, they reported that immature cells of etiolated apices of sprouts growing from *H. tuberosus* tubers exhibited Ca^{2+} -dependent transglutaminase activity on fibronectin (more efficiently) and dimethylcasein as substrates (Beninati et al. 2013). Three main transglutaminase bands of about 85, 75 and 58 kDa were isolated. These three fractions had catalytic activity as catalysed polyamine conjugation to N-benzyloxycarbonyl-L- γ -glutamyl-L-leucine (Z-L-Gln-L-Leu) and the corresponding glutamyl derivatives were identified. Their findings suggested that multiple transglutaminase forms were active in the same organ.

Antioxidant Activity

Tuber peel of tubers were found to contain relatively high levels of total phenolics (39–129 mg GAE/100 g FW) and exhibited high antioxidant capacity (98–296 mg ascorbic acid equivalents/100 g) (Seljåsen and Sliemstad 2007). The level of total phenols was correlated to the antioxidant capacity. The

flesh of tubers contained very low levels of phenols, and antioxidant capacity was not detected for any of the cultivars.

Studies showed that the flavonoids extract (FE) from Jerusalem artichoke had strong DPPH radical scavenging activities (Liu et al. 2009). DPPH radical scavenging activity of FE (95.2 %) was more potent than BHT (77.3 %) and close to the ascorbic acid (97.7 %). In addition, the antioxidation capability of FE was confirmed in lard system, and it was similar to BHT and rutin. Another study showed that the scavenging ability of flavonoid from *H. tuberosus* leaves on superoxide and hydroxyl radicals increased with the increase of flavonoid concentration, up to 66.45 and 69.33 %, respectively, when the flavonoid concentration was 100 µg/mL (Yang et al. 2011). Flavonoid from *H. tuberosus* leaves also had good antioxidant activity on lard and could inhibit the increase of polyphenol oxidase. A more recent study found Jerusalem artichoke leaves to be a potential source of natural antioxidants (Yuan et al. 2012b). The ethyl acetate leaf fraction contained the highest total phenolic content (266.69 mg GAE/g dry extract) accompanied by the strongest free radical scavenging abilities. Six phenolic compounds which strongly quenched free radicals were separated from ethyl acetate fraction. Among them, 3-*O*-caffeoylquinic acid and 1,5-dicaffeoylquinic acid played a dominant role due to their strong free radical scavenging abilities and their high contents. The content of 3-*O*-caffeoylquinic acid in *n*-butanol fraction was 74.58 mg/g, while 1,5-dicaffeoylquinic acid in ethyl acetate fraction was 104.51 mg/g.

Studies by Kim et al. (2010) found that high hydrostatic pressure treatment of fermented Jerusalem artichoke tubers with enzymes significantly improved the extractability of bioactive phenolics and fructooligosaccharides compared to conventional water extraction or high hydrostatic pressure alone. Also, 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical scavenging activity and superoxide dismutase (SOD)-like activity were enhanced compared to the control group.

Antidiabetic and Hypolipidaemic Activities

Due to its low polyamine contents and the abundance of inulin, which could be converted into fructose, Barta and Rosta (1958) in their studies on sugar metabolism of diabetic children suggested the preferential utilisation of Jerusalem artichoke tuber in the diet of people with special needs. In a study of 28 diabetic subjects, daily intake of fructooligosaccharides by 18 diabetic subjects for 2 weeks ameliorated the derangements of carbohydrate and lipid metabolism in diabetic subjects in comparison to ten control diabetic subjects administered with sucrose (Yamashita et al. 1984). The levels of serum HDL cholesterol, triacylglycerides or free fatty acids were not significantly affected either by fructooligosaccharides or sucrose. In an animal study, daily administration of a 10 % (w/w) oligofructose (OFS)-containing diet to normolipidaemic male rats resulted in a decrease in plasma triacylglycerides, phospholipids and cholesterol (Fiordaliso et al. 1995). The triglyceride-lowering effect was observed after 1 week and lasted for at least 16 weeks and was associated with a reduction in plasma very-low-density lipoproteins, indicating that the hypolipidaemic effect of OFS may be due to changes in liver lipid metabolism. They also found that chronic feeding of an OFS-supplemented diet to rats significantly reduced the capacity of isolated hepatocytes to synthesise triacylglycerides from palmitate. Results of a study of 35 patients aged 46–58 with type 2 diabetes mellitus by Meshcheriakova et al. (1995) did not support the use of Jerusalem artichoke as dietary treatment of non-insulin-dependent diabetes mellitus. It was shown that experimental diet containing topinambur caused slight increasing of postprandial hyperglycaemia. In patients eating experimental diet with reduced caloric contents, an increase of serum blood triglyceride level was observed.

In a double-blind randomised placebo-controlled parallel study of 54 healthy middle-aged men and women with moderately raised total plasma cholesterol (TC) and triacylglycerol (TAG) levels, daily addition of 10 g inulin to the diet significantly reduced fasting insulin concentrations during the 8-week test period and resulted in lower plasma TAG levels, particularly in subjects in whom fasting TAG levels were greater than 1.5 mmol/L (Jackson et al. 1999). In a

randomised, double-blind, crossover design with no washout period of 12 hypercholesterolaemic men, dietary inulin supplementation was found to improve blood lipid profiles and altered the colonic environment in a manner that may be beneficial (Causey et al. 2000). Daily intake of 20 g of inulin significantly reduced serum triacylglycerides by 40 mg/dL. A trend towards a reduction in serum cholesterol was observed, and trends towards short-chain fatty acid (SCFA) profile changes were also observed after inulin administration.

Jerusalem artichoke tuber, a rich source for fructooligosaccharides (e.g. inulin), was reported to act as sweeteners that do not affect blood sugar levels after ingestion and could be tolerated by diabetics (Seljåsen and Slimestad 2007). Fructooligosaccharides made up 30–54 % of total carbohydrates, and the rest were sugars (mainly sucrose and low levels of fructose). Righetti et al. (2008) found that in comparison to soya bean products, tofu and soy sauce, the edible part (parenchymatous medulla tissue) of Jerusalem artichoke tuber contained very low levels of polyamines, which preferentially accumulated in the buds. Their data suggested a preferential utilisation of *Helianthus* tuber in the diet of people with special needs, such as patients treated by chemotherapy and patients with diabetes.

Animal studies showed Jerusalem artichoke (JA) as a source of inulin was effective in modifying intestinal characteristics, blood metabolites and liver enzymes in laying hens (Yildiz et al. 2008). Although, with unchanged serum cholesterol and albumen content, 5 % JA increased glucose and decreased fructose, triglyceride and total protein contents when compared with control diet. In contrast 10 % JA reduced serum glucose as well as fructose levels. Serum aspartate aminotransferase levels were increased by 5 % JA in addition, and alkaline phosphatase levels were decreased by 10 % JA. Administration of the ethanol extract of *H. tuberosus* tuber exhibited an inhibitory effect (24.5 %) on diabetic rat kidney tissue thiobarbituric acid reactive substance (TBARS) levels but did not restore GSH (reduced glutathione) levels in the kidney, liver and heart tissues of diabetic rats (Aslan et al. 2010). Studies by Yang et al. (2012) reported that Jerusalem artichoke and chungkookjang (fermented soybeans) enhanced

glucose tolerance in different manners and exhibited partially additive and complementary effects by reversing insulin resistance and enhancing β -cell function in diabetic rats. The combined treatment reduced visceral fat without modulating energy intake compared to the diabetic control.

Animal studies showed that Jerusalem artichoke tuber syrup possessed hypoglycaemic activity (Rakhimov et al. 2011). The hypoglycaemic effect after just a single administration to rats at a dose of 0.4 mL/100 g was 21.2 % after 3 hours; the syrup was more active than arfazetin (11 %) and adebit (14.2 %). Blood sugar level continued to remain at a reduced level over the 2-week period of multiple administrations of the syrup, dropping by 23.3 and 27.8 % with respect to the initial value after 7 and 14 days. During the same periods, blood glucose dropped by 14.1 and 16.5 %, respectively, for arfazetin and by 18.8 and 19.9 % for adebit. The hypoglycaemic effect of the syrup was even more evident during disrupted carbohydrate exchange when the initial blood glucose level was rather high. A pronounced hypoglycaemic effect of Jerusalem artichoke syrup was also determined for alloxan hyperglycaemia and alloxan diabetes. Administration of the syrup for a week lowered the blood glucose level by 31.7 %, while arfazetin exhibited a hypoglycaemic effect of 10.4 % and adebit by 25.4 %. The hypoglycaemic properties of Jerusalem artichoke syrup in tests on normal animals were also manifested to a greater extent than adebit. Their effects were equivalent overall in tests on animals with hyperglycaemia.

Oral administration of Jerusalem artichoke inulin was found to reduce blood glucose and lipid in streptozotocin-induced diabetic rats (Park 2011). Blood glucose was significantly lowered in the inulin-administrated groups. Compared with diabetic control rats, the decrease of blood glucose in the inulin-administrated groups was 60.73–63.4 % in the fourth week and showed a tendency of gradual recovery. Triacylglycerides in the blood, total cholesterol, LDLC and atherogenic index were significantly decreased by 27.13–32.91, 22.42–23.31, 35.41–38.28 and 49.71–57.11 %, respectively, in the inulin-administrated groups compared to

the diabetic control group. Conversely, HDLC was significantly increased by 24.89–47.20 %. The weights of the liver, kidney and heart but not the spleen were significantly heavy in the diabetic control group, compared with the inulin-administrated groups.

A study of eight healthy subjects found that after *H. tuberosus* fructans ingestion blood glucose (BG), insulin increments were very low, much lower than after fructose ingestion, whereas hydrogen production was much higher and fructans were malabsorbed (Rumessen et al. 1990). Areas under BG curves tended to be smaller when 10 g fructans was added to a 50 g wheat starch meal, but there was no apparent interference with starch absorption. Orocaecal transit times were longer for fructans than for lactulose and fructose. In a 4-week double-blind crossover design study of 12 healthy subjects, 20 g of a mixture of short-chain fructooligosaccharides (SC-FOS), namely, kestose (glucose–fructose–fructose, GF2), nystose (GF3) and fructosyl–nystose (GF4) decreased basal hepatic glucose production but had no detectable effect on insulin-stimulated glucose metabolism in healthy subjects (Luo et al. 1996). Serum triacylglycerines, total and high-density lipoprotein cholesterol, apolipoproteins A-I and B and lipoprotein (a) were not modified by FOS. They found that colonic fermentation pattern of indigestible carbohydrates may be relevant to predicting their metabolic effects. In another double-blind crossover design study of six men and four women with type 2 diabetes, 4 weeks of 20 g/day of short-chain fructooligosaccharides (SC-FOS) had no effect on glucose and lipid metabolism. SC-FOS did not modify fasting plasma glucose and insulin concentrations or basal hepatic glucose production.

In a randomised, single-blind, crossover design clinical study involving 20 patients with type 2 diabetes, Alles et al (1999) found that 20 days of dietary supplementation with fructooligosaccharides had no major effect on blood glucose, serum lipids or serum acetate in patients. This lack of effect was not due to changes in dietary intake, insufficient statistical power or noncompliance of the patients. Their results did not support earlier claims that fructooligosaccharides lowered

fasting glycaemia and serum total cholesterol concentrations, possibly via effects of short-chain fatty acids produced during fermentation.

Of nine studies conducted in both normo- and moderately hyperlipidaemic subjects that investigated the response of blood lipids (usually total and LDL cholesterol and triacylglycerol) to inulin or oligofructose supplementation in human volunteers, three had observed no effects of inulin or oligofructose on blood levels of cholesterol or triacylglycerol and three had shown significant reductions in triacylglycerol, while four have shown modest reductions in total and LDL cholesterol (Williams and Jackson 2002). They stated that variability in response may be a reflection of differences in background diet or the experimental foods used, and it did not appear to be due to differences in the type or dose of oligosaccharides used nor the duration of the studies.

Anticancer Activity

Pierre et al. (1997) showed that short-chain fructooligosaccharides counteracted advanced stages of colon carcinogenesis in mice, possibly via stimulation of antitumoral immunity by modulation of the colonic ecosystem. Wounds from Jerusalem artichoke tubers were reported to excrete bioactive metabolites including proteins that were cytotoxic to some human tumour cell lines, especially the human mammary tumour cells MDA-MB-231 (Griffaut et al. 2007). The active agent was found to contain an 18 kDa superoxide dismutase (SOD) polypeptide, tightly linked to a 28 kDa alkaline phosphatase (AP) polypeptide. The superoxide dismutase polypeptide was shown to be involved in the antitumour activity, but the presence of smaller factors (MW <10 kDa), such as salicylic acid, could enhance this activity. Extracts of *H. tuberosus* aerial parts were found to possess antimicrobial and antifungal activities, and heliangin, a germacrene sesquiterpene lactone isolated from the leaves of this plant, exhibited significant activity in-vitro against Ehrlich ascites carcinoma cells (Ahmed et al. 2005).

Two germacrene-type sesquiterpene lactones isolated from Jerusalem artichoke, 4,15-isoatriplicolide angelate and 4,15-isoatriplicolide methacrylate, were found to be cytotoxic on MCF-7 human breast cancer cell line (Pan et al. 2009). The CH₂Cl₂ extract of *Helianthus tuberosus* leaves exhibited potent cytotoxic activity against the cultured human tumour cell lines including lung carcinoma A-549, adenocarcinoma SK-OV-3, malignant melanoma SK-MEL-2, central nervous system tumour XF498 and colon adenocarcinoma HCT-15 in-vitro (Choi et al. 2012). Of the four cytotoxic sesquiterpene lactones isolated from the extract, $\Delta^{4,15}$ -isoatripliciolide tiglate showed the most potent cytotoxic activity ($0.26 \mu\text{M} < \text{ED}_{50} < 2.16 \mu\text{M}$) against all of the cell lines tested. Eleven sesquiterpene lactones isolated from leaves exhibited cytotoxicity against MCF-7, A549 and HeLa cancer cell lines, while two isolated flavones showed selective inhibitory activity against HeLa cell lines (Yuan et al. 2013). Among them compound 3 exhibited significant growth inhibitory activity against all three cell lines and the IC₅₀ values of compound 3 against MCF-7, A549 and HeLa were 1.97, 7.79 and 9.87 $\mu\text{g/ml}$, respectively.

Antimicrobial Activity

The new epoxy steroids compounds from the leaves, 5 α ,8 α -epidioxy-22 β ,23 β -epoxyergosta-6-en-3 β -ol (1) and 5 α ,8 α -epidioxy-22 α ,23 α -epoxyergosta-6-en-3 β -ol (2), exhibited weak antibacterial activity and no antifungal activity (Li et al. 2011). Compound (1) showed weak inhibitory activity against *Escherichia coli* and *Staphylococcus aureus* and compound (2) against *Escherichia coli*.

Heltuba, lectin from *H. tuberosus* tubers, was highly specific for the disaccharides Man α 1-3 Man or Man α 1-2 Man, two carbohydrates that were particularly abundant in the glycoconjugates exposed on the surface of viruses, bacteria and fungi and on the epithelial cells along the gastrointestinal tract of lower animals, indicating heltuba to be a good candidate as a defence protein against plant pathogens or predators (Bourne et al. 1999).

Prebiotic/Probiotic/Synbiotic Activities

Studies with rats and in-vitro studies with bacteria isolated from the large intestine of man showed that inulin (a prebiotic) was almost completely metabolised in the large intestine where it provided a selective growth substrate for bifidobacteria (Hidaka et al. 1986; Wang and Gibson 1993). Animal studies by Campbell et al. (1997) found that dietary incorporation of fermentable, indigestible oligosaccharides, by providing short-chain fatty acids, lowering pH and increasing caecal bifidobacteria, may be beneficial in improving gastrointestinal health.

In a study of 12 healthy adult human subjects, 4 g fructooligosaccharide (neosugar)/day for 42 days altered the faecal flora (increased bifidobacteria densities) in a manner perceived as beneficial by decreasing activities of some reductive enzymes, β -glucuronidase and glycocholic acid hydroxylase (Buddington et al. 1996). In another study of 20 volunteers, ingestion of fructooligosaccharides (FOS), at a clinically tolerated dose of 12.5 g/day for three consecutive 12-day periods, led to an increase in colonic bifidobacteria and β -fructosidase activity (Bouhnik et al. 1996). FOS ingestion had no significant effect on the faecal total anaerobes, pH, the activities of nitroreductase, azoreductase and β -glucuronidase and the concentrations of bile acids and neutral sterols. The observed effect was not associated in healthy humans with beneficial changes in various factors potentially involved in the pathogenesis of colonic cancer. In a study of eight healthy human subjects, prolonged administration (up to 21 days) of transgalacto-oligosaccharides, at a dose which did not induce digestive symptoms, increased the number of bifidobacteria, altered the fermentative activity of colonic flora and caused a significant decrease in breath hydrogen in humans. Short-chain fructooligosaccharide (SC-FOS) administration dose dependently increased faecal bifidobacteria in healthy humans (Bouhnik et al. 1999). A significant correlation between the dose of SC-FOS ingested and the faecal bifidobacteria counts was observed at day 8. In subsequent studies they showed that 4-week 8 g/day SC-FOS ingestion was well tolerated and led to a significant increase in faecal bifidobacteria and

cholesterol excretion in healthy elderly subjects (Bouhnik et al. 2007).

Studies by Kocsis et al. (2007) on the effect of seasonal changes and varieties on the soluble carbohydrate (sucrose, inulin) profiles would help in selecting suitable cultivars and deciding the appropriate harvest time for an optimum processing of tubers for their application as prebiotic and novel food component. They found a high content (60–65 % of dry mass DM) of water-soluble carbohydrates (sucrose, inulin) in early harvested varieties (Bella and Bianka) and middle early varieties (Topstar and Gigant) harvested 22–25 weeks after planting. In late varieties (Waldspindel, Violet de Rennes, Rote Zonenkugel), a similar amount was obtained (55–60 % of DM) when harvested 29–33 weeks after planting. There was a distinctive impact on maturing process as well as frost period alterations which resulted in conversion of high polymer inulin to low polymer inulin as well as to sucrose. Studies showed that *Lactobacillus* strains could be used for the fermentation of Jerusalem artichoke tuber juice (rich in the prebiotic inulin), which in fermented form could be used alone or mixed with other raw food material, as a new synbiotic functional food (Zalán et al. 2011).

Adding dried Jerusalem artichoke to diets of entire male pigs 1 week before slaughter resulted in a dose-dependent decrease in skatole levels in the hindgut and adipose tissue (Vhile et al. 2012). The reduced skatole levels might be related to the decrease in *Clostridium perfringens* in the colon and rectum and enterobacteria in the colon and also to the increase in short-chain fatty acids (SCFA) with subsequent reduction in pH.

In a 4 week, double-blind, randomised, placebo-controlled trial involving 66 adult men with functional constipation, dietary supplementation (twice daily) of a symbiotic mixture comprising fructooligosaccharides (prebiotics) and *Bifidobacterium*, *Lactobacillus* and *Streptococcus* species (probiotics) significantly increased stool frequency compared to control at week 2 (Fateh et al. 2011). In another randomised, double-blind, placebo-controlled study of 20 women and 16 men (25–45 years old), dietary administration of a

commercialised synbiotic product containing *Lactobacillus acidophilus* La5, *Bifidobacterium animalis* ssp. *lactis* Bb-12, *Lactobacillus delbrueckii* ssp. *bulgaricus*, *Lactobacillus paracasei* ssp. *paracasei*, *Streptococcus thermophilus* and fructooligosaccharides caused a significant improvement in overall self-reported gastrointestinal symptoms and bowel habit (Nova et al. 2011). A marginal effect of treatment was observed with L-selectin, which showed a significant decrease in the synbiotic group. In a randomised, double-blind, placebo-controlled study involving 100 constipated adult women, dietary supplementation with a synbiotic composed of fructooligosaccharides (prebiotics) with *Lactobacillus* and *Bifidobacterium* (probiotics) improved evacuation parameters and constipation intensity of chronically constipated women, without influencing abdominal symptom (Waitzberg et al. 2012).

Immunomodulatory Activity

Gamma inulin (g-IN), a polymorph identified as the active component of inulin preparations that specifically activates the alternative pathway of complement (APC) that is central to many leucocyte functions, including B cell activation, was found to be a potent adjuvant for both humoral- and cell-mediated responses to a variety of antigens (Cooper and Steele 1988). Gamma inulin and especially Algammulin (alum and inulin) were reported to be potent enhancers of the Th1 immune response pathway, boosting seroconversion rates and immunological memory in protective Ab classes and enhancing cell-mediated immunity (Cooper 1995). They are also Th2 pathway enhancers, especially for IgA, and the emphasis on Th2 might be varied by altering the alum-to-inulin ratio in the final formulation. Their primary targets *in vivo* were probably lymphocytes rather than macrophages. Gamma inulin-based adjuvants comprise new, safe, potent and attractive candidates for enhancing responses to human and veterinary vaccines, especially those requiring cell-mediated defences. Finely divided, insoluble inulin (gamma inulin), given intraperitoneally (i.p.) to C57BL mice 1–3 days after i.p. B16 melanoma cells, very significantly increased their mean

survival time (MST) in low doses (Cooper and Carter 1986). The gamma inulin was pure and free of endotoxin and soluble inulin and was developed as a potent reagent specific for activating the alternative pathway of complement (APC). The minimum i.p. dose of gamma inulin found to activate serum APC in-vivo was 50 mcg (2.5 mg/kg), i.e. close to the minimum antitumour dose.

Results of studies suggested that dietary fructooligosaccharides (FOC) supplementation to BALB/c mice altered the intestinal environment of microflora and led to upregulation of immunoglobulin A (IgA) secretion in CD4+ Peyer's patch cells in intestinal mucosa and to suppression of the systemic immune response to type 2 helper T (Th2) dominant (Hosono et al. 2003). Similarly, it was shown that dietary FOS increased the intestinal IgA response and immunoglobulin receptor (pIgR) expression in the small intestine as well as the colon in infant mice (Nakamura et al. 2004).

Calcium and Magnesium Absorption Activity

Studies found that feeding rats with fructooligosaccharides significantly increased calcium and magnesium absorption and that indigestible and fermentable carbohydrate facilitated colorectal absorption of calcium and magnesium (Ohta et al. 1995). Animal studies showed that the ingestion of all the tested fructans 10 % oligofructose (OF) (DP (av) 4) or 10 % HP-inulin (DP (av) 25), a blend of 50 % OF and 50 % HP-inulin 10 % oligofructose (OF) (DP (av) 4) or 10 % HP-inulin (DP (av) 25) and a blend of 50 % OF and 50 % HP-inulin led to a considerable caecal fermentation in rats (Coudray et al. 2003). All tested compounds increased the intestinal absorption and balance of Mg significantly. Also, all tested compounds increased the intestinal absorption and balance of Ca numerically, but only the blend OF + HP-inulin increased apparent intestinal absorption and balance of Ca significantly.

Traditional Medicinal Uses

Jerusalem artichoke is reported to be aperient, aphrodisiac, cholagogue, diuretic, spermatogenic, stomachic and tonic. It has been reported to be used as a folk remedy for diabetes and rheumatism (Duke and Wain 1981). Additionally, the leaves of *H. tuberosus* showed antipyretic, analgesic, anti-inflammatory effects and were therefore used as folk medicine in China for the treatment of bone fracture, skin wound, swelling and pain (Yuan et al. 2008c, 2012b). *Helianthus tuberosus* tubers are used as folk remedy for the treatment of diabetes in Turkey (Aslan et al. 2010). *H. tuberosus* has aperient, aphrodisiac, cholagogue, diuretic, spermatogenic, stomachic and tonic effects and has been utilised as a folk medicine for the treatment of rheumatism for the presence of inulin, which can be converted into fructose (Kays and Nottingham 2007).

Other Uses

Inulin Production

Helianthus tuberosus had proven to be a rich source of inulin and was well characterised as potential crops for commercial fructose production (Fleming and GrootWassink 1979).

The Jerusalem artichoke is an excellent crop for inulin production, and the United States, Russia and some European countries use it in their food and in pharmaceutical industries as a raw material because of its valuable properties (Ziyan and Pekyardimci 2003).

Taha et al. (2012) combined the use of biotic elicitor, *Aspergillus niger*, and methyl jasmonate to enhance inulin accumulation in Jerusalem artichoke cell cultures.

Fructans can be used in the food industry and in several nonfood industrial and medical applications, and Jerusalem artichoke accumulates fructans as storage reserves and is widely appreciated for its high fructans yield with low input techniques (Monti et al. 2005).

Animal Feed

Jerusalem artichoke herbage was found to be a good source of a high-quality protein isolate rich in lysine and may provide good ruminant feed (Rawate and Hill 1985).

Studies suggested that whether Jerusalem artichoke is mixed with other forbs or grasses in a pasture or hay or whether it is used as silage, it appeared to have the potential to provide a satisfactory nutrition level for ruminants (Seiler 1988). Crude protein (CP) concentrations of 140 g/kg and above occurred in leaves of 11 of 19 genotypes at the vegetative stage, and 15 of the 19 genotypes had whole plant CP of 60–90 g/kg at all stages of maturity. Nutritionally adequate amounts of Ca (2–8.6 g/kg), Mg (1 g/kg) and K (6.5 g/kg) were present in leaves, stems and whole plants of all genotypes at all stages of maturity. Leaves, stems and whole

plants of most genotypes had suboptimal P (<2 g/kg) levels for ruminants at all stages of maturity. Nutritionally adequate amounts of CP, Ca, Mg and P were present in whole seeds of most genotypes. Seiler (1993) found the cultivated Jerusalem artichoke ‘Sunchoke’ had the highest forage yield (6.3 Mg/ha) which was comparable to some common forage species. The cultivated genotypes also had the highest mean tuber yield (7.19 Mg/ha). At maturity, the allocation of biomass for Jerusalem artichoke was 68, 23 and 9 % for stems, leaves and heads, respectively. At flowering, the whole plant concentration of in-vitro digestible dry matter (IVDDM) was above the accepted level (598 g/kg) for adequate animal nutrition for most. *H. tuberosus* is an economically important crop species, with aerial parts, and the tubers are used as forage for cattle (Long et al. 2008). Tubers contain adequate amounts of macro- and microelements for use as cattle feed. There was an adequate amount of studied mineral elements except for phosphorus in Jerusalem artichoke herbage for use as ruminant cattle feed (Terzić et al. 2012). Of all the analysed essential elements in leaves (N, P, Ca, Mg, K, Fe, Mn, Zn and Cu), Ca was the most abundant (36 g/kg), while in tubers it was only the fourth of the nine analysed elements. The Ca/P ratio was approximately the same in tubers of all accessions which corresponds to a desired ratio for cattle feed (1:1–2:1). The leaves contained 18 times more Ca than P. Studies by Meijer and Mathijssen (1991) have suggested that *H. tuberosus* can be utilised as a stalk crop, which can be harvested at the beginning of flowering, since its above-ground biomass is high and stores temporary amounts of fructans in the stalk. Then the tops can be fed fresh or ensiled, although the forage does not ensile well because of its high concentration of soluble sugars and high moisture content.

Fructose Production

Jerusalem artichoke tubers are an important source of fructose as a sweetener for the food industry (Pilnik and Vervelde 1976). Analysis involving 37 cultivars originating from France or overseas showed that among the early cultivars studied, ‘Grando’ appears to be the richest with 193 mg/g fresh wt of

dry matter (DM) and 508 mg/g DM of fructose (as fructan) (Chekroun et al. 1996). For fructose production, among the late white cultivars analysed, 'Kharkov' gave the best performance with 179 mg/g fresh wt of DM, 531 mg/g DM of fructose and 710 mg/g DM of total carbohydrates. The French cultivars 'Miello', 'Dub' and 'Rico' were considered in their group as the most productive with 549, 545 and 540 mg/g DM of fructose, respectively. Jerusalem artichoke can also be used as a perennial sugar (fructose) crop by only harvesting the stalks for many years around the flowering time before the carbohydrate translocation to the tubers occurs (D'egidio et al. 1998). The possibility of exploiting the stalk of the plant, instead of the tuber, as a source of sugar was reported by Caserta and Cervigni (1991) using a late hybrid characterised by well-developed stalks and low production of tubers on marginal land. Glucose-free fructose production from Jerusalem artichoke inulin was achieved using recombinant inulinase-secreting strain of *Saccharomyces cerevisiae* in a one-step fermentation (Yu et al. 2011).

Biogas, Biofuel: Ethanol, Biodiesel Production

Anaerobic digestion experiments showed that fresh and ensiled above-ground parts of the plant could produce 480–680 l biogas per kg organic material (Gunnarson et al. 1985). Their results confirmed that economic biogas production from above-ground parts of Jerusalem artichoke was possible under certain conditions. Jerusalem artichoke also has a great deal of unused potential as a producer of ethanol for fuel, using inulin-adapted strains of yeast for fermentation. Jerusalem artichoke tubers have been reported to have one of the highest carbohydrate yields of known agricultural crops ranging between 2,400 and 900 kg sugars per acre/year which is equivalent to about 1,000–2,400 kg ethanol/acre/year assuming an ethanol yield of 80 % of the theoretical (Margaritis et al. 1981). Margaritis et al. (1981) used batch of Jerusalem artichoke tubers by seven yeasts and *Zymomonas mobilis* to convert to ethanol and microbial biomass. Williams and Ziobro (1982) used *Kluyveromyces fragilis* fermentation

for the production of ethanol from Jerusalem artichoke tubers and inulin. Groot Wassink and Fleming (1980) found that *Kluyveromyces fragilis* inulase (β -fructofuranosidase) to be a better alternative to *Saccharomyces cerevisiae* invertase presently used in industry for fermentation. *H. tuberosus* was used as a raw material for the production of motor fuel alcohol during the Second World War and had been sporadically used for this purpose until now (Chekroun et al. 1996).

Studies by Cheng et al. (2009) showed that it was feasible to produce biodiesel from Jerusalem artichoke tuber using heterotrophic microalga *Chlorella protothecoides*. Lipids produced could be converted into biodiesel by transesterification. Cetane acid methyl ester, linoleic acid methyl ester and oleic acid methyl ester were the dominating components of the biodiesel produced. Unsaturated fatty acids methyl ester constituted over 82 % of the total biodiesel content.

The yield of ethanol from Jerusalem artichoke tubers by using *Kluyveromyces marxianus* in batch fermentation was calculated to be in the range of 1,400 kg ethanol/acre/year to a maximum of 2,700 kg ethanol/acre/year (Margaritis and Bajpai 1982). Single-cell protein yields for *K. marxianus* were calculated to range between 130 and 250 kg dry wt cell/acre/year. Yeasts with inulinase activity could be used to produce ethanol from Jerusalem artichoke tubers with good profitability, obtaining 25–65 hl ethanol/ha with by-products usable as feed (Guiraud et al. 1981). Guiraud et al. (1982) obtained the following fermentation yield from fermentation of Jerusalem artichoke extract by various yeast cultivated in anaerobiosis: *Candida kefir* (95 %), *C. macedoniensis* (91.5 %), *C. pseudotropicalis* (86.5 %), *Kluyveromyces marxianus* (98 %), *K. fragilis* (95 %), *Saccharomyces fermentati* (94 %), *Schwanniomyces castellii* (89 %) and *Torulopsis colliculosa* (96.5 %). Guiraud et al. (1986) found that using an aerobic phase to increase biomass of early harvest tubers prior to the anaerobic fermentation by *Kluyveromyces marxianus* could enhance ethanol yield. The ethanol yield after enzymatic hydrolysis before fermentation (expressed as % theoretical yield) was 78.3–90.0 % and 72.4–84.2 % for the bacterium

Zymomonas mobilis and yeasts (distillery yeast *Saccharomyces cerevisiae* and a yeast with inulinase activity), respectively, in tubers as well as 78.3–88.1 % and 74.4–82.2 % for the bacterium and yeasts in juices (Szambelan et al. 2004). The yield was 2.0–9.2 % higher than after acid hydrolysis. The yeast with an active inulinase yielded better when juices were used for fermentation than on mashed tubers. Although enzymatic hydrolysis with an inulinase gave less reducing sugars, it was significantly more efficient in fermentation process. Studies by Curt et al. (2006) showed that bioethanol can be produced from Jerusalem artichoke stems, and they estimated that the potential of the stems of the mid-season/late clones for bioethanol was 38 % that of the tubers. Studies showed that the carbohydrates derived from Jerusalem artichoke stalks could be converted efficiently to ethanol by acidic hydrolysis followed by fermentation with *Saccharomyces cerevisiae* or by direct fermentation of inulin using *Kluyveromyces marxianus* strains (Negro et al. 2006). Fresh Jerusalem artichoke tubers grown in salina and irrigated with 25 and 50 % seawater were found to be sustainable feedstock for ethanol fuel production by *Kluyveromyces marxianus* fermentation; also it did not compete with other crops for arable land (Yuan et al. 2008b). The yeast *Kluyveromyces cicerisporus* was found to be a promising candidate for industrial ethanol production from Jerusalem artichoke tubers by simultaneous saccharification and fermentation approach (Yu et al. 2010).

Yuan et al. (2012a) developed a consolidated bioprocessing (CBP) strategy that integrated inulinase production, saccharification of inulin contained in Jerusalem artichoke tubers and ethanol production from sugars released from inulin by the enzyme was developed with the inulinase-producing yeast *Kluyveromyces marxianus* Y179 and fed-batch operation. Thermotolerant *Kluyveromyces marxianus* and *Saccharomyces cerevisiae* strains were found to have promising potential for bioethanol production from Jerusalem artichoke by consolidated bioprocessing (Hu et al. 2012). Kim and Kim (2014) reported a cost-effective consolidated bioprocessing strategy for bioethanol production from the whole Jerusalem artichoke plant using *Kluyveromyces*

marxianus. The ethanol yield was 0.252 g ethanol per g dry biomass or 0.32 g ethanol per g fermentable sugars, with a fermentable sugar conversion rate of 60 %.

Sun et al. (2009) showed Jerusalem artichoke tuber to be a favourable substrate for 2,3-butanediol production, one of many promising bulk chemicals with wide applications for biofuel production. The application of fed-batch simultaneous saccharification and fermentation by *Klebsiella pneumoniae* for its conversion could result in a more cost-effective process. *Helianthus tuberosus* was reported to be a good source of dimethylfuran production and to be better than ethanol for biofuel production (Cao et al. 2008). 5-Hydroxymethylfurfural (HMF) was produced from monosaccharide (fructose and glucose), polysaccharide (inulin) and the Jerusalem artichoke juice by a simple one-pot reaction including hydrolysis and dehydration using solid acid under mild condition (Yang et al. 2010). A simple method for hydroxymethylfurfural (HMF) production from non-crop biomass of the Jerusalem artichoke was developed using the Fenton reaction, in a mixture of 2-butanol and water by Seo and Han (2012).

Industrial Chemical/Pharmaceutical Production

Kays and Nottingham (2007) have listed a long list of chemicals derived from Jerusalem artichoke inulin and their potential industrial uses: inulin, oligofructose, fructooligosaccharides as prebiotic ingredient in numerous foods; inulin dietary fibre as low-calorie fibre/bulking agent and thickener; inulin ingredient as fat replacement in low-calorie foods; inulin ingredient as sweetener/low-calorie sugar replacement; fructose (crystallised), fructose (syrops, high syrops) in numerous food industry uses; fructose dianhydrides as low-calorie sweeteners; highly purified inulin for medicinal/diagnostic uses; inulin esters as plasticisers, surfactants and binders; cyclic inulooligosaccharides for many potential industrial uses; furfural solvent, used in oil refining and in resins; hydroxymethylfurfural, mannitol acetone, butanol and succinic acid for numerous industrial uses;

glycerol and lactic acid for numerous food and nonfood industry uses; 1,2-propanediol for food, nonfood and medicinal uses; ethylene glycol as antifreeze; 2,3-butenediol fuel additive and use in plastics; *O*-succinylated inulin as drug carrier; methylated inulin and dialdehyde inulin as precursors for additional products; inulin carbonates for insolubilisation of biologically active molecules; *O*-(carboxymethyl) inulin as detergent binders; inulin ethers immunological assays; inulin carbamates emulsions and suspensions; inulin-amino acids for medicinal usage, *O*-(cyanoethyl) inulin paper industry usage; *O*-(3-amino-3-oxopropyl) inulin emulsifier and surfactant; *O*-(3-hydroxyimino-3-aminopropyl) inulin chemical industry uses; *O*-(aminopropyl) inulin used in detergents; *O*-(aminopropyl) inulin derivatives range of industrial uses, including cosmetics; stearyl amide surfactant and emulsifier used in detergents; N-carboxymethylaminopropylated inulin sequestering agent for detergents; cycloinulohexaose derivatives used in cosmetics; alkoxylated inulin stabilising properties inulin phosphates thermally reversible gels; and complexing agents precipitation of heavy metals.

Compounds produced by *Lactobacillus* strains during fermentation of Jerusalem artichoke tuber juice included organic acids (lactic acid, 110–337 mmol/L; acetic acid, 0–180 mmol/L; and succinic acid, 0–79 mmol/L), hydrogen peroxide (0.25–1.77 mg/L), mannitol (0.06–3.24 g/L), acetoin and diacetyl production (Zalán et al. 2011).

Lactic acid and high yield of fructose was produced by hydrolysis of Jerusalem artichoke tubers using the commercial glucoamylases, GA-L New from Genencor (Dao et al. 2013). GA-L New was used as the inulinase and *Pediococcus acidilactici* DQ2 as the fermenting strain in the simultaneous saccharification and lactic acid fermentation of the tubers. A high lactic acid titre, yield and productivity of 111.5 g/L, 0.46 g/g DM and 1.55 g/L/hour, respectively, were obtained within 72 hours.

Ornamental and Bee Plant

Free-blooming Jerusalem artichoke cultivars are also grown as ornamental and as a source of nectar for bees.

Soil Phytoremediation and Improvement

In pot experiment studies, Jerusalem artichoke was found to remove heavy metals Cd, Pd, Ni, Cu and Zn from heavy metal-contaminated soils and accumulating them in the plant (Jasiewicz and Antonkiewicz 2002). Ma et al. (2011) reported that Jerusalem artichoke, a salt-resistant plant, has been widely cultivated in Shanxi, Heilongjiang, Shandong and Jiangsu provinces for improving salt-alkaline soils, oil-polluted soils and coal-mining soils. Several Jerusalem artichoke genotypes were found to have promising soil phytoremediation activity in removal of heavy metal pollutants like cadmium from contaminated soil (Long et al. 2013).

Antifungal Control Agents

The ethyl acetate leaf extract exerted the highest antifungal activity, with inhibitory rates of 77.91 %, 100 and 100 % against plant pathogens *Rhizoctonia solani*, *Alternaria solani* and *Botrytis cinerea*, respectively, at a concentration of 20 mg/mL (Liu et al. 2007). The crude leaf extract and its *n*-butanol fraction exhibited antifungal activity in-vitro against *Botrytis cinerea*, *Colletotrichum gloeosporioides*, *Phytophthora capsici* and *Rhizoctonia cerealis*, with the values of IC₅₀ ranging from 2.166 to 2.534 g/L for the crude leaf extract and 0.232–1.911 g/L for *n*-butanol fraction (Chen et al. 2013). The severity of grey mould caused by *B. cinerea* was significantly reduced by *n*-butanol fraction applied at 1 and 2 g/L with the control efficiency of 71.3 and 77.8 %, respectively, compared with commercial fungicide carbendazim. Among the phenolic acids isolated from the *n*-butanol fraction, caffeic acid, 3,4-dicaffeoylquinic acid and 1,5-dicaffeoylquinic acid played a dominant role and were active in bioassays against *Gibberella zeae*, with respective minimum inhibitory concentrations (MIC) being 108, 60 and 4.2 µg/mL.

Weed Management

Studies showed that diethyl ether shoot extract of *H. tuberosus* cultivar Fuseau was consistently most inhibitory to germination and seedling growth of lettuce (Tesio et al. 2010). Salicylic acid (*o*-hydroxybenzoic acid) and the closely related compound *p*-hydroxybenzaldehyde, as well as minor quantities of *o*-coumarinic acid and coumarin, were identified in the active fraction inhibiting lettuce seedling growth. Field observations provided further evidence for the allelopathic potential of *H. tuberosus* residues, as significant weed growth inhibition was observed in Jerusalem artichoke-infested plots with soil-incorporated residues in comparison to noninfested field sites, both in terms of weed seedling emergence and growth. The allelopathic potential of *H. tuberosus* may be of interest in the implementation of integrated weed management programmes in the field.

Comments

Jerusalem artichoke is propagated by tubers, and planting is usually done in the spring.

Smallanthus sonchifolius

T. K. Lim¹✉

(1) Canberra, Aust Capital Terr, Australia

Scientific Name

***Smallanthus sonchifolius* (Poepping and Endlicher) H.
Robinson**

Synonyms

Polymnia sonchifolia Poepping and Endlicher, *Polymnia edulis* Wedd.

Family

Asteraceae

Common/English Names

Bolivian sunroot, Earth Apple, Strawberry jicama, Sweet root, Yacón, Yacon Strawberry

Vernacular Names

Argentina: Llacon, Llacjon, Illag'on, Yacón

Bolivia: Aricona, Aricoma, Aricuma (Aymara), Llacon, Llacjon, Llacoma, Llacón (Quechua), Illag'on, Polaco, Puhe, Racón, Shicama, Taraca, Yacón

Columbia: Arbolocao, Chicama, Colla, Jacón, Jicama, Jíquima, Jiquimilla

Ecuador: Chicama, Jicama, Jiquima, Jiquimilla, Shicama

French: Poire De Terre

Japanese: Yaakon

Peru: Aricoma (Aymara), Llacon, Llacjon, Llacoma, Llacón, (Quechua), Illag'on Polaco, Puhe, Racón, Shicama, Taraca, Yacón

Quechua: Llamón, Llaqon, Yacumpi

Spanish: Jíquima, Jiquimilla, Llacon, Yacón

Venezuela: Chicama, Colla, Jacón, Jicama, Jíquima, Jiquimilla

Origin/Distribution

Yacon is indigenous to the humid slopes of northern and central Andes from southern Columbia to northern Argentina. The area with the largest clone diversity extends from northern Bolivia to central Peru where native Quechua and Aymara names are used. Diversity of clones is more reduced in Ecuador. The plant has naturalised elsewhere in South America. It has become an important crop in Brazil especially in the state of Sao Paulo. It grows well in southern Australia, Tasmania and New Zealand, where the climate is mild and the growing season long. It has recently been introduced to the Philippines, Malaysia (Cameron Highlands), southern USA, Czech Republic, Russia, Taiwan, Korea and Japan and is now widely available in local markets.

Agroecology

The native habitat of yacon is in areas with tropical montane climates between 1,800 and 2,800 m altitude. Although the mountain forests of central Peru and northern Bolivia are evergreen and supplied with abundant rainfall and mist during most of the year, they are subjected to a relatively dry winter period lasting 2–4 months. This drier and slightly cooler interval may generate conditions under which large tuberous roots could have an adaptive advantage. Yacon will grow in a range of climates (temperate and subtropical) and soils from sea level up to 3,200 m elevation. Optimal growth has been reported in temperatures ranging from 18 to 25 °C; aerial organs cannot withstand frost and sustain damage in temperatures below –1 °C. Mean annual rainfall of 800 mm or more is deemed optimum. Yacon thrives best in light, deep, well-drained soils rich in organic matter and with neutral to slightly acidic pH.

Edible Plant Parts and Uses

Yacon tubers are crisp and sweet tasting and can be eaten raw after peeling the skin; it has a texture and flavour described as a blend of apple and watermelon. In yacon producing countries, products made from yacon root includes flour, dehydrated products, slice or chips, juices, purees and sweeteners in the form of syrup or tea with high fructooligosaccharide (FOS), and yacon leaves are dried and used for tea (NRC 1989). Both yacon root syrup and teas are popular among diabetic people and dieters because the fructose sugar (FOS) these products contain is not hydrolysed or absorbed by humans. The FOCs act as prebiotic as they encourage the proliferation of friendly probiotic bacteria in the colon that boost the immune system and help digestion. FOCs are increasingly added to pastries, confectionery and dairy products (Campbell et al. 1997). Yacon and maca are already on the European market as prospective functional foods and dietary supplements, mainly for use in certain risk groups of the population, e.g. seniors, diabetics, postmenopausal women, etc. (Valentová and Ulrichová 2003). Yacon roots are a rich source of fructooligosaccharides (FOSs) and have a long use tradition as food in the Andean region (Genta et al. 2005). Yacon root is generally peeled and sliced and consumed fresh like a fruit or used in fruit salad with other fruits (Choque Delgado et al. 2013). Yacon root can also be baked or blended and its juice consumed as a refreshing beverage. Yacon and maca are already on the European market as prospective functional foods and nutraceuticals for use in certain risk groups of population (Valentová et al. 2001). Moscatto et al. (2006) found that a chocolate cake formulation with 20 % of the wheat flour replaced with yacon root meal, 153 mL of water and no inulin showed the best values for hardness (3.638 N), cohesiveness (0.691) and specific volume (1.86 cm³/g). A formulation with 40 % of the wheat flour replaced with yacon meal, 6 % replaced with inulin and containing 126 mL of water showed similar values to the optimised formulation for the three parameters mentioned, but, in addition, it had a greater content of fructooligosaccharides and inulin. Both

formulations may give useful functional foods with physical parameters comparable with the control formulation. Japanese scientists are considering developing yacón as a source for purified fructan and a variety of processed products such as fermented pickles, dried tuber slices and fructose. Yacon slices and stripes retain crunchiness during cooking and have shown potential in Asian stir-fried dishes. The stems and rhizomes may also be eaten as vegetables.

Botany

The yacon is an erect perennial herb, 1.5–2.5 m tall (Plate 1). The root system is composed of 4–20 fleshy tuberous, fusiform storage roots that can reach a length of 25 cm by 10 cm in diameter (Plates 5 and 6), with an extensive system of thin fibrous roots. The aerial stems are cylindrical or subangular, hollow at maturity with few branches in most cultivars or ramified in others, densely pubescent, green to purplish. Lower leaves are broadly ovate and hastate or subhastate, connate and auriculate at the base, densely pubescent (Plate 2). Upper leaves are deltoid and hastate to 33 cm long by 22 cm wide, dentate, densely pubescent, with lateral wings, connate and auriculate at the base. Lower and upper epidermises have trichomes (0.8–1.5 mm long, 0.05 mm diameter) and glands. Inflorescences are terminal, composed of 1–5 axes, each one with 3 capitula, peduncles densely pilose (Plate 3). Phyllaries 5, uniseriate and ovate, 15 mm long, 10 mm wide. Flowers are yellow to bright orange; ray flowers 13–15, with 2- or 3-toothed ligule, to 12 mm long by 7 mm broad, pistillate; and disc flowers about 60 or more, about 7 mm long, pubescent staminate (Plate 4). Immature cypselas are purple and turn dark brown or black at maturity.

Nutritive/Medicinal Properties

Root Phytochemicals

Members of the Compositae like Jerusalem artichoke and yacon had been found to be the richest plant source of fructooligosaccharides (FOCs) like 1-kestose (1-kestriose, GF₂), nystose (1,1-kestotetraose; GF₃) and 1F- β -fructofuranosylnystose (1,1,1-kestopentaose; GF₄) (Campbell et al. 1997; Dumitriu 2004).

The bulk of yacon tuber dry matter had been reported to contain as storage compound mainly fructans of low polymerisation, i.e. fructooligosaccharides (FOSs) with inulin-type structures, i.e. β (1 $\rightarrow$ 2) fructofuranosyl saccharose, free sugars – low glucose, sucrose and fructose content (Ohyama et al. 1990; Asami et al. 1991; Wei et al. 1991).

The oligosaccharides in yacon tuberous roots were confirmed to be β -(2 $\rightarrow$ 1) fructooligosaccharides (FOSs) with terminal sucrose (inulin-type oligofructans) (Goto et al. 1995). The major FOSs found in yacon included 1-kestose, and nystose, similar to those found in *Helianthus tuberosus* (Choque Delgado et al. 2010; Ohyama et al. 1990; Moscatto et al. 2006). FOSs are sweet tasting and are considered to be indigestible by the human small intestine and serve mainly as dietetic sweeteners. The relative proportions of oligofructans and free sugars fluctuated significantly during the growing period and after harvesting (Asami et al. 1991; Fukai et al. 1995). Asami et al. (1991) reported that oligofructans accounted for 67 % of the total carbohydrates in fresh yacon tubers, while Ohyama et al. (1990) found only 20 % oligofructans, 3–22 % fructose and glucose 2–5 % of root dry matter in stored tubers. Ohyama et al. (1990) reported the following saccharides (mg/g DW) in yacon tubers stored for 96 days after harvest: fructose (350.1 mg), glucose (158.3 mg), sucrose (74.5 mg), glukosylfructose (GF) GF₂ (1-kestose) (60.1 mg), GF₃ (nystose) (47.4 mg), GF₄ (33.6 mg), GF₅ (20.6 mg), GF₆ (15.8 mg), GF₇ (12.7 mg), GF₈ (9.6 mg), GF₉ (6.6

mg) and inulin (13.5 mg). Itaya et al. (2002) reported that yacon tubers accumulated over 60 % of inulin-type β (1 $\rightarrow$ 2) fructans mainly GF₂–GF₁₆ oligomers. Variations in the concentration of such carbohydrates and in the chain length of fructans may occur during plant growth and after harvesting. Tuberous yacon roots were found to contain highest amounts of oligofructans (GF₂, GF₃, GF₄), and lower stem and tubers also had high content, but leaves contained small amount; highest sucrose–sucrose fructosyl transferase (SST) activity was detected in the lower stems, and invertase activity was high in the leaves and upper stem (Fukai et al. 1993). In the lower stem, tubers and tuberous roots invertase activity was low, but SST activity was detected in these plant parts. Tubers had the highest degree of polymerisation of oligofructans. Asami et al. (1992) found that tubers and tuberous roots harvested in late fall contained about 57 and 66 % DM basis respectively of oligofructans; however, tuber, tuberous roots and shoots contained only a small amount of inulin and starch.

Calvino (1940) reported the following nutrient composition of fresh and dry yacon tubers, respectively: water (69.5 %, –), ash (2.4 %, 6.71 %), proteins (2.22 %, 7.31 %), lipids (0.13 %, 0.43 %), fibre (1.75 %, 5.73 %) and saccharides (19.67 %, 67.53 %). Chemical composition of 10 yacon accessions per kg of root fresh matter was determined as dry matter 98–136 g, total carbohydrates 89–127 g, fructans 31–89 g, DP (degree of polymerisation) 3.6–4.3, total free sugars 18–42 g, free glucose 2.3–5.9 g, free fructose 3.9–21.1 g, free sucrose 10–19 g, total fructose/total glucose ratio 1.95–2.86, °Brix 9.0–12.6, protein 2.7–4.9 g, fibre 3.1–4.1 g, fat 112–464 mg, energy 148–224 kcal, ash 4,275–6,014 mg, Ca 56–131 mg, P 182–309 mg and K 1,843–2,936 mg (Hermann et al. 1998). Hermann et al. (1998) reported that yacon fructans are of low molecular mass. Grau and Rea (1997) reported the following nutrient composition of yacon tubers on a fresh weight basis compiled from various sources: water 93–70 %, ash 0.3–0.2 %, fat 0.1–0.2 %, fibre 0.3–0.7 %, minerals (mg/g) Ca 23 mg, P 21 mg, Fe 0.3 mg, vitamins (mg/g) retinol 10 mg, carotene 0.08 mg, thiamine 0.01 mg, riboflavin 0.1 mg, niacin 0.33 mg and ascorbic acid 13 mg.

The New Zealand genotype had highest fructose (217 g/kg DM) but lower in inulin content. Valentová and Ulrichová (2003) reported yacon tuber to contain 70–93 % water, 0.4–2.0 % proteins, 12.5 % saccharides, 0.1–0.3 % lipids, 0.3–2.0 % ash, 0.3–1.7 % fibre and mg/100 g of Ca 23 mg, P 21 mg, Fe 0.3 mg, Cu 0.96 mg, Mn 0.54 mg, Zn 0.67 mg, retinol 10 mg, thiamine 0.01 mg, ascorbate 13.1 mg, carotene mg, riboflavin 0.11 mg and niacin 0.34 mg.

Moscatto et al. (2006) reported the following chemical composition of yacon root: moisture 7.49 %, protein 6.48 %, lipid 0.31 %, ash 3.56, carbohydrate 82.16 %, fructose 4.13 %, glucose 1.96 %, sucrose 3.25 %, 1-kestose (GF₂) 8.19 % and nystose (GF₃) 5.36 %. Lobo et al. (2007) reported the following chemical composition of yacon flour g/100 g: protein 2.64 g, lipid 0.61 g, ash 3.85 g, insoluble fibre 7.85 g, soluble fibre 3.36 g, Ca 0.83 mg/g, Mg 0.62 mg/g, fructose 13.51 g, glucose 8.97 g, sucrose 13.42 g and FOS/fructans 55.33 g. Choque Delgado et al. (2012) reported the following chemical composition of yacon root: moisture 8.02 %, protein 2.45 %, lipid 0.87 %, ash 2.53 %, insoluble fibre 3.46 %, carbohydrate 86.13 %, fructose 14.10 %, glucose 7.30 %, sucrose 10.5 %, FOS/fructans 34.31 %, 1-kestose (GF₂) 13.99, nystose (GF₃) 13.72 % and fructofuranosyl-nystose (GF₄) 6.59 %.

Lachman et al. (2007) found considerable variation among yacon ecotypes from New Zealand, Bolivia, Ecuador and Germany in total polyphenolics (TP) of plant biomass (tuberous roots, rhizomes and leaves) (34.94–68.49 mg/g), inulin (nd-289 g/kg DM), saccharose (nd-30.4 g/kg DM), glucose (nd-103 g/kg DM) and fructose (nd-217 g/kg DM). The highest TP content was found in the rhizomes and lowest in tuberous roots. The New Zealand genotype had highest TP content (68.49 mg/g DM) in the biomass. The approximate proportion of TP in the tuberous roots, leaves and rhizomes was 1:1.4:3.3.

Earlier, Lachman et al. (2004) reported considerable differences among the ecotypes were observed in their inulin and fructose concentrations (141–289 mg/kg d.m. and 195–

217 mg/kg d.m., resp.), but no differences were found in glucose and saccharose concentrations. The concentrations of all saccharides were significantly influenced by the year of cultivation. Tubers contained much higher levels of inulin (179 g/kg d.m.) and fructose (193 g/kg d.m.) than rhizomes. No significant differences were found for saccharose (higher in rhizomes) and glucose (lower in rhizomes). Inulin and fructose concentrations in the upper and lower parts of tubers were inversely proportional. Inulin concentration decreased by 48.7 %, and fructose, glucose and saccharose concentrations increased by 9.97 %, 31.4 % and 12.9 %, respectively, during the storage (140 days, 10 °C, 75 % relative humidity).

Graefe et al. (2004) found that after a 6-day shade, storage oligofructans (fructooligosaccharides, FOSs) in yacon root concentrations were smaller at the lower (36–48 % of DM) than at the higher altitude (39–58 % of DM). After 12 days, FOS concentrations were nearly equal at both sites (27–39 % of DM). The concentration of free sugars (fructose, glucose, sucrose) increased accordingly from 29–34 to 48–52 %. During the 6-day sun-drying experiment, FOS concentrations decreased from 50–62 to 29–44 % and free sugars increased from 29–34 to 45–51 %. The results indicate that partial hydrolysis of oligofructans starts shortly after harvest. In another study, during storage of yacon tuberous roots at low or room temperature, their fructooligosaccharides (FOSs) content significantly decreased, whereas the fructose content increased, indicating that the extent of the changes was dependent on temperature (Narai-Kanayama et al. 2006). Freezing storage at –20 °C was able to prevent the decline of FOSs in tuberous roots. They elucidated the involvement of FOS-metabolising enzymes in FOS decline during storage at 90 % relative humidity and 8 °C, and found enzyme activities acting on sucrose, both invertase (β -fructofuranosidase) and sucrose–sucrose 1-fructosyltransferase, were weakened after storage for a month (Narai-Kanayama et al. 2007). Further, the activity of fructan 1-exohydrolase acting on short FOSs such as 1-kestose (GF₂) and 1-nystose (GF₃) was higher than that of fructan/fructan 1-fructosyltransferase. These results suggested that the continuous decline in FOSs of low DP during storage

was dependent mainly on the fructan 1-exohydrolase activity. Fructans were the predominant water-soluble carbohydrate in the tubers and tuberous roots throughout the growth period of yacon (Fukai et al. 1995). The amount of fructans in the tubers increased rapidly in November and remained constant during the dormancy. While the amount of fructans in the tuberous roots increased dramatically in September, there was a significant decrease in fructan content during the period between October and March. During summer, the amount of fructan (g/plant) accumulated in each plant part was minimal despite the existence of relatively high specific activities (units/mg protein) of sucrose–sucrose fructosyltransferase and fructan–fructan fructosyltransferase in the stems, roots, tuberous roots and rhizomataceous stem (Fukai et al. 1997). In contrast, from October to December, the amount of fructan in the tuberous roots and rhizomataceous stem significantly increased along with an increase of the total activities of sucrose–sucrose fructosyltransferase and fructan–fructan fructosyltransferase. Significant variations in tuber shape, weight, content of oligofructans as well as in leaf isozymes, phenolics and relative DNA contents were found among four yacon accessions cultivated in the field (Valentová et al. 2006). A significantly higher content of beta-(2→1) oligofructans was noted in two accessions 48 and 88 compared to 6 and 60; accession 6 exhibited separate acid phosphatase and esterase isoforms and had highest content of phenolics, while accession 88 had the lowest relative DNA content. No difference in sucrose, glucose and fructose levels was observed.

The following compound were reported from the tuberous roots: inulin and inulin derivatives (Zardini 1991); chlorogenic acid and tryptophan (Yan et al. 1999); ferulic acid (Simonovska et al. 2003); two novel, water-soluble, phenolic compounds octulosonic acid derivatives with a 6,8-dioxabicyclo[3.2.1]octane skeleton structures elucidated as (1*R*,2*S*,3*S*,4*R*,5*S*,7*R*)-4-hydroxy-7-hydroxymethyl-3-[3-(3,4-dihydroxyphenyl)-1-oxo-2-propenyloxy]-6,8-dioxabicyclo[3.2.1]octan-5-carboxylic acid (4-*O*-caffeoyl-2,7-anhy-dro-D-glycero-β-*D*-galacto-oct-2-ulopyranosonic acid) and (1*R*,2*S*,3*R*,4*R*,5*S*,7*R*)-2,4-dihydroxy-7-hydroxymethyl-2,3-bis[3-(3,4-dihydroxy-phenyl)-1-oxo-2-propenyloxy]-6,8-

dioxabi-cyclo[3.2.1]octan-5-carboxylic acid (4,5-di-*O*-caffeoyl-2,7-anhydro- β -D-glycero- β -D-galacto-oct-2-ulopyranosonic acid) (Takenaka and Ono 2003); five caffeic acid derivatives, namely, chlorogenic acid (3-caffeoylquinic acid) and 3,5-dicaffeoylquinic acid, caffeic acid esters of altraric acid: 2,4- or 3,5-dicaffeoylaltaric acid, 2,5-dicaffeoylaltaric acid and 2,3,5- or 2,4,5-tricaffeoylaltaric acid (Takenaka et al. 2003) and *ent*-kaurenoic acid (Ragusa et al. 2008). Phenolic compounds, flavonoids, alkaloids, steroids, glycosides and carbohydrates were found in yacon roots (Alvarez et al. 2008). From the root cortex of four *Smallanthus* species including *S. sonchifolius*, *ent*-16-kauren-19-oic acid (kaurenoic acid) methyl ester was the main component; minor components included grandiflorenic acid methyl ester, *ent*-16-kauren-19-al, 16 α ,17-epoxy-15 α -angeloyloxy-kauran-19-oic acid methyl ester and several O-acyl derivatives at C-15 or C-18 of kaurenoic acid (Coll Aráoz et al. 2010). One of the minor components, 18-isobutyroyloxy-*ent*-kaur-16-en-19-oic acid was a new kaurenoic acid derivative. Grandiflorenic acid and 15- α -angeloyloxy-16,17- α -epoxy-*ent*-16-kauren-19-oic acid were present only in *Smallanthus sonchifolius* and *Smallanthus siegesbeckius*.

Inoculation of sliced yacon tubers with *Pseudomonas cichorii* resulted in the formation of three major antifungal phytoalexins identified as 4'-hydroxy-3'-(3-methylbutanoyl)acetophenone, 4'-hydroxy-3'-(3-methyl-2-butenyl)acetophenone and 5-acetyl-2-(1-hydroxy-1-methylethyl)benzofuran (Takasugi and Masuda 1996). Polyphenol oxidase (PPO) with molecular weight of about 45,490 Da and K_m values of 0.23, 1.14, 1.34 and 5.0 mM for the substrates caffeic acid, chlorogenic acid, 4-methylcatechol and catechol, respectively, was extruded from yacon roots (Neves and da Silva 2007). The optimum pH varied from 5.0 to 6.6, depending on substrate. PPO activity was inhibited by various phenolic and nonphenolic compounds. Sucrose, maltose, glucose, fructose and trehalose at high concentrations appeared to protect yacon PPO against thermal inactivation at 75 and 80 °C.

Powdered yacon pulp showed a laminar-type structure, and good encapsulation of the yacon juice by starch was observed in the samples of concentrated juice powder (Lago et al. 2012). Powdered yacon pulp before drying and after drying at 70 °C was found to contain (g/100 g dm), respectively, 3.15 g, 2.70 g inulin, 10.98 g, 12.82 g glucose and 4.30 g, 9.44 g fructose, while starch-encapsulated yacon juice before drying and after drying at 70 °C contained (g/100 g dm), respectively, 1.07 g, 0.90 g inulin, 3.30 g, 3.51 g glucose and 2.99 g, 3.55 g fructose (Lago et al. 2012). The process used to dry starch-encapsulated yacon juice and yacon pulp indicated that the higher the drying air temperature, the shorter the time taken to reach equilibrium. All dehydrated products presented water activity values below 0.3, indicating the stability of the powders.

In addition to prebiotics, fructooligosaccharides (FOSs) and inulin, yacon had been found to contain flavonoids, phenolic acids and tryptophan, which exhibited antioxidant, anti-inflammatory, antimicrobial and anticancer activities (Choque Delgado et al. 2013). The consumption of FOS and inulin had been reported to improve the growth of bifidobacteria in the colon, enhanced mineral absorption and gastrointestinal metabolism and to play role in the regulation of serum cholesterol (Choque Delgado et al. 2010, 2013). Additionally, studies reported that the consumption of these prebiotics promoted a positive modulation of the immune system, improving resistance to infections and antimicrobial activity as well as attenuating allergic reactions and cancer in experimental models.

Leaf and Stem Phytochemicals

Valentová and Ulrichová (2003) reported yacon leaf to contain 10.47 % water, 21.48 % proteins, 4.2 % lipids, 12.52 % ash, 11.63 % fibre and mg/100 g of Ca 1,805 mg, P 543 mg, Fe 10.82 mg, Cu <0.5 mg, Mn 3.07 mg and Zn 6.2 mg. They reported yacon stem to contain 9.73 % proteins, 1.98 % lipids, 9.6 % ash, 23.82 % fibre and mg/100 g of Ca 967 mg, P 415 mg, Fe 7.29 mg, Cu <0.5 mg, Mn <0.5 mg and Zn 2.93 mg.

The following compounds were found in the leaves: an antifungal melampolide, 8-angeloyl-1(10),4,11(13)-germacuratrien-12,6-olid-14-oic acid methyl ester, named sonchifolin, and three known melampolides, polymatin B, uvedalin and enhydrin (Inoue et al. 1995); protocatechuic (2.5 and 0.12 mg/g), chlorogenic (9.9 and 1.7 mg/g), caffeic (14.7 and 0.09 mg/g) and ferulic (traces) acids (Valentová et al. 2003); six sesquiterpene lactones, 8 β -tigloyloxymelampolid-14-oic acid methyl ester, 8 β -methacryloyloxymelampolid-14-oic acid methyl ester, sonchifolin, uvedalin, enhydrin and fluctuanin (Lin et al. 2003); chlorogenic, caffeic and ferulic acid, isomers of dicaffeoylquinic acid, an unidentified derivative of chlorogenic acid, flavonoid quercetin and an unidentified flavonoid (Simonovska et al. 2003); four diterpenoids named smaditerpenic acid A–D and five known compounds (Dou et al. 2008b); *ent*-kaurane-3 β ,16 β ,17,18-tertol, 3*R*,7*E*-9-butoxyl-megastigma-3-ol-3-*O*- β -D-glucopyranoside, 3*S*,5*R*,6*Z*-megastigma-6-en-3,5,8,9-tertol and five known compounds octacosanol, 3',4',5-trihydroxy-3,7-dimethoxyflavone, 3,4-dihydroxybenzaldehyde, isorhamnetin and *ent*-kaurane-3 β ,16 β ,17-triol (Qiu et al. 2008); *ent*-kaurenoic acid (Ragusa et al. 2008); smallanthaditerpenic acid A, smallanthaditerpenic acid B, smallanthaditerpenic acid C, smallanthaditerpenic acid D, *ent*-kaurane-3 β , 16 β , 17, 19-tetrol and *ent*-kaurane-16 β , 17, 18, 19-tetrol (Dou et al. 2008a); gallic acid, β -sitosterol, behenic acid, kaempferol, quercetin, vanillic acid and hexadecanoic acid (Xie et al. 2008); two new melampolide-type sesquiterpene lactones, 8 β -epoxyangeloyloxy-9 α -ethoxy-14-oxo-acanthospermolide and 8 β -angeloyloxy-9 α -ethoxy-14-oxo-acanthospermolide along with 11 known melampolide allo-schkuhriolide, enhydrin, polymatin A, fluctuanin, 8 β -angeloyloxy-9 α -acetoxyl-14-oxo-acanthospermolide, 8 β -angeloyloxy-14-oxo-acanthospermolide, 8 β -methacryloyloxymelampolid-14-oic acid methyl ester, uvedalin, polymatin B, 8 β -tigloyloxymelampolid-14-oic acid methyl ester and sonchifolin (Hong et al. 2008); octadecatrienoic acid elucidated as 13(*R*)-hydroxy-octadeca-(9*E*,11*E*,15*Z*)-trienoic acid and a benzyl glycoside elucidated as benzyl alcohol 7-*O*- α -L-arabinopyranosyl(1'' $\rightarrow$ 2')- β -D-glucopyranoside, along with

a known compound 13(*R*)-hydroxy-octadeca-(9*Z*,11*E*,15*Z*)-trienoic acid (Xiang et al. 2009); smallanthaditerpenic acids A, B, C and D and chlorogenic and caffeic acids (Xiang et al. 2010b); two diterpenes, named *ent*-kaurane-3 β ,16 β ,17, 19-tetrol and *ent*-kaurane-16 β ,17,18,19-tetrol (Dou et al. 2010); a hexenol glycoside elucidated as *Z*-hex-3-en-1-ol *O*- α -L-arabinopyransyl (1" $\rightarrow$ 2')- β -D-glucopyranoside and two known compounds *ent*-15 β -hydroxy-kaur-16-en-19-oic acid and *ent*-18-hydroxy-kaur-16-en-19-oic acid (Xiang et al. 2010a); caffeic, chlorogenic and three dicaffeoylquinic acids and enhydrin (Genta et al. 2010); two acyclic diterpenoids, smaditerpenic acid E and F, along with 19 melampolide-type sesquiterpene lactones (Mercado et al. 2010); enhydrin, polymatin B and allo-schkuhriolide (Choi et al. 2010); and enhydrin, uvedalin and sonchifolin (Siriwan et al. 2011).

The dried yacon leaves were found to contain a total of 0.97 % of the antidiabetic sesquiterpene lactone enhydrin 1 and the glandular trichome extract contained 0.07 mg/mL (Schorr and Da Costa 2005). The following phenolic acids gallic acid, protocatechuic acid, chlorogenic acid, caffeic acid and ferulic acid were detected in the ethyl acetate extract of dried yacon leaves and in the leaf aqueous decoction, and aqueous tea infusion gallic acid and ferulic acid were not detected (Jirovský et al. 2003).

Yacon glandular trichomes and leaves were found to be rich in *ent*-kaurenic acid (*ent*-kaur-en-19-oic acid) and to contain a kaurene derivative 15- α -angeloyloxy- *ent*-kaur-en-19-oic acid 16-epoxide and 2 known angeloyloxykaurenic acids *ent*-kaur-16-en-19-oic acid 15 angeloyloxy ester and 18-angeloyloxy- *ent*-kaur-16-en-19-oic acid (Kakuta et al. 1992). Trichomes were found to accumulate sesquiterpene lactones uvedalin and enhydrin and their epoxyangelate esters (Lopes et al. 2013). The major compounds found in yacon leaf essential oil were β -pinene, caryophyllene and γ -cadinene (Adam et al. 2005).

Calvino (1940) reported the nutrient composition of fresh and dry yacon leaves respectively as follows: water (83.2 %, -), ash (2.68 %, 15.98 %), proteins (2.87 %, 17.12 %), lipids

(1.24 %, 7.40 %), fibre (1.68 %, 10.04 %) and saccharides (1.44 %, 8.58 %).

Antioxidant Activity

Yacon root exhibited 1, 1-diphenyl-2-picrylhydrazyl (DPPH) radical scavenging activity, and two major antioxidants chlorogenic acid and tryptophan were isolated from the methanol root extract (Yan et al. 1999). The phenolic acids, chlorogenic, caffeic and ferulic acid isolated from the crude extract of yacon leaves gave significant contribution to the radical scavenging activity detected directly on the TLC plate sprayed with 1,1-diphenyl-2-picrylhydrazyl (DPPH) (Simonovska et al. 2003). Protocatechuic (2.5 and 0.12 mg/g), chlorogenic (9.9 and 1.7 mg/g), caffeic (14.7 and 0.09 mg/g) and ferulic (traces) acids were determined in the two fractions of yacon leaves (Valentová et al. 2003). Both fractions showed potent antioxidant activity in DPPH (IC_{50} = 16.1 and 24.3 mg/mL) and xanthine/XOD superoxide radical scavenging (42.0 and 34.3 SOD equivalents (U/mg)) tests, they inhibited the lipoperoxidation of rat liver subcellular membranes and they protected rat hepatocytes against oxidative injury. Yacon leaf aqueous extracts exhibited DPPH (IC_{50} 16.14–33.39 µg/mL) and HO* scavenging activities (IC_{50} 4.49–6.51 mg/mL) in-vitro (Valentová et al. 2005). The extracts did not scavenge phenylglyoxylic ketyl radicals, but they retarded their formation. The extracts' total phenolic content was 10.7–24.6 %. In the xanthine/xanthine oxidase superoxide radical generating system, the extracts' activities were 26.10–37.67 superoxide dismutase equivalents/mg. As one of the extracts displayed xanthine oxidase inhibitory activity, the effect of the extracts on a nonenzymatically generated superoxide was determined (IC_{50} 7.36–21.01 µg/mL). The extracts inhibited *t*-butyl hydroperoxide-induced lipoperoxidation of microsomal and mitochondrial membranes (IC_{50} 22.15–465.3 µg/mL). All 13 melampolides isolated from leaves inhibited lipopolysaccharide (LPS)-induced nitric oxide production in murine macrophage RAW 264.7 cells (Hong et al. 2008).

The content of total phenol was the highest by 45.53 % in ethyl acetate fraction of yacon extract (Min et al. 2008), and the results of electron donating abilities were 65.20 % (100 µg/mL), 91.81 % (500 µg/mL) and 95.06 % (1,000 µg/mL), and those of nitrite scavenging abilities were 11.71 % (100 µg/mL), 36.81 % (500 µg/mL) and 59.70 % (1,000 µg/mL) in ethyl acetate fraction, which were higher concentration than the control group. Xanthine oxidase inhibitory activities were 23.74 % (100 µg/mL) and 43.41 % (500 µg/mL) which were higher than the control group.

Antihyperglycemic/Hypoglycaemic Activity

In-Vitro Studies

Ent-kaurenoic acid, dissolved in dimethyl sulfoxide, exhibited potential antidiabetes and anti-toxicity activity (Ragusa et al. 2008). Smallanthaditerpenic acids A, B, C and D isolated from yacon leaves exhibited inhibitory effect on α -glucosidase and their IC₅₀ were determined to be 0.48 mg/mL, 0.59 mg/mL, 1.00 mg/mL and 1.17 mg/mL, respectively (Xiang et al. 2010b).

Yacon leaf extract was found to show potent antidiabetic activity (Dou et al. 2008a, 2010).

Animal Studies

Ten per cent yacon leaf decoction produced a significant decrease in plasma glucose levels in normal rats when administered by intraperitoneal injection or gastric tube (Aybar et al. 2001). In a glucose tolerance test, a single administration of 10 % yacon leaf decoction lowered the plasma glucose levels in normal rats. In contrast, a single oral or intraperitoneal administration of yacon leaf decoction produced no effect on the plasma glucose levels of streptozotocin-induced diabetic rats. However, the administration of 2 % yacon tea ad libitum instead of water for 30 days produced a significant hypoglycaemic effect on

streptozotocin-induced diabetic rats. After 30 days of yacon tea administration, diabetic rats showed improved body (plasma glucose, plasma insulin levels, body weight) and renal parameters (kidney weight, kidney to body weight ratio, creatinine clearance, urinary albumin excretion) in comparison with the diabetic controls. Their results suggested that yacon leaf water extract produced an increase in plasma insulin concentration. The potential of yacon tubers to treat hyperglycaemia, kidney problems and for skin rejuvenation and the antihyperglycaemic and cytoprotective activity of its leaves appeared to be related mostly to its oligofructan and phenolic content, respectively (Valentová and Ulrichová 2003). Aqueous leaf extracts and fractions tested exhibited strong protective effect against oxidative damage induced by tert-butyl hydroperoxide (t-BH) and allyl alcohol to rat hepatocyte primary cultures in concentrations ranging from 1 to 1,000 µg/mL and reduced hepatic glucose production via gluconeogenesis and glycogenolysis at 1,000 µg/mL (Valentová et al. 2004). Moreover, the effects of the organic fractions (200 and 250 µg/mL) and, to a lesser extent, the tea infusion (500 µg/mL) on rat cytochrome CYP2B and CYP2E mRNA expression were comparable to those observed with insulin. The combination of radical scavenging, cytoprotective and antihyperglycaemic activity suggested the potential for yacon leaves to be used for prevention and treatment of chronic diseases involving oxidative stress, particularly diabetes. Aqueous yacon leaf extract reduced blood glucose and cholesterol of KKAY mice 6 weeks after repeated administration but did not affect blood glucose in normal mice (Miura et al. 2004; Miura 2007). Yacon also improved hyperglycaemia after glucose tolerance. Yacon also tended to decrease blood glucose in an insulin tolerance test. Results showed yacon to be useful for hyperglycaemia and hyperlipidemia of type 2 diabetes.

Treatment with yacon leaf ethanol extract for 14 days reduced glycemia in diabetic and nondiabetic rats, but this reduction was not observed in animals treated with cold or hot yacon leaf extracts (Baroni et al. 2008). Additionally, yacon leaf ethanol extract restored the activity of the plasma enzymes (AST, ALT, ALP) that were altered and improved weight gain

in the diabetic animals. The results suggested that the effectiveness of the yacon extracts was related to the method of preparation and to the time of treatment rather than to reduction of food intake or to interference of the extract with intestinal absorption of carbohydrates. Hypoglycaemic activity was observed in normoglycaemic mice orally administered with the aqueous yacon leaf tea extract, alloxan-induced diabetic mice orally administered with ent-kaurenoic acid (from yacon leaves) and normoglycaemic mice intraperitoneally administered with ent-kaurenoic acid (Raga et al. 2010). The methanol, butanol and chloroform yacon leaf extracts showed effective hypoglycaemic activity at minimum doses of 50, 10 and 20 mg/kg body weight, respectively (Genta et al. 2010). Oral administration of a single dose of each extract produced a slight lowering effect in the fasting blood glucose level of normal healthy rats, whereas each extract attenuated significantly the hyperglycaemic peak after food ingestion in transiently hyperglycaemic and streptozotocin (STZ) diabetic rats. Daily administration of each extract for 8 weeks produced an effective glycaemic control in diabetic animals with an increase in the plasma insulin level. Phytochemical analysis of the most active fraction, the butanol extract, showed that caffeic, chlorogenic and three dicaffeoylquinic acids were significant components. Additionally, enhydrin, the major sesquiterpene lactone of yacon leaves, was also effective to reduce postprandial glucose and useful in the treatment of diabetic animals (minimum dose: 0.8 mg/kg body weight). Administration of yacon leaf decoction for 4 weeks significantly decreased high blood glucose level in streptozotocin-induced diabetic rats and improved insulin production (Honoré et al. 2012). Diabetic-dependent alterations in urinary albumin excretion, creatinine clearance, kidney hypertrophy and basement membrane thickening were attenuated by yacon decoction. These findings were associated with a marked decrease in TGF- β 1/Smad2/3 signalling and expression of molecular markers of diabetic nephropathy such as collagen IV, laminin-1, fibronectin and collagen III in the yacon-treated group compared to control diabetic group. The results suggested yacon leaf decoction to be a protective agent against renal damage in diabetic

nephropathy, whose action can be mediated by TGF- β /Smads signals.

Oral administration of yacon tuber extract (200 mg/kg) and its active constituent, chlorogenic acid (CGA) (10 mg/kg) for 6 weeks produced a significant hypoglycaemic effect in streptozotocin-induced diabetic rats (Park et al. 2009). Yacon and CGA-treated rats exhibited significantly decreased plasma glucose surge during the glucose tolerance test. Total cholesterol (TC) and triglyceride (TG) concentrations were significantly decreased by 33 % and 49 %, respectively, in yacon-treated rats significantly decreased by 26 % and 41 %, respectively, in CGA-treated rats. In the DPPH assay, free radical scavenging activity of CGA was similar to that of vitamin E, a positive control. This study suggested that yacon tuber extract and its constituent, CGA, may be a useful option for management of hyperglycaemia and diabetic nephropathy.

The aqueous yacon tuberous root extract decreased water and food intake, glycaemia, total cholesterol, VLDL-c, LDL-c and triacylglycerol levels in diabetic rats (Oliveira et al. 2013). Yacon treatment normalised alanine aminotransferase (ALT) but had no effect on lactate dehydrogenase activity. The results suggested that yacon tuber extract sufficient for controlling water and food consumption, hyperglycaemia and dyslipidaemia and promote the reduction of the ALT, suggesting a hepatoprotective effect in rats with streptozotocin-induced diabetes mellitus. In the basal state, yacon feeding of male Zucker fa/fa rats for 5 weeks had an effect of lowering fasting glucose levels from 184.1 to 167.8 mg. dl as well as basal hepatic glucose output (HGO) from 9.9 to 7.4 mg/kg/minutes (Satoh et al. 2013). During the clamp studies, the glucose infusion rate required to maintain euglycemia was increased by 12.3 % in yacon-fed rat. The insulin suppression of HGO was also increased in yacon-fed rats compared with control rats. Consistent with the clamp data, the insulin-stimulated phosphorylation of Akt was significantly enhanced in liver but not in skeletal muscle. Further, tribbles 3 (Trb3) expression, a negative regulator of Akt activity, was markedly reduced in the liver of yacon-fed rats compared with control rats. The results indicated that the

effect of yacon feeding in reducing blood glucose was likely due to its beneficial effects on hepatic insulin sensitivity in the insulin resistant state.

Antiatherogenic/Antihyperlipidemic Activities

Animal Studies

Administration of fructooligosaccharides-rich yacon flour to streptozotocin-induced diabetic Wistar rats for 90 days significantly decreased fasting plasma triacylglycerol and very low-density lipoprotein levels and did not significantly alter the body weight of animals throughout the experimental period (Habib et al. 2011). Yacon treatment was also able to protect the diabetic rats of the postprandial peak of plasma triacylglycerol. Yacon-supplemented rats showed an increased insulin-positive pancreatic cell mass distributed in small cell clusters within the exocrine parenchyma. Glucagon like peptide-1 content in the cecum was significantly higher in diabetic rats treated with a diet supplemented with yacon flour compared with untreated diabetic animals. The results suggested that yacon root flour rich in fructooligosaccharides could be well positioned as a nutraceutical product with beneficial effects on diabetes-associated hyperlipidemia. In another animal study, serum ALT, AST, ALP and LDH activities elevated by a high fat–high cholesterol diet were significantly decreased by Yacon powder administration in obese male Sprague-Dawley rats (Kim et al. 2010). Levels of serum total cholesterol, LDL-cholesterol, atherogenic index and cardiac risk factor showed a decreasing tendency in the Yacon powder-fed groups compared with high fat-high cholesterol diet group (HFC) group. The serum HDL-cholesterol level decreased in the HFC group and markedly increased in the Yacon powder-fed groups. Levels of total cholesterol and triglyceride in liver and adipose tissues were lower in Yacon powder-administered groups than those in HFC group. The results suggested that Yacon powder may improve lipid metabolism of serum, liver and adipose tissue and potentially reduce lipid storage.

Clinical Studies

In a 120-day double-blind placebo-controlled study of obese and slightly dyslipidemic premenopausal women, daily consumption of yacon syrup equivalent to 0.14 g fructooligosaccharides/kg/day produced a significant decrease in body weight, waist circumference and body mass index (Genta et al. 2009). Additionally, decrease in fasting serum insulin and homeostasis model assessment index was observed. The results suggested that long-term consumption of yacon root produced beneficial health effects on obese premenopausal women with insulin resistance.

In a randomised placebo-controlled 90-day study of patients suffering from the metabolic syndrome, the combination silymarin + yacon appeared to be promising as a nutraceutical in the prevention of diseases with a proatherogenic lipoprotein profile and liver steatosis (Valentová et al. 2008). No adverse effects were found in volunteers using silymarin (0.8 g/day), silymarin + yacon (0.8 + 2.4 g/day) and silymarin + maca (0.6 + 0.2 g/day).

Anticancer Activity

The hexane fraction of yacon extract had the highest growth inhibitory activities for human gastric cancer SNU-1 cells of 23.75 % (10 µg/mL), 34.67 % (50 µg/mL) and 54.21 % (100 µg/mL) (Min et al. 2008). The hexane fraction demonstrated high growth inhibitory activities by 41.38 % (10 µg/mL), 50.53 % (50 µg/mL) and 60.91 % (100 µg/mL) and butanol fraction had 17.05 % (10 µg/mL), 43.87 % (50 µg/mL) and 62.99 % (100 µg/mL) for cervical cancer HeLa cells.

Enhydrin, uvedalin and sonchifolin from yacon leaves in doses of 0.22–10 µM inhibited cervical cancer cell proliferation and induced apoptosis in both a dose- and time-dependent fashion (Siriwan et al. 2011). The apoptotic effect was associated with caspase-3/7 activation and NF-κB inhibition. Enhydrin possessing two epoxide units was found to be the most cytotoxic compound.

Consumption of yacon root extract was found to have a protective effect on colon carcinogenesis induced by 1,2-dimethylhydrazine (DMH) in male Wistar rats (de Moura et al. 2012). At week 20, a significant reduction in number and multiplicity of aberrant crypt foci and in number of invasive adenocarcinomas was observed in the groups orally treated with 1.0 % yacon or the synbiotic formulation (1.0 % yacon plus *Lactobacillus casei* at 2.5×10^{10} CFU per g diet). Tumour multiplicity (noninvasive plus invasive) was significantly lower in the group fed synbiotic formulation. A significant reduction in cell proliferation in colonic crypts and tumours and short chain fatty acids caecal contents was observed in the groups orally treated with 1.0 % yacon or the synbiotic formulation.

Antimicrobial Activity

Sonchifolin isolated from yacon leaf exhibited the highest fungicidal activity against *Pyricularia oryzae*, a fungus causing rice blast disease, and the ED₅₀ value for the spore germination was 22 ppm (Inoue et al. 1995). Aqueous yacon leaf extract at all concentrations tested induced inhibition of aflatoxin B1 production by *Aspergillus flavus* in-vitro (Pinto et al. 2001). The aqueous extract showed in-vitro cytotoxicity to Vero cells only at concentrations above 500 µg/mL. The sesquiterpene lactone, 8β-methacryloyloxymelampolid-14-oic acid methyl ester, isolated from yacon leaves, exhibited potent antimicrobial activity against *Bacillus subtilis* and *Pyricularia oryzae*, while 8β-tigloyloxymelampolid-14-oic acid methyl ester showed lower activity (Lin et al. 2003). Fluctuanin exhibited the strongest antibacterial activity against *B. subtilis* among the six sesquiterpene lactones isolated.

Ent-kaurenoic acid showed low antimicrobial activities against *Escherichia coli*, *Pseudomonas aeruginosa*, *Staphylococcus aureus*, *Candida albicans* and *Trichophyton mentagrophytes*, but was found to be inactive against *Bacillus subtilis* and *Aspergillus niger* (Ragusa et al. 2008). Under light illumination at 4,000 lux for 18 hours, the n-hexane fraction of yacon leaf methanol extract showed antibacterial effect against

six strains of methicillin-resistant *Staphylococcus aureus* (MRSA) and one standard methicillin-susceptible *S. aureus* (MSSA) with a MIC of 15.6 µg/mL (Joung et al. 2010). No activity was detected in the absence of light. The hexane leaf fraction mixed with ampicillin or oxacillin showed a synergistic effect under similar illumination with all fractional inhibitory concentration values being below 0.5. These results suggest that only enhydrin from yacon leaves showed good in-vitro antibacterial activity against all tested strains of methicillin-resistant *Staphylococcus aureus* (MIC = 125–500 µg/mL), while polymatin B and allo-schkuhriolide did not (Choi et al. 2010).

Ent-kaurenoic acid from the dichloromethane extract of yacon leaves was found to be active *Staphylococcus aureus*, *Staphylococcus epidermidis* and *Bacillus subtilis* at the lowest concentration of 1,000 µg/L, while it was active against the fungus *Trichophyton rubrum* at 10,000 µg/L in the disc diffusion method (Padla et al. 2012). No inhibitory activity was observed against *Candida albicans*, *Epidermophyton floccosum* and all the Gram-negative test strains, *Escherichia coli*, *Enterobacter aerogenes*, *Klebsiella pneumoniae* and *Pseudomonas aeruginosa*. Results of the broth dilution MIC determination revealed that *ent*-kaurenoic acid exhibited moderate activity against *S. aureus* and *S. epidermidis* with MIC values of 125 µg/mL and 250 µg/mL, respectively, and weak activity against *B. subtilis* with a MIC of 1,000 µg/mL.

Yacon flour administration to BALB/c mice had a protective effect against enteric infection caused by a strain of *Salmonella enteritidis* serovar *typhimurium* (*S. typhimurium*) from 15 to 30 days of treatment (Velez et al. 2013). A peak of total secretory IgA production in mice without translocation of the pathogen was observed for these periods. Longer periods (45 days) of administration had no protective effect. Therefore, yacon could prevent enteric infection caused by *S. typhimurium* when given up to 30 days; this effect would be mediated by enhancing nonspecific immunity, such as total S-IgA, that improved the immunological intestinal barrier.

Spermatogenic Activity

After administering yacon tuber extract or its constituent, chlorogenic acid, to rats for 5 weeks, numbers of sperm in epididymis were increased by 34 % and 20 %, respectively, and significantly inhibited effect of testosterone degradation in rat liver homogenate (Park and Han 2013). Yacon tuber extract and ferulic acid (another constituent) also increased sperm numbers by 43 % and 37 %, respectively, in rats. The results suggested the possibility of yacon as ameliorable agents of infertility by sperm deficiency and late onset hypogonadism syndrome with low level of testosterone.

Prebiotic Activity

Yacon being rich in fructooligosaccharides (FOSs) had been reported to confer another health benefit as studies had shown that they stimulated the growth of bifidobacteria in the human colon to suppress putrefactive pathogens and to reduce cholesterol levels (Hermann et al. 1998). The consumption of yacon FOS and inulin was reported to improve the growth of bifidobacteria in the colon, enhance mineral absorption and gastrointestinal metabolism and play a role in the regulation of serum cholesterol (Choque Delgado et al. 2013). Further, literature reported that the consumption of these prebiotics promoted a positive modulation of the immune system, improving resistance to infections and allergic reactions.

Yacon root fructooligosaccharides was found to be a potential novel source of prebiotics (Pedreschi et al. 2003). Their study found that *Lactobacillus acidophilus*, *Lactobacillus plantarum* and *Bifidobacterium bifidum* were able to ferment yacon root fructooligosaccharides (FOSs). *L. plantarum* and *L. acidophilus* completely utilised 1-kestose molecules, while *B. bifidum* was able to utilise 1-kestose molecules as well as molecules with a higher degree of polymerisation.

Anti-inflammatory Activity

Studies in BALB/c mice showed that daily consumption of yacon root for 30 days did not exert negative effects on the immune system, helped to preserve an anti-inflammatory state

in phagocytic cells by significantly reducing proinflammatory cytokine IL-1 β and improved mucosal immunity by elevation of the levels of faecal IgA (Choque Delgado et al. 2012). The results suggested that consumption of yacon root possibly prevented the risks associated with autoimmune and metabolic diseases.

Bone Mineral Absorption Enhancement

Animal studies by Lobo et al. (2007) showed an important role of yacon roots in the maintenance of healthy bones. Yacon flour consumption by rats significantly resulted in a positive Ca and Mg balance, leading to higher values of bone mineral retention and biomechanical properties (peak load and stiffness) when compared to the control group. There was an increase in the depth and number of total and bifurcated crypts in rats fed yacon flour. The increased number of bifurcating crypts might be related to the higher mineral absorption caused by the enlargement of the absorbing surface in the large intestine of the animals.

In a random, double-blinded study of 50 girls and 50 boys aged 9–13, daily consumption of a combination of prebiotic short- and long-chain inulin-type fructans significantly increased calcium absorption and enhanced bone mineralisation during pubertal growth at 8 week and 1 year after supplementation (Abrams et al. 2005).

Antiparasitic Activity

The sesquiterpene lactones enhydrin (1), uvedalin (2) and polymatin B from yacon showed significant trypanocidal activity against the epimastigote forms of *Trypanosoma cruzi* with IC₅₀ values of 0.84 μ M (1), 1.09 μ M (2) and 4.90 μ M (3), respectively (Frank et al. 2013). After a 24 hour treatment with 10 μ g/mL of enhydrin or uvedalin, the parasites were not able to recover their replication rate. Compounds 1 and 2 showed IC₅₀ values of 33.4 μ M and 25.0 μ M against *T. cruzi* trypomastigotes, while polymatin B was not active. Against the intracellular forms of *T. cruzi*, all three compounds were

able to inhibit the amastigote replication with IC_{50} of 5.17 μ M, 3.34 μ M and 9.02 μ M for 1, 2 and 3, respectively. The cytotoxicity of the compounds was evaluated in Vero cells obtaining CC_{50} values of 46.5 μ M (1), 46.8 μ M (2) and 147.3 μ M (3). According to these results, enhydrin and uvedalin may have potentials as agents against Chagas disease.

Pharmacokinetic Studies

In a 2-week crossover design placebo-controlled, double-blind study of 16 healthy volunteers, administration of yacon significantly accelerated colonic transit (Geyer et al. 2008). Yacon was well tolerated with an excellent side effect profile. Stool frequency increased from 1.1 to 1.3 two times per day and the consistency showed a tendency for softer stools. The authors asserted that due to the low caloric content of yacon, the root could be a useful treatment in constipated diabetics or obese patients.

Toxicological Studies

In a subchronic toxicity studies, dried yacon root flour administered as a diet supplement to normal Wistar rats for 4 months was well tolerated and did not produce any negative response, toxicity or adverse nutritional effect at both intake levels (340 mg and 6,800 mg fructooligosaccharides/body used (Genta et al. 2005). Yacon root consumption showed no hypoglycaemic activity in normal rats and resulted in significantly reduced postprandial serum triacylglycerol levels in both doses assayed. Conversely, serum cholesterol reduction was not statistically significant. Caecal hypertrophy was observed in rats fed only the high dose. The results indicated lack of toxicity with yacon consumption and a certain beneficial metabolic activity in normal rats.

A repeated-dose toxicity study in Wistar rats for 90 days found that renal damage was associated with increased blood glucose levels after prolonged oral administration of the yacon leaf extract (de Oliveira et al. (2011). This observation suggested that the hypoglycaemic effect observed after

treatment for 30 days in an earlier study was reversible and was likely the result of renal injury caused by the toxicity of yacon. Sesquiterpene lactones were detected in both aqueous leaf tea infusion and leaf rinse extract, suggesting that these sesquiterpene lactones were the main toxic compounds in yacon leaves.

Adverse Effects

A 55-year-old woman who developed syncope and generalised urticaria after ingesting yacon roots was reported by Yun et al. (2010). The patient had positive skin prick and intradermal tests to yacon extract. An open food challenge test was performed to confirm food anaphylaxis and was positive 10 minutes after the consumption of yacon roots.

Studies showed that Wistar rats fed fortified ultra rice with micronised ferric pyrophosphate had high iron bioavailability, but the addition of yacon flour at 7.5 % FOS reduced iron bioavailability (Della Lucia et al. 2013).

Traditional Medicinal Uses

The leaves are used in folk medicine as a medicinal tea for hypoglycaemia (Valentová et al. 2003). Owing to its high contents of fructooligosaccharides (FOSs), the yacon root is used in traditional Andean medicine as a substitute for cane sugar in diabetes and for obesity prevention (Choque Delgado et al. 2012).

Other Uses

Smallanthus sonchifolius (yacon) is a perennial plant mostly cultivated in South America, primarily for use of the tubers as a food crop and the leaves as fodder for livestock (Joung et al. 2010).

Yacon extract was found to be a good substrate to produce inulinase by yeast *Kluyveromyces marxianus* var. *bulgaricus* (Cazetta et al. 2005). The highest activity was observed at 60 °C and pH 4.0.

Comments

Yacon is commonly propagated vegetatively from its fleshy rhizome by partitioning it into 6–14 propagules. Alternatively, nodal or stem cuttings can be rooted for vegetative propagation. Sexual reproduction of yacon is difficult because of the lack of fertile botanical seeds formed.

Tragopogon porrifolius

T. K. Lim¹✉

(1) Canberra, Aust Capital Terr, Australia

Scientific Name

Tragopogon porrifolius L.

Synonyms

Tragopogon australis Jord., *Tragopogon porrifolius* var. *cupani* (Guss.) Fiori, *Tragopogon sinuatus* Avé-Lall.

Family

Asteraceae

Common/English Names

Common Salsify, Goatsbeard, Jerusalem Star, John-Go-To-Bed-At-Noon, Joseph's Flower, Oyster Plant, Purple Goatsbeard, Purple Salsify, Salsify, Vegetable Oyster, Vegetable Oyster Plant, White Salsify, Wild Quinine, Wild Salsify

Vernacular Names

Afrikaans: Haverwortel

Bulgarian: Salzifi

Catalan: Barbeta, Barba De Cabra, Salsifi

Chinese: Bo Lou Men Shen, Po Lo Min Shin, Suan Ye

Ukrainian: Vivsjanij Korin

Vietnamese: Cây Củ Hạ

Origin/Distribution

T. porrifolius is indigenous to the Mediterranean regions of southern Europe (i.e. France, Spain, Italy, Bulgaria, Greece, Romania and Yugoslavia), western Asia (i.e. western Turkey), northern Africa (i.e. northern Algeria, northern Libya, Morocco and Tunisia) and the Canary Islands. It has been introduced elsewhere into the British Isles, North America, South Africa and Australia.

Agroecology

Salsify adapts best to a moist environment on a wide variety of soils from sandy loams to clayey loams to clays. It flourishes in both disturbed and more established, productive sites. It will grow in areas with mean annual temperature of 10–30 °C and is frost intolerant.

Edible Plant Parts and Uses

Roots can be eaten raw or cooked (Grieve 1971; Hedrick 1972; Organ 1960; Facciola 1990); its flavour is mild and sweet and is said to resemble oysters (Facciola 1990). The young root can be grated in salads and eaten raw (Loewenfeld et al. 1980); older roots are best consumed cooked (Facciola 1990). Young shoots are edible raw or cooked (Hedrick 1972; Loewenfeld et al. 1980; Organ 1960; Facciola 1990). Flowers are edible raw and added to salads, and sprouted seeds can be added to salads or sandwiches (Facciola 1990). The root latex is used as a chewing gum (Yanovsky 1936; Tanaka 1976; Facciola 1990). The greens may also be eaten and have a sweet taste (Fritz et al. 1992). Salsify roots are used in soups and salads and as a coffee substitute or a dietetic medicine (Körber-Growthnee (1987) cited in Fritz et al. (1992)). Salsify is used in soups and stews; it can be boiled, cut into small pieces and creamed like asparagus. Also it can be cut into long strips, boiled and then fried in butter or mashed (Stephens 2009).

Botany

A robust, erect, biennial herb 50–110 cm high with a long cylindrical fleshy, tapering taproot (15–30 cm long and 2.5–3 cm wide, brownish yellow outside skin and white flesh) (Plate 1); older roots possess a milk sap and sparsely distally branched, glabrescent stem. Leaves are basal and cauline, alternate, sessile, sheathing lamina linear to linear lanceolate (grasslike), 20–40 cm long, entire margin, flat, straight apices, glabrescent on both surfaces and green. Flowering head is liguliflorous, solitary, terminal on long, bractless peduncle and distally inflated. Involucre is cylindrical, urn shaped or conic in bud, campanulate in flower; phyllaries are 5–11, in one series, linear to lanceolate, acute, receptacle flat to convex, glabrous and epaleate. Florets are 30–50; ligules are purple (Plate 2). Fruit is pale brown cypsela 2.5–4 cm, fusiform and ribbed with pale brown pappus.

Plate 1 Tapering fleshy cylindrical taproot (CG Kinsley)

Plate 2 Purple flowering head (M. Charters)

Nutritive/Medicinal Properties

The proximate nutrient composition of salsify root per 100 g edible portion had been reported as water 77 g, energy 82 kcal (343 kJ), protein 3.30 g, total lipid 0.2 g, ash 0.9 g, carbohydrate 18.60 g, total dietary fibre 3.3 g, Ca 60 mg, Fe 0.70 mg, Mg 23 mg, P 75 mg, K 380 mg, Na 20 mg, Zn 0.38 mg, Cu 0.089 mg, Mn 0.268 mg, Se 0.8ug, vitamin C 8 mg, thiamine 0.08 mg, riboflavin 0.220 mg, niacin 0.5 mg, pantothenic acid 0.371 mg, vitamin B6 0.277 mg and total folate 26ug (USDA, ARS 2014). The volatile fraction of salsify aerial parts comprised mainly of carbonylic compounds (24.6 %), phenols (21.5 %) and fatty acids and esters (19.7 %) (Formisano et al. 2010). The most abundant compounds were 4-vinyl guaiacol (19.0 %), hexadecanoic acid (17.9 %), hexahydrofarnesyl acetone (15.8 %) and hentriacontane (10.7 %). More than 80 of the volatile compounds mainly high molecular weight sesquiterpenes, acids and esters were identified in salsify (Riu-Aumatell et al. 2011). They found that headspace solid-phase microextraction (HS-SPME) was useful for the analysis of alcohols and hydrocarbons of low molecular weight and high volatility that are involved in the characteristic volatile profile of salsify and its sensory perception. The average content of inulin in fresh salsify roots was 15.17 % (Konopiński 2009). Total sugar content of salsify root was found to be 33.6 %; the low DP (degree of polymerization) compounds (oligosaccharides with DP2 to DP7) formed the majority representing 86.6 % of total sugars (Beirão-da-Costa et al. 2009). Sucrose was the main sugar (25.4 %) corresponding to 75.6 % of total sugars, glucose 2.3 %, fructose 2.2 %, oligosaccharides with DP3 3.2 % and oligosaccharides with DP7 0.5 %. Salsify root had a low calorific value but rich in proteins, vitamin B6, fibre, Ca, Fe, Mg, K, riboflavin and 4–11 % fructans (inulin and/or fructooligosaccharides).

The flavonoids, isoorientin, isovitexin, lucenin-1, luteolin, orientin, quercetin 3-*O*- β -D-glucoside, vicenin-1, vicenin-2 and vitexin, were detected in *T. porrifolius* (Kroschewsky et al.

1969). Rees and Harborne (1984) reported quercetin in all five of the *Tragopogon* species examined: *T. crocifolius*, *T. hybridus*, *T. longirostris*, *T. porrifolius* and *T. pratensis*.

T. porrifolius afforded a number of acylated pentacyclic triterpene saponins, tragopogonsaponins A–R (Warashina et al. 1991). The ubiquitous quinic acid derivatives chlorogenic acid and 3,5-dicaffeoylquinic acid were identified by HPLC/DAD and HPLC/MS in crude extracts of subaerial parts of *T. porrifolius* (Zidorn et al. 2003). Apigenin (4',5,7-trihydroxyflavone), apigenin 8-C- β -D-glucopyranoside (vitexin), luteolin (3',4',5,7-tetrahydroxyflavone), luteolin 8-C- β -D-glucopyranoside (orientin), apigenin 6-C- α -L-arabinopyranosyl-8-C- β -D-GLUCOPYRANOSIDE (isoschaftoside) were identified from salsify (Sareedenchai et al. 2009). Three accessions of *Tragopogon porrifolius* subsp. *porrifolius* yielded three new bibenzyl derivatives 5,4'-dihydroxy-3- α -l-rhamnopyranosyl-(1 $\rightarrow$ 3)- β -D-xylopyranosyloxybibenzyl, 2-carboxyl-3,4'-dihydroxy-5- β -D-xylopyranosyloxybibenzyl and tragopogonic acid (2'carboxyl-3',5',4"-trihydroxyphenylethanone), and scorzocreticoside 1 and 6-O-methylscorzocreticoside I (Zidorn et al. 2005), and yielded (7*S*,15*S*)-2,4,12-trihydroxy-7-(4-hydroxyphenyl)-10-methoxy-15-(4-methoxyphenyl)-7,8,15,16-tetrahydrodibenzo[*c,i*][1,7]dioxacyclododecine-5,13-dione, named tragoponol, a dimeric dihydroisocoumarin (Zidorn et al. 2010). Tragoponol was made up of open-chained forms of two different monomethoxylated dihydroisocoumarin moieties, scorzocreticin and hongkongenin, which were connected via two ester bonds to form a macrolide with two lactone moieties featuring a 12-membered ring. From *Tragopogon porrifolius*, 2,4-dihydroxy-6-[2-(4-hydroxyphenyl)-2-oxo-ethyl]-benzoic acid was isolated; this compound was deemed to be a biogenetic intermediate between dihydrostilbenes and dihydroisocoumarins (Zidorn 2007). β -amyrin was isolated from the aerial parts (Hariri et al. 2013).

Antioxidant Activity

Two bibenzyls showed moderate, and two dihydroisocoumarins showed weak 2,2-diphenyl-1-

picrylhydrazyl (DPPH) radical scavenging activities (Zidorn et al. 2005). The methanolic extract of the aerial part of *T. porrifolius* exhibited antioxidant activity of 744 $\mu\text{mol Fe}^{2+}/\text{g}$ in the FRAP assay (Mroueh et al. 2011). The extract was found to contain 37.1 mg/g GAE total phenolic content and 16.6 mg/g QE flavonoid content per gram dry weight of the extract.

Antihyperlipidaemic Activity

Studies showed that consumption of salsify aerial parts extract for a period of 4 weeks resulted in a marked improvement of the lipid profile (triglycerides, total cholesterol, LDL and HDL cholesterol) in rats fed a high-carbohydrate or high-fat diet (Zeeni et al. 2013). Body weight, food intake and intra-abdominal fat were also lower in animals given salsify extract (100 and 250 mg/kg). Additionally, *T. porrifolius* extract preload produced a dose-dependent decrease in food intake observed over 24 hours. The intake of *T. porrifolius* aqueous extract therefore improved lipidaemia and increased satiety in rats with no visible adverse effects.

Hepatoprotective Activity

The methanolic extract of the aerial part of *T. porrifolius* exhibited protective effect against CCL_4 -induced hepatotoxicity in rats (Mroueh et al. 2011). In-vivo, the extract (50, 100 and 250 mg/kg body weight) exhibited a dose-dependent increase in the activity of liver antioxidant enzymes. The highest dose used increased the activity of catalase, superoxide dismutase and glutathione S-transferase by 222, 149 and 68 %, respectively. *T. porrifolius* extract also showed substantial hepatoprotective capacity against CCL_4 -induced hepatic injury by restoring the activity of aspartate aminotransferase, alanine aminotransferase and lactate dehydrogenase to normal levels at 250 mg/kg body weight dose.

Anti-inflammatory Activity

The methanolic extract of salsify aerial parts exhibited maximum anti-inflammatory activity (60 %, 250 mg/kg), followed by ethyl acetate (36 %, 250 mg/kg) and chloroform (29 %, 100 mg/kg) extract, when compared with the untreated control group when tested using the carrageenan-induced paw oedema model in mice (Hariri et al. 2013). The inhibition of paw oedema by the methanolic extract was comparable in effect to that of diclofenac (10 mg/kg) treatment (69 %). GC-MS analysis revealed the presence of β -amyirin acetate in the three extracts: 20.9 % in the methanolic (major), 9.52 % in the ethyl acetate and 7.42 % in the chloroform extracts. β -amyirin acetate had been reported in the literature to possess anti-inflammatory and nociceptive activities and might be partly responsible for the anti-inflammatory effects of the three *Tragopogon porrifolius* extracts.

Antifatigue/Antianoxia Activities

Administration of *Tragopogon porrifolius* root extract was found to have an antifatigue effect in mice by prolonging the duration of swimming and stick climbing (Long and Tian 1990). The extract also enhanced the tolerance of anoxia in several models of rats and mice.

Traditional Medicinal Uses

Salsify is used in herbal medicine as a cleansing food and is perceived to have a beneficial effect upon the liver and gall bladder (Chevallier 1996). The root is antibilious, slightly aperient, deobstruent and diuretic (Grieve 1971; Lust 1974). It is especially employed in the treatment of obstructions of the gall bladder and jaundice (Chopra et al. 1986) and is also used in the treatment of arteriosclerosis and high blood pressure (Chevallier 1996).

Other Uses

Besides being used as food vegetable, salsify also has medicinal uses and is cultivated in home gardens for both purposes.

Comments

Salsify (*Tragopogon porrifolius*) is regarded as an environmental weed in Victoria, South Australia, Tasmania, Western Australia and the ACT.

Swedish: Ulluko

Venezuela: Michuri, Michiruí Migurí, Mucuchi, Ruba, Rubia, Timbós, Tiquiño

Origin/Distribution

Ulluco is indigenous to the Andean mountains and is completely a domesticated crop in Peru, Bolivia, Columbia, Ecuador and northern Argentina. Wild forms are found in Peru, Bolivia and northern Argentina. The area of cultivation extends from northern Argentina (23°S) to Columbia (9°N). It has been introduced to New Zealand, Australia, Sri Lanka and elsewhere.

Agroecology

In its native Andean range, ulluco is found at mid (2,500 m) to high altitudes 4,250 m (Parra-Quijano et al. 2012). It adapts well to temperate areas and will grow in the cooler and moist tropical highlands. Ulluco is frost resistant and thrives well in moist conditions and is moderately drought tolerant. Although ulluco's water requirements are unknown, it has been reported to be probably in the range of 800–1,400 mm per year during the growing season in the Andes.

Although they thrive under high light intensities, ulluco plants produce tubers poorly in hot climates. Ulluco was found to be characterised by absolute requirement for long day length for flowering and short day length for tuberisation (Markarov 2002). Day lengths of 10–13.5 hours are normally needed for tuber production. They found that cold nights retarded the destruction of gibberellic acid in plants during the dark period of diurnal cycle and ensured a permanently high level of gibberellins, which facilitated flowering of long-day species under short-day conditions. The high level of abscisic acid was considered a plant response to short-day conditions, which was favourable for tuberisation.

Ulluco tolerates a wide range of soil conditions but thrives best in a fertile, well-drained loamy soils, rich in organic matter, with a pH between 5.5 and 6.5.

Edible Plant Parts and Uses

Of the three Andean tubers (oca, maca and ulluco), ulluco is the most popular and commonly served on tables in rural and urban homes in the Andean region. Its tubers have been eaten by millions of people since the ancient times. The major appeal of the ulluco is its crisp texture which remains when cooked, like the jicama. Traditional ulluco food preparations include *mellocos* soup in Ecuador, *olluquito con charqui* (ulluco with meat) in Peru, *chupe* (potato, meat, egg, cheese stew) and *aji de paplisas* (ulluco pepper) in Peru and Bolivia (Arbizu and Tapia 1994). Ulluco tubers are also pickled or mixed with hot sauces. Generally, however, they are used to thicken soups and stews. For this, they are preferred to potatoes, because they yield a smooth, silky soup rather than a grainy one. In urban households and restaurants in Ecuador, they are frequently boiled and served cold as salad. In Columbia, ulluco is used as a basic ingredient together with cubio (*Tropaeolum tuberosum*) in the typical Colombian dish *cocido boyacense*. Tubers are also frozen and dried alternately and stored to produce a long-lasting product called *lingli* in Peru. Such processed tubers have a much stronger taste than the fresh ones. They are usually ground into flour and added to cooked foods. The green leaves of ulluco are also nutritious. In Colombia and Peru, the mucilaginous ulluco leaves are occasionally eaten in salads and as a vegetable (Parra-Quijano et al. 2012). They are also sometimes boiled to make soup or used like Malabar spinach, which they resemble in taste. Ulluco is grown and marketed as earth gems in New Zealand.

Botany

An erect, compact, low growing 20–50 cm or trailing prostrate succulent, mucilaginous annual herb, producing new shoots from tubers. Stem angular with decurrent ridges, greenish or reddish. Stolons bearing tubers. Tubers vary in shape, size and colour; shapes vary from subspherical, oblongish, rhomboid to elongate, cylindrical and falcate, thin skinned and with waxy, glossy surfaces of various colours ranging from white, light green, yellow, pink, orange, magenta, red or magenta spots mixed on a yellow background (Plate 1). Leaves alternate, glabrous, simple cordate (heart-shaped) margins smooth, entire, on long petioles. Inflorescence an axillary raceme. Flowers pedicellate, subtended by a pair of hornlike bracteoles free to base, persistent; sepals two yellowish, petals five yellowish to reddish, connate at base and adnate to petals, inserted on a shallow floral cup. Stamens 5 epipetalous, with erect filaments connate and adnate for half their length to petals, anther basifixed, deltoid thecae connate at apex, dehiscence of anthers by pore-like slits. Nectary annular. Ovary superior, 3 carpellate, unilocular with one basal ovule. Style single; stigma simple and mammilose. The fruit is an obovate, dry indehiscent nutlet, rugose, partially enclosed in parchment-like perianth, containing one seed with thin rust-coloured testa inside the thickened fruit wall. The embryo is strongly curved and encircles the scanty perisperm.

Plate 1 Ulluco tubers © International Potato Center (CIP)

Nutritive/Medicinal Properties

Ulluco contained high carbohydrate and fibre levels, moderate protein and low fat (Busch et al. 2000). Their sensory evaluation study found that red was the most preferred skin and tissue colour of ulluco over plain yellow and mixtures of yellow, green and red. There were no significant differences in panellists' preferences for taste between ulluco cultivars, although panellists disliked the appearance of the multicoloured cultivars.

The nutritional composition (dry weight basis) of ulluco tubers was reported as protein 10.8–15.7 %, carbohydrate 73.5–81.1 %, fat 0.1–1.4 %, ash 2.8–4.2 %, fibre 3.6–5.0 %, moisture 86.0–86.2 % and energy 370–381 cal/100 g (King and Gershoff 1987). They also contained all of the essential amino acids (mg/g protein): lysine 41–55 mg, threonine 23–30 mg, valine 33–37 mg, isoleucine 34–48 mg, leucine 41–57 mg, phenylalanine + tyrosine 49–70 mg, tryptophan 7.6–10.6 mg and methionine + cystine 27–34 mg.

Nutrient values (ppm, dry weight basis) of ulluco tubers were also reported by Duke (1994) as carbohydrate 118–912 ppm, protein 10–73, fat 2–14.6, fibre 3–44, ascorbic acid 230–1,750, Ca 30–365, Fe 7–58, P 340–2,775, riboflavin 0.2–2.2, thiamine 0.4–4.3, β -carotene 0.7 and energy 500–3,725 Kcal.

From *Ullucus tuberosus* were isolated: three flavonoids, rutin, narcissin and kaempferol 3-*O*-(2'',6''-di-*O*- α -L-rhamnopyranosyl)- β -D-glucopyranoside (Dini et al. 1991a); two triterpenoid saponins were isolated 28-*O*- β -D-glucopyranosyl-epihederagenine and 28-*O*- β -D-glucopyranoside-3-*O*- β -D-GLUCOPYRANOSYL (1'' $\rightarrow$ 2')- β -D-glucopyranosyl-oleanoate (Dini et al. 1991b). Three triterpenoid saponins, tuberosides A, B and C were isolated as sodium and choline salts from the methanolic extract of the tubers of *Ullucus tuberosus* (Espada et al. 1996).

Both the yellow and red ulluco tubers were rich in yellow betaxanthins, and the most prominent among the 20 identified were histidine-betaxanthin, arginine-betaxanthin and

glutamine-betaxanthin (Svenson et al. 2008). Twelve betacyanins were found in red tubers, with roughly 50 % of this content being betanin/isobetanin. Betacyanin levels vary from 41.2 up to 70.4 µg/g fresh weight in red tubers but were below quantifiable levels in yellow tubers. Betaxanthin levels were up to 50 µg/g fresh weight in yellow tubers. Low concentrations of betalains were detected in leaves, whereas stems contained total levels similar to the tubers, with dopamine-betaxanthin and betanin being the major pigments.

Ulluco tuber was reported to contain up to 85 % moisture, 1–2 % protein and 14 % carbohydrate. According to Gross et al. (1989), the main sugars were glucose and fructose. Chemical composition of ulluco tubers was reported as follows: protein 8.06 %, lipid 0.65 %, soluble fibre 6.49 %, insoluble fibre 7.22 %, total sugar 5.26, starch 64.96 %, mineral residues 5.40 % and moisture 87.40 % (Valcárcel-Yamani et al. 2013). Chemical composition of ulluco starch was reported as lipid 0.08 %, starch 99.05 %, amylose 26.49 %, mineral residues 0.17 % and moisture 10.97 %. Ulluco starch granules consisted of ellipsoid, oval, conical, pear-shaped and prismatic forms, ellipsoids and oval granules with lengths up to 32.09 µm. Ulluco starch had less swelling power, forming opaque, less firm gels. The physical, chemical and functional characterisation of starches from Andean tubers oca, mashua and ulluco suggested that these starches could be used in food systems and other industrial applications, in products that require easy cooking, high viscosity and stability under refrigeration and that do not need to be frozen. The absence of protein in the isolated starches indicated the utility of these starches for preparing syrups with high glucose content. The starches were found to cook easily and to have a high degree of swelling and solubility, high viscosity, low stability to stirring and cooking or mechanical action and a low tendency towards retrogradation. These starches showed high clarity but with high syneresis when subjected to freeze–thaw cycle.

The seeds of ulluco were formed sexually and not apomictically and contained the following enzyme systems:

malate dehydrogenase, glutamate oxaloacetate transaminase and 6-fosfoglucoose dehydrogenase (Pietila et al. 1990).

Antioxidant Activity

For ulluco tubers, the hydrophilic antioxidant capacity (HAC) as determined by ABTS (2,2'-azino-bis (3-ethylbenzothiazoline-6-sulfonic acid)) ranged from 483 to 1,524 µg TE/g, and when expressed on a phenolic basis, the highest specific HAC among the ulluco genotypes was found in genotype DP-03-43 with 2,322 mg TE/g chlorogenic acid equivalent (Campos et al. 2006). Ulluco did not present any lipophilic antioxidant capacity for the genotypes studied. Ulluco tubers had the lowest total phenolic content which ranged from 0.41 to 0.77 mg/g and had no anthocyanins and carotenoids. Ulluco tuber pigments corresponded to betalains in the base form of betacyanins (red pigment TBS) and acid form of betaxanthins (yellow pigment TBX). TBX in ulluco tubers ranged from 22 to 96 µg/g; only one genotype with red tubers presented betacyanins TBS = 64 µg/g. A low correlation between HAC and total phenolic content was observed ($R^2 = 0.64$), most likely due to different phenolic profiles among ulluco cultivars. Among the phenolics present in ulluco, the flavonoid kaempferol had been reported to exhibit strong antioxidant activity. HAC and TBX were not correlated, suggesting that the TBX does not contribute to the HAC in ulluco. According to the results obtained, the HAC range values for the crops studied followed the descending order mashua $\geq$ oca $\geq$ native potato $\geq$ ulluco.

Hypoglycaemic Activity

Three triterpenoid saponins, tuberosides A, B and C isolated from ulluco tubers, showed hypoglycaemic activity (Espada et al. 1996).

Other Uses

The plant is primarily grown as a root vegetable and secondarily as a leaf vegetable; no other uses have been recorded.

Comments

The crop is normally propagated by planting small tubers. The tubers sprout and grow readily when temperatures rise above about 18 °C. However, the plant is also easily propagated by stem cuttings.

Origin/Distribution

Its exact origin is obscure, most probably Eastern Europe (S. Russia, Ukraine) and west Asia. However, no natural populations of *Armoracia rusticana* were found in Austria, Bulgaria, Romania or Russia (Sampliner and Miller 2009). Horseradish is now cultivated widely in Europe and North America, where it has frequently naturalised.

Agroecology

A cool climate species, it grows in temperate and subtemperate areas with temperature range of 5–19 °C and annual rainfall of 500–1,700 mm. It is found growing in yards, gardens, roadsides, ditches, banks, waste ground, rubbish tips and waterside meadows. Although the plant will grow on any soil type, the best growth is found in deep, well-drained, moist, fertile, loamy soil high in organic matter with soil pH of 5–7.5 (6.8). It grows in full sun to partial shade.

Edible Plant Parts and Uses

Horseradish roots and leaves are eaten especially in Europe. Horseradish has very pungent roots that are used as condiment and contain oil with a strong pungent odour and hot, biting taste. As a condiment the horseradish root is usually grated or minced and mixed with vinegar, salt, cream, oil, tomato or yogurt or other flavourings to make sauce, paste or relish in Bulgaria, Romania and Russia (Sampliner and Miller 2009). These are often used with fish or other seafood or as an appetiser with meats. Grated horseradish is also employed as an ingredient in some catsups and mustards and, in salads, as a condiment for any cooked meat (e.g. lamb, pig and chicken) and mixed with red beets or other vegetables as garnish. In Romania, grated roots, with or without oil, are eaten with potatoes or polenta or are grilled and eaten with cream accompanying lamb and chicken; a mix of grated horseradish, apples, salt, sugar and vinegar is used as garnish for meals, while small pieces of the root are eaten in soups. In Tomsk (Russia), *A. rusticana* or *A. sisymbrioides* roots are grated and mixed with tomato and other spices to make a sauce. In Austria, freshly grated horseradish (or tinned product) is frequently mixed with grated apples (sour varieties preferred), and this mixture called *Apfelkren* is then eaten as a spicy relish to fried or cooked meat. In Bulgaria, Romania and Russia, the whole root, grated root or root pieces are still used to flavour, help ferment, aerate pickling liquid and conserve cabbage for the winter. In Germany, horseradish roots cut in very small pieces, crushed and mixed with salt and vinegar are often added to fish and meat dishes and also mixed in catsup used to flavour ground beets or added to mustard as a seasoning (Courter and Rhodes 1969). In Poland, roots and leaves are used for seasoning or as preservatives: the roots are utilised as a condiment, with pickled cucumbers, grated with chopped boiled eggs, soups or meat dishes, often used at Easter (Łuczaj Szymański 2007). Horseradish was used by European Jews as a symbolic food in the ritual meal as bitter herb of Passover because its bitterness reflected the suffering of their ancestors of the Exodus from Egypt (Schaffer 1981).

Horseradish root is still relished in Europe and North America and is appreciated freshly grated, mixed with vinegar or in a sauce to form a condiment often used with meats or fish and as a flavour in other recipes in salads and soups, on sandwiches and in cocktail drinks such as the Bloody Mary (Wedelsback Bladh and Olsson 2011).

In Bulgaria, Romania and Russia, *Armoracia rusticana* roots and leaves are used in the pickling of various vegetables including cucumbers, carrots, peppers or mixed vegetables (Sampliner and Miller 2009). In Romania, horseradish leaves are used for *sarmale*, a Romanian dish made from meat, rice and vegetables wrapped in *A. rusticana* leaves and then boiled; the leaves can also be put into bread dough, which is then grilled. Leaves can also be cut and used to conserve cut vegetables for the winter. The leaves of *A. rusticana* are used as an antiseptic or clearing ingredient as well as a fermenting agent in the preparation of alcohols in Bulgaria and Romania. They are used in the preparation of *tuica* (a Romanian fruit brandy). In Russia, leaves of *A. rusticana* and *A. sisymbrioides* are used for preparing canned cucumbers and conserves (Sampliner and Miller 2009). In Italy, the leaves are used for salad and mixed with other vegetable species (Pieroni et al. 2005; Sarli et al. 2012). In Poland, the leaves are placed in the oven under baking bread, partly to prevent the bread from sticking and partly to flavour the bread (Łuczaj and Szymański 2007). Horseradish is also often consumed boiled as a pot herb (Shehata et al. 2009).

Botany

An erect, glabrous robust, herbaceous, rhizomatous perennial, 50–120 cm high (Plate 1), branching sparsely in the upper part with a fleshy, pungently aromatic, fusiform or cylindrical taproot (Plate 2). Basal leaves few, alternate and in a rosette, long petiolate, 10–30 cm long, with elliptic–ovate or oblong–lanceolate, bluish green, lamina with cordate base and crenate, undulating margins (Plate 1). Proximal cauline leaves entire to pinnately lobed and serrate, distal cauline leaves alternate, sessile to subsessile, smaller than lower leaves, lanceolate, crenate, serrate or entire. Flowers in a terminal raceme, mildly fragrant, actinomorphic, small, 1–.5 cm wide, sepals 4 ovate; petals 4 white, 5–8 mm long, obovate and rounded; stamens 6, 4 long and 2 short, style 5 mm with capitate stigma, ovary with 8–12 ovules in two rows per chamber. Fruit a silique, 4–6 mm long, rarely produced, ovoid to obovate, few-seeded, generally aborted or weakly developed.

Nutritive/Medicinal Properties

Root Nutrients/Phytochemicals

The proximate nutrient composition of horseradish (prepared) per 100 g edible portion had been reported as water 85.08 g, energy 48 kcal (201 kJ), protein 1.18 g, total lipid 0.69 g, ash 1.76 g, carbohydrate 11.29 g, dietary fibre 3.3 g, total sugars 7.99 g, Ca 56 mg, Fe 0.42 mg, Mg 27 mg, P 31 mg, K 246 mg, Na 420 mg, Cu 0.05 mg, Mn 0.126 mg, Se 2.8 µg, vitamin C 24.9 mg, thiamine 0.08 mg, riboflavin 0.024 mg, niacin 0.386 mg, pantothenic acid 0.093 mg, vitamin B6 0.073 mg, total folate 57 µg, total choline 6.5 mg, β-carotene 1 µg, vitamin A 2 IU, lutein + zeaxanthin 10 µg, vitamin E (α-tocopherol) 0.01 mg, vitamin K (phylloquinone) 1.3 µg, total saturated fatty acids 0.09 g, 12:0 (lauric acid) 0.002 g, 14:0 (myristic acid) 0.001 g, 16:0 (palmitic acid) 0.061 g, 18:0 (stearic acid) 0.021 g, total monounsaturated fatty acids 0.130 g, 16:1 undifferentiated (palmitoleic acid) 0.001 g, 18:1 undifferentiated (oleic acid) 0.127 g, 20:1 (gadoleic acid) 0.001 g, 22:1 undifferentiated (erucic acid) 0.001 g, total polyunsaturated fatty acids 0.339 g, 18:2 undifferentiated (linoleic acid) 0.285 g, 18:3 undifferentiated (linolenic acid) 0.053 g and phytosterols 9 mg (USDA-ARS 2014).

Volatile organic compounds found in fresh and 12 hours horseradish samples (ppm) were determined by D'Auria et al. (2004), respectively, as thiobismethane (0.8, 1.4 ppm) carbon disulfide (0.8, 0 ppm), 3-butenenitrile (2.38, 0 ppm), 3-methylbutanal (0.4, 0.6 ppm), 2-ethylfuran (1.2, 5.8 ppm), hexanal (4.5, 3 ppm), *E*-2-hexenal (1.6, 3 ppm), allyl isothiocyanate (3,300,175 ppm), isobutyl isothiocyanate (15,0 ppm), 4-isothiocyanato-1-butene (63,0 ppm), butyl isothiocyanate (13,0 ppm), butyl isothiocyanate (13,0 ppm), 3-methylbutyl isothiocyanate (8.6, 0 ppm), pentyl isothiocyanate (3.7, 0 ppm), nonanal (1.6, 1.4 ppm), 4-methylpentyl isothiocyanate (0.4, 0 ppm), benzenepropanenitrile (0.8, 0.2 ppm), benzyl isothiocyanate (14,8.8 ppm), 2-phenylethyl isothiocyanate (400, 432 ppm), 3-methyl-1-butanol (0, 1.4 ppm), toluene (0, 0.8), heptanal (0, 0.3 ppm), benzaldehyde

(0,0.5 ppm), 2-pentylfuran (0, 3 ppm), 2-ethyl-1-hexanol (0,1.8 ppm), phenylacetaldehyde (0, 0.3 ppm), 4-ethylbenzaldehyde (0,0.4 ppm), *L*-(-)-menthol (0, 0.2 ppm), naphthalene (0, 0.2 ppm), decanal (0, 0.5 ppm), *trans,trans*-nona-2,4-dienal (0, 0.2 ppm), junipene (0,0.2 ppm) and italicene (0,0.8 ppm). Several new compounds were detected 12 hours after fresh horseradish was cut. Thiobismethane was also identified as a flavour component. The presence of four aldehydes, viz. 3-methylbutnal, hexanal, E-2-hexanal and nonanal, probably contributed to its aromatic bouquet.

In horseradish sprouts and roots, Agneta et al. (2012) confirmed the presence of sinigrin, 4-hydroxyglucobrassicin, glucobrassicin, gluconasturtiin and 4-methoxyglucobrassicin and identified glucoiberin, gluconapin, glucocochlearin, glucoconringianin, glucosativin, glucoibarin, 5-hydroxyglucobrassicin, glucocapparilinearisin or glucobrassicinapin, glucotropaeolin and glucoarabishirsutain, not previously characterised in horseradish. Of particular note was the presence of the putative 2-methylsulfonyl-oxo-ethyl-glucosinolate.

Phytochelatins (PC)-related peptides including isophytochelatins (Gln) (iso-PC(Gln) (γ Glu-Cys) $_n$ -Gln, $n = 3-4$) were identified in horseradish hairy roots exposed for 3 days to cadmium (1 mM) along with reduced glutathione (2 mM) (Kubota et al. 2000).

A full-length cDNA encoding myrosinase (ArMY1) was cloned from horseradish root (Li et al. 2007). Myrosinase (β -thioglucoside glucohydrolase) had been reported as the only known S-glucosidase in plants, catalysing the hydrolysis of glucosinolates into compounds with diverse biological activities. Horseradish peroxidase isoenzymes were found to contain fucose, arabinose, xylose and mannose; synthesis of the peptide portion of peroxidase was completed before these monosaccharide residues were attached to the molecule (Lew and Shannon 1973). Fujiyama et al. (1988) isolated, cloned and characterised three cDNAs and two genomic DNAs corresponding to the mRNAs and genes for the horseradish peroxidase isoenzyme C. The peroxidase enzyme purified from horseradish roots, a heme-containing enzyme, was

homogeneous with a molecular weight of approximately 40 kDa, a high specific activity of 772 U/mg protein and an isoelectric point of 8.8 and a Reinheitszahl value of 3.39 (Lavery et al. 2010).

Studies showed that the accumulation of glucosinolate concentration in horseradish in-vitro plants had a direct association with the sulphur concentration in the medium (Alnsour et al. 2013). Cultivation in 1.7 mmol/L sulfate resulted in the accumulation of 16.2 $\mu\text{mol/g DW}$ glucosinolates, while the glucosinolate concentration increased to more than 23 $\mu\text{mol/g DW}$ when 23.5 mmol/L sulfate was used in the medium. Correspondingly, the glucosinolate concentration decreased to 1.6 $\mu\text{mol/g DW}$ when sulphate concentration was lowered to 0.2 mmol/L.

Isaac and Kohlstaedt (1962) reported allyl isothiocyanate and β -phenylethyl isothiocyanate as the main pungent components of horseradish grown in Japan. Volatile components identified in horseradish and black mustard included: methyl isothiocyanate, isopropyl thiocyanate, methyl thiocyanate, ethyl thiocyanate, sec-butyl thiocyanate, isobutyl thiocyanate, allyl thiocyanate and 3-butenyl thiocyanate (Kishima et al. 1970). Significant level of isopropyl isothiocyanate between horseradish and black mustard was observed.

Gilbert and Nursten (1972) identified five major essence compounds in horseradish roots: allyl thiocyanate, 4-pentenyl isothiocyanate, 2-butyl isothiocyanate, β -phenylethyl isothiocyanate and allyl thiocyanate as well as methyl isothiocyanate, ethyl isothiocyanate, isopropyl isothiocyanate and 2-phenethyl isothiocyanate. Eight major volatile components were identified from horseradish roots: isopropyl isothiocyanate, allyl isothiocyanate, 3-butenyl isothiocyanate, 4-pentyl isothiocyanate, phenyl isothiocyanate, 3-methylthiopropyl isothiocyanate, benzyl isothiocyanate and β -phenylethyl isothiocyanate (Kojima et al. 1973). Of the ten steam-volatile constituents identified in horseradish, six were isothiocyanates, two were nitriles, one was allyl thiocyanate and one was carbon disulfide (Mazza 1984). The distribution and concentration of flavour components in crowns, primary

and secondary roots and rootlets differed from those in tops. The primary and secondary roots and crowns accounted for the bulk of the weight of the root fraction as well as its essence content.

Grob and Matile (1980) identified 30 glucosinolates in horseradish: 2-methylthioethyl-glucosinolate (glucoviorylin), isopropyl glucosinolate (glucoputranjivin), allyl glucosinolate (sinigrin), 2-hydroxypropyl-glucosinolate (glucoarabidopsithalin), 3-methylthiopropyl glucosinolate (glucoiberin), 3-methylsulfinylpropyl glucosinolate (glucoiberin), 3-methylsulfonylpropyl-glucosinolate (glucocheirolin), *n*-butyl glucosinolate, *sec*-butyl-glucosinolate, isobutyl glucosinolate (glucoconringianin), 3-butenyl-glucosinolate (gluconapin), 3-hydroxybutyl-glucosinolate (glucocappariflexin), 4-methylthiobutyl glucosinolate (glucoerucin), *n*-pentyl-glucosinolate (glucokohlrabiin), 3-methylbutyl-glucosinolate, 2-methylbutyl-glucosinolate, 4-pentenyl glucosinolate (glucobrassicinapin), 2-hydroxypentyl-glucosinolate (glucomoracialapathin), 3-hydroxy-4-pentenyl glucosinolate, 5-methylthiopentyl-glucosinolate (glucoberteroin), 3-hydroxy-5-methylthiopentyl-glucosinolate, iso-hexyl-glucosinolate structure unknown, 5-hexenyl-glucosinolate (glucowasabiamin), 6-methylthiohexyl-glucosinolate (glucolesquerellin), iso-heptyl-glucosinolate structure unknown, benzyl glucosinolate (glucotropaeolin), 2-phenylethyl-glucosinolate (gluconasturtiin), 3-phenylpropyl-glucosinolate (glucoarmoracialapicin), 4-phenylbutyl-glucosinolate (glucoarmoracialafolicin) and methoxybenzyl glucosinolate. The common names in brackets had been recognised by Fahey et al. (2001), Bellostas et al. (2007) and Clarke (2010). The accumulation of indole glucosinolates and its common precursor L-tryptophan in the vacuole of root storage tissues was reported by Helmlinger et al. (1983). The presence and concentration of indole-3-methylglucosinolate [=glucobrassicin; 0.49 $\mu\text{mol/g}$ dry weight (dw)] and its 1-methoxy derivative (0.38 $\mu\text{mol/g}$ dw) were determined.

Seven isothiocyanates (ITCs) were identified and measured as flavour compounds in New Zealand-grown

wasabi rhizomes and horseradish roots (Sultana et al. 2003). These were isopropyl isothiocyanate, sec-butyl isothiocyanate, allyl isothiocyanate (AITC), 3-butenyl isothiocyanate (3-BITC), 4-pentenyl isothiocyanate (4-PITC), 5-hexenyl isothiocyanate C (5-HITC) and 2-phenylethyl isothiocyanate (2-PEITC). AITC was the highest concentration isothiocyanate in both wasabi (1,937.8 mg/kg of fresh rhizome) and horseradish (1,658.1 mg/kg fresh root). AITC comprised a higher proportion of the total isothiocyanate concentration of wasabi (93.7 %) than of horseradish (87.2 %). The level of 4-PITC in wasabi was 47.97 mg/kg of rhizome (2.32 % of the total isothiocyanate concentration in wasabi), whereas in horseradish the level was only 8.99 mg/kg of the root, which was significantly lower (81 %) than for wasabi. The proportion of 4-PITC of the total isothiocyanate concentration in horseradish was also very small (0.47 %). 2-Phenylethyl ITC was only detected in horseradish (185.2 mg/kg of root) and was the second highest ITC in horseradish root, contributing 9.74 % to the total isothiocyanate content. The concentrations of 3-BITC in wasabi and horseradish were not significantly different (43.13 and 39.43 mg/kg of the sample, respectively). sec-Butyl ITC was present at 18.78 mg/kg of wasabi rhizome but was only 2.77 mg/kg in horseradish root. The proportion of sec-butyl ITC of total isothiocyanate concentration in wasabi and horseradish was very small (0.91 % and 0.15 %, respectively). The levels of isopropyl ITC in wasabi and horseradish were 12.81 mg/kg and 3.57 mg/kg, respectively. Very small amounts of 5-HITC were found in wasabi (7.06 mg/kg of rhizome) and horseradish (2.77 mg/kg of root). The total isothiocyanate content in wasabi was 2,067.55 mg/kg of rhizome, while the level in horseradish was 1,900.7 mg/kg of roots.

Chemical composition of the pungent components of *A. rusticana* grown in China was determined by Jiang et al. (2006) as isopropyl isothiocyanate (0.1 %), allyl isothiocyanate (78.4 %), butyl isothiocyanate (0.1 %), 3-butenyl isothiocyanate (1.5 %), 2-pentyl isothiocyanate (2.1 %), phenyl isothiocyanate (0.1 %), 3-methylthiopropyl isothiocyanate (0.3 %), benzyl isothiocyanate (0.1 %) and β -phenylethyl isothiocyanate (9.4 %). A total of 15 volatile

compounds were detected in various Latvian horseradish genotype roots: 2-butyl isothiocyanate, isobutyl isothiocyanate, allyl isothiocyanate, 3-methylbutyl isothiocyanate, 3-butenyl isothiocyanate, pentyl isothiocyanate, cyclopentyl isothiocyanate, benzyl isothiocyanate, 2-phenethyl isothiocyanate and the rest unidentified (Tomsone et al. 2013). The main compound in all horseradish samples was allyl isothiocyanate constituting 64–82 % of total identified volatile compounds; the samples also contained significant amounts of 2-phenylethyl isothiocyanate (4–26 %).

The content of allyl isothiocyanate (AITC) in creamy and white horseradish roots ranged from 800 to 2,000 mg/kg fresh weight (Horbowicz and Rogowska 2006). The concentration of phenylethyl isothiocyanate (PEITC) in roots of both horseradish types was 3–10 times lower than AITC. The roots of creamy-type horseradish contained higher level of PEITC than the white type. A decline of PEITC level was observed during vegetation of horseradish. Kaempferol level decreased in horseradish roots during cultivation period, and only traces of quercetin in roots of both horseradish types were detected. Freshly harvested roots of the Polish horseradish contained higher content of analysed allyl and phenylethyl isothiocyanates (AITC and PEITC) in comparison to horseradish of the Hungarian origin (Kosson and Horbowicz 2008). During long-term storage in cold room (0–1 °C), variation of content of both isothiocyanates was observed, but mean level of the pungent compounds: AITC and PEITC. During long-term storage of both horseradish root types in cold room, the significant decline of ascorbic acid content was noted, but after 10 months of storage period, its level was still high. They found that the higher the temperature of storage, the higher the content of reducing sugar in horseradish cream was observed (Kosson and Horbowicz 2009). Content of allyl isothiocyanate (AITC) and especially phenylethyl isothiocyanate (PEITC) in fresh horseradish cream was lower in comparison to non-processed horseradish roots. Content of both isothiocyanates decreased significantly during storage period. The highest decline of isothiocyanate level was observed during the first 4 months of storage. The highest

temperature of storage studied (18 °C) caused faster decline of both isothiocyanate concentrations in horseradish cream.

Mevy et al. (1997) found that the qualitative production of glucosinolates was similar in both horseradish regenerated plantlets and wild plants with regard to 2-phenylethyl- and 2-propenyl-glucosinolates. In contrast, thioglucoside contents varied with cell differentiation because indole glucosinolates occurred only in calli, suspension cells and embryoids. Additionally, it was shown that the specific activity of myrosinase, the enzyme responsible for glucosinolate hydrolysis, declined with tissue age.

Horseradish plantlets produced significantly higher amounts of total glucosinolates than tumour and teratoma tissues with the aliphatic glucosinolate sinigrin being dominant (Redovniković et al. 2008). Plantlets also contained lower amounts of an aromatic glucosinolate, gluconasturtiin, and indole compounds: glucobrassicin, 4-methylglucobrassicin and 4-hydroxyglucobrassicin. In tumour and teratoma tissues, only these indole glucosinolates were detected. The activity of enzyme myrosinase (β -thioglucosidase) was significantly higher in plantlets than in teratoma tissues. No myrosinase activity was recorded in tumour tissues. Total peroxidase activity was 30–50 times higher in tumour and teratoma than in plantlets. Immobilisation of horseradish cells reduced the assimilation of the hexoses released into the culture medium (Mevy et al. 1999). Although sucrose hydrolysis occurred prior to uptake, the decrease of acid invertase activity in immobilised cells was accompanied by an increased yield (two- to threefold) of the intracellular sucrose. Glucosinolates accumulated as indolic forms only during the stationary stage of cell growth. Their amount in immobilised cells may be increased twofold compared to the control cultures. In contrast, intracellular sucrose concentration declined, while the cleavage activity of sucrose synthase increased simultaneously with production of indole-3-methyl- and 4-hydroxy-indole-3-methyl-glucosinolates.

Total glucosinolates in accessions of horseradish roots and leaves ranged from 2 to 296 $\mu\text{mol/g}$ of dry weight in both tissues (Li and Kushad 2004). Four glucosinolates (sinigrin,

glucobrassicin, neoglucobrassicin and gluconasturtiin) were detected in major quantities. In fully developed roots, sinigrin concentration accounted for approximately 83 %, gluconasturtiin approximately 11 % and glucobrassicin approximately 1 % of the total glucosinolates. Approximately the same proportions of individual glucosinolates appeared in fully developed leaves, except that glucobrassicin substituted by neoglucobrassicin and gluconasturtiin concentration was significantly lower (<1 %). At least four other glucosinolates were detected in very small quantities (<1 %) in both roots and leaves. Myrosinase (β -thioglucoside glucohydrolase), the enzyme responsible for the hydrolysis of the parent glucosinolates into biologically active products, was detected in the roots and leaves, ranging from 1.2 to 57.1 units/g dw. Significant differences in myrosinase activity were detected between the roots and leaves, ranging from 1.2 to 57.1 units/g dw. In the leaves, significant correlations were found between myrosinase activity and total glucosinolates ($R^2 = 0.78$) and between myrosinase activity and sinigrin ($R^2 = 0.80$). Glucosinolate content and myrosinase activity were also correlated in young and fully developed roots and leaves and during tissue crushing. Glucobrassicin concentration in the roots and neoglucobrassicin concentration in the leaves were significantly higher in young than in fully developed tissue. Crushing of the tissue resulted in rapid hydrolysis of sinigrin and glucobrassicin, as expected, from the presence of myrosinase. Myrosinase was found to have a mass of about 130 kDa made up of two subunits of similar molecular mass of about 65 kDa, and it exhibited high activity at broad pH 5–8 and temperature (37 and 45 °C) (Li and Kushad 2005).

Horseradish root had been found to be rich in the glucosinolate sinigrin (thio- β -glucopyranosyl-1-N-sulfate-2-propenylimidate) (>80 %) followed by gluconasturtiin and glucobrassicin (Wedelsback Bladh et al. 2013). Sinigrin levels in 168 Nordic accessions varied between 10 and 45, gluconasturtiin between 1.3 and 7.4 and glucobrassicin between 0.1 and 2.6 $\mu\text{mol/g DM}$. Accessions with high levels of both sinigrin and gluconasturtiin were found. Glucosinolates and their degradation products are responsible

for the characteristic pungent taste and odour of *Brassica* crops such as horseradish, cabbage, mustard and broccoli (Wedelsback Bladh et al. 2013), and myrosinase, or thioglucoside glucohydrolase, the trivial name for the enzyme, had been reported to be responsible for the hydrolysis of glucosinolates such as sinigrin into isothiocyanate following disintegration of root cells, generating the spicy taste of horseradish-containing food (Loebers et al. 2010). The products of glucosinolate hydrolysis include isothiocyanates, nitriles, thiocyanates, indoles and oxazolidinethiones (Mucete et al. 2006b). Mucete et al. (2006b) found that sinigrin–myrosinase activity can be optimised under the following conditions: temperature of 55 °C, and reaction time was of 210 minutes for rubbed out horseradish samples and of 240 minutes for unrubbed horseradish samples.

A recent review by Nguyen et al. (2013) had focused on the pharmacological properties of its major chemical compounds, allyl and phenethyl isothiocyanates, mainly in areas of anticancer and antimicrobial activities, covering in-vitro and animal studies, and pharmacokinetics.

Antioxidant Activity

Horseradish exhibited antioxidative and superoxide scavenging potency and peroxidase activity (Kinae et al. 2000). Majewska et al. (2004) found that although leaf and root extracts derived from four Polish types of horseradish did not exhibit strong antioxidant properties, the different environmental conditions of plant growth affected these properties significantly. Volatile oil obtained from horseradish roots revealed stronger antioxidant properties than pure allyl isothiocyanate and was significantly affected by types as well as environmental factors. Diet containing horseradish had no effect on antioxidant plasma and heart activity in mice.

Horseradish extract obtained by supercritical extraction was found to have the highest antioxidant capacity, compared to fresh and lyophilised horseradish (Cirimbei et al. 2013). This was attributable to contents of flavonoid and phenols. Horseradish extract obtained by supercritical extraction had

the highest contents of flavonoids rutin and quercetin and phenols gallic and tannic acids.

Antimicrobial Activity

Growth of *Staphylococcus aureus*, *Escherichia coli* O157:H7, *Salmonella typhimurium*, *Listeria monocytogenes* and *Serratia grimesii* on agar was completely inhibited for 7 days in aerobic storage at 12 °C when 4,000 nL horseradish root distillate/L air was added to a sealed model system at the outset (Ward et al. 1998). Complete inhibition of *Lactobacillus sake* required 20,000 nL/L. Bactericidal activity varied between species and increased with distillate concentration. Bacteria inoculated on roast beef were more resistant to the bacteriostatic effect of the distillate and 20,000 nL/L were required to completely inhibit growth. *Lactobacillus sake* was weakly inhibited at this concentration. Bactericidal activity was observed only for *Staphylococcus aureus*, *Escherichia coli* and *Serratia grimesii*. Differences in bacteriostatic and bactericidal activities were attributed to enhanced depletion of residual allyl isothiocyanate in the meat model system.

Isothiocyanates from cut horseradish roots were found to be inhibitory in-vitro to *Bacillus subtilis* *Staphylococcus aureus* and *Escherichia coli* (Mucete et al. 2006a). Horseradish extract was found to be an effective agent against saprolegniasis (Khomvilai et al. 2006). The minimum inhibitory concentration of its main constituent allyl isothiocyanate, for mycelial growth of *Saprolegnia parasitica*, was 68 mg/L after 60 minutes exposure and 42.5 mg/L for zoospore germination after 5 minutes exposure.

Isothiocyanates (ITCs) extracted from horseradish root exhibited antimicrobial activity in-vitro against oral microorganisms: six strains of facultative anaerobic bacteria, *Streptococcus mutans*, *Streptococcus sobrinus*, *Lactobacillus casei*, *Staphylococcus aureus*, *Enterococcus faecalis* and *Aggregatibacter actinomycetemcomitans*; one strain of yeast, *Candida albicans*; and three strains of anaerobic bacteria, *Fusobacterium nucleatum*, *Prevotella nigrescens* and *Clostridium perfringens* (Park et al. 2013). The minimum

bactericidal concentration (MBC) of the ITCs extracted from horseradish root ranged from 1.25 to 5.00 mg/mL against six strains of facultative anaerobic bacteria and one strain of yeast and 4.17–16.67 mg/mL against three strains of anaerobic bacteria. The ITCs extracted from horseradish root showed the strongest antimicrobial activity, with an MBC of 1.25 mg/mL, against *C. albicans* among facultative microorganisms and 4.17 mg/mL against *F. nucleatum* among anaerobic bacteria.

Anticancer Activity

A combination of horseradish peroxidase and indole-3-acetic acid or its derivatives is currently being evaluated as an agent for use in targeted cancer therapies (Veitch 2004). Allyl isothiocyanate (AITC), a constituent of cruciferous vegetables including parsnip, significantly inhibited survival of PC-3 and LNCaP human prostate cancer cells in culture, whereas proliferation of a normal prostate epithelial cell line was minimally affected by AITC even at concentrations that were highly cytotoxic to the prostate cancer cells (Xiao et al. 2003). They also demonstrated that AITC administration retarded growth of human prostate cancer xenografts in-vivo (Srivastava et al. 2003). Approximately 70 % reduction in the levels of antiapoptotic protein Bcl-2 in the tumour lysate of AITC-treated mice was found compared with that of control mice. Further, the tumours from AITC-treated mice, but not control mice, exhibited cleavage of BID, known to promote apoptosis. Statistically significant reduction in the expression of several proteins that regulated G2/M progression, including cyclin B1, cell division cycle (Cdc)25B and Cdc25C (44, 45 and 90 % reduction, respectively, compared with control), was also observed in the tumours of AITC-treated mice relative to control tumours.

Cyclooxygenase and human tumour cell growth inhibitory extracts of horseradish roots yielded active compounds plastoquinone-9 (1), 6-*O*-acyl- β -D-glucosyl- β -sitosterol (2) and 1,2-dilinolenoyl-3-galactosylglycerol (3) (Weil et al. 2005). 3-Acyl-sitosterols, sinigrin, gluconasturtiin and phosphatidylcholines isolated from horseradish were inactive. At a concentration of 60 μ g/mL, compounds 1 and 2

selectively inhibited COX-1 enzyme by 28 and 32 %, respectively, while at 250 µg/mL compound 3 gave 75 % inhibition. In a dose–response study, compound 3 inhibited the proliferation of colon cancer cells (HCT-116) by 21.9, 42.9, 51.2 and 68.4 % and lung cancer cells (NCI-H460) by 30, 39, 44 and 71 % at concentrations of 7.5, 15, 30 and 60 µg/mL, respectively.

Antihypercholesterolemic Activity

Balasinska et al. (2005) demonstrated that horseradish lowered plasma cholesterol and faecal bile acid excretion in mice fed the cholesterol-enriched diet with horseradish compared with those fed cholesterol-enriched diet. Horseradish increased the excretion of cholesterol and coprostanol when compared with mice fed the control diet and with cholesterol. It was suggested that the cholesterol-lowering action of horseradish could be due to the interference with exogenous cholesterol absorption.

Antimutagenic Activity

Horseradish and wasabi (*Wasabi japonica*) exhibited antimutagenic activity towards 2-amino-3,8-dimethylimidazo[4,5-f]quinoxaline [MeIQx], a well-known mutagen/carcinogen in broiled fish and meat, and also decreased His+ revertant colonies of 3-chloro-4-dichloromethyl-5-hydroxy-2(5H)-furanone (MX) in the Ames test, a strong mutagen and carcinogen in chlorine-disinfected tap water (Kinae et al. 2000). 3-Allyl-5-substituted 2-thiohydantoins (ATH-amino acids) derived from allyl isothiocyanate and amino acids were found to inhibit the mutagenicity of 2-amino-3-methylimidazo[4,5-f]quinoline (IQ) in the *Salmonella* assay (Takahashi et al. 2005). It was found that ATH-amino acids could act as S9 inhibitors, thereby inhibiting metabolic activation of IQ.

Insecticidal Activity (House Health Pest)

In-vitro studies showed that horseradish ethanol extracts exhibited only a fungistatic activity against *Sclerotium rolfsii*,

Fusarium oxysporum and *F. culmorum* but showed significant insecticidal activity against larvae of the mosquito, *Aedes albopictus*, with a higher efficacy (LC₅₀ value of 2.34 g/L), approximately two times higher than the garlic one (LC₅₀ value of 4.48 g/L) (Tedeschi et al. 2011). Horseradish oil (24 hours LC₅₀, 1.54 µg/cm²) and allyl isothiocyanate (2.52 µg/cm²) were highly toxic to *Dermatophagoides farinae*, house dust mites (Yun et al. 2012). Among the other organic isothiocyanates, benzyl isothiocyanate (LC₅₀, 0.62 µg/cm²) was the most toxic compound, followed by 4-chlorophenyl, 3-bromophenyl, 3,5-bis(trifluoromethyl)phenyl, cyclohexyl, 2-chlorophenyl, 4-bromophenyl and 2-bromophenyl isothiocyanates (0.93–1.41 µg/cm²). All were more effective than either benzyl benzoate (LC₅₀, 4.58 µg/cm²) or dibutyl phthalate (24.49 µg/cm²). In the vapour-phase mortality bioassay, these isothiocyanates were consistently more toxic in closed versus open containers, indicating that their mode of delivery was, in part, a result of vapour action.

Antigenotoxic Activity

Plant extracts of *Armoracia rusticana*, *Ficus carica*, *Zea mays* and their mixture decreased the level of mutations induced by N-methyl-N'-nitro-N-nitrosoguanidine (MNNG), an environmental mutagen, in *Vicia faba* cells, chlorophyll mutations in *Arabidopsis thaliana* and NaF-induced mutability in rat marrow cells (Agabeili and Kasimova 2005). *Gentiana asclepiadea* (methanolic and aqueous haulm extracts, 0.25 mg/mL) and *Armoracia rusticana* (methanolic root extract, 0.025 mg/mL) enhanced the adaptive response and decreased DNA damage (genotoxic impact) caused by zeocin in human lymphocytes (Hudecova et al. 2012).

Antioestrogenic Activity

Horseradish peroxidase (HRP) was found to oxidise known endocrine-disrupting alkylphenols such as bisphenol A (2,2-bis(4-hydroxyphenyl)propane; BPA), *p*-nonylphenol (*p*-NP) and *p*-octylphenol (*p*-OP) (Sakuyama et al. 2003). Their study

showed that when Japanese rice fish (*Oryzias latipes*) were exposed to BPA, vitellogenin in the blood increased, but no increased vitellogenin was observed in medaka exposed to HRP-oxidised BPA. The enzymatic oxidation of BPA using HRP was able to eliminate its oestrogen-like activity.

Traditional Medicinal Uses

Horseradish has been used for a long time in traditional medicine for its therapeutic, stimulant, rubefacient, stomachic, diaphoretic, diuretic, expectorant, antiscorbutic, antiseptic and vermifugal properties (Grieve 1971; Cirimbei et al. 2013). Horseradish is useful in the treatments of dropsy, when infused in wine horseradish root will stimulate the whole nervous system and promote perspiration; an infusion of sliced horseradish in milk provides an excellent cosmetic for the skin (Grieve 1971). Horseradish juice mixed with white vinegar is applied externally to remove freckles, and the same mixture diluted with water and sweetened with glycerine is administered to children for whooping cough. Horseradish may help to relieve rheumatism by stimulating blood flow to inflamed joints (Shehata et al. 2009). Horseradish is best known to cure scurvy, due to its high vitamin C content (Wedelsback Bladh and Olsson 2011).

In Eastern Europe (Austria, Bulgaria, Romanian and Russia), grated horseradish roots or leaves are put in a cloth (sometimes with alcohol or vinegar) and applied to the skin to ease rheumatic pain and to the head to soothe headaches (Sampliner and Miller 2009). Roots are mixed with vinegar, salt and sugar and taken for lowering blood pressure. The root extract is applied to the throat to ease breathing problems and to cure sinuses. Grated roots are mixed with *Robinia pseudoacacia* honey and employed for coughs and bronchitis.

In the community of Russlanddeutsche (Germans from Russia) living in Künzelsau (Germany), it was reported that the Russian sauerkraut, used as an important home medicine for treating flu and liver disease, contained horseradish among other herbs (Pieroni and Gray 2008). In the Basilicata region (South Italy), horseradish leaves and roots have been

traditionally used as a remedy for rheumatism, headaches, sinusitis, coughs and bronchitis (Sarli et al. 2012). Added to water, vinegar, salt and sugar or aromatised with dill and bay leaves and pickled tomatoes, horseradish is also used as a remedy for treating drunkenness. Leaves are added to dog food, for its antimicrobial activity (Pieroni et al. 2004; Pieroni and Quave 2005; Sarli et al. 2012).

In America, the Cherokees used horseradish as an abortifacient for obstructed menses, to treat rheumatism, as a remedy for cold and asthma, as a urinary aid for gravel (kidney stones), as a diuretic, as a gastrointestinal aid to improve digestion and to treat mouth and tongue ailments (Moerman 1998, 2009). The Ontario and Delaware natives used the leaf poultice as an analgesic for neuralgia. The Iroquois used an infusion of pulverised roots for the blood and plant infusion for diabetes. The Mohegans applied leaf poultice externally to cheeks for toothache.

Other Uses

Horseradish has insecticidal and nematicidal properties. Of 40 plant essential oils tested for insecticidal activity against larvae of *Lycoriella ingénue* using a biofumigant assay, horseradish, anise and garlic oils showed the most potent insecticidal activities among the plant essential oils. At 1.25 µL/L, horseradish, anise and garlic oils caused 100, 93.3 and 13.3 % mortality (Park et al. 2006). One compound from horseradish, allyl isothiocyanate, was found to be the most toxic with LC50 value of 0.15 µL/L. Studies found that allyl isothiocyanate obtained from *A. rusticana* may be an alternative to phosphine and methyl bromide against the four major pest species of stored products, maize weevil *Sitophilus zeamais*, lesser grain borer *Rhyzopertha dominica*, *Tribolium ferrugineum* and book louse *Liposcelis entomophila* (Wu et al. 2009). *A. rusticana* essential oil containing 97.81 % of allyl isothiocyanate was active against different life stages of *Plodia interpunctella* and adults of *Sitophilus zeamais* (Chen et al. 2011). The results indicated that it may be possible to achieve toxicity levels similar to those of standard chemical fumigants through the applications of essential oils from *A. rusticana*.

Aissani et al. (2013) found that the methanol–aqueous extract of fresh horseradish roots had nematicidal activity against second stage (J2) *Meloidogyne incognita* with EC₅₀ of 251 mg/L after 3 days exposure. Allyl isothiocyanate was the most abundant compound and in pure form induced J2 paralysis with an EC₅₀ of 52.6 and 6.6 mg/L after 1 hour and 3 days of incubation.

A pilot scale testing demonstrated that minced horseradish roots (1:10 roots to swine slurry ratio), with calcium peroxide (CaO₂ at 34 mM) or hydrogen peroxide (H₂O₂ at 68 mM), could be used for the complete removal of phenolic odorants (with a detection limit of 0.5 mg/L) from the swine slurry; also horseradish could be recycled (reused) five times while retaining significant reduction in the concentration of phenolic odorants (Govere et al. 2007).

The structure and function of horseradish peroxidase offer the opportunity to develop engineered enzymes for practical applications in natural product and fine chemical synthesis, medical diagnostics and bioremediation (Veitch 2004). Horseradish peroxidase is used in medical research and analytical techniques and in detoxification of industrial wastewaters (Wedelsback Bladh and Olsson 2011). Studies by Taudt et al. (2012) demonstrated that horseradish stems could be used in the development of natural fibre-reinforced polymers (NFRPs) as in the design of automotive exterior and interior parts.

Comments

Sampliner and Miller (2009) hypothesised that *Armoracia rusticana* is a species known only from cultivation and that cultivated *A. rusticana* populations were derived from natural populations of either *Armoracia macrocarpa* or *Armoracia sisymbrioides*.

Brassica napus var. *napobrassica*

T. K. Lim¹✉

(1) Canberra, Aust Capital Terr, Australia

Scientific Name

***Brassica napus* var. *napobrassica* (L.) Reichenbach**

Synonyms

Brassica oleracea var. *napobrassica* L., *Brassica campestris* L. var. *napobrassica* (L.) DC., *Brassica napobrassica* (L.) Miller, *Brassica napus* subsp. *napobrassica* (L.) Hanelt, *Brassica napus* var. *edulis* Delile, *Brassica napus* var. *rapifera* Metzger, *Brassica rutabaga* DC. ex H. Léveillé

Family

Brassicaceae

Common Names

Eddie, Neep, Rutabaga, Swede, Swede Turnip, Swedish Turnip, Wax Turnip, Yellow Turnip

Vernacular Names

Chinese: Man Jing Gan Lan

Czech: Tořna

Danish: Kålroe

Dutch: Koolraapen

Finnish: Lanttu

French: Chou-Navet, Navet De Suède, Rutabaga

German: Kohlrübe, Steckrübe, Wruke

Hungarian: Svéd Karórépa

Italian: Navete, Navone, Rapaccio

Japanese: Rutabaga, Suwhēden-Kabu

Norwegian: Kålrot, Kålrabi

Portuguese: Nabo

Polish: Brukiew

Russian: Brjukva

Scots: Neep, Tumshie

Spanish: Col Nabo, Colinabo, Nabo

Swedish: Kålrot

Origin/Distribution

Brassica napus is native to Europe but not known in the wild; it perhaps evolved in the sixteenth century as an allotetraploid derived from wild cabbage *Brassica oleracea* and turnip *Brassica rapa* (Cheo et al. 2001). Two varieties of *Brassica napus* are recognised: var. *napus* and var. *napobrassica* (rutabaga or swede). Rutabagas are grown for human and animal consumption (Undersander et al. 1992). Rutabagas have been introduced to North America, North Asia and elsewhere including Australia and New Zealand. It is cultivated occasionally in the highlands in Southeast Asia.

Agroecology

Rutabaga is adapted to a humid cool climate as found in the Mediterranean to subtemperate areas. Optimum temperatures for growth are 15–20 °C. Rutabaga plants are both cold hardy and drought tolerant. They thrive best in a moderately deep, moderately well-drained, fertile and slightly acid sandy loams, loams and clay loams with pH 6–6.8 in full sun.

Edible Plant Parts and Uses

The edible tuberous root is eaten raw or cooked. In Finland, rutabaga is boiled, baked, roasted, used as a flavour enhancer for soups and roasted served with meat dishes as the main ingredient in the popular Christmas dish swede casserole 'lanttulaatikko'. Uncooked, rutabaga is thinly julienned as a side dish or used in a salad.

In Sweden and Norway, rutabaga is cooked and mashed with potatoes, carrots with butter, cream or milk to produce a puree called 'kålrot/kålrabistappe' or 'rotmos', respectively. In Norway *kålrot/kålrabistappe* is an essential accompaniment to many festive dishes including salted herring, *smalahove* and *pinnekjøtt*.

Scots boil and mash rutabagas and potatoes separately to produce 'tatties and neeps' served traditionally with the Scottish national dish of 'haggis'. Neeps are also mashed with potatoes to make 'clapshot', a traditional Scottish dish, and used in soups and stews. In Yorkshire and Lincolnshire, rutabagas are mashed with carrots and eaten as accompaniment to the traditional Sunday roast.

Canadians used rutabagas as filler in foods such as mincemeat and Christmas cake or as a side dish with Sunday dinner. Americans consumed rutabagas mainly in stews and casseroles and served mashed with potatoes or baked in a pasty.

Botany

A biennial, glabrous, glaucous herb, 30–150 cm high with a fleshy, napiform or globose root. The ‘root’ consists of the hypocotyl – the plant part that lies between the true root and the first seedling leaves (cotyledons) – and the base of the leafy stem. The storage root may be purple, white or yellow or greenish tinged, with yellowish flesh (sometimes yellowish-white flesh) (Plates 1 and 2). Stems erect, branched above. The basal and lowermost cauline leaves long petiolate; petiole to 15 cm; glaucous (bluish green), leaf blade ovate, oblong or lanceolate in outline, 5–25(–40) by 2–7(–10) cm, pinnately lobed or lyrate. Upper leaves sessile, lanceolate, ovate or oblong, to 8 by 3.5 cm, base amplexicaul, auriculate, margin entire or repand. Flowers not raised above the unopened buds on the raceme. Sepals oblong, ascending or rarely suberect. Petals pale creamy yellow, broadly obovate, apex rounded; claw distinct 5–9 mm. Stamens 6, filaments 5–10 mm, anthers oblong. Fruit linear, 4–11 cm × 2.5–5 mm, terete or slightly 4 angled, sessile, divaricate or ascending. Seeds dark brown or blackish, globose, 1–2 mm to 3 mm across, minutely reticulate.

Plate 1 (a, b) Globose rutabaga cultivars

Plate 2 Napiform-shaped rutabaga

Nutritive/Medicinal Properties

Proximate nutrient composition (per 100 g edible portion) of raw rutabaga (*Brassica napus* var. *napobrassica*) tuber was reported as water 89.66 g; energy 36 kcal (151 kJ); protein 1.20 g; total lipid 0.20 g; ash 0.81 g; carbohydrate 8.13 g; total dietary fibre 2.5 g; total sugars 5.60 g; minerals, Ca 47 mg, Fe 0.52 mg, Mg 23 mg, P 58 mg, K 337 mg, Na 20 mg, Zn 0.34 mg, Cu 0.040 mg, Mn 0.170 mg and Se 0.7 µg; vitamins, vitamin C 25 mg, thiamine 0.090 mg, riboflavin 0.040 mg, niacin 0.700 mg, pantothenic acid 0.160 mg, vitamin B6 0.100 mg, total folate 21 µg, total choline 14.1 mg, vitamin A 2 IU, β-carotene 1 µg, vitamin K (phylloquinone) 0.3 µg and vitamin E (α-tocopherol) 0.30 mg; total saturated fatty acids 0.027 g, 16:0 (palmitic acid) 0.024 g and 18:0 (stearic acid) 0.003 g; total monounsaturated fatty acids 0.025 g and 18:1 undifferentiated (oleic acid) 0.025 g; total polyunsaturated fatty acids 0.088 g, 18:2 undifferentiated (linoleic acid) 0.035 g and 18:3 undifferentiated (linolenic acid) 0.053 g; and amino acids, tryptophan 0.013 g, threonine 0.046 g, isoleucine 0.050 g, leucine 0.038 g, lysine 0.039 g, methionine 0.010 g, cystine 0.011 g, phenylalanine 0.031 g, tyrosine 0.023 g, valine 0.048 g, arginine 0.148 g, histidine 0.030 g, alanine 0.033 g, aspartic acid 0.087 g, glutamic acid 0.142 g, glycine 0.027 g and serine 0.035 g (USDA ARS 2014).

Rutabaga was reported to contain the flavone apigenin (mean 3.85 mg, maximum 15.4 mg/100 g) (Hertog et al. 1992; Lugasi and Hovari 2000) and flavonols myricetin (mean 2.13 mg, max 8.54 mg/100 g) (Hertog et al. 1992; Lugasi and Hovari 2000), kaempferol (mean 0.32 mg, max 2.27 mg/100 g) (Hertog et al. 1992; Lugasi and Hovari 2000; Huang et al. 2007) and quercetin (mean 0.05 mg, max 0.32 mg/100 g) (Hertog et al. 1992; Lugasi and Hovari 2000; Huang et al. 2007).

Major glucosinolates found in rutabaga roots were 2-hydroxy-3-butenyl glucosinolate, 2-phenylethyl glucosinolate, 3-indomethyl glucosinolate, 4-(methylthio)butyl glucosinolate (Carlson et al. 1981). Glucosinolates generally were higher in roots of rutabaga than in those of turnip (Ju et al. 1980). Accumulation of different glucosinolates in roots of both species occurred at different times during the growing season in the sequence after seeding: indolyl glucosinolates yielding ionic thiocyanate at the 2-week stage, glucosinolates yielding volatile isothiocyanate hydrolysis products at the 4-week stage and 2-hydroxy-3-butenyl glucosinolate (progoitrin) yielding 5-vinyl-oxazolidine-2-thione (goitrin) at the 6- or 8-week

stage. Mean total glucosinolate content of rutabaga and turnip grown on organic soil was 15 % and 38 % higher than those grown on loam soil, respectively. The contents of goitrin and volatile isothiocyanates were inversely correlated in the seed of both species. Nine glucosinolates were found in rutabaga grown on soil capped over a coal fly ash landfill or on normal clay and silt loam soil (Anderson et al. 1990). Progoitrin (2-hydroxy-3-butenyl glucosinolate) and neoglucobrassicin (1-methoxy-3-indolylmethyl glucosinolate) were the most abundant glucosinolates found. Progoitrin and three other minor glucosinolates were present in the natural soil-grown rutabaga in greater amounts than in that grown in fly ash soil. However, fly ash-grown rutabaga contained comparatively greater levels of glucobrassicin (3-indolylmethyl glucosinolate) and neoglucobrassicin, the major glucosinolate present.

Glucosinolate-derived nitrile and isothiocyanate of rutabaga and turnip cultivars ($\mu\text{g/g}$ FW) were 1-cyano-4-methylthiobutane, 3-phenylpropionitrile, 1-cyano-5-methylthiopropene, 4-ethylthiobutyl isothiocyanate, 2-phenylethyl isothiocyanate, goitrin and 5-methylthiopentenyl isothiocyanate, and also methyl palmitate was detected (Mullin et al. 1980). Thiocyanate ions, normally formed from isothiocyanates, had been found to be derived from indolyl glucosinolate. The goitrin content of rutabaga and turnip was found to vary between 9 and 124 $\mu\text{g/g}$. S-methyl and phenylethyl isothiocyanates and nitriles were major contributors to the flavour and aroma of rutabaga and turnip. Autolysis reduced the concentration of glucosinolate hydrolysis products and was particularly effective in reducing goitrin content in rutabaga (Mullin 1980). During low temperature storage (0 and 10 °C for 8 weeks) of field-harvested rutabaga roots, the total sugar concentration (sucrose, fructose and glucose) increased rapidly during the first 2 weeks and then levelled off (Shattuck et al. 1991). The total sugar concentration in roots was not influenced by storage temperature. The low temperature treatment (0–12 °C for 11 days) of plants resulted in a 10 % increase in the total sugar concentration in roots. Low temperature altered the concentration of several glucosinolates in peeled root and peeled tissues, but did not induce a qualitative change in the glucosinolate profile. Changes in the glucosinolate concentrations at low temperature were dependent on the treatment, temperature and root tissue examined.

Only one of the 14 root glucosinolates detected from swede roots (*Brassica napus* subsp. *rapifera*), 3-indolylmethyl glucosinolate, rose significantly with increasing levels of turnip root fly, *Delia floralis* attack (Hopkins et al. 1998). Swede roots that had been damaged by

D. floralis contained approximately three times the concentration of total indolyl glucosinolates of control roots. This change was strongly influenced by a fourfold increase in the concentration of 1-methoxy-3-indolylmethyl glucosinolate. The total glucosinolate concentration found in swede roots remained unchanged overall as a result of a fall in the concentration of five of the aliphatic glucosinolates, which balanced the rise in aromatic glucosinolates.

Three new phytoalexins, named isalexin, brassicanate A and rutalexin, were isolated together with five known phytoalexins, brassinin, 1-methoxybrassinin, spirobrassinin, brassicanal A and brassilexin, from rutabaga (*Brassica napus* L. subsp. *rapifera*) tubers (Pedras et al. 2004). Biosynthetic studies using tetra- and penta-deuterated precursors established indolyl-3-acetaldoxime and brassinin as precursors of brassicanate A and rutalexin and cyclobrassinin as a biosynthetic precursor of rutalexin. Tryptamine was found not to be a precursor of rutabaga phytoalexins.

The amount of wax extracted from the periderm of rutabaga tuber was 14.7 mg/kg of chloroform-extractable material, equivalent to 59 % weight of chloroform extract or 5 $\mu\text{g}/\text{cm}^2$ wax/surface area (Espelie et al. 1980). The composition of rutabaga wax comprised 4.7 % hydrocarbon, 1.8 % wax ester, 21 % fatty alcohol, 49 % fatty acids and 23 % unknown component. Chain-length distribution of the fatty alcohols, fatty acids, ω -hydroxy acids and dicarboxylic acids in the polar fraction of the CHCl_3 extract of rutabaga storage organ was 3.28 %, 3.37 %, 0.24 % and 0.15 %, respectively.

Total glucosinolates in rutabaga leaves amounted to 15.14 $\mu\text{mol}/\text{g}$ DW made up of aliphatic glucosinolates: progoitrin 5.46 μmol , epiprogoitrin 0.04 μmol , sinigrin 0.02 μmol , gluconapoleiferin 1.12 μmol , glucoalyssin 1.88 μmol , gluconapin 1.22 μmol , glucobrassicinapin 2.54 μmol ; indole glucosinolate: glucobrassicin 1.16 μmol , 4-hydroxyglucobrassicin 0.21 μmol , neoglucobrassicin 1.20 μmol , 4-methoxyglucobrassicin 0 μmol ; and aromatic glucosinolate: gluconasturtiin 0.36 μmol (Velasco et al. 2008).

Total glucosinolates in rutabaga seeds amounted to 107.70 $\mu\text{mol}/\text{g}$ DW comprising aliphatic glucosinolates: progoitrin 71.57 μmol , epiprogoitrin 1.46 μmol , sinigrin 0.53 μmol , gluconapoleiferin 1.46 μmol , glucoalyssin 1.26 μmol , gluconapin 22.13 μmol , glucobrassicinapin 2.43 μmol ; indole glucosinolates, glucobrassicin 0.15 μmol , 4-hydroxyglucobrassicin 5.61 μmol , neoglucobrassicin 0 μmol , 4-methoxyglucobrassicin 0.39 μmol ; and aromatic glucosinolate: gluconasturtiin 0.70 μmol (Velasco et al. 2008).

In black-seeded and yellow-seeded *B. napus* var. *napus*, sinapine, sinapic acid and 1,2-disinapoylglucose were found as the most abundant phenolic compounds in the seeds and 16 flavonoids were also identified including (–)-epicatechin, five monocharged oligomers of (–)-epicatechin ([DP 2](–), [DP 3](–), [DP 4] [DP 2](–) B2 and [DP 2](–) B5), quercetin, kaempferol, isorhamnetin-dihexoside, kaempferol-sinapoyl-trihexoside, isorhamnetin-sinapoyl-trihexoside, isorhamnetin-hexoside-sulfate and isorhamnetin-3-*O*-glucoside (Jiang et al. 2013). Most of the flavonoids accumulated with seed development, whereas some rapidly decreased during maturation. The content of these flavonoids was lower in the yellow-seeded materials than in the black seeds. Additionally, variations of insoluble procyanidin oligomers and soluble phenolic acids were observed among the varieties. A total of 91 flavonoids and hydroxycinnamic acid derivatives were detected, including 39 kaempferol derivatives, 11 isorhamnetin derivatives, 5 quercetin derivatives, 6 flavanols and their oligomers and 30 hydroxycinnamic acid derivatives in *Brassica napus* var. *napus* seeds (Shao et al. 2014).

Baenas et al. (2014) in their study of the use of bioelicitors to enrich ready-to-eat sprouts in health-promoting glucosinolates found that phytohormones methyl jasmonate and jasmonic acid and oligosaccharides glucose and sucrose acted as effective elicitors, increasing the total glucosinolate glucobrassicin content of rutabaga sprouts from 29.6 to 186 mg/100 g.

Antioxidant Activity

Studies showed that rutabaga sprouts had significantly higher antioxidant activity than seeds and roots, which may result from different contents of polyphenols (Pasko et al. 2013).

Anticancer Activity

The major physiologically active compounds derived from glucosinolates from *Brassica* crops were found to be isothiocyanates, nitriles and oxazolidine-2-thiones, and many of them possessed anticarcinogenic activities (Fenwick and Heaney 1983). Many isothiocyanates, derived from the hydrolysis of glucosinolate precursors of cruciferous vegetables, exhibited anticarcinogenic activity by reduced activation of carcinogens and increasing their detoxification. Recent studies showed that they exhibited antitumour activity by affecting multiple pathways including apoptosis, MAPK

(mitogen-activated protein kinase) signalling, oxidative stress and cell cycle progression (Wu et al. 2009). A number of epidemiological studies have identified an inverse association between consumption of *Brassica* leaf and root vegetables and the risk of colon and rectal cancer (Verkerk et al. 2009). Yang et al. (2002) demonstrated the chemopreventive efficacy of the N-acetylcysteine conjugates of phenethyl isothiocyanate (PEITC) and benzyl isothiocyanate (BITC) administered in the mice diet after a single dose of benzo(a)pyrene for lung tumorigenesis and provided the first in-vivo evidence that activation of MAP kinases, AP-1 transcription factors and p53 phosphorylation and the induction of apoptosis may be involved in the chemopreventive activity of these compounds. In-vitro studies showed that phenethyl isothiocyanate (PEITC) was a stronger inducer of apoptosis than sulphoraphane as it covalently bind to cellular proteins in human non-small lung cancer cells more strongly than sulphorane (Mi et al. 2007). Rutabaga extracts (especially 8-day sprouts) inhibited the tumour cell line HepG2 proliferation and had a slight effect on the normal mammalian CHO-K1 culture (Pasko et al. 2013). The extracts exerted cell death via apoptosis. The results suggested that one of the biological activities of rutabaga was antiproliferative and proapoptotic potential specific to tumour cells.

Goitrogenic Issues

One of the most potent goitrogens, 5-vinyl-oxazolidine-2-thione (goitrin), had been found to be derived from the hydrolysis of 2-hydroxy-3-butenyl glucosinolate (progoitrin), a predominant glucosinolate in rutabaga (Chong et al. 1982). Goitrin is a potent antithyroid agent; it had been reported to reduce the production of thyroid hormones such as thyroxine (McMillan et al. 1986). Administration of goitrin to rats was found to cause hyperplasia of the thyroid (Carroll 1949).

Swede was found to contain undesirable glucosinolates such as sinigrin (tr, 0.4 $\mu\text{mol/g}$ DM), 1.8–5.6 progoitrin ($\mu\text{mol/g}$) and gluconapoleiferin (tr, 1.8 $\mu\text{mol/g}$) (Olsson and Jeppsson 1984). Sinigrin and its degradation product are both bitter substances in *Brassica* vegetables which included swede. Progoitrin and gluconapoleiferin are tasteless, but their hydrolytic products, oxazolidinethiones, are very bitter. They are also goitrogenic substances and may contribute to hypothyroidism even if there is enough iodine in the diet.

Other Uses

Brassica napus is one of the most important sources of seed vegetable oil. The seed oil is also used in the manufacture of lubricants, grease, lacquers, varnishes, soap, resins, nylon, plastics, insect repellents, stabilisers and pharmaceuticals. Rutabagas with yellow flesh, which have a bitter taste, are usually used for human nutrition, while those with whitish flesh are used as fodder crop. Rutabaga is also used as forage for livestock.

Comments

Rutabagas, or swede turnips, are the large, yellow-fleshed roots commonly referred to as ‘table’ turnips. The yellow-fleshed types are preferred over white-fleshed types. Sinskaja (1928) used the shape of the hypocotylous tuber and its skin colour and the shape of the leaves to describe different varieties (Šebalina and Sazonova 1985).

Russian: Kol'rabi

Serbian: Keleraba

Slovenščina: Koleraba

Spanish: Col Rábano, Coli Rábano, Colirrábano,
Colinabo

Swedish: Kålrabbi

Vietnamese: Su Hào

Volapük: Kaulabrasid

Origin/Distribution

The origin of kohlrabi is reported to be in northwestern Europe, where it was developed from marrow-stem kale, a fodder crop with a thickened stem. It was grown by the ancient Romans and the gardeners of the emperor Charlemagne. Today it is cultivated globally, including the tropics up in the cool mountainous areas. The Mediterranean area and Western Europe are the main areas of cultivation and centres of diversity. Kohlrabi is a popular vegetable in Europe, Asia, northern USA and Canada.

Agroecology

Kohlrabi is adapted to temperate climate but is grown in the cool highlands in the subtropics and tropics. Kohlrabi is more tolerant of heat and drought than most of the cabbage relatives and it can withstand frosts down to at least -12°C . It flourishes in full sun in well-drained, fertile soil rich in organic matter. It does best in full sun, but kohlrabi can stand a little shade and it needs frequent watering. Kohlrabi is fast growing, producing harvest-sized, above-ground, subglobose corms (tuberous stem) within 50–70 days, depending on the variety.

Wiebe et al. (1992) found that temperatures below 11°C supported tuber modification (vernalisation), while temperatures above 11°C inhibited it (devernalisation). Devernalisation increased with increasing temperature.

Edible Plant Parts and Uses

The young, swollen, fleshy, subglobose kohlrabi stem base is peeled and eaten raw served with a little salt and vinegar. It tastes like a combination of mild turnip and sweet apple. It has a mild cabbage flavour or a very sweet turnip with celery or nutty overtones. When finely grated it makes a good addition to mixed salads and, when cooked, boiled or steamed, is an excellent vegetable. Kohlrabi can be eaten as baked fries or wedges. Leaves are cooked as a vegetable or the young leaves can also be added to salads.

Kohlrabi is an important part of the Kashmiri diet and one of the most commonly cooked foods. It is prepared with its leaves and served with a light gravy and eaten with rice. Kohlrabi stem is used in the vegetarian curry *ganth gobi sabzi*, kohlrabi stew (*Monji Kalia*) or fried kohlrabi curry (*Dum Monji*). The swollen stem and leaves are also used together in a dish called *Monji Haak*.

Botany

An erect, glabrous annual or biennial herb up to 50 cm tall at the mature vegetative stage, with unbranched, highly shortened, swollen, subglobose to globose, fleshy corm or bulbotuber-like stem up to 12 cm in diameter, pale greenish-white, purple and strongly branched root system (Plates 1, 2 and 3). Leaves alternate, simple or with some small side lobes at base; exstipulate; all leaves with distinct, slender, terete petiole; blade ovate or oblong-elliptical in outline, 20–28 cm long by 14–16 cm wide, irregularly incised, blue green. Inflorescence, a terminal paniculate raceme. Flowers bisexual, regular, 4-merous; pedicel up to 2 cm long; sepals oblong, about 1 cm long, erect; petals obovate, 1.5–2 cm long, clawed, pale to bright yellow or yellowish white; stamens 6; ovary superior, cylindrical, 2-loculed, stigma globose. Fruit, a linear or curved silique 5–10 cm long by 5 mm wide, with a tapering beak 5–15 mm long, dehiscent, containing up to 30 seeds. Seeds globose, 1.5–2 mm across, finely reticulate, dark brown.

Nutritive/Medicinal Properties

Kohlrabi swollen stems and leaves are rich in vitamins, essential minerals and antioxidants. The proximate value per 100 g edible portion of raw kohlrabi stem had been reported as: water 91 g; energy 27 kcal (113 kJ); protein 1.7 g; total lipid 0.01 g; ash 1 g; carbohydrate 6.2 g; total dietary fibre 3.6 g; total sugars 2.6 g; minerals, Ca 24 mg, Fe 0.04 mg, Mg 19 mg, P 46 mg, K 350 mg, Na 20 mg, Zn 0.03 mg, Cu 0.129 mg, Mn 0.139 mg and Se 0.7 µg; vitamins, vitamin C 62 mg, thiamine 0.05 mg, riboflavin 0.2 mg, niacin 0.4 mg, pantothenic acid 0.165 mg, vitamin B6 0.15 mg, total folate 16 µg, total choline 12.3 mg, vitamin A 36 IU or 2 µg RAE, vitamin E (α -tocopherol) 0.48 mg, vitamin K (phylloquinone) 0.1 µg, β -carotene 22 µg, total saturated fatty acids 0.013 g, 16:0 (palmitic acid) 0.011 g, 18:0 (stearic acid) 0.001 g, total monounsaturated fatty acids 0.007 g, 18:1 undifferentiated (oleic acid) 0.007 g, total polyunsaturated fatty acids 0.048 g, 18:2 undifferentiated (linoleic acid) 0.020 g and 18:3 undifferentiated (linolenic acid) 0.026 g; and amino acids, tryptophan 0.010 g, threonine 0.049 g, isoleucine 0.078 g, leucine 0.067 g, lysine 0.056 g, methionine 0.013 g, cystine 0.007 g, phenylalanine 0.039 g, valine 0.05 g, arginine 0.105 g and histidine 0.019 g (USDA, ARS 2014). Kohlrabi with a vitamin C content of 47–66 mg/100 g was than Swede turnip (14 mg), Hamburg parsley 15 mg and turnip 18–24 mg (Warne 1942).

Duke and Ayensu (1985) reported on proximate nutrient composition of the stem and leaf as stem (fresh weight per 100 g edible portion): water 90.3 %, energy 29 cal, protein 2 g, fat 0.1 g, carbohydrate 6.6 g, fibre 1 g, ash 1 g, Ca 41 mg, P 51 mg, Fe 0.5 mg, Na 8 mg, K 372 mg, vitamin A 20 mg, thiamine 0.06 mg, riboflavin 0.04 mg, niacin 0.3 mg and vitamin C 66 mg. Leaves (dry weight per 100 g edible portion): energy 320 cal, protein 23.5 g, fat 2.5 g, carbohydrate 62.5 g, fibre 13 g, ash 10.5 g, Ca 430 mg, P 450 mg, Fe 10.5 mg, Na 80 mg, K 3,100 mg, vitamin A 15,000 mg, thiamine

0.6 mg, riboflavin 0.7 mg, niacin 4.5 mg and vitamin C 670 mg.

Among the proximate compositions, the crude fat of kohlrabi peel contained lower than that of kohlrabi flesh, while the contents of carbohydrate and the crude protein were higher in the kohlrabi peel (Cha et al. 2013). Total free sugar content of kohlrabi flesh was higher than that of the peel, and the major free sugars of the flesh kohlrabi and peel were identified as fructose and glucose. The value of glutamic acid was greater in amino acids of kohlrabi flesh than kohlrabi peel, and the contents of total amino acids and essential amino acids were higher in kohlrabi peel compared with kohlrabi flesh. Kohlrabi flesh also contained a higher level of unsaturated fatty acids than kohlrabi peel. The contents of organic acid were higher in kohlrabi peel, and the level of oxalic acid was the highest in both parts. The vitamin C contents of kohlrabi flesh and peel were 231.36 mg/100 g and 402.75 mg/100 g, respectively. The mineral content of the kohlrabi peel was higher than that of the flesh and the mineral contents of the flesh and peel in the order of K>Ca>Mg>Na. Overall, the contents of total amino acid, essential amino acid, organic acid, vitamin C and mineral were higher in kohlrabi peel, and the free sugar and unsaturated fatty acid contents were higher in kohlrabi flesh.

Kohlrabi was reported to contain total phenolics 44.9 mg GAE/100 g fresh mass and total flavonoids mg 8.9 mg CE/100 g fresh mass (Marinova et al. 2005). Flavonoid aglycones found in kohlrabi included luteolin 1.3 mg, kaempferol 2.4 mg and quercetin 0.4 mg (Lugasi and Hovari 2000). The insoluble fibre lignins in kohlrabi were classified as balanced lignins with guaiacyl–syringyl G–S ratio ($0.3 < \text{G–S ratio} < 3$) (Bunzel et al. 2005).

The kohlrabi had harder texture than the radish and contained less reducing sugars, cellulose and pectin than the radish (Choi et al. 2010). The total amino acid content in the kohlrabi was 2.7-fold higher than that in the radish; in particular the hydrophilic amino acids including aspartate, glutamate and arginine were about threefold higher in the kohlrabi, suggesting that the kohlrabi was more palatable than

the radish. The total contents of glucosinolates in the radish in inner and outer section were higher than those in the kohlrabi, by 12.4- and 28.5-fold, respectively. In a sensory test, the kohlrabi was evaluated less bitter and pungent than the radish. The kohlrabi contained more glucoraphanin, an anticancer compound, than the radish.

The following glucosinolate (GS) content ($\mu\text{mol}/100\text{ g FW}$) was determined in kohlrabi: 86.1 μmol total GS, 9.7 μmol 3-methylthiopropyl GS, 2.3 μmol 3-methylsulfinylpropyl GS, 0.3 μmol 2-hydroxy-3-butenyl GS, 33.6 μmol 4-methylthiobutyl GS, 4.3 μmol 4-methylsulfinylbutyl GS, 1.8 μmol 2-phenylethyl GS and 27.7 μmol 3-indolylmethyl GS (Carlson et al. 1987). Ally GS and 3-butenyl GS were not detected. The predominant GSs in kohlrabi were 4-methylthiobutyl GS and 3-methylthiopropyl GS. The seed was found to contain higher levels of the corresponding sulfinyl compounds than of the two methylthio compounds, and 4-methylsulfinylbutyl GS was the GS present in the largest amount in the seed. The glucosinolates in 9 *Brassica* vegetable seeds including kohlrabi were significantly higher than in sprouts, and day 8 of germination was considered the optimum for consumption of edible sprouts (Baenas et al. 2012). The sprouts with higher concentrations of glucosinolates in 8-day-old sprouts were white mustard, turnip and kohlrabi (circa 815, circa 766 and circa 653 $\text{mg}/100\text{ g FW}$, respectively). The importance of dietary sulforaphane in helping maintain good health continues to gain support within the health-care community and awareness among US consumers (West et al. 2004). They found that crucifer seeds including kohlrabi to be good sources for obtaining glucoraphanin, the natural precursor to sulforaphane, owing to a higher concentration of glucoraphanin and the relative ease of processing seeds as compared to vegetative parts. The major glucosinolates identified in kohlrabi by Ciska et al. (2000) were glucoraphanin, glucoerucin, glucoiberin and glucobrassicin.

Park et al. (2013) found that after 10-days storage at 4 °C, total glucosinolates (GSs) in white kohlrabi increased markedly from 16.72 to 48.35 $\mu\text{mol}/\text{g DW}$. The highest

amount of GS found was glucobrassicinapin (4-pentyl GS), followed by glucoerucin (4-methylthiobutyl GS) and sinigrin (2-propenyl GS). Other GSs present included progoitrin (2-hydroxy-3-butenyl GS), glucoraphanin (4-methylsulfinylbutyl GS), glucobrassicin (3-indolymethyl GS), 4-methoxyglucobrassicin (4-methoxy-3-indolymethyl GS) and neoglucobrassicin (1-methoxy-3-indolymethyl GS). GSs glucoalyssin (5-methylsulfinylpentyl GS), gluconapin (3-butenyl GS) and gluconasturtiin (2-phenylethyl GS) were not detected in white kohlrabi. In red kohlrabi, TGSs increased sharply after 1 and 3 days and then decreased sharply after 10 days, registering an overall slight decline from 53.71 $\mu\text{mol/g}$ DW at day 0 to 50.3 $\mu\text{mol/g}$ DW after 10-day storage. This trend was observed for all GSs present. The highest amount of GS found was glucobrassicinapin (4-pentyl GS), followed by glucoerucin (4-methylthiobutyl GS) and glucobrassicin (3-indolymethyl GS). Other GSs found in red kohlrabi included progoitrin (2-hydroxy-3-butenyl GS), glucoraphanin (4-methylsulfinylbutyl GS), glucoalyssin (5-methylsulfinylpentyl GS), 4-methoxyglucobrassicin (4-methoxy-3-indolymethyl GS), gluconasturtiin (2-phenylethyl GS) and neoglucobrassicin (1-methoxy-3-indolymethyl GS). GSs not found were sinigrin (2-propenyl GS) and gluconapin (3-butenyl GS). Vicas et al. (2013) found 4.89 $\mu\text{mol/g}$ dw of total glucosinolate content in kohlrabi, predominated by indolyl glucosinolates (glucobrassicin, neoglucobrassicin, 4-methoxyglucobrassicin).

Analysis of the skin and flesh of pale green and purple kohlrabis revealed the presence of 8 glucosinolates, 12 anthocyanins, 2 carotenoids and 7 phenylpropanoids (Park et al. 2012). Glucosinolate contents are varied among the different parts and types of kohlrabi. Glucoerucin contents were fourfold higher in the flesh of purple kohlrabi than those in the skin. Among the 12 anthocyanins, cyanidin 3-(feruloyl) (sinapoyl) diglucoside-5-glucoside levels were the highest. Carotenoid levels were much higher in the skins than the flesh of both types of kohlrabi. The levels of most phenylpropanoids were higher in purple kohlrabi than in pale green ones. *Trans-cinnamic* acid content was 12.7-fold higher in the flesh of purple kohlrabi than that in the pale green ones.

The health-promoting properties of *Brassica* vegetables including kohlrabi emanate from isothiocyanates (ITCs) the breakdown products released after hydrolysis of glucosinolates (GSs) by myrosinase. Cutting and chewing of cruciferous vegetables releases the thioglucosidase enzyme myrosinase, which degrades glucosinolates to isothiocyanates and other minor metabolites (Krul et al. 2002).

About 190 µg of aroma components were obtained per gram fresh weight of green kohlrabi, and 83 volatile components (ca 96 % w/w of the sample) were identified (Macleod and Macleod 1990). Sulphur compounds provided a high proportion of kohlrabi volatiles (ca 37 % w/w), with dimethyl trisulfide (ca 25 %) being the major component. Isothiocyanates, derived from glucosinolates, were also important aroma volatiles of kohlrabi. Eight glucosinolates were thus characterised in kohlrabi, the major ones being 4-methylthiobutyl glucosinolate, 3-methylthiopropyl glucosinolate and 2-phenethyl glucosinolate. Two unusual sulphur-containing ketones were also identified, 4-methylthiobutan-2-one and 1-methylthiopentan-3-one. In another study, the major volatile products (µg/100 g fresh mass) from the edible part of kohlrabi were 3-methylthiopropyl ITC (212.94 µg), 4-methylthiobutyl ITC (233.64 µg) and allyl ITC (37.73 µg) (Fischer 1992). The two corresponding organic cyanides 3-methylthiopropyl cyanide and 4-methylthiobutyl cyanide and dimethyl disulfide, dimethyl trisulfide and dimethyl tetrasulfide were also present in high amounts. *n*-Nonenal, (*E*)-2-hexenal, (*E,E*)-2,4-heptadienal and some isothiocyanates of unknown structure appeared in the volatile fraction as minor constituents. The sulphur- and nitrogen-containing components could be related to the enzymatic cleavage (myrosinase) of glucosinolates, naturally occurring precursors in *Brassica* plants. The presence of 3-methylthiopropyl isothiocyanate indicated glucoibervirin as a new precursor in the vegetable part of kohlrabi. The presence of allyl ITC in kohlrabi concurred with the findings of Josefsson (1967).

Gawęda and Nizioł-Lukaszewska (2011) found that during 5 months of storage, very low losses of kohlrabi mass were

detected. The decrease in dry matter found was between 15 and 18 %. After a brief increase, soluble sugar content that decreased during storage of L-ascorbic acid was well preserved in the kohlrabi, since 90 % remained after storage was completed. The isothiocyanate content changed little, and the vegetable remained a good source of these compounds throughout the storage period. Gerendás et al. (2008) found that the ITC of kohlrabi tubers was dominated by methylthiobutyl ITC (11–1,350 $\mu\text{mol/g DM}$), followed by sulforaphane (7–120 $\mu\text{mol/g DM}$), phenylethyl ITC (5–34 $\mu\text{mol/g DM}$) and allyl ITC (5–38 $\mu\text{mol/g DM}$), resulting from the hydrolysis of glucoerucin, glucoraphanin, gluconasturtiin and sinigrin, respectively. They found that the concentrations of all ITCs were substantially reduced in response to increasing nitrogen and decreasing sulphur supply.

Four glucosinolates, i.e. glucoraphanin, glucobrassicin, gluconasturtiin and neoglucobrassicin, were identified in the leaves of five kohlrabi genotypes cultivated in Southern Italy (Branca et al. 2013). The glucosinolate profile of the stems and leaves were similar. However, stems showed a lower glucosinolate amount and the presence of glucoerucin. The total polyphenol and ascorbic acid content was slightly higher in the leaves than in the stems. With regard to total anthocyanins, higher values were found in the leaves with respect to the skins, with the exception of cv. CR17.

Infection by the phytopathogenic fungus, *Cladosporium cucumerinum*, elicited the production of the indole phytoalexin 1-methoxyspirobrassinin on kohlrabi (Gross et al. 1994). The phytoalexin could also be elicited abiotically by cuprous chloride.

Both enantiomers of α -aminooxy- β -phenylpropionic acid (AOPP), potent inhibitors of L-phenylalanine ammonia-lyase, and their N-benzyloxycarbonyl (N-BOC) derivatives inhibit anthocyanin formation in seedlings of kohlrabi and red cabbage with little interference with their normal development (Amrhein and Holländer 1979). Kohlrabi seedlings tolerated up to 0.3 mM L-AOPP and N-BOC–L-AOPP without a reduction of fresh weight or chlorophyll content, while anthocyanin was reduced to less than 20 %.

Total phenols per baked biscuit unit fortified with kohlrabi stem flour were calculated after baking (Hassan et al. 2011). The results revealed that total phenols were higher in the leaves as compared to stems in both red and green kohlrabi cultivars. Salicylic acid represented the maximum fraction detected in the green skin kohlrabi stems (56.1 mg/100 g dw), almost double the value in the red cultivar (28.5 mg/100 g dw). Maximum recovery of total phenols was 83.4 and 52.0 mg per 1 biscuit unit (of ca.22 and 18 g) at 15 % and 8 % levels of the added green and red kohlrabi stems in the blend, respectively. Slight changes were recorded in the final baking characteristics due to kohlrabi stem flour addition. An enriched nutritive value and a prolonged shelf life of the baked biscuit product were observed. This could be due to the bioactive antioxidants existed in kohlrabi.

Antioxidant Activity

Kohlrabi leaves generally showed higher antiradical activity in terms of DPPH quenching (ranging from 62.5 to 134.6 mmol ascorbic acid/100 g dw) compared to skins and stems, with the exception of cv. CR22 that was the highest in stems 18.4 mmol ascorbic acid/100 g dw) (Fig. Branca et al. 2013). In contrast, leaves and skins had a similar peroxy radical (ROO.) scavenging capacity, presumably influenced by the presence of anthocyanins, as suggested by the high correlation between peroxy radical scavenging capacity and total anthocyanin content ($R^2 = 0.81$). As expected, a significant correlation was found between DPPH quenching and ascorbic acid content and between peroxy radical and total carotenoids. Interestingly, an unexpected correlation was found between glucosinolate and DPPH determinations and may be related to very high content of glucoerucin.

Antidiabetic Activity

Administration of the aqueous extract of kohlrabi stem to alloxan-induced diabetic rats significantly lowered the blood glucose compared to pretreatment level (Srinivas and Patil 1993). In another study, hyperglycaemic animals showed

significant decrease in the blood glucose level after 60 days of treatment with Knol-Khol extract and pioglitazone, compared to streptozotocin-induced diabetic control rats (Rasal et al. 2006). The concentration of malondialdehyde (MDA) was significantly decreased in the Knol-Khol extract and pioglitazone-treated groups. The glutathione content and levels of antioxidant enzymes superoxide dismutase, catalase and glutathione peroxidase were significantly increased in the Knol-Khol extract and pioglitazone-treated groups as compared to diabetic control rats. Sections of the pancreas from the Knol-Khol extract treated diabetic rats showed a good number of regenerating tiny islets, compared to a reduced number of islets in diabetic rats. It was concluded that the petroleum ether extract of Knol-Khol regenerated the pancreas and lowered hyperglycaemia and oxidative stress.

Anticancer Activity

Kohlrabi contained more glucoraphanin, an anticancer compound, than the radish (Choi et al. 2010). Numerous studies in chemically induced models of cancer had found sulforaphane and other isothiocyanates to be potent anticancer (Hecht 2000; Kuroiwa et al. 2006; Razis and Noor 2013).

The major mechanism of inhibition of carcinogenesis by isothiocyanates appeared to be a selective inhibition of cytochrome P450 enzymes involved in carcinogen metabolic activation (Hecht 2000). Isothiocyanates also induced phase II enzymes and enhanced apoptosis, and these properties may also be involved in their chemopreventive activity. Phenethyl isothiocyanate, a particularly effective inhibitor of lung tumour induction by the tobacco-specific nitrosamine 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone, was being developed as a chemopreventive agent against lung cancer. In-vitro studies in Hep G2 cells found that sulforaphane, the breakdown product of glucoraphanin, was more superior than its precursor in modulating various phase I and phase II enzymes involved in carcinogen-metabolising enzyme systems (Razis and Noor 2013). Animal studies by Kuroiwa et al. (2006) suggested that diet supplementation with naturally occurring ITCs like benzyl isothiocyanate and sulforaphane

could block N-nitrosobis(2-oxopropyl)amine (BOP) initiation of hamster pancreatic carcinogenesis.

A 12-week dietary intervention study with high-glucoraphanin (HG) broccoli found that the metabolic changes observed with the HG broccoli diet were consistent with a rebalancing of anaplerotic and cataplerotic reactions and enhanced integration of fatty acid β -oxidation with TCA cycle activity (Armah et al. 2013). It was concluded that these modifications may contribute to the reduction in cancer risk associated with diets that are rich in cruciferous vegetables.

Antimutagenic Activity

Except for Chinese cabbage, all cruciferous vegetables including kohlrabi were found to have strong to moderate antimutagenic activities induced by 2-amino-3-methyl[4,5-f]-quinoline (IQ) and in part by 2-amino-3,4-dimethylimidazo[4,5-f]quinoline (MeIQ) or 2-amino-3,8-dimethylimidazo[4,5-f]quinoxaline (MeIQx) in *Salmonella typhimurium* TA98 and TA100 (Edenharder et al. 1994).

Trypsin Inhibitory Activity

A trypsin inhibitor with a K_m of 5×10^{-5} M was isolated from kohlrabi (Svendsen et al. 1989). It weakly inhibited subtilisin DY and not chymotrypsin. The inhibitor was closely related to napin as determined by amino acid sequence analysis which also showed the inhibitor to be polymorphous.

Pharmacokinetic Studies

The production of allyl isothiocyanate from sinigrin was investigated in a dynamic in-vitro large intestinal model, after inoculation with a complex microflora of human origin (Krul et al. 2002). Peak levels of allyl isothiocyanate were observed between 9 and 12 hours after the addition of sinigrin. Between 10 and 30 % (mean 19 %) of the sinigrin was converted into allyl isothiocyanate.

Other Uses

As stock feed, kohlrabi can be grazed by ruminants. The young plants are tender and palatable, but the older plants can be tough (Fuller 2004).

Studies indicated that kohlrabi peel was an attractive biomaterial for removing cationic dyes from the dye wastewater (Gong et al. 2007).

Crude extract of kohlrabi was found to be a rich source of peroxidase (POx) (Manzoori et al. 2006). POx catalysed the hydrogen peroxide oxidation of homovanillic acid to produce a dimer which showed strong fluorescence at 420 nm with excitation at 312 nm. This spectrofluorometric method was successfully applied to the determination of hydrogen peroxide in honey.

Comments

A case of methaemoglobinaemia in an infant following nitrite poisoning after a dinner of kohlrabi was reported by Ritter and Schulze (1971). Methaemoglobinaemia is a disorder characterised by the presence of a higher than normal level of methaemoglobin (ferric $[\text{Fe}^{3+}]$ rather than ferrous $[\text{Fe}^{2+}]$ haemoglobin) in red blood cells. This results in a decreased availability of oxygen to the tissues.

Brassica rapa var. *rapa*

T. K. Lim¹✉

(1) Canberra, Aust Capital Terr, Australia

Scientific Name

Brassica rapa var. *rapa*

Synonyms

Barbarea derchiensis S.S. Ying, *Brassica campestris* var. *campestris*, *Brassica campestris* subsp. *rapa* (L.) Hook. f., *Brassica campestris* subsp. *rapifera* (Metzg.) Sinskaya, *Brassica cibaria* Dierb., *Brassica rapa* var. *quadrivalvis* (Hook. f. and Thomson) Kitam., *Brassica rapa* var. *rapa*, *Brassica rapoasiatica* Sinskaya, *Brassica rapoeuropea* Sinskaya, *Napus rapa* (L.) Schimp. and Spenn., *Raphanus rapa* (L.) Crantz, *Sinapis rapa* (L.) Brot., *Sinapis tuberosa* Poir.

Family

Brassicaceae

Common/English Names

Fodder Turnip, Italian Kale, Rapini, Seven Top Turnip,
Stubble Turnip, Turnip, White Turnip

Vernacular Names

Afghanistan: Shalgham

Chinese: Man Jing, Wu Jing, Yuan Bian Zhong

Czech: Brukev Řepák Vodnice, Brukev Vodnice

Danish: Høstroe, Majroe

Dutch: Meiraap, Raap, Stopelknol

Origin/Distribution

Wild *Brassica rapa* subsp. *oleifera* [includes var. *silvestris*] is regarded as the species from which *B. rapa* var. *rapa* L. (cultivated turnip) and *B. rapa* var. *silvestris* (Lam.) Briggs (turnip rape) originated. It is native throughout Europe, Russia, Central Asia and the Near East (Prakash and Hinata 1980), with Europe proposed as one centre of origin. Turnip has been used as a vegetable for human consumption in Europe since prehistoric times; it was reported as a well-established crop in Roman and Hellenistic times (Undersander et al. 1992). Nowadays it is cultivated nearly all over the world and has also been introduced to tropical countries, where it is grown at higher altitudes.

Agroecology

Turnip is a cool season crop, recording good growth in full sun during relatively low (4.5–16 °C) temperatures, although it has a temperature range of 3.5–27 °C. Temperatures below 10 °C cause bolting. Hot temperatures cause the roots to become woody and bad tasting. It is cold hardy and drought tolerant, thriving best on a moderately deep, highly fertile, friable loamy soil with pH 5.5–6.8. Turnip can be grown in the tropics at the higher and cooler altitudes.

Edible Plant Parts and Uses

Turnip edible parts are consumed as a raw, boiled and/or fermented vegetable (Ryu et al. 2012). Turnip roots are eaten raw, pickled, braised, pureed or used in soups, stews, casseroles, etc. (Facciola 1990). Bread is sometimes made from turnip with added wheat flour. Small turnips (also called baby turnips) are specialty varieties and can be eaten whole, including their leaves. Leaves are eaten as “turnip greens” (“turnip tops” in the United Kingdom), and they resemble mustard greens in flavour. The cooked leaves make an acceptable vegetable, though they are coarser than the related cabbage. Young leaves can also be added in small quantities to salads, they have a slightly hot cabbage-like flavour and some people find them indigestible. Turnips are fermented and used in *Kimchee* in Korea (Wu et al. 2012).

Botany

A biennial herbaceous plant, to 1 m high with a fleshy, purple, red or greenish or white bulbous, napiform or globose, white-fleshed, 5–20 cm diameter, storage organ that protrudes above ground which is developed from the root and stem base tissues (Plates 1, 2 and 3). The main tap root is thin and about 10 cm long. Basal leaves rarely up to 10, obscurely rosulate; lamina lyrate-pinnatifid or rarely sinuate-dentate, glabrous and green on slender fleshy petioles, petiole slender. Upper leaves are sessile, subentire, oblong lanceolate and often constricted above the base. Branches originate in the axils of the highest leaves on the stem, and each terminates in an inflorescence. The inflorescence is an elongated raceme, and the flowers are densely clustered at the top with open flowers borne at or above the level of terminal buds and open upward from the base of the raceme. Flowers bisexual, regular, 4-merous; pedicel up to 3 cm long, ascending; sepals 5–8 mm long, spreading, yellow-green; petals obovate, 0.5–1 cm long, clawed, bright yellow; stamens 6; ovary superior, cylindrical, 2-celled, stigma globose. Fruit is a linear silique 4–10 cm by 2–4 mm, with a tapering beak, dehiscent, up to 30 seeded. Seeds are globose, 1–1.5 mm in diameter, finely reticulate and dark brown.

Plate 2 Globose turnip with leaf bases

Plate 3 Turnip minus leaf bases

Nutritive/Medicinal Properties

Turnip Root

Analyses carried out in the United States reported raw, turnip root to have the following proximate composition (per 100 g edible portion): water 91.87 g, energy 28 kcal (117 kJ), protein 0.9 g, total lipid 1.10 g, ash 0.70 g, carbohydrates 6.43 g, total dietary fibre 1.8 g, total sugars 3.80 g, Ca 30 mg, Fe 0.30 mg, Mg 11 mg, P 27 mg, K 191 mg, Na 67 mg, Zn 0.27 mg, Cu 0.085 mg, Mn 0.134 mg, Se 0.7 µg, vitamin C 21 mg, thiamine 0.04 mg, riboflavin 0.030 mg, niacin 0.40 mg, pantothenic acid 0.200 mg, vitamin B6 0.090 mg, total folate 15 µg, vitamin E (α -tocopherol) 0.03 mg, vitamin K (phylloquinone) 0.1 µg, total saturated fatty acids 0.011 g, 16:0 (palmitic) 0.010 g, 18:0 (stearic) 0.001 g, total monounsaturated fatty acids 0.006 g, 16:1 undifferentiated (palmitoleic) 0.001 g, 18:1 undifferentiated (oleic) 0.006 g, total polyunsaturated fatty acids 0.053 g, 18:2 undifferentiated (linoleic) 0.012 g, 18:3 undifferentiated (linolenic) 0.040 g, phytosterols 7 mg, tryptophan 0.009 g, threonine 0.025 g, isoleucine 0.036 g, leucine 0.033 g, lysine 0.036 g, methionine 0.011 g, cystine 0.005 g, phenylalanine 0.017 g, tyrosine 0.013 g, valine 0.030 g, arginine 0.024 g, histidine 0.014 g, alanine 0.035 g, aspartic acid 0.063 g, glutamic acid 0.130 g, glycine 0.025 g, proline 0.026 g and serine 0.029 g (USDA, ARS 2014). Linolenic acid (18:3) was the major fatty acid comprising 56.6–58.6 % of the total fatty acids in turnips, followed by linoleic acid (18:2) (13.9–19.1 %), palmitic acid (16:0) (13–15 %), oleic acid (18:1) (7.1–9.1 %), 17:1 (1.4–2.6 %), stearic acid (18:0) (0.8–1.7 %) and palmitoleic acid (16:1) (0.7–1.1 %) (Lepage 1967). Components of neutral lipids identified were sterol, fatty acid, triglyceride, fatty acid methyl ester, sterol glucosides and sterol ester. Sterol ester, sterol and triglyceride were the most important neutral lipids, but traces of mono- and diglycerides, fatty acid and tocopherol were also present. Among the common phospholipids, cardiolipin and phosphatidylglycerol were abundant components, and phosphatidic acid was also found. Other neutral lipid components detected included

phosphatidylcholine, phosphatidylethanolamine, phosphatidylinositol, digalactosyl diglyceride and monogalactosyl diglyceride (Lepage 1967). Palmitic acid was higher in phosphatidylinositol and digalactosyl diglyceride than in the other components. On the other hand, linoleic acid was less in these two components and linolenic acid was the major fatty acid in all of them. β -sitosterol was the principal sterol followed by campesterol, and stigmasterol was found in traces. Carotenoids detected in turnip included lycopene (41.9 %), γ -carotene (28.3 %), cryptoxanthin 17.5 % and an unidentified fraction (12.3 %) (Lepage 1967).

Shattuck et al. (1991) found that cold-stored turnip roots decreased in both starch and total sugar concentration (sucrose, fructose and glucose) when compared to freshly harvested roots. Greenhouse-grown plants subjected to low temperatures had roots with a similar starch content but with a higher concentration of total sugars than the control. Cold treatments in the greenhouse and storage induced a slight but significant increase in root sucrose concentration. The ascorbic acid concentration of roots was not affected by low temperature. In both the field and greenhouse studies, low temperature did not change the total concentration of the eight major GSs identified in peeled root and peel tissues, but did alter the concentration of specific glucosinolates.

Glucosinolate levels of field-grown turnip roots at 0 and 4 weeks cold storage (0 °C) without peel ($\mu\text{mol/g dw}$) were determined as 2-hydroxy-3-butenyl glucosinolate (4, 48, 6.00 μmol), 3-hydroxy-4-pentenyl glucosinolate (1.92, 1.94 μmol), 5-methylsulfinylpentyl glucosinolate (0.56, 0.73 μmol), 3-butenyl glucosinolate (0.35, 0.36 μmol), 4-hydroxy-3-indolymethyl glucosinolate (0.36, 0.40 μmol), 4-pentenyl glucosinolate (2.92, 2.51 μmol), 2-phenylethyl glucosinolate (1.93, 1.80 μmol), 1-methoxy-3-indolymethyl glucosinolate (0.48, 0.45 μmol) and total glucosinolates (13.01, 14.19 $\mu\text{mol/g}$). Other glucosinolates found in traces included 3-indolymethyl glucosinolate, 4-methoxy-3-indolymethyl glucosinolate and an unidentified saturated butyl-glucosinolate. In *B. rapa* subsp. *rapa*, the main glucosinolate was the aryl glucosinolate gluconasturtiin (44–47 %) with a relatively high level between 23.6 and 35.9 mg/100 g FM

(Krumbein et al. 2005). The major volatile constituents of *Brassica rapa* L. subsp. *rapa* tuberous tap root were 2-phenylethyl isothiocyanate (32.6 %), sec-butyl isothiocyanate (25.7 %), 4-pentenyl isothiocyanate (12.8 %), 5-methylthiopentyl isothiocyanate (10.0 %) and 2-hexenal (4.6 %) (Afsharypour and Tahmasian 2010).

In a study of 82 different varieties of *Brassica rapa* including 18 varieties of turnip, Yang and Quiros (2010) found that all 18 varieties of turnip from Japan and Wellesbourne, United Kingdom, did not contain the aliphatic glucosinolate, gluconapoleiferin (2-hydroxy-4-pentenyl glucosinolate). The aliphatic glucosinolates found in most of the turnip varieties included progoitrin (2-hydroxy-3-butenyl glucosinolate) (12 varieties), sinigrin (2-propenyl glucosinolate) (3 varieties), glucoalyssin (5-methylsulfinylpentyl glucosinolate) (13 varieties), 2-methyl-2-propenyl glucosinolate (6 varieties), gluconapin (3-butenyl glucosinolate) (17 varieties), glucocochlearin (*n*-butyl glucosinolate) (13 varieties), glucobrassicinapin (4-pentenyl glucosinolate) (18 varieties), glucoerucin (4-methylthiobutyl glucosinolate) (11 varieties); indolic glucosinolates detected included 4-hydroxyglucobrassicin (4-hydroxy-3-indolymethyl glucosinolate) (18 varieties), glucobrassicin (3-indolymethyl glucosinolate) (18 varieties), 4-methoxyglucobrassicin (4-methoxy-3-indolymethyl glucosinolate) (18 varieties), (18 varieties), neoglucobrassicin (*n*-methoxy-3-indolymethyl glucosinolate); and one aromatic glucosinolate found was gluconasturtiin (2-phenylethyl glucosinolate) (18 varieties). Turnips contained much higher levels of aliphatic glucosinolates than indolic glucosinolates. No glucoraphanin was found in all *B. rapa* accessions. Lee et al. (2013) distinguished 4 clusters of 48 turnip accessions from different geographical origins based on 11 different intact and desulfo glucosinolates in the turnip tubers.

Studies showed that nitrogen and sulfur inputs could affect the glucosinolate levels in turnip roots (Li et al. 2007). Total glucosinolate concentration (mg/100 g root fresh weight) varied widely from 9.7 mg at nitrogen 320 kg/ha combined with sulfur 10 kg/ha supply to 91.6 mg (N₁₆₀S₆₀) at nitrogen

160 kg/ha plus sulfur 60 kg/ha. Individual glucosinolate concentrations were increased with increasing S supply regardless of the N treatment, whereas enhanced N supply (160–320 N ha) at the high S level (60 kg/ha) did not affect total glucosinolate concentration. Individual glucosinolate biosynthesis concentration of N-containing tryptophan-derived indole glucosinolate was highest with increased N supply, whereas S-containing methionine-derived aromatic and aliphatic glucosinolates decreased with increasing N supply combined at low S level (10–20 kg/ha). Turnip cultivars differed in glucosinolate concentrations with the white turnip cultivar, having the highest gluconapin (3-butenyl glucosinolate) concentrations in root and shoot tissues and the red turnip cultivar having the highest total glucosinolate concentration in root tissues (Justen et al. 2012). Blue, red and yellow photoselective netting did not significantly influence total or individual glucosinolates in root tissues. Netting was only a significant factor for glucobrassicinapin (4-pentenyl glucosinolate) concentration in shoots with no netting treatments, resulting in the highest glucobrassicinapin concentrations. May plantings resulted in 50 % higher total glucosinolate concentrations than August plantings. Planting date $\times$ year interactions were significant for total and individual glucosinolate concentrations.

Two new indoles, 2-C- β -D-glucopyranosyl-1-methoxyindole-3-acetonitrile and 6-hydroxy-1-methylindole-3-acetonitrile, along with two known indoles caulilexin C and arvelexin, were isolated from turnip roots (Wu et al. 2012). A new benzyl α -D-fructofuranoside, along with six known phenol compounds, benzyl- β -D-GLUCOPYRANOSIDE, dihydrosyringin, syringin, triandrin, phillyrin and neoolivil-4-O- β -D-glucopyranoside, were isolated from turnip roots (Wu et al. 2013). Five flavonoids were isolated from the roots: licochalcone A, 4,4'-dihydroxy-3'-methoxychalcone, liquiritigenin, liquiritin and isoliquiritin (Jeong et al. 2013).

The amount of wax extracted from the periderm of turnip storage organ was very small – 10.3 mg/kg of chloroform extractable material, equivalent to 49 % weight of chloroform extract or 4 $\mu\text{g}/\text{cm}^2$ /surface area (Espelie et al. 1980). The

composition of parsnip wax comprised 60 % hydrocarbon, 0.7 % wax ester, 7 % fatty alcohol, 29 % fatty acids and 3 % unknown component. Chain length distribution of the fatty alcohols, fatty acids, ω -hydroxy acids and dicarboxylic acids in the polar fraction of the CHCl_3 extract of turnip storage organ were 0.95 %, 3.17 %, 0.47 % and 0.9 % respectively.

Turnip Greens/Aerial Parts

Analyses carried out in the United States reported turnip greens (excluding root crown, tough stems and discarded leaves) to have the following proximate composition (per 100 g edible portion): water 89.67 g, energy 32 kcal (132 kJ), protein 1.50 g, total lipid 0.30 g, ash 1.40 g, carbohydrates 7.13 g, total dietary fibre 3.2 g, total sugars 0.81 g, glucose 0.52 g, fructose 0.29 g, Ca 190 mg, Fe 1.10 mg, Mg 31 mg, P 42 mg, K 296 mg, Na 40 mg, Zn 0.19 mg, Cu 0.350 mg, Mn 0.466 mg, Se 1.2 μg , vitamin C 60 mg, thiamine 0.07 mg, riboflavin 0.10 mg, niacin 0.60 mg, pantothenic acid 0.380 mg, vitamin B6 0.263 mg, total folate 194 μg , vitamin A 579 μg RAE, vitamin A 11,587 IU, β -carotene 6,952 μg , lutein + zeaxanthin 12,825 μg , vitamin E (α -tocopherol) 2.86 mg, γ -tocopherol 0.16 mg, vitamin K (phylloquinone) 251 μg , total saturated fatty acids 0.070 g, 10:0 (capric) 0.002 g, 12:0 (lauric) 0.002 g, 14:0 (myristic) 0.003 g, 16:0 (palmitic) 0.054 g, 18:0 (stearic) 0.010 g, total monounsaturated fatty acids 0.020 g, 16:1 undifferentiated (palmitoleic) 0.014 g, 18:1 undifferentiated (oleic) 0.005 g, total polyunsaturated fatty acids 0.120 g, 18:2 undifferentiated (linoleic) 0.036 g, 18:3 undifferentiated (linolenic) 0.084 g, phytosterols 12 mg, tryptophan 0.026 g, threonine 0.082 g, isoleucine 0.078 g, leucine 0.137 g, lysine 0.098 g, methionine 0.034 g, cysteine 0.017 g, phenylalanine 0.092 g, tyrosine 0.058 g, valine 0.102 g, arginine 0.094 g, histidine 0.036 g, alanine 0.103 g, aspartic acid 0.158 g, glutamic acid 0.204 g, glycine 0.090 g, proline 0.071 g and serine 0.061 g (USDA, ARS 2014).

The average dry weight of the edible parts, flower buds, leaves and stems in the medium or late vegetable turnip rape types, was twofold higher (3.20 g) than that of the early types

(1.61 g) (Kim et al. 2003). The relative proportion of each edible part to the dry weight in the early types was approximately 31, 35 and 35 % for the flower buds, leaves and stems, respectively. Two glucosinolate compounds, gluconapin and glucobrassicinapin, were mainly found in all the edible parts. The relative proportion of gluconapin to the total glucosinolate content was higher than that of glucobrassicinapin in the early types, but the reverse was observed in the medium or late types. The total glucosinolate content of edible parts ranged from 60 to 80 mmol/kg DW in all the cultivars, except for “Syunrai” (30 mmol/kg DW) and “No. 88” (31 mmol/kg DW). The phenolic compounds and organic acids of turnip (*Brassica rapa* var. *rapa*) edible parts (leaves and stems, flower buds and roots) were found to compose of 14 phenolics, 3-*p*-coumaroylquinic, caffeic, ferulic and sinapic acids, kaempferol 3-*O*-sophoroside-7-*O*-glucoside, kaempferol 3-*O*-sophoroside-7-*O*-sophoroside, kaempferol 3-*O*-(feruloyl/caffeoyl)-sophoroside-7-*O*-glucoside, kaempferol 3,7-*O*-diglucoside, isorhamnetin 3,7-*O*-diglucoside, kaempferol 3-*O*-sophoroside, 1,2-disinapoylgentiobiose, 1,2'-disinapoyl-2-feruloylgentiobiose, kaempferol 3-*O*-glucoside and isorhamnetin 3-*O*-glucoside, and six organic acids, aconitic, citric, ketoglutaric, malic, shikimic and fumaric acids (Fernandes et al. 2007). The major phenolics were kaempferol 3-*O*-sophoroside-7-*O*-glucoside, kaempferol 3-*O*-(feruloyl/caffeoyl)-sophoroside-7-*O*-glucoside, isorhamnetin 3,7-*O*-diglucoside and isorhamnetin 3-*O*-glucoside as the main phenolics, and malic acid was the organic acid present in highest amounts.

The major isothiocyanate found in turnip were β -phenylethyl isothiocyanate (37,381 $\mu\text{mol}/100 \text{ g dw}$) followed by 4-pentenyl isothiocyanate (5,357 $\mu\text{mol}/100 \text{ g dw}$) and 3-butenyl isothiocyanate (1,858 $\mu\text{mol}/100 \text{ g dw}$) (Hong and Kim 2008). The amounts of 3-butenyl and 4-pentenyl isothiocyanates in turnip leaf were higher than those in other parts. β -phenylethyl isothiocyanate, abundant in the root peel, showed the highest content in turnip.

Glucosinolates found in turnip greens included aliphatic glucosinolates, glucoiberin (3-methylsulfinylpropyl

glucosinolate), progoitrin (2-hydroxy-3-butenyl glucosinolate), glucoalysiin (5-methylsulfinylpentyl glucosinolate), glucoraphanin (4-methylsulfinylbutyl glucosinolate), gluconapin (3-butenyl glucosinolate), glucobrassicinapin (4-pentenyl glucosinolate), glucoiberin (3-methylthiopropyl glucosinolate), gluconapoleiferin (2-hydroxy-4-pentenyl glucosinolate), glucobrassicin (3-indolylmethyl glucosinolate), neoglucobrassicin (1-methoxy-3-indolylmethyl glucosinolate) and 4-hydroxyglucobrassicin (4-hydroxy-3-indolylmethyl glucosinolate), and aromatic glucosinolate, gluconasturtiin (2-phenylethyl glucosinolate) (Padilla et al. 2007; Cartea and Velasco 2008). Sixteen glucosinolates identified in 113 varieties of turnip greens from northwestern Spain included aliphatic glucosinolates, glucoiberin (3-methylsulfinylpropyl glucosinolate), progoitrin (2-hydroxy-3-butenyl glucosinolate), glucoalysiin (5-methylsulfinylpentyl glucosinolate), glucoraphanin (4-methylsulfinylbutyl glucosinolate), gluconapin (3-butenyl glucosinolate), glucobrassicinapin (4-pentenyl glucosinolate), glucoiberin (3-methylthiopropyl glucosinolate), gluconapoleiferin (2-hydroxy-4-pentenyl glucosinolate), glucobrassicin (3-indolylmethyl glucosinolate), neoglucobrassicin (1-methoxy-3-indolylmethyl glucosinolate) and 4-hydroxyglucobrassicin (4-hydroxy-3-indolylmethyl glucosinolate), and aromatic glucosinolate, gluconasturtiin (2-phenylethyl glucosinolate) (Padilla et al. 2007). The aliphatic glucosinolates, gluconapin and glucobrassicinapin, were the most abundant. Other aliphatic glucosinolates, such as progoitrin, glucoalyssin and gluconapoleiferin were relatively abundant in varieties with a different glucosinolate profile. Indolic and aromatic glucosinolate concentrations were low and showed few differences among varieties. Differences in total glucosinolate content, glucosinolate profile and bitterness were found among varieties, with a total glucosinolate content ranging from 11.8 to 74.0 $\mu\text{mol/g dw}$ at one site and from 7.5 to 56.9 $\mu\text{mol/g dw}$ at the other site. Sensory analysis comparing bitterness with variation in glucosinolate, gluconapin and glucobrassicinapin concentrations suggested that these compounds and their breakdown products and other phytochemicals were probably involved in the characteristic bitter flavour. Turnip greens were reported to be characterised

by a sulfurous aroma, pungent flavour and a bitter taste due to isothiocyanates, degradation products of glucosinolates; the intensity of mustard oil/mustard green aroma and flavour and bitterness was significantly affected by variety (Jones and Sanders 2002). Mustard oil/mustard green aroma and flavour, bitterness and bitter aftertaste increased significantly with maturity. Glucosinolates found in turnip tops included aliphatic glucosinolates, glucoiberin (3-methylsulfinylpropyl glucosinolate), progoitrin (2-hydroxy-3-butenyl glucosinolate), gluconapin (3-butenyl glucosinolate), glucobrassicinapin (4-pentenyl glucosinolate), glucoiberin (3-methylthiopropyl glucosinolate), glucobrassicin (3-indolylmethyl glucosinolate), neoglucobrassicin (1-methoxy-3-indolylmethyl glucosinolate) and 4-hydroxyglucobrassicin (4-hydroxy-3-indolylmethyl glucosinolate), and aromatic glucosinolate, gluconasturtiin (2-phenylethyl glucosinolate) (Rosa 1997; Cartea and Velasco 2008). The major glucosinolates were gluconapin (3-butenyl glucosinolate), glucobrassicinapin (4-pentenyl glucosinolate) and gluconasturtiin (2-phenylethyl glucosinolate). Flavonoids isorhamnetin, kaempferol and quercetin glycosides and hydroxycinnamic derivatives were identified in turnip tops (Romani et al. 2006).

Twelve intact glucosinolates, belonging to the three chemical classes, and more than 30 phenolic compounds were found in *B. rapa* leaves and young shoots (turnip greens and turnip tops) (Francisco et al. 2009a). The main naturally occurring phenolic compounds identified were flavonoids and derivatives of hydroxycinnamic acids. The majority of the flavonoids were kaempferol, quercetin and isorhamnetin glycosylated and acylated with different hydroxycinnamic acids. Significant differences for most of compounds were found between plant organs. Total glucosinolate content value was 26.84 $\mu\text{mol/g dw}$ for turnip greens and 29.11 $\mu\text{mol/g dw}$ for turnip tops; gluconapin being the predominant glucosinolate (23.2 $\mu\text{mol/g dw}$). Phenolic compounds were higher in turnip greens 51.71 $\mu\text{mol/g dw}$ than in turnip tops 38.99 $\mu\text{mol/g dw}$, in which flavonols were always the major compounds. Phenolic compounds found in turnip greens and top were quercetin derivatives including quercetin-3-*O*-sophorotrioside-7-glucoside, quercetin-3,7-di-*O* -glucoside,

quercetin-3-*O*-sophoroside, quercetin-7-*O*-glucoside, quercetin-3-*O*-*glucoside*, quercetin-3-*O*-(caffeoyl)-sophoroside-7-*O*-glucoside, quercetin-3-*O*-(methoxycaffeoyl)-sophoroside-7-*O*-glucoside, quercetin-3-*O*-(feruloyl)-sophoroside; kaempferol derivatives kaempferol-3-*O*-sophorotrioside-7-*O*-sophoroside, kaempferol-3-*O*-sophoroside-7-*O*-glucoside, kaempferol-3,7-di-*O*-glucoside, kaempferol-3-*O*-sophoroside, kaempferol-7-*O*-*glucoside*, kaempferol-3-*O*-(caffeoyl)sophoroside-7-*O*-glucoside, kaempferol-3-*O*-(methoxycaffeoyl)sophoroside-7-*O*-glucoside, kaempferol-3-*O*-(sinapoyl)-sophoroside-7-*O*-*glucoside*, kaempferol-3-*O*-(feruloyl)-sophoroside-7-*O*-glucoside, kaempferol-3-*O*-(*p*-coumaroyl)-sophoroside-7-*O*-glucoside, kaempferol-3-*O*-(methoxycaffeoyl)-sophoroside, kaempferol-3-*O*-(sinapoyl)-sophoroside, kaempferol-3-*O*-(feruloyl)-sophoroside, kaempferol-3-*O*-(*p*-coumaroyl)-sophoroside; isorhamnetin derivatives isorhamnetin -3,7-di-*O*-glucoside, isorhamnetin-3-glucoside; hydrocinnamic acids 3-caffeoyl quinic acid, 3-*p*-coumaroyl quinic acid, sinapylglucoside, ferulic acid, sinapic acid; 1,2-disinapoylgentiobiose; 1-sinapoyl-2-feruloylgentiobiose; 1,2,2'-trisina-poylgentiobiose; and 1,2'-disina-poyl-2-feruloylgentiobiose (Francisco et al. 2009a; Fererres et al. 2008; Cartea et al. 2011). In subsequent studies, Francisco et al. (2009b) found total glucosinolate concentration in turnip tops (25.6 $\mu\text{m/g}$) was higher than in turnip greens (17.6 $\mu\text{m/g}$), attributable to differences in aliphatic glucosinolates 20.6 $\mu\text{m/g}$ and 12.8 $\mu\text{m/g}$, respectively. They found that leaf and stalk firmness and resistance to cutting had negative, significant and moderate to high correlations (ranging from $R = -0.58^*$ to $R = -0.88^{**}$) with indolic glucosinolate content and with the aromatic glucosinolates. Gluconapin (the major glucosinolate in these crops) showed positive and significant correlations with aftertaste, moistness, acid and bitter taste. Hydroxycinnamic acids and flavonoids had a weak relationship with the sensory traits evaluated in turnip tops. Flavonoids kaempferol-3-*O*-(caffeoyl)sophoroside-7-*O*-glucoside and quercetin-3-*O*-(caffeoyl)sophoroside-7-*O*-*glucoside* displayed correlations highest than $R = 0.60$ for leaf and stalk firmness (once again negatives) and for taste traits

(acid, salty, bitter and aftertaste persistence). The highest coefficient correlation was found between salty taste and quercetin-3-*O*-(caffeoyl)sophoroside-7-*O*-glucoside ($R = 0.82$). The highest difference between turnip greens and turnip tops was found in the hydroxycinnamic acids content. Turnip greens had 27 $\mu\text{m/g}$ of hydroxycinnamic acids concentration and turnip tops 19.3 $\mu\text{m/g}$. Indolic and aromatic glucosinolates appeared to be more related to traits indicative of texture, while all glucosinolate types (indolic, aliphatic and aromatic) appeared to affect considerably flavour traits, mainly bitterness, acid taste and aftertaste. Results of further studies showed that total glucosinolates and phenolics of turnip greens and turnip tops (sprouting shoots) were significantly affected by the cooking procedure and the loss rate varied among individual compounds (Francisco et al. 2010). Steaming better preserved glucosinolates and phenolic compounds. Conventional boiling and high-pressure cooking methods resulted in similar rate of losses of total glucosinolate content (64 %) and total phenolic content (more than 70 %). Degradation among glucosinolate classes, aliphatic or indolic, was similar. The total flavonoids lost in turnip greens were 64 and 67 % for conventional boiling and high pressure, respectively. Vitamin C concentration suffered a drastic loss in the process of sample handling and after cooking. The results also showed high retentions of individual compounds in steaming, and the lowest retentions were obtained in the traditional high-pressure cooking.

The major volatile components of turnip leaf oil were 4-pentenyl isothiocyanate (53.7 %), sec-butyl isothiocyanate (24.3 %) and 3-butenyl isothiocyanate (15.8 %) (Afsharypuor and Tahmasian 2010). The main volatile constituents of the seed were 3-butenyl isothiocyanate (59.7 %), 4-pentenyl isothiocyanate (31.0 %) and sec-butyl isothiocyanate (1.7 %).

Baenas et al. (2014), in their study of the use of bioelicitors to enrich ready-to-eat sprouts in health-promoting glucosinolates, found that phytohormones methyl jasmonate and jasmonic acid, oligosaccharides glucose and sucrose acted as effective elicitors, increasing the total glucosinolate

glucobrassicin content of turnip sprouts from 23.4 to 91.0 mg/100 g.

Antioxidant Activity

Ethanol extract of turnip showed potent scavenging effect on DPPH and inhibitory effect on lipid peroxidation (Choi et al. 2006). Of turnip edible parts (leaves and stems, flower buds and roots), the flower buds exhibited the strongest antioxidant capacity in the DPPH radical scavenging assay (Fernandes et al. 2007).

Hepatoprotective Activity

Oral administration of turnip ethanol extract to D-galactosamine-induced experimental liver injured rats significantly reduced the serum AST, ALT and LDH enzyme activities (Choi et al. 2006). Pretreatment of rats with turnip juice protected the animals against CCL₄-induced hepatotoxicity (Rafatullah et al. 2006). The treatment significantly reduced the serum glutamate-oxaloacetate transaminase (GOT), glutamate-pyruvate transaminase (GPT), alkaline phosphatase (ALP) and bilirubin level at a dose of 16 mL/kg body weight. Besides, the juice also replenished the lowered nonprotein sulfhydryl (NP-SH) concentration in the liver tissue after CCl₄ treatment. Turnip aqueous extract exhibited anti-hepatofibrogenic in thioacetamide-induced liver fibrogenesis (Li et al. 2010). Turnip extract significantly decreased hepatofibrosis in thioacetamide animals.

In another study, administration of ethanolic turnip root extract to alloxan-induced diabetic rats significantly decreased the levels of serum biomarkers of hepatic injury (Daryoush et al. 2011). Additionally, the extract decreased lipid peroxidation and elevated the decreased levels of antioxidant enzymes in diabetic rats. Histopathologically, the changes were in agreement with biochemical findings.

Nephroprotective Activity

In-vitro studies showed that pretreatment of LLC-PK₁ cells with ethanol root extract of *B. rapa* (EBR) prevented cisplatin-induced decreases in cell viability and cellular glutathione content (Kim et al. 2006). In in-vivo studies, pretreatment of EBR 14 days before cisplatin administration in rats lowered blood levels of blood urea nitrogen and creatinine and of urinary lactate dehydrogenase caused by cisplatin. Moreover, EBR prevented the rise of malondialdehyde production and the induction of aldehyde oxidase and xanthine oxidase activities. This extract also restored the decreased activities of glutathione peroxidase (GPx), superoxide dismutase (SOD) and catalase (CAT) caused by cisplatin. The data indicate that the ethanol extract of roots of *Brassica rapa* exhibited a protective effect against cisplatin-induced nephrotoxicity by attenuating oxidative stress.

Pretreatment of rats with turnip root ethanolic extract for 30 days prior to ischemia/reperfusion operation improved renal function and reduced ischemia/reperfusion-induced renal inflammatory and oxidative injury (Mohajeri et al. 2013). The results of this study showed that the extract significantly prevented renal ischemia/reperfusion-induced functional and histological injuries.

Antidiabetic Activity

Studies by Jung et al. (2008) showed that *B. rapa* root ethanol extract may exert an antidiabetic effect in type 2 diabetic mice by enhancing the glucose and lipid metabolism. The extract and rosiglitazone improved the glucose and insulin tolerance and lowered the blood glycosylated haemoglobin, plasma insulin, C-peptide and glucagon levels as well as reversed these hepatic glucose-regulating enzyme activities in db/db mice. The extract also increased the insulin/glucagon ratio and hepatic glycogen content. The extract and rosiglitazone lowered the elevated plasma-free fatty acid and plasma and hepatic cholesterol and triglyceride levels in db/db mice and simultaneously reduced the hepatic phosphatidate phosphohydrolase, 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA reductase), acyl-coA cholesterol acyltransferase

(ACAT), β -oxidation and carnitine palmitoyltransferase activities. Further, the extract lowered the hepatic fatty acid synthase activity, hepatic lipid droplets accumulation and adipose tissue weight and size.

Anticancer Activities

Isothiocyanates had been shown to possess anticarcinogenic properties and to induce apoptosis in various cancer cell lines (Huang et al. 1998; Bonnesen et al. 2001; Yang et al. 2002; Hong and Kim 2008). β -phenylethyl isothiocyanate from turnip root inhibited the growth of human-derived hepatoma cell line (HepG2) in a concentration-dependent manner (IC₅₀ value of 24.5 μ M), as assessed by the MTT [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide] method (Hong and Kim 2008). Earlier, Huang et al. (1998) reported that phenylethyl isothiocyanate blocks tumor promoter (12-*O*-tetradecanoylphorbol-13-acetate or epidermal growth factor)-induced cell transformation in mouse epidermal JB6 cells via apoptosis. They demonstrated that p53 elevation was required for phenylethyl isothiocyanate-induced apoptosis. Animal studies by Yang et al. (2002) found that activation of MAP kinases, AP-1 transcription factors, p53 phosphorylation and the induction of apoptosis may be involved in the chemopreventive activity of phenylethyl isothiocyanate and benzyl isothiocyanate. The natural indoles 3,3'-diindolylmethane, ascorbigen, indole-3-carbinol and indolo[3,2-*b*]carbazole, as well as the natural isothiocyanates sulforaphane, benzyl isothiocyanate and phenethyl isothiocyanate, all possessed cancer chemopreventive properties by both stimulating apoptosis and enhancing intracellular defences against genotoxic agents (Bonnesen et al. 2001).

Antimicrobial Activity

β -phenylethyl isothiocyanate exhibited antimicrobial activity against food-borne pathogens *Vibrio parahaemolyticus*, *Staphylococcus aureus* and *Bacillus cereus* (Hong and Kim

2008). It was most potent against *Vibrio parahaemolyticus* with minimum inhibitory concentration (MIC) of 100 µg/mL.

Analgesic Activity

Animal studies showed that pretreatment of adult male rats with alcoholic *B. rapa* root extract at doses of 100 and 200 mg/kg body weight caused a significant reduction of pain induced by subcutaneous injection of formalin in the acute phase and at 200 mg/kg body weight caused a significant reduction of pain in chronic phase in comparison to the control group (Hosseini et al. 2013).

Traditional Medicinal Uses

A decoction of turnip leaves or stems is used in the treatment of cancer (Duke and Ayensu 1985). Root boiled with lard is used to treat breast cancer; powdered seed is used as folk remedy for cancer and a slave derived from the flowers is used for skin cancer (Duke 1983). Crushed ripe seeds are used as a poultice on burns (Foster and Duke 1998). In Ganghwa Island, Korea, turnip has been used as a diuretic, digestive and curative for jaundice, etc. (Choi et al. 2006).

Other Uses

Turnip root has been a popular livestock fodder and fodder crops for ruminants. Turnip root peelings contain a natural insecticide. The chopped roots can be brewed into a tea with flaked soap; this is then strained before use against aphids, red spider mites and flies.

Comments

B. rapa and *B. campestris* were first described as two distinct species by Linnaeus, with *B. rapa* being the turnip form and *B. campestris* the wild weedy form. Metzger in 1833 concluded that these were the same species and combined the taxa under the name *B. rapa* (Toxeopus et al. 1984). *B. rapa* (A genome, $n = 10$) was categorised into three well-defined groups based on morphological characteristics: (1) the oleiferous or oil-type rape, referred to in Canada as Polish rape or summer turnip rape; (2) the leafy-type *B. rapa*, including the chinensis group (pak-choi, celery mustard), the pekinensis group (Chinese cabbage) and the perviridis group (tendergreen); and (3) the rapiferous-type *B. rapa*, comprising the rapifera group (turnip, rapini) and the ruvo group (turnip broccoli, Italian turnip) (Hortus Third 1976; Prakash and Hinata 1980).

Family

Brassicaceae

Common/English Names

Cultivated Wasabi, Japanese Horseradish, Wasabi

Vernacular Names

Brazil: Rabanete Japonês, Raiz-Forte (Portuguese)

Chinese: Kuai Jing Shan Yu Cai, Shan Yu Cai, Shan Kui

Czech: Wasabi japonská

Danish: Japansk Peberrod

Dutch: Bergstokroos, Wasabi

Esperanto: Vasabio

French: Raifort Du Japon, Raifort Vert

German: Bergstockrose, Japanischer Kren, Japanischer Meerrettich

Hungarian: Vaszabi

Italian: Wasabi

Japanese: *seiyō* wasabi, namida, Wasabi, Wasabi Daikon

Korean: Wasabi

Russian: Vasabi, Iaponskii Khren

Slovaščina: Wasabi

Spanish: Rabanete Japonês, Wasábia

Swedish: Japansk Pepparrot

Origin/Distribution

Wasabi is native to Japan, Korea, Russia (Far East) and North China. It is cultivated in China, Alisan in Taiwan, Dalat highlands in Vietnam, New Zealand and Tasmania in Australia.

Agroecology

A temperate species, naturalised in wet areas along streams in mountains from near sea level to 2,500 m. The earliest cultivation of wasabi in Japan dates back to the tenth century. It is now widely cultivated for its edible rhizomes, which are the source of the pungent condiment wasabi. In Japan, it is grown in wet upland orchard soils for leaves, petioles and small enlarged stems and in flooded gravel and sand fields along streams or near springs to produce whole plants and large succulent green enlarged stems (Chadwick et al. 1993).

Wasabi thrives in cool, damp conditions and will sometimes grow if left undisturbed in misty mountain stream beds. It generally requires a climate with an air temperature between 8 and 20 °C and prefers high humidity in summer. Since it is quite intolerant of direct sunlight, wasabi is typically grown under shade cloth or beneath a natural forest canopy.

Edible Plant Parts and Uses

Rhizome plus the base part of the stem is freshly grated to prepare wasabi – a pungent, hot sweetish, relish that is a highly prized culinary ingredient spice and condiment in elite restaurants and sushi bars and homes in Japan. Traditionally, wasabi has been served with raw fish dishes in Japan, because the active constituents within the plant may have been an antidote for food poisoning by killing microbes. This popular spice is preferred fresh and is prepared tableside, often accompanying raw fish (sashimi), sushi (sashimi with boiled rice cake) and cold buckwheat noodles (soba) in Japanese meals (Hodge 1974; Chadwick et al. 1993). Wasabi is also indispensable for preparing *nigiri-zushi*, a special kind of small kneaded ball combining vinegared rice and fish slices. Outside of Japan, this spice is only available dried in the form of a pale green powder or in form of a green paste. Wasabi goes well with dishes containing different kinds of raw fish. Together with a sprinkle of soy sauce, wasabi paste and water go also very well with *tempura*, deep-fried battered vegetables such as Perilla–Giso and in dishes such as sushimi and soba. Wasabi imparts a unique flavour and heat to foods and can be served as a spice or an herb in a dish or as a condiment on the side. A special pickle is also made from fresh-sliced wasabi rhizomes which are cured in the residue left from fermenting rice wine (*sake*). The leaves, flowers, leafstalks and freshly sliced rhizome are soaked in salt water and then mixed with sake lees to make a popular Japanese pickle called *wasabi-zuke*. The leaves can be dried and used for flavour in foods such as cheese, salad dressings and crackers (Sultana and Savage 2008). Also, wasabi wine and a higher alcohol content wasabi liqueur are being sold in some specialty stores.

Botany

An herb growing up to 20–75 cm high, glabrous or sparsely pilose on the upper parts. The rhizome and basal part of the stem is fleshy, to 3 cm in diameter (Plates 2 and 3). Stem is erect or decumbent, simple. Basal leaves rosulate; petiole usually 10–20 cm long and dilated at the base. The leaf blade is cordate or reniform, usually 6–20 cm wide by 6–18 cm long base cordate, margin dentate, denticulate, shallowly crenate, repand or subentire, apex rounded or obtuse (Plate 1). Middle cauline leaves with petioles 1–6 cm; leaf blade broadly ovate to ovate-cordate, 1.5–6 × 2–6 cm, palmately veined, base and margin as in basal leaves, apex acute. Inflorescence a lax raceme, bracteate throughout or basally. Pedicels ascending or divaricate, slender, 1–3.5(–5) cm. Sepals oblong, 3–4 × 2–2.5 mm, caducous. Petals white, oblong-spatulate, 6–8(–9) × 2–3 mm. Filaments white, 3.5–5 mm; anthers oblong, 0.6–0.8 mm. Fruit linear, 1–2 cm × 1.5–2 mm, terete, torulose. Seeds 6–8, oblong, plump, 2–3 × 1–1.5 mm.

Plate 3 Preserved wasabi root

Nutritive/Medicinal Properties

Analyses carried out in the United States reported raw wasabi roots (excluding 23 % peel) to have the following proximate composition (per 100 g edible portion): water 69.11 g, energy 109 kcal (456 kJ), protein 4.8 g, total lipid 0.63 g, ash 1.92 g, carbohydrates 23.54 g, total dietary fibre 7.8 g, Ca 128 mg, Fe 1.03 mg, Mg 69 mg, P 80 mg, K 568 mg, Na 17 mg, Zn 1.62 mg, Cu 0.155 mg, Mn 0.391 mg, vitamin C 41.9 mg, thiamine 0.131 mg, riboflavin 0.114 mg, niacin 0.743 mg, pantothenic acid 0.203 mg, vitamin B6 0.274 mg, total folate 18 µg, vitamin A 35 IU and β -carotene 21 µg (USDA, ARS 2014).

From the nutrient data, wasabi root is rich in minerals like Ca, Mg, K and P; vitamin C; vitamin A; and protein. It also has thiamine, riboflavin, niacin, pantothenic acid, vitamin B6, total folate and β -carotene. In wasabi hydrolysate, the following ten volatile components were detected: methyl, isopropyl, allyl, sec-butyl, 3-butenyl, 4-pentenyl, 5-hexenyl, hexyl, 6-heptenyl and β -phenylethyl isothiocyanates (Kojima et al. 1973).

The best quality wasabi products were reported to be produced from the rhizomes (stems) although other parts of the plant such as petioles and leaves also possessed some pungency and also used as raw materials (sultana et al. 2000). The characteristic flavour of wasabi emanated from the volatile isothiocyanates (ITCs) evolved from glucosinolates by enzymatic hydrolysis when tissues were macerated. The level of total of 6 ITC ranged from 2,425 to 2,810 mg/kg fresh weight, which was significantly higher than the values reported in the literature for wasabi grown in Japan (mean 1,659 mg/kg). Allyl isothiocyanate (AITC) was the main ITC, and it contributed between 86 and 92 % of the total ITC measured in the rhizomes.

Ina et al. (1989) isolated three ω -methylthioalkyl isothiocyanates, namely, 6-methylthiohexyl isothiocyanate, 7-methylthioheptyl isothiocyanate and 8-methylthiooctyl isothiocyanate as the fresh characteristic greenish flavour components in wasabi. Volatile ω -methylsulfinylalkyl

isothiocyanates (NCS) found in the ether extract of wasabi root, stem and leaf were identified as allyl NCS (most abundant), *n*-butyl NCS, 3-butenyl NCS, 4-pentyl NCS, 5-hexyl NCS, 5-methylthiopentyl NCS, 6-methylthiohexyl NCS, 7-methylthioheptyl NCS, 5-methylsulfinylpentyl NCS, 6-methylsulfinylhexyl NCS, 7-methylsulfinylheptyl NCS and fatty acids palmitic acid, linolenic acid and oleic acid (Etoh et al. 1990). The flavour of ω -methylsulfinylalkyl isothiocyanates was also slightly wasabi-like although weaker than that of the ω -methylthioalkyl isothiocyanates isolated earlier. The major sulfur-containing compound in wasabi intact root was found to be sinigrin (1-thio- β -D-glucopyranose 1-N-(sulfoxy)-3-butenimide) and related congeners; disrupting the cells by applying local pressure allowed the conversion of the sulfur moieties in sinigrin to isothiocyanates and sulfate in approximately equimolar amounts (Yu et al. 2001). Alpha-tocopherol, ubiquinone-10, linolenoyloleoyl-3- β -galactosylglycerol and 1,2-dipalmitoyl-3- β -galactosylglycerol were isolated from wasabi rhizome (Weil et al. 2005).

Volatile components found in the essential oil of different parts of upland wasabi were 1-penten-3-ol (leaf and rhizome), 3-butenonitrile (leaf, petiole, rhizome, root), isopropyl isothiocyanate (leaf), *trans*-2-hexenal (leaf), *sec*-butyl isothiocyanate (leaf, petiole, rhizome, root), *cis*-2-penten-1-ol (leaf, petiole, rhizome, root), isobutyl isothiocyanate (leaf, petiole, rhizome, root), 1-hexanol (leaf, petiole, rhizome, root), allyl isothiocyanate (leaf, petiole, rhizome, root), unknown (leaf), *cis*-3-hexen-1-ol (petiole, rhizome), *trans*-2-hexen-1-ol (leaf, petiole, rhizome, root), 3-butenyl isothiocyanate (leaf, petiole, rhizome, root), 4-pentyl isothiocyanate (leaf, petiole, rhizome, root), 5-hexenyl isothiocyanate (petiole, rhizome, root), 6-heptenyl isothiocyanate (petiole, rhizome, root), unknown (leaf), 4-methylthiobutanonitrile (leaf, petiole, root), 3-methylthiopropyl isothiocyanate (leaf, petiole, rhizome, root), 6-methylthiohexanonitrile (leaf, petiole, rhizome, root), 4-methylthiobutyl isothiocyanate (rhizome, root), 7-methylthioheptanonitrile (leaf, petiole, rhizome, root), 5-methylthiopentyl isothiocyanate (leaf, petiole, rhizome, root), 6-methylthiohexyl isothiocyanate (leaf, petiole, rhizome, root)

and 7-methylthioheptyl isothiocyanate (leaf, petiole, rhizome, root) (Kumagai et al. 1994).

Rhizome contained a glucoside, sinigrin, which when hydrolysed in the presence of an enzyme produces the pungent taste (Hodge 1974). The most prized and hence the most widely grown is a form with green petioles and large knobby greenish rhizomes having a strong pungency.

Wasabi had been reported to produce phytoalexins methyl 1-methoxyindole-3-carboxylate, wasalexins A and B, with antifungal activity against *Phoma lingam* (*Leptosphaeria maculans*, teleomorph) and *Phoma wasabiae* (Pedras and Sorensen 1998; Pedras et al. 1999).

From fresh wasabi leaves five novel flavonoids, isovitexin derivatives acylated by a *trans*-sinapoyl group at C-7, were isolated together with five known flavonoids, apigenin, luteolin, isoorientin (luteolin 6-C- β -D-glucopyranoside), isovitexin (apigenin 6-C- β -D-glucopyranoside) and isosaponarin (isovitexin 4'-O- β -D-GLUCOPYRANOSIDE) (Hosoya et al. 2005). Wasabi leaves were found to contain an antimicrobial, hevein-like protein, designated WjAMP-1 (Kiba et al. 2003).

From methanol wasabi leaf extract, seven phenylpropanoid gentiobiosides, namely, 1-(3'',4''-dihydroxy-5''methoxy)-O-*trans*-cinnamoyl-2'-O-*trans*-sinapoyl gentiobiose; 1,2'-di-O-*trans*-sinapoyl gentiobiose; 1-O-*trans*-feruloyl-2'-O-*trans*-sinapoyl gentiobiose; 1-O-*trans*-caffeoyl-2'-O-*trans*-sinapoyl gentiobiose; 1,2'-di-(3'',4''-dihydroxy-5''-methoxy)-O-*trans*-cinnamoyl gentiobiose; 1-(3'',4''-dihydroxy-5''-methoxy)-O-*trans*-cinnamoyl-2'-O-*trans*-feruloyl gentiobiose; and 1-(3'',4''-dihydroxy-5''methoxy)-O-*trans*-cinnamoyl gentiobiose, were isolated along with eight known phenylpropanoids: *trans*-p-hydroxycinnamic acid; *trans*-ferulic acid; *trans*-sinapic acid; 3,4-dimethoxy-*trans*-cinnamic acid; *trans*-ferulic acid methyl ester; *trans*-sinapic acid methyl ester; 3,4-dihydroxy-5-methoxy-*trans*-cinnamic acid; and 3,4-dihydroxy-5-methoxy-*trans*-cinnamic acid methyl ester (Hosoya et al. 2008).

Antioxidant Activity

Of the phenylpropanoid glycosides isolated from wasabi leaves, 1-(3'',4''-dihydroxy-5''methoxy)-*O-trans*-cinnamoyl-2'-*O-trans*-sinapoyl gentiobiose; 1-*O-trans*-caffeoyl-2'-*O-trans*-sinapoyl gentiobiose; 1,2'-di-(3'',4''-dihydroxy-5''-methoxy)-*O-trans*-cinnamoyl gentiobiose; 1-(3'',4''-dihydroxy-5''-methoxy)-*O-trans*-cinnamoyl-2'-*O-trans*-feruloyl gentiobiose; 3,4-dihydroxy-5-methoxy-*trans*-cinnamic acid; and 3,4-dihydroxy-5-methoxy-*trans*-cinnamic acid methyl ester exhibited good superoxide anion radical scavenging in the electrospin resonance method with IC₅₀ values of 28.5, 84.5, 17.1, 36.0 and 31.3 µM, respectively, compared with ascorbic acid 140 µM (Hosoya et al. 2008). Lee et al. (2010) found that the aqueous wasabi leaf extracts had strong scavenging activities towards 1,1-diphenyl-2-picrylhydrazyl (DPPH) and nitric oxide (NO) free radicals in cell-free systems. The extract also inhibited NO production and the expressions of inducible NO synthase (iNOS) mRNA and enzyme protein in lipopolysaccharide (LPS)-stimulated RAW 264.7 macrophage cells.

Anticancer Activity

Animal studies showed that administration of wasabi to male Wistar rats suppressed glandular stomach carcinogenesis induced by the carcinogen MNNG (N-methyl-N'-nitro-N-nitrosoguanidine) (Tanida et al. 1991). The water extract fraction of wasabi markedly suppressed the growth of MKN-28 human stomach cancer, and the morphology of the cancer cells was altered leading to frequent cell death (Fuke et al. 1994). 6-Methylsulfinylhexyl isothiocyanate was identified in wasabi as one of the suppressing components on the growth of MKN-28 (Ono et al. 1996). In subsequent studies, they found that 4-methylsulfinylhexyl isothiocyanate (4-MITC) (a potent inducer of phase 2 detoxification enzymes from broccoli) and 6-MITC (a potent antiproliferative principal from wasabi), 2-MITC and 8-MITC suppressed the growth of murine tumour cells (Fuke et al. 1997). They were also cytotoxic to mouse peritoneal exudate macrophages which were not proliferating

in-vitro and inhibited the production of nitric oxide (a potent radical carcinogen) by peritoneal macrophages. Both 4-MITC and 6-MITC slightly inhibited the induction of mouse skin tumour in a two-stage process of carcinogenesis (initiator, 9,10-dimethyl-1,2-benzanthracene; promoter, 12-*O*-tetradecanoylphorbol-13-acetate), but the effect was not significant. Both compounds, however, significantly inhibited the mutation of the skin resulting from topical applications of the carcinogens. Oral administration of 6-methylsulfinylhexyl isothiocyanate (6-MITC) or a 6-MITC-containing T-wasabi fraction from wasabi root inhibited the macroscopic pulmonary metastasis and growth in a murine B16-BL6 melanoma model (Fuke et al. 2006). The number of metastasised foci per lung in either subcutaneous or intravenous injection was significantly reduced by intake of 6-MITC or a T-wasabi fraction.

6-MITC directly affected the cells in the human cancer cell panel such as breast cancer and melanoma cell lines and inhibited their growth in culture, with EC₅₀ of 3.9 µM, which was a sufficiently low dosage for practical use (Nomura et al. 2005). The suppression influenced not only the cell growth but also the survival of these cells. The mean concentration to suppress cells to a 50 % survival was 43.7 µM.

6-Methylsulfinylhexyl isothiocyanate (6-MSITC) from wasabi-induced apoptosis in human monoblastic leukaemia U937 cells and human stomach cancer MKN45 cells (Watanabe et al. 2003). Pretreatment of 6-methylthiohexyl isothiocyanate (6MHITC) isolated from wasabi inhibited the development of lung tumours in mice treated with 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone(NNK), due to the suppression of tumorigenesis initiation stage (Yano et al. 2000). Hou et al. (2000) found that the cancer chemopreventive effect of 6-methylsulfinylhexyl isothiocyanate (6-MSITC) from wasabi was associated with the induction of the cellular expression of nicotinamide adenine dinucleotide phosphate–quinone oxidoreductase (QR) in murine neptoma Hepa 1c1c7 cell. The induction of transcription of the QR gene by 6-MSITC involved an antioxidant/electrophile-responsive element (ARE/EpRE)

activation. In a subsequent study, they found that 6-methylsulfinylhexyl isothiocyanate (6-MSITC) exerted cytoprotective and cancer chemopreventive effects by modulating nuclear factor E2-related factor 2 (Nrf2)/Kelchlike ECH-associating protein 1 (Keap1) system in antioxidant-responsive element (ARE)-mediated nicotinamide adenine dinucleotide phosphate (NADP)–quinone oxidoreductase 1 (NQO1) expression (Hou et al. 2011). Similarly 6-methylthiohexyl isothiocyanate (6-MTITC), another major bioactive ingredient in wasabi, was found to have cytoprotective and cancer chemopreventive effects modulated by the same mechanism (Korenori et al. 2013). The natural wasabi compound 6-MITC and its chemical derivative and 6-methylsulfinylhexyl isothiocyanate (I7557) but not 6-methylsulfinylhexyl isothiocyanate (I7447) inhibited the viability of both pancreatic cancer PANC-1 and BxPC-3 cells in a dose- and time-dependent manner (Chen et al. 2014). Morphological observation showed mitotic arrest and apoptosis in 6-MITC- and I7557-treated cells. These two compounds induced G2/M phase arrest and hypoploid population. Percentages of aldehyde dehydrogenase-positive PANC-1 cells were markedly reduced by 6-MITC and I7557 treatment.

Cyclooxygenase and human tumour cell growth inhibitory extract of wasabi rhizome on purification yielded linolenoyl-3- β -galactosylglycerol, 1,2-dipalmitoyl-3- β -galactosylglycerol, α -tocopherol and ubiquinone-10 (Weil et al. 2005). At a concentration of 250 μ g/mL, linolenoyl-3- β -galactosylglycerol and 1,2-dipalmitoyl-3- β -galactosylglycerol exhibited 42 and 47 % inhibition of COX-1 enzyme. Alpha-tocopherol and ubiquinone-10 isolated from wasabi rhizomes were inactive. At a concentration of 60 μ g/mL, linolenoyl-3- β -galactosylglycerol inhibited the growth of colon, lung and stomach cancer cells by 28, 17 and 44 %, respectively.

Gastroprotective Activity

Oral administration of wasabi leaf extract of 50 and 200 mg/kg bw/day for 10 days to Mongolian gerbils significantly

attenuated the elevated level of 8-oxo-7,8-dihydro-2'-deoxyguanosine (8-oxodG) in the stomach and oxidative DNA damage in peripheral erythrocytes caused by simultaneous loading of *Helicobacter pylori* infection and physical stress (Sekiguchi et al. 2010).

Antimicrobial Activity

The antimicrobial activities of distilled water wasabi root extracts were stronger than those of ethanol extracts and stronger against moulds than bacteria (Shin and Lee 1998). Phytoalexins methyl 1-methoxyindole-3-carboxylate, wasalexins A and B, with antifungal activity against *Phoma lingam* (*Leptosphaeria maculans*, teleomorph) and *Phoma wasabiae* were isolated from wasabi (Pedras and Sorensen 1998; Pedras et al. 1999). Of the four kinds of bacteria, *Vibrio parahaemolyticus* was mostly inhibited by the distilled water wasabi root extracts. Hasegawa et al. (1999) found that growth of *Vibrio parahaemolyticus* was inhibited more in fatty tuna meat suspension with a fat content of 3.0 % than in lean tuna meat suspensions, with a fat content of 0.006 %, by wasabi and allyl isothiocyanate. An ethereal extract from wasabi stems had potent antibacterial activity, and 6-methylsulfinylhexyl isothiocyanate was isolated as the active compound from the extract (Ono et al. 1998). Some homologues of 6-methylsulfinylhexyl isothiocyanate were also active against *Escherichia coli* and *Staphylococcus aureus*.

Shin et al. (2004) reported that wasabi roots, stems and leaves exhibited bactericidal activities against *Helicobacter pylori* strains. The leaves of Korean and Japanese wasabi showed the highest bactericidal activities with the minimum bactericidal concentration of 1.05–1.31 mg of dry weight/mL against three strains of *H. pylori*. The roots showed a slightly lower bactericidal activity with 2.09–4.17 mg of dry weight/mL. The bactericidal activity of leaves was higher than that of roots, although the allyl isothiocyanate level of leaves was lower than that of roots. An antimicrobial protein, designated WjAMP-1, purified from wasabi leaves showed antimicrobial activity against both fungi and bacteria (Kiba et al. 2003). The deduced amino acid sequence of cDNA of

WjAMP-1 showed 60 and 70 % identity with a hevein from *Hevea brasiliensis* and a hevein-like protein from *Arabidopsis thaliana*, respectively. However, matured WjAMP-1 lacked the hevein domain and may correspond to the C-terminal domain of hevein. WjAMP-1 may be a useful defence gene to generate resistant plants against fungal and bacterial pathogens.

Antidiabetic Activity

6-(methylsulfinyl)hexyl (6-MSITC) derived from *Wasabia japonica* was found to be an inhibitor of glycogen synthase kinase-3 β (GSK-3 β), a ubiquitous serine/threonine kinase involved in the molecular pathogenesis of human diseases such as type 2 diabetes and Alzheimer's disease (Yoshida et al. 2011). The most potent isothiocyanate, 9-methylsulfinylhexyl isothiocyanate (9-MSITC), inhibited glycogen synthase kinase 3 at a K_i value of 10.5 μ M and showed ATP competitive inhibition. The structure–activity relationship revealed an inhibitory potency of methylsulfinyl isothiocyanate dependent on the alkyl chain length and the sulfoxide, sulfone and/or the isothiocyanate moiety. Their results indicated that MSITCs, including 6-MSITC, could be good lead compounds as GSK-3 β inhibitors. They proposed that 6-MSITC or the food ingredient containing it may be useful functional compounds for the treatment of type 2 diabetes.

Antimutagenic Activity

The antimutagenic activity of distilled water wasabi root extracts from horseradish root was stronger against 3-amino-1,4-dimethyl-5H-pyrido (4,3- β)indole than 2-amino-3,8-dimethylimidazo-(4,5-f) quinoxaline in the Ames test with *Salmonella typhimurium* TA 98 (Shin and Lee 1998).

Antihypercholesterolemic Activity

Studies showed that feeding hypercholesterolemic Sprague-Dawley rats with wasabi leaf diet for 4 weeks significantly increased serum HDL cholesterol levels compared with the

normal diet hypercholesterolemia rats. In contrast, the serum LDL cholesterol levels and liver xanthine oxidase (XO) activity in wasabi leaf diet groups were significantly decreased (Lee 2008; Lee et al. 2010). There were no differences in body weight gain, food intake and food efficacy ratio.

Antiobesity Activity

Hot water wasabi leaf extract suppressed the increase in glycerol-3-phosphate dehydrogenase (GPDH) activity and triglyceride (TG) accumulation, markers of adipogenesis, in a dose-dependent manner (Ogawa et al. 2010). Wasabi leaf extract significantly reduced the mRNA expression levels of peroxisome proliferator-activated receptor (PPAR) γ and CCAAT/enhancer-binding protein (C/EBP) α , both key adipogenic transcription factors, as subsequently were the mRNA expression levels of their target genes, such as adipocyte fatty acid binding protein 2 (aP2). The protein expression levels of both PPAR γ and C/EBP α were also inhibited by wasabi leaf extract. The results suggested that wasabi leaf extract may prevent obesity and insulin resistance by inhibiting the differentiation of preadipocytes. Yamasaki et al. (2013) demonstrated that wasabi leaf extract dietary supplement induced mild suppression of obesity in a high-fat diet-induced mice, possibly due to suppression of lipid accumulation in the liver and white adipose tissue. In epididymal white adipose tissue of the wasabi leaf extract group, expression of leptin, PPAR γ and C/EBP α was significantly suppressed and adiponectin was significantly enhanced. Acox, related to fatty acid oxidation in adipocytes, was also enhanced.

Anti-inflammatory Activity

6-(Methylsulfinyl)hexyl isothiocyanate (6-MITC) attenuated cyclooxygenase-2 (COX-2) production in lipopolysaccharide (LPS)-activated murine macrophage RAW264 cells in a dose-dependent manner (Uto et al. 2005a). It suppressed the activation of JNK-mediated AP-1 and ERK/p38 kinase-mediated CREB or C/EBP δ . They also found that 6-MITC

suppressed inducible nitric oxide synthase expression through the inhibition of Janus kinase 2-mediated JNK pathway in lipopolysaccharide-activated murine macrophages. Chen et al. (2010) determined the array of anti-inflammatory genes targeted by 6-MSITC in macrophages. Among 22,050 oligonucleotides, the expression levels of 406 genes were increased by ≥ 3 -fold in lipopolysaccharide (LPS)-activated RAW264 cells, 238 gene signals of which were attenuated by 6-MSITC (≥ 2 -fold). Expression levels of 717 genes were decreased by ≥ 3 -fold in LPS-activated cells, of which 336 gene signals were restored by 6-MSITC (≥ 2 -fold). They suggested that the anti-inflammatory effects of 6-methylsulfinylhexyl isothiocyanate (6-MSITC) may be elucidated by its inhibition of the expression of various proinflammatory genes such as nuclear factor (NF), interleukins IL-1 β and IL-6, prostaglandin-endoperoxide synthase 2 (PTGS2) and cyclooxygenase-2 (COX-2) in LPS (lipopolysaccharide)-activated macrophages. On the other hand, 6-MSITC also restored the expression levels of LPS-reduced CC chemokines (CCL11 and CCL25), interleukins (IL-3) and receptors such as interleukin receptor antagonist 12 (IL-1ra12), interleukin 8 receptor alpha (IL-8ra) and tumour necrosis factor receptors (TNFRSF23 and TNFRSF4) to control levels. The data suggested that wasabi 6-MSITC might not only attenuate the expression of certain proinflammatory genes induced by LPS but also restore the expression level of anti-inflammatory genes reduced by LPS. They found that wasabi 6-MSITC regulated the relevant networks of chemokines, interleukins and interferons to exert its anti-inflammatory function.

6-Methylsulfinylhexyl isothiocyanate (6-MSITC) was found to have anti-inflammatory and anticoagulant effects on human umbilical vein endothelial cells (HUVECs) (Okamoto et al. 2014). 6-MSITC modulated endothelial cell function and suppressed cell adhesion. It modulated the generation of activated protein C, essential for negative regulation of blood coagulation, on normal endothelial cells. Also, 6-MSITC reduced tumour necrosis factor- α (TNF- α)-induced interleukin 6 and monocyte chemoattractant protein-1 expression. 6-MSITC markedly attenuated TNF- α -induced adhesion of

human monoblastic U937 cells to HUVECs and reduced vascular cell adhesion molecule-1 and E-selectin mRNA expression in activated endothelial cells. This mechanism of the anti-inflammatory effect of 6-MSITC suggested that 6-MSITC may have therapeutic potential as a treatment for vasculitis and vascular inflammation.

Antidiarrhoeal Activity

Studies by Nakayama et al. (1998) found that wasabi extract could inhibit intestinal chloride secretion by inhibiting submucosal secretomotor nerves and prostaglandin synthesis in guinea pig colon and may therefore have an antidiarrhoeal effect. Wasabi extract on the serosal side of the colon reduced basal short-circuit current. The extract reduced the increases in short-circuit current caused by serotonin added to the serosal side and by electrical field stimulation as well.

Collagen Synthesis Enhancing Activity

The results of studies by Nagai et al. (2010) suggested that isosaponarin, from wasabi leaf, increased type I collagen synthesis in human fibroblasts, by increasing TGF-beta type II receptor (TbetaR-II) protein and TbetaR-II mRNA and prolyl 4-hydroxylase (P4H) protein and P4H mRNA production.

Antiplatelet Activity

Inhibition of platelet aggregation was found in the essential oils extracted from the various parts of upland wasabi (Kumagai et al. 1994). The antiplatelet activity in descending order was highest in roots ($IC_{50} = 112.1 \mu\text{g/mL}$), petioles ($IC_{50} = 125.7 \mu\text{g/mL}$) and rhizomes ($IC_{50} = 157.3 \mu\text{g/mL}$) and lowest in leaves ($IC_{50} = 265.6 \mu\text{g/mL}$). Most of the volatile components in upland wasabi oils were ω -alkenyl isothiocyanates and ω -methylthioalkyl isothiocyanates, allyl isothiocyanate being the main component in every oil. Essential oils from roots and petioles contained rather large amounts of ω -methylthioalkyl isothiocyanates. Although every authentic isothiocyanate inhibited platelet aggregation, ω -

methylthioalkyl isothiocyanates were more inhibitory, which explained the stronger inhibitory effects of essential oils from roots and petioles on platelet aggregation. 6-Methylsulfinylhexyl isothiocyanate (6-MSITC) isolated from wasabi was found to be a potential inhibitor of human platelet aggregation in-vitro (Morimitsu et al. 2000a, b). 6-MSITC administered to rats or mice also showed both activities in-vivo.

Anti-allergic Activity

Various isothiocyanates (ITC) from wasabi were found to inhibit type I allergies by inhibiting chemical mediator release and that the inhibitory effects on each chemical mediator were due to differences in the side chain structure of the wasabi ITCs (Yamada-Kato et al. 2012). Allyl ITC, *sec*-butyl ITC and 3-butenyl ITC, with 3 or 4 carbon chains, inhibited histamine release but did not inhibit the release of leukotriene B4 (LTB4) or cysteinyl LTs (CysLTs). 4-Pentenyl ITC and 5-hexenyl ITC, with 5 or 6 carbon chains and an unsaturated bond at the end, inhibited LTB4 release but did not inhibit the release of histamine or CysLTs. 6-Methylthiohexyl ITC, 6-methylsulfinylhexyl ITC and 6-methyl-sulfonylhexyl ITC, with a sulfur atom inserted at the end of a 6-carbon chain, inhibited the release of histamine, LTB4 and CysLTs and the elevation in intracellular Ca^{2+} .

Bone Stimulatory Activity

Suzuki and Yamaguchi (1999a) demonstrated that wasabi leafstalk extract had an anabolic effect on bone metabolism in rats in-vivo. The extract caused a significant increase in alkaline phosphatase activity, deoxyribonucleic acid (DNA) and calcium contents in the femoral–metaphyseal tissues. They also showed that wasabi leafstalk extract had a stimulatory effect on bone calcification in mouse calvaria tissue culture in-vitro (Suzuki et al. 1997; Suzuki and Yamaguchi 1999b). The extract had an appreciable effect on increasing bone calcium content; the effect was greater at 10 and 50 $\mu\text{g/mL}$, but at higher concentrations (100–300 $\mu\text{g/mL}$)

the effect was weaker. The bone deoxyribonucleic acid (DNA) content was not significantly altered by the presence of wasabi leafstalk extract (10 and 50 µg/mL). The presence of wasabi leafstalk extract (50 µg/mL) caused a significant increase in calcium content, alkaline phosphatase activity and deoxyribonucleic acid (DNA) content in the diaphyseal and metaphyseal tissues in-vitro (Yamaguchi et al. 2003). However, the effect of wasabi leafstalk extract (50 µg/mL) in increasing bone components was completely abolished in the presence of cycloheximide (10–6 M), an inhibitor of protein synthesis. The results suggested the intake of wasabi leafstalk extract may have a preventive effect on bone loss with increasing age. Wasabi leafstalk extract exerted an enhancing effect on the anabolic action of 17β-oestradiol or insulin, which regulates bone formation and calcification in-vitro (Suzuki and Yamaguchi 2003). The active substance in wasabi leafstalk extract differed from genistein and 17β-oestradiol and had a comparatively lower molecular weight of 158 (Suzuki and Yamaguchi 2004).

Pain-Related Behaviour Activity

Two wasabi non-pungent ITCs, 6-methylsulfinylhexyl isothiocyanate (6-MSITC) and 6-methylsulfinylhexyl isothiocyanate (6-MTITC), dose-dependently activated both murine transient receptor potential ankyrin 1 (TRPA1) (EC_{50} = 147 µM for 6-MSITC and 30 µM for 6-MTITC) and human TRPA1 (EC_{50} = 39 µM for 6-MSITC and 34 µM for 6-MTITC) and caused pain-related behaviour that was similar to many other TRPA1 agonists (Uchida et al. 2012). Furthermore, this activation occurred through covalent modification as would be expected from their structures, which were similar to ally ITC. 6-MSITC also activated transient receptor potential vanilloid 1 (TRPV1), a capsaicin receptor, but not other transient receptor potential channels expressed in sensory neurons.

Antiviral Activity

Japanese scientists discovered a potent anti-influenza virus activity in summer leaves of Japanese wasabi (Mochida and Ogawa (2008)). The extracts of summer leaves exhibited the same anti-influenza virus activity as winter leaves and showed a stronger activity than stems, roots and rhizomes. The ethanol leaf extract inhibited replication of influenza virus strain (AH1N1, A/shimane/48/2002), its subtype (AH3N2, A/shimane/122/2002) and type B strain (B/shimane/2/2002) regardless of the haemagglutinin antigen type indicating that such extracts could be a promising source of a novel anti-influenza virus agent.

Traditional Medicinal Uses

Traditionally, wasabi has been used as a natural herb for deodorisation and detoxification purposes, as well as for its antimicrobial activity (Okada and Mitsuhashi 2002). The wasabi rhizome is a pungent warming herb that is used internally as an antidote to fish poison (Bown 1995).

Other Uses

Isothiocyanates extracted from *Wasabia japonica* can be used to produce antibiotics, fungicides, insecticides, nematicides and as wood preservatives (Brown and Morra 1997). Studies by Sexton et al. (1999) had shown that volatiles released from glucosinolates in the tissues of *Wasabia japonica* were toxic to the blackleg fungus, *Leptosphaeria maculans*, a major threat of oilseed *Brassica* crops like rapeseed and canola. Wasabi had been reported to produce phytoalexins with antifungal activity, methyl 1-methoxyindole-3-carboxylate, wasalexins A and B, against *Phoma lingam* (*Leptosphaeria maculans*, teleomorph) and *Phoma wasabiae* (Pedras and Sorensen 1998; Pedras et al. 1999).

Comments

Wasabi is commonly propagated from tissue culture offshoots and seeds.

Lepidium meyenii

T. K. Lim¹✉

(1) Canberra, Aust Capital Terr, Australia

Scientific Name

Lepidium meyenii Walp.

Synonyms

Lepidium affine Wedd., *Lepidium gelidum* Wedd., *Lepidium marginatum* Griseb., *Lepidium meyenii* var. *affine* (Wedd.) Thell., *Lepidium meyenii* subsp. *gelidum* (Wedd.) Thell., *Lepidium meyenii* subsp. *marginatum* (Griseb.) Thell., *Lepidium orbignyanum* Wedd., *Lepidium peruvianum* G. Chacón de Popovici, *Lepidium weddellii* O.E. Schulz

Family

Brassicaceae

Common/English Names

Andean Ginseng, Maca, Mace, Pepper grass, Pepper weed,
Peruvian Ginseng, Peruvian Maca

Vernacular Names

Czech: Řeřicha Meyenova

Dutch: Maca

French: Maca

Peru: Mace

Quechuan: Ayak Chichira, Ayak Wilku, Huto Huto

Spanish: Maca Andina, Maca-Maca, Maino

Swedish: Maca

Origin/Distribution

The species is native to the high Andean region of Peru and Bolivia. It is also cultivated in some parts of Brazil. The plant has been introduced into the United States, Europe and very recently to China where it is being cultivated in the Yunnan province.

Maca is an octoploid plant (Quiros et al. 1996). Molecular DNA studies (RAPD) conducted on 29 cultivated accessions of maca (*Lepidium meyenii*) and 27 accessions of wild species of *Lepidium* from Ecuador, Peru and Bolivia found that none of three wild species *L. bipinnatifidum*, *L. kalenbornii* and *L. chichicara* was related enough to be considered ancestral to the cultivated *L. meyenii* (Toledo 1998). *L. bipinnatifidum* comprised mostly of tetraploids and a single octoploid accession; *L. kalenbornii* comprised only of tetraploid accessions; and *L. chichicara* consisted of mostly octoploid and a few tetraploid accessions.

Agroecology

Lepidium meyenii grows in a rather restricted ecological zone in the Andes at 11–12 S latitude and at an elevation of 3,800–4,400 m above sea level (Tello et al. 1992; Gonzales et al. 2003a; Clément et al. 2010a, b). Maca has one of the highest frost tolerances of any cultivated plant that can be grown at such high altitudes as it is able to grow in the puna where only alpine grasses and bitter potatoes thrive (Bonnier 1986). At these elevations, temperatures of the growing season vary between –2 and 13 °C in monthly mean minimum or maximum, respectively, and maca will survive subzero temperatures down to –10 °C; relative humidity is moderately high, with an average of 70 % (Tello et al. 1992; Clément et al. 2010a, b). However, maca may be grown outside its native habitat, the Andean highlands of Junín, and the suggesting that its range of adaptation is not as narrow as previously thought (Tello et al. 1992). Today, maca is still mainly cultivated in Peru, in the high Andes of Bolivia, and to a small extent also in Brazil (Flores et al. 2003).

In its high and cold native habitat, maca has adapted to relatively poor agricultural soils, the strong, fierce winds and intense sunlight where few other crops can be grown (Johns 1981). The natural soil in the maca production native habitat is acidic, having a pH of 5 or less (Tello et al. 1992). In its native range, maca grows as an annual crop, completing its life cycle in 1 year (Quiros et al. 1996). However, it is generally regarded as a true biennial plant because it has a vegetative cycle that is followed by a reproductive phase in the following season.

Edible Plant Parts and Uses

Maca (tuberous hypocotyl/root) is used as a food both fresh and dry (Leon 1964). Maca is cooked in pachamancas (underground pits lined with hot stones) or stored dried for later consumption (Leon 1964; Ochoa 2001). Dried macas are cooked in water or milk and used to prepare a kind of sweet and aromatic porridge, *mazamorra*. The small macas are preferred, since they are less fibrous. Macas are also placed in sugar cane rum (*aguardiente*), to which they impart a special aroma. The dried roots are eaten after boiling in water or milk and are sometimes mixed with honey and fruit for preparation of juices and addition of sugarcane rum for cocktails and other alcoholic beverages (Johns 1981; Tello et al. 1992). Flour is also prepared from the dried roots for making bread and cookies. Maca is mixed with *chuño* (freeze-dried potatoes), oca, quinoa and soybeans to prepare different dishes and dessert. In Huancayo, Peru, maca jam and pudding are popular, and maca is often made into a sweet, fragrant, fermented drink or weak beer called *chicha de maca* (Ochoa 2001; Muhammad et al. 2005). The tuberous hypocotyls/roots have a tangy, sweet taste and an aroma similar to that of butterscotch. In 2010 a US-based brewery called Andean Brewing Company became the first company to produce and commercialise beer made from Maca under the brand KUKA Beer (Wikipedia 2014). Toasted and ground maca is used to prepare “maca coffee” (Castro de Leon 1990). Many food supplements containing dried powdered maca hypocotyls are available on the world market (Valentová et al. 2006) such as value-added maca products such as pills, capsules, flour, drinks, liquor, tonic and mayonnaise (Li et al. 2001).

Maca leaves are eaten raw or cooked and have a hot cress-like flavour (Popenoe et al. 1989; Ochoa 2001).

Botany

Lepidium meyenii is an annual or biennial, low-growing herbaceous plant, growing 12–20 cm in height (Plates 1 and 2). The aerial part consists of a rosette of 12–20 frilly, basal leaves on short decumbent stems arising from an underground tuberous, fleshy, turnip-shaped organ formed by the fusion of the hypocotyl and main tap root. The hypocotyl/root varies in size from 3 to 5 cm in its broadest diameter with a circumference of about 15 cm and found in many shades and combinations of white, cream, yellow, grey, purple and red (Plate 3). The tap root bears numerous very thin, lateral roots. The basal leaves are roughly elliptical in outline, 5 cm in length, petiolated and bipinnatifid (Plate 2). The central leaves are 3 cm in length and are deeply bipinnatifid. The apical leaves are less divided, and 1–2 cm in length. According to some authorities, the leaves exhibit dimorphism, being larger in the vegetative phase and reduced in the reproductive cycle. Flowers are small, white, inconspicuous on short 5 mm slender pedicels and are arranged in axillary racemes on generative shoots. Flowers have four erect, concave sepals, four small white petals, oval, bicarpellary ovary with a short style and two fertile stamens with well-developed anthers and several staminodes. The fruit is a two-celled dehiscent silique, slightly emarginated at the apex, 3.5–5 mm long by 2.5 mm wide. The seeds are ovoid, 1.5–2 mm across, smooth and reddish.

Nutritive/Medicinal Properties

Hypocotyl/Root Nutrient/Phytochemicals

The dried hypocotyls of maca were reported to contain approximately 13–16 % protein and to be rich in essential amino acids. Fresh hypocotyls contained 80 % water with high amounts of iron and calcium (Valerio and Gonzalez 2005).

The proximate nutrient composition of maca hypocotyl root per 100 g edible portion had been reported as energy 314 cal, water 15.3 g, protein 11.8 g, fat 1.6 g, carbohydrates 66.40 g, ash 5 g, Ca 247 mg, P 183 mg, Fe 14.7 mg, thiamine 0.2 mg, riboflavin 0.35 mg and ascorbic acid 2.5 mg (National Institute of Nutrition, Lima Peru 1993). Maca had been reported to have the following proximate nutrient composition: protein 10.2 %, fat 2.2 %, carbohydrates 59.0 %, fibre 8.5 %, ash 4.9 %, minerals mg/100 g) Fe 16.6 mg, Mn 0.8 mg, Cu 5.9 mg, Zn 3.8 mg, Na 18.7 mg, K 2,050 mg and Ca 150 mg; amino acids mg/g protein, aspartic acid 91.7 mg, glutamic acid 156.5 mg, serine 50.4 mg, histidine 21.9 mg, glycine 68.3 mg, threonine 33.1 mg, cysteine n/d, alanine 63.1 mg, arginine 99.4 mg, tyrosine 30.6 mg, phenylalanine 55.3 mg, valine 79.3 mg, methionine 28 mg, isoleucine 47.4 mg, leucine 92 mg, lysine 54.3 mg, tryptophan n/d, hydroxyproline 26 mg, proline 0.5 mg and sarcosine 0.7 mg; and fatty acids, lauric 0.8 %, 7-tridecenoic 0.3 %, tridecanoic 0.1 %, myristic 1.4 %, 7-pentadecanoic 1.1 %, palmitoleic 2.7 %, palmitic 23.8 %, 9-heptadecanoic 1.8 %, heptadecanoic 1.8 %, linoleic 12.6 %, oleic 11.1 %, stearic 6.7 %, 11-nonadecanoic 1.3 %, nonadecanoic 0.4 %, 15-eicosenoic 2.3 %, arachidic 1.6 %, behenic 2.0 %, nervonic 0.4 %, lignoceric 0.4 %, total SFA 40.1 % and total UFA 52.7 % (Dini et al. 1994; Comas et al. 1997; Valerio and Gonzalez 2005). Maca was also found to contain sterols as steryl acetate derivatives: brassicasteryl acetate 9.1 %, ergosteryl acetate 13.6 %, campestryl acetate 27.3 %, ergostadienyl acetate 4.5 % and sitosteryl acetate 45.5 % (Dini et al. 1994).

Dried maca hypocotyl was found to contain 10.4 % water, 10.2 % proteins, 59 % saccharides, 2.2 % lipids, 4.9 % ash and

8.5 % fibre and mg/100 g of Ca 150 mg, Fe 16.6 mg, Cu 5.9 mg, Mn 0.8 mg, Zn 3.8 mg, thiamine 0.28 mg, ascorbate 8 mg and riboflavin 0.65 mg (Valentová and Ulrichová 2003). Dried maca root from Yunnan province was found to contain protein (12.31 %), crude fibre (32.57 %), fat (0.92 %), vitamins C (314.97 mg/kg), Ca (1,818 mg/kg), Fe (81.2 mg/kg), Zn (23.8 mg/kg), K (18.7 mg/kg), P (1,895 mg/kg) and other mineral elements (Du et al. 2010). Fatty acids consisted of linoleic acid (38.64 %), linolenic acid (26.46 %) and palmitic acid (17.73 %). The content of amino acids was 14.04 %. Maca also contained catechins but much lower than in tea (2.5 mg/g vs. 145 mg/g (Sandoval et al. 2002).

A dehydrated maca hypocotyl (tuber) powder was found to contain 11.6 % protein, 1.09 % fat (of which 86.7 % steroids), 9.08 % fibre, 60.0 % carbohydrates (23.4 % sucrose, 1.55 % glucose, 4.56 % oligosaccharides and 30.4 % polysaccharides), 5.0 % ash and 663 kJ/100 g energy value (Valentová et al. 2006). Ash consisted mainly of potassium (16.2 mg/g), sodium (260 mg/kg), zinc (58.4 mg/kg), iron (72.3 mg/kg), copper (5.14 mg/kg) and nickel (0.49 mg/kg). The contents of arsenic, lead, cadmium and nitrates were below the limit set for foodstuffs. Fatty acids and steroids in maca methanol (2.5 mg/g fatty acids and 14.9 mg/g steroids) and aqueous extracts (6.2 mg/g fatty acids and 9.1 mg/g steroids) expressed as percentage of total fatty acids or steroid content were, respectively, as follows: phenyl hydroxyacetic acid (4.1 %, –), 2-oxononadecanoic acid (2.6 %, –), octadecanoic acid (2.2 %, –), nonadecanoic acid (21.8 %, –), palmitic acid (36.8, 44 %), stearic acid (13.0, 23.9 %), oleic acid (7.2, 11.6 %), linoleic (3.6 %, 8.7 %), linolenic acid (5.4, 5.8 %), eicosanoic acid (1.3, 6 %), 3,5-stigmastadiene (1.6, 3.8 %), 3-hydroxy-5-ergostene 19.2, –%), β -sitosterol 69.8, 48.5 %), 3,5-stigmastadien-7-one (6, 2.6 %), homo- β -sitosterol (3.4, 0.8 %), brassicasterol (–, 18.8 %), isomer of brassicasterol (–, 23.1 %) and avenasterol (–, 4.4 %) (Valentová et al. 2006). Corredo (2008) reported the following nutrient composition of maca hypocotyls: protein 8.87–11.60 %, lipid 1.09–2.2 %, carbohydrate 54.60–60 %, fibre 8.23–9.08 %, ash 4.90–5 % and minerals (mg/100 g) Fe 16.1 mg, Mn 0.8 mg, Cu 5.9 mg, Zn 3.8 mg, Na 18.7 mg, K 2,050 mg

and Ca 250 mg. The proximate composition analysis of maca showed 6.57 % moisture, 12.83 % crude protein, 1.05 % crude fat, 4.80 % ash and 74.75 % carbohydrate (Kwon et al. 2009).

Maca root starch presented oval and irregular morphology, with granule size between 7.4 and 14.9 μm in length and 5.8 and 9.3 μm in diameter (Rondán-Sanabria and Finardi-Filho 2009). Maca starch contained 0.28 % lipids, 0.2 % fibre and 0.12 % fixed mineral residue, and no protein; the ratio between the amylose and amylopectin contents was 20:80. It exhibited the following features: purity of 87.8 %, solubility at 90 °C was 61.4 %, the swelling power was 119.0 g water/g starch and the water absorption capacity was 45.9 g water/g starch; the gel turbidity rose 44 % during storing time; the gelatinisation temperature was 47.7 °C and the transition enthalpy 6.22 J/g; the maximum viscosity reached 1,260 UB at 46.4 °C, with breakdown, setback and consistence of 850, 440 and -410 UB, respectively. The low gelling temperature and the stability during gel refrigeration could be adequate for foods requiring moderate temperature process, but not for frozen food.

The polysaccharide in the maca filtrate was extracted by water and precipitated with ethanol, and its content was determined to be 2.25 % (Chen et al. 2007). The optimum extraction parameters for maca polysaccharides were as follows: temperature 100 °C, time 2 hours and solid ratio 1:40 (Chen et al. 2008). The extraction rate of maca polysaccharides by ultrasonic wave was 74.4 % under the optimum extracting conditions: ratio of solid to liquid 1:20, time 20 minutes, temperature 50 °C and ultrasonic power 200 W (Pu and Wang 2010). Four *Lepidium meyenii* polysaccharides LMP-60, LMP-70, LMP-80 and LMP-90 were obtained from maca aqueous extract by changing the concentration of ethanol in the process of polysaccharide precipitation (Zha et al. 2014). All of the LMPs were composed of rhamnose, arabinose, glucose and galactose and differed in the contents of monosaccharide. Amylase and glucoamylase were found to effectively remove starch in maca polysaccharides.

Maca had been reported to contain secondary metabolites such as macaridine, macaene (unsaturated fatty acids), macamides and maca alkaloid (Zheng et al. 2000). *Lepidium meyenii* tubers were found to contain the benzylated derivative of 1,2-dihydro-*N*-hydroxypyridine, named macaridine, together with the benzylated alkamides (macamides), *N*-benzyl-5-oxo-6*E*,8*E*-octadecadienamide and *N*-benzylhexadecanamide, as well as the acyclic keto acid, 5-oxo-6*E*,8*E*-octadecadienoic acid (Muhammad et al. 2002). Five additional alkamides, namely, *N*-benzyl-9-oxo-12*Z*-octadecenamide; *N*-benzyl-9-oxo-12*Z*,15*Z*-octadecadienamide; *N*-benzyl-13-oxo-9*E*,11*E*-octadecadienamide; *N*-benzyl-15*Z*-tetracosenamide; and *N*-(3-methoxybenzyl)hexadecanamide were isolated (Zhao et al. 2005). The main macamides in maca tubers were identified as *n*-benzylhexadecanamide, *n*-benzyl-(9*Z*)-octadecenamide, *N*-benzyl-(9*Z*, 12*Z*)-octadecadienamide, *N*-benzyl-(9*Z*, 12*Z*, 15*Z*)-octadecatrienamide and *N*-benzyl-octadecanamide (McCollom et al. 2005). The amount of macamides in the dried plant material ranged from 0.0016 to 0.0123 %. Two macamides, *N*-benzyl-5-oxo-6*E*,8*E*-octadecadienamide and *N*-benzylhexadecanamide, were isolated and purified from maca (Lee et al. 2008). The following macamides were found in maca pentane extract: *N*-benzylhexadecanamide 1.75 %; *N*-benzyloctadecanamide 0.16 %; *N*-benzyl-9*Z*-octadecenamide 0.34 %; *N*-(3-methoxybenzyl)-9*Z*-octadecanamide 0.14 %; *N*-benzyl-(9*Z*,12*Z*)-octadecadienamide 1.26 %; *N*-(3-methoxybenzyl)-(9*Z*,12*Z*)-octadecadienamide 0.10 %; *N*-benzyl-(9*Z*, 12*Z*, 15*Z*)-octadecatrienamide 2.13 %; *N*-(3-methoxybenzyl)-(9*Z*,12*Z*,15*Z*)-octadecatrienamide 0.26 %, *N*-(3-methoxybenzyl)-hexadecanamide 0.08 %; *N*-benzyl-(15*Z*)-tetracosenamide 0.02 %; and the following comprised 93.76 %: *N*-(3-methoxybenzyl)-6-phenylhexanamide; *N*-(3-methoxybenzyl)-6-phenylheptanamide; *N*-(3-methoxybenzyl)-7-oxo-7-phenylheptanamide; *N*-(4-florobenzyl)-hexadecanamide; *N*-(4-chlorobenzyl)-hexadecanamide; *N*-benzyl-5-oxooctadecanamide; *N*-(4-chlorobenzyl)-5-oxooctadecanamide; *N*-(3-methoxybenzyl)-6-hexanamide; *N*-(3-methoxybenzyl)-6-heptanamide; *N*-(3-methoxybenzyl)-7-oxo-7-phenylheptanamide; *N*-benzyl-5-oxo-6*E*, 8*E*-octadecadienamide and

N-pyridine-9*Z*-octadecanamide (synthetic derivative). Melnikovova et al. (2012) found that maca hypocotyls grown in the field in the Czech Republic had significantly lower concentration of macamides compared to Peruvian samples, and no macamides were detected in maca grown in the greenhouse. The main macamides identified in the samples were: *N*-benzylhexadecanamide, *N*-benzyl-(9*Z*)-octadecanamide, methoxy-*N*-benzyl-(9*Z*,12*Z*)-octadecadienamide, *N*-benzyloctaeca namide, *N*-benzyl- (9*Z*,12*Z*,15*Z*)-octadecatrienamide and *N*-benzyl-(9*Z*,12*Z*,15*Z*)-octadecadienamide and methoxy-*N*-benzyloctadecatrienamide. Macamides *N*-benzylpalmitamide, *N*-benzyloleamide and *N*-(3-methoxybenzyl) palmitamide were isolated from maca pentane extract (Alquraini et al. 2014). Hadju et al. (2014) isolated the following macamides (*N*-alkylamides) from maca roots: *N*-(3-methoxybenzyl)-(9*Z*,12*Z*,15*Z*)-octadecatrienamide, *N*-benzyl-(9*Z*,12*Z*,15*Z*)-octadecatrienamide and *N*-benzyl-(9*Z*,12*Z*)-octadecadienamide.

The macaene and macamide of the purified standardised product, M-01 and M-02, of dried maca tubers were determined by high-performance liquid chromatography and included three new compounds, *N*-benzyl octanamide, *N*-benzyl-16-hydroxy-9-oxo-10*E*,12*E*,14*E*-octadecatrieneamide and *N*-benzyl-9,16-dioxo-10*E*,12*E*,14*E*-octadecatrieneamide and 17 other analogues of macaene and macamide (Zheng et al. 2000). The product also contained 3.72 % free fatty acids, which included 0.14 % caprylic acid, 0.13 % capric acid, 0.97 % lauric acid, 0.38 % myristic acid, 0.67 % palmitic acid, 0.92 % palmitoleic acid, 0.17 % stearic acid, 0.21 % oleic acid, 0.69 % linoleic acid and 0.33 % linolenic acid. Other minor constituents were 0.03–0.04 % sterols (campesterol, stigmasterol, β -sitosterol) and 0.10–0.15 % benzyl isothiocyanate.

Putative active constituents of maca extract contained mg/g: linoleic acid (18:2) 35.5 mg, palmitic acid (C16:0) 25.8 mg, oleic acid (C18:1) 18.5 mg, α -linolenic acid (C18:3) 17.2 mg, β -sitosterol 5.7 mg and campesterol 1.4 mg and macamides *N*-benzylhexadecanamide 5 mg and *N*-benzyl-5-oxo-6*E*,8*E*-octadecadienamide 2.9 mg (Cho et al. 2013).

Benzyl isothiocyanate was the principal isothiocyanate isolated together with small amount of *p*-methoxybenzyl from maca roots (Johns 1981). Two glucosinolates benzyl glucosinolate (glucotropaeolin) and *m*-methoxybenzyl glucosinolate were isolated from the methanol extract of maca tubers (Dini et al. 2002). Bernart (2006) quantified benzyl isothiocyanate released by the hydrolytic action of the thioglucosidase enzyme on the substrate glucotropaeolin, the predominant glucosinolate of maca hypocotyls. The methanol maca root extract was found to contain free sugars and amino acids; glucosinolates, glucotropaeolin and 3-methoxyglucotropaeolin; isothiocyanates benzyl isothiocyanate and 3-methoxybenzylisothiocyanate; and other compounds (uridine, malate, benzoylmalate) and an alkaloid (1*R*,3*S*)-1-methyltetrahydro- β -carboline-3-carboxylic acid, a molecule which is reported to exert many activities on the central nervous system (Piacente et al. 2002). Another alkaloid identified as a benzylated 1,2-dihydro-N-hydroxypyridine derivative named macaridine was isolated (Muhammad et al. 2002). Two imidazole alkaloids (lepidiline A and lepidiline B) were isolated from maca tuber and identified as 1,3-dibenzyl-4,5-dimethylimidazolium chloride (1) and 1,3-dibenzyl-2,4,5-trimethylimidazolium chloride (2), respectively (Cui et al. 2003). Maca was found to contain a mixture of alkaloids known as macaines 1, 2, 3 and 4 (Chac'on de Popovici 1997; Dini et al. 1994). The contents of total alkaloids in purple maca, white maca and yellow maca cultivated in Yunnan were 4.4078, 2.9193 and 2.2241 mg/g, respectively (Gan et al. 2010). The content of total alkaloids in purple maca was the highest and close to the content of total alkaloids in maca grown in Peru. Maca was found to contain 5 % alkaloids using ultrasonic-assisted extraction with ratio of solid-to-liquid 1:40, time 30 minutes, temperature 70 °C and ultrasonic power 200 W (Du and Pu 2011). Luo et al. (2011) used a combination of ultrasonic wave and microwave for extraction of maca alkaloids. The best condition was determined as ultrasonic power of 300 W, microwave power of 352 W, time of 1.2 minutes and solution-to-solid ratio of 60:1 (mL/g), and the content of alkaloids of maca extracted could reach 0.69 %, which was 8.7 % higher than the Soxhlet extraction method.

The following compounds were used as the main marker compounds for maca and its products: linoleic acid, linolenic acid, macaene and macamides, *N*-benzyl-5-oxo-6*E*, 8*E*-octadecadienamide and *N*-benzylhexadecanamide (Ganzera et al. 2002). Jin et al. (2007a) found that major essential oil components (e.g. phenylacetonitrile, benzaldehyde, 3-methoxyphenylacetonitrile) of maca produced distinct characteristic peaks, and these behaviours could be applied to the identification of maca or maca products in the market. A total of 32 components (totalling 1.72 %) were identified in the essential oil extracted from Xinjiang maca by steam distillation (Jin et al. 2009). The main components were identified as benzyl isothiocyanate and benzyl nitrile. Meng et al. (2013) found differences in major compounds extracted from maca using different extraction methods and solvents. The main compounds of essential oils extracted from maca by petroleum ether leaching were [(1,1-dimethylethoxy)methyl]-benzene (26.00 %), *N*-(phenylmethyl)-acetamide (23.47 %) and phthalic acid hexyl octyl ester (23.49 %). The main compounds extracted by steam distillation were 1-isocyano-2-methyl-benzene (81.80 %), while those by ether extraction were benzyl nitrile (56.29 %) and methoxy-acetaldehyde (10.35 %). Volatile compounds from maca root and leaf were different from those of the essential oil or other extracts (Zheng et al. 2013). In the root volatiles, isothiocyanate contents were the highest (27.26 %), especially 4-ethylphenyl isothiocyanate (>20 %), followed by chloro compounds (circa 20 %) and tetrahydro-3-methylfuran (14 %). These three types of chemicals were probably important factors for maca's special odour. In the leaf volatiles, the highest contents (about 30 %) were found in acids and anhydrides. Ester (<5 %) and terpene (<1 %) compounds in the volatiles of root and leaf were different from that found in maca essential oil.

The major glucosinolates found in fresh maca hypocotyls were the aromatic glucosinolates, benzyl glucosinolate (glucotropaeolin) (16.94 $\mu\text{Mol/g}$) and *p*-methoxybenzyl glucosinolate (6.38 $\mu\text{Mol/g}$), and other glucosinolates such as 5-methyl sulfinylpentyl glucosinolate (glucoalyssin) (0.57 $\mu\text{Mol/g}$), *p*-hydroxybenzyl glucosinolate (glucosinalbin) (1.61 $\mu\text{Mol/g}$), *m*-hydroxybenzyl glucosinolate (0.3 $\mu\text{Mol/g}$), pent-4-

enyl glucosinolate (glucobrassicinapin) (0.15 $\mu\text{Mol/g}$), indolyl-3-methyl glucosinolate (glucobrassicin) (0.05 $\mu\text{Mol/g}$) and 4-methoxyindolyl-3-methyl glucosinolate (4-methoxyglucobrassicin) (0.2 $\mu\text{Mol/g}$) (Li et al. 2001). Total glucosinolates found in maca hypocotyls were 25.66 $\mu\text{Mol/g}$.

At harvest, six glucosinolates (GLs) were identified: 5-methylsulfinylpentyl, 4-hydroxybenzyl, benzyl, 3-methoxybenzyl, 4-hydroxy-3-indolylmethyl and 4-methoxy-3-indolylmethyl, of which benzyl glucosinolate was the most abundant in the hypocotyls of yellow, red and black maca ecotypes, representing 80 % of the total GLs (Yábar et al. 2011). A significant increase in GLs was observed for the three ecotypes during the 90 days before harvest and during the 15–30 days of postharvest drying. This was followed by an important decrease of GLs during the 30–45-day period, which was attributed to cell breakdown, due to fluctuations in temperatures during the drying process and was correlated with a high myrosinase action. During the last period of postharvest drying, GLs were much lower and correlated to lower myrosinase activity and lower maca hypocotyl humidity. Tu et al. (2011) found that myrosinase in maca could be inactivated completely after 60 seconds microwave treatment at a microwave intensity of 14 W/g and a material/liquid ratio of 2:1 (g/mL). The losses of glucosinolates and vitamin C in maca subjected to microwave treatment revealed a decrease by 28 % and 21 % when compared with conventional hot water blanching. However, no significant difference in protein loss between both treatment methods was observed.

Clément et al. (2010a) found that in maca hypocotyls, the colour type effect was significant for most secondary metabolites; exceptions were β -sitosterol and campesterol. The lead-coloured, yellow and violet maca hypocotyls were rich in glucosinolates, macaene and macamides, respectively. Previous cultivation affected macaene, campesterol and indole glucosinolate concentrations. Effects on metabolite concentrations in the leaves were minor. Hypocotyls were richer in macaene, macamides and glucosinolates than were leaves but were poorer in β -sitosterol and total phenols. Leaves may be interesting for animal nutrition purposes as

they contained essentially the same secondary metabolites as the hypocotyls but in clearly lower concentrations. Zhao et al. (2012) found that planting site was the major determining factor with regard to metabolite variations in maca hypocotyls, while the colour of maca accession appeared to be of minor importance in this respect.

Maca was found to contain (1R,3S)-1-methyl-1,2,3,4-tetrahydro- β -carboline-3-carboxylic acid (MTCA), a biologically active alkaloid (Gonzales and Gonzales-Castañeda 2009). Maca meal was reported to contain flavonoids like quercetin (Lee et al. 2005). Optimal conditions for the ultrasonic-assisted extraction of flavonoids from maca by response surface methodology were an ethanol concentration of 70.3 %, solid-to-liquid of 1:27 and ultrasonic time of 28.4 minutes (Zhou et al. 2012).

Seed Phytochemicals

In maca seeds, the glucosinolates were: 5-methyl sulfinylpentyl glucosinolate (glucoalyssin) (11.18 $\mu\text{Mol/g}$), *p*-hydroxybenzyl glucosinolate (glucosinalbin) (1.7 $\mu\text{Mol/g}$), *m*-hydroxybenzyl glucosinolate (19.31 $\mu\text{Mol/g}$), benzyl glucosinolate (glucotropaeolin) (29.7 $\mu\text{Mol/g}$) and 4-methoxyindolyl-3-methyl glucosinolate (4-methoxyglucobrassicin) (7.56 $\mu\text{Mol/g}$) (Li et al. 2001). Total glucosinolates found in maca seeds were 69.45 $\mu\text{Mol/g}$.

Leaf Phytochemicals

In maca fresh leaves, the glucosinolates were the same as those found in the hypocotyls: 5-methyl sulfinylpentyl glucosinolate (glucoalyssin) (0.09 $\mu\text{Mol/g}$), *p*-hydroxybenzyl glucosinolate (glucosinalbin) (0.25 $\mu\text{Mol/g}$), *m*-hydroxybenzyl glucosinolate (0.2 $\mu\text{Mol/g}$), pent-4-enyl glucosinolate (glucobrassicinapin) (0.1 $\mu\text{Mol/g}$), benzyl glucosinolate (glucotropaeolin) (2.3 $\mu\text{Mol/g}$), indolyl-3-methyl glucosinolate (glucobrassicin) (0.02 $\mu\text{Mol/g}$), *p*-methoxybenzyl glucosinolate (0.66 $\mu\text{Mol/g}$) and 4-methoxyindolyl-3-methyl glucosinolate (4-methoxyglucobrassicin) (0.15 $\mu\text{Mol/g}$) (Li et

al. 2001). Total glucosinolates found in maca fresh leaves were 3.7 $\mu\text{Mol/g}$.

Maca leaves and roots were found to contain large quantities of glucosinolates with glucotropaeolin as the main glucosinolate around 20 $\mu\text{mol/g dm}$ in the leaves and up to 195 $\mu\text{mol/g dm}$ in the roots (Marthe et al. 2003). In addition, other glucosinolates were found in leaf and root in smaller amounts: sinalbin, benzyl glucosinolate, 4-hydroxy-glucobrassicine, benzyl glucosinolate and 4-methoxy-glucobrassicine. Glucosinolates X6 and X8 were not identified. Also, small quantities of flavonoids were determined, but not identified.

Fourteen components were identified in yellow maca leaf oil, which represented more than 99 % of the total composition of the oil (Wang and Zhao 2011). The major components of yellow maca leaf oil were: butanol (26.35 %), ethyl acetate (17.10 %) and benzyl isothiocyanate (16.95 %). Other minor constituents were acetaldehyde diethyl acetal (3.04 %), benzyl nitrile (2.88 %), benzyl thiocyanate (2.04 %), tricosane (3.90 %), 4-methoxybenzylisothiocyanate (0.68 %), docosane (0.20 %), tetracosane (2.67 %), pentacosane (6.92 %), heptacosane (10.52 %), octacosane (6.48 %) and nonacosane (0.25 %). The red maca leaf oil was found to contain appreciable amounts of butanol (66.02 %), heptacosane (8.90 %) and pentacosane (7.33 %). Other minor components were ethyl acetate (5.81 %), benzyl isothiocyanate (1.02 %), docosane (0.42 %), tricosane (5.74 %), tetracosane (0.64 %), octacosane (3.81 %) and nonacosane (0.23 %).

Phenyl acetonitrile (85.9 %), benzaldehyde (3.1 %) and 3-methoxyphenylacetonitrile (2.1 %) were the major components of the 53 components steam distilled oil from maca aerial plant (Tellez et al. 2002).

Phytochemicals in Maca Products

The following glucosinolates ($\mu\text{M/g}$) were found in some products derived from maca (Li et al. 2001): sprout 5-methylsulfinylpentyl glucosinolate (0.73 μM), *p*-hydroxybenzyl glucosinolate (12.64 μM), benzyl glucosinolate (0.2 μM) and *p*-methoxybenzylglucosinolate (4.66 μM); flour

5-methylsulfinylpentyl glucosinolate (0.05 μM), *p*-hydroxybenzyl glucosinolate (0.49 μM), benzyl glucosinolate (2.7 μM) and *p*-methoxy-benzylglucosinolate (0.88 μM); capsule 5-methylsulfinylpentyl glucosinolate (0.11 μM), *p*-hydroxybenzyl glucosinolate (0.50 μM), benzyl glucosinolate (3.78 μM), *p*-methoxy-benzylglucosinolate (1.35 μM) and 4-methoxyindolyl-3-methyl glucosinolate (1.01 μM); pill 5-methylsulfinylpentyl glucosinolate (0.1 μM), *p*-hydroxybenzyl glucosinolate (0.41 μM), benzyl glucosinolate (2.31 μM) and *p*-methoxybenzylglucosinolate (0.58 μM); and mayonnaise allyl glucosinolate (sinigrin) (2.14 μM), benzyl glucosinolate (0.48 μM), *p*-methoxybenzylglucosinolate (0.07 μM). No glucosinolates were detected in liquor and tonic. β -sitosterol was extracted from the lipid fraction of maca; from 5 g of dry maca flour and 8 g of maca; pill, 0.18 mg and 0.22 mg of β -sitosterol per gram of sample were obtained (Parvina et al. 2009).

Pharmacological Activities

Numerous studies had reported on the effects of maca on sexual function, spermatogenesis, female reproductive function, memory, ageing, depression and anxiety and energy as well as effects on benign prostatic hyperplasia, osteoporosis, metabolic syndrome and safety in consumption (Gonzales et al. 2014). Differences have been shown between the effects of the black, yellow and red maca varieties. Black maca showed the best results on spermatogenesis, memory and fatigue, while red maca is the variety that is effective in reversing benign prostatic hyperplasia and experimentally induced osteoporosis. In addition, maca reduced the glucose levels, and its consumption was related to the lowering of blood pressure and an improved health score. Maca alkaloids, steroids, glucosinolates, isothiocyanates and macamides were held to be probably responsible for its aptitude to act as a fertility enhancer, aphrodisiac, adaptogen, immunostimulant and anabolic and to influence hormonal balance (Valentová and Ulrichová 2003). Experimental scientific evidence showed maca to have nutritional, energiser and fertility-enhancer properties and to act on sexual dysfunctions as well as

increasing sperm count and motility, osteoporosis, benign prostatic hyperplasia, memory and learning and to protect skin against ultraviolet radiation (Gonzales 2012). Randomised clinical trials had shown that maca has favourable effects on energy and mood and may decrease anxiety and improve sexual desire. Maca had also been shown to improve sperm production, sperm motility and semen volume (Gonzales et al. 2009). Maca also exhibited great potential as an adaptogen and appeared to be promising as a nutraceutical in the prevention of several diseases. Muhammad et al. (2005) had published a review on maca providing an analysis of in-vitro and in-vivo biological activity, including clinical studies of various crude extracts from different types of maca for its uses for nutritional, chemoprevention, aphrodisiac and fertility-enhancing purposes.

Antioxidant Activity

The aqueous extract of maca (0.3–1 mg/mL) scavenged peroxynitrite (300 mM) by 15.0 and 41.1 %, respectively (Sandoval et al. 2002). Maca (0.03–3 mg/mL) quenched DPPH (100 mM) in a dose-dependent manner with IC₅₀ value for DPPH inhibition was 0.61 mg/mL. Results from the peroxy assays indicated that maca decreased peroxy formation, a key step in lipid peroxidation with IC₅₀ value for peroxy was 0.43 mg/mL. The results demonstrated that maca contained water-soluble scavengers that may contribute to decompose peroxyls produced during inflammatory states; hence maca may provide cytoprotective effects. Also, maca (1–3 mg/mL) afforded deoxyribose protection against hydroxyl radicals in the range of 57–74 %, respectively. Maca (1 mg/mL) protected Raw 264.7 macrophages against DNA damage induced by peroxynitrite in which had been shown to induce apoptosis in several cell lines and increased ATP production in cells treated with hydrogen peroxide. The concentrations of catechins in maca was lower than in green tea (2.5 mg vs 14.5 mg/g). The catechins found in maca included: catechin 0.32 mg/g, epicatechin 0.17 mg, epicatechin gallate 0.37 mg, epigallocatechin 0.66 mg and epigallocatechin gallate 0.92 mg. The results indicated that

maca had the capacity to scavenge free radicals and to protect cells against oxidative cells. The observed cytoprotective effects of maca may be due in part to its capacity to diminish the deleterious effects of excessive production of reactive oxygen species.

The aqueous and methanol extracts of dehydrated maca hypocotyl exhibited weak DPPH radical scavenging activity with IC_{50} values of 3.46 and 0.71 mg/mL, respectively (Valentová et al. 2006). The extracts did not exhibit cytotoxicity in hepatocyte primary cultures up to 10 mg/mL as measured by the MTT viability test and lactate dehydrogenase (LDH) and aspartate aminotransferase (AST) leakage. Moreover, after 72 hours, the extracts inhibited LDH and AST leakage from the hepatocytes. When hepatocytes were intoxicated by t-butyl hydroperoxide, neither extract prevented oxidative damage. In contrast, Lee et al. (2005) reported an IC_{50} of 100–500 μ g/mL for DPPH scavenging activity.

The extraction yields of maca with water, methanol and ethanol extracts were 46.2 %, 21.4 % and 16.8 %, respectively, while the acetone, ethyl acetate, chloroform and hexane exhibited very low extraction yield, ranging from 0.2 to 1.0 % (Kwon et al. 2009). Total polyphenol contents and the nitrite scavenging ability were the highest in maca water extract. Electron-donating ability and the superoxide dismutase (SOD)-like activity were the highest in the methanol extract. When water extract was drawn out at different extraction temperatures (30, 70, 100 °C) and time (1, 3, 5 hours), the improved biological activities (total polyphenol contents, electron donating ability, SOD-like activity and nitrite scavenging ability) were found in extracts treated at 100 °C for 3 or 5 hours). Maximum yields of 16.4 μ mol/g of dried matter (DM), 9.89 mg of gallic acid equivalents (GAE)/g of DM and 61.4 μ mol of trolox equivalents (TE)/g were obtained from maca hypocotyls at conditions of 47, 70 and 70 °C; liquid-to-solid ratio of 10, 16 and 10 ml/g; extraction time of 90, 30 and 48 minutes; and ethanol concentration of 60 %, 60 % and 50 %, for glucosinolates (GLs), total phenolic compounds (TPC) and antioxidant capacity (AC), respectively (Campos et al. 2013). Optimal extraction conditions for the simultaneous

extraction of GLs, TPC and AC determined by response surface methodology were 70 °C, 10 ml/g, 90 minutes and 58 % ethanol with extraction yields of 14.2 µmol/g of DM, 9.3 mg of GAE/g of DM and 56.9 µmol TE/g for GLs, TPC and AC, respectively. Under these conditions, glucotropaeolin represented 79 % of total GLs, and catechins and gallocatechin derivatives represented 97 % of total phenolics.

Maca polysaccharide exerted weak effect of scavenging superoxide anion $O_2^{\cdot-}$, but it exhibited a significant potency in inhibiting murine erythrocyte haemolysis; the maximal rate of inhibition was 76.9 % when its concentration reached 50 µg/mL (Zhang et al. 2005). It also reduced lipid peroxidation; malondialdehyde was remarkably decreased in guinea pig liver homogenate. Pu and Wang (2009) reported maca polysaccharide exhibited marked effect of antioxidation in-vitro. Their studies showed that 80 % alcohol-precipitated polysaccharide of maca had the strongest in-vitro antioxidant activities (DPPH radical, the ability to remove hydroxyl radical and the scavenging activity of superoxide anion radical) while the 60 % alcohol-precipitated polysaccharides had the weakest in-vitro antioxidant activities. Chen et al. (2010) reported that antioxidation before and after carboxymethylation showed maca polysaccharide to be quite effecting in scavenging hydroxyl free radical using the Fe^{2+} – H_2O_2 system. Antioxidant activity tests revealed that of four *Lepidium meyenii* polysaccharides LMP-60, LMP-70, LMP-80 and LMP-90, and LMP-60 showed good capability of scavenging hydroxyl free radical and superoxide radical at 2.0 mg/mL; the scavenging rates were 52.9 % and 85.8 %, respectively (Zha et al. 2014).

Anticancer Activity

Benzyl isothiocyanate had been reported to exert an inhibitory effect on the occurrence of 7,12-dimethylbenz(a)anthracene-induced neoplasia of the breast of Sprague-Dawley rats (Watterberg 1981). Benzyl isothiocyanate was found to have chemopreventive effects against diethylnitrosamine (DEN)-induced hepatocarcinogenesis in rats (Sugie et al. 1993). Maca

imidazole alkaloid compounds 1,3-bis(phenylmethyl)-4,5-dimethyl-1H-imidazolium chloride and 1,3-bis(phenylmethyl)-2,4,5-trimethyl-1H-imidazolium chloride exhibited potential to treat proliferative diseases, including cancer (Cui et al. 2005).

Lepidium meyenii (Red Maca) was listed as one of several plants providing some improvements on benign prostatic hyperplasia (Shrivastava and Gupta 2012).

Freeze-dried aqueous extract of red maca, hydroalcoholic extract of red maca and finasteride reduced prostate weight in rats with prostatic hyperplasia induced by testosterone enanthate (Gonzales et al. 2007, 2008). No difference was observed between the data obtained from aqueous extract or hydroalcoholic extract of red maca. A dose-dependent reduction of prostate weight was observed with the increase of the dose of benzyl glucosinolates in red maca extracts. Testosterone enanthate increased prostatic stromal area, and this effect was prevented by treatment with red maca after 7 days treatment. After 21 days of treatment with red maca, prostate size and weight of prostate hyperplastic mice were reduced. In another study, red maca administered orally in rats appeared to exert an inhibitory effect at a level post-DHT (dihydrotestosterone) conversion, on testosterone enanthate-induced benign prostatic hyperplasia (Gasco et al. 2007b). The prostate weight diminished in a dose-dependent fashion in rats treated with red maca, and the effect of red maca was better than that observed with finasteride. Administration of red maca extract from day 1 to day 14 reduced prostate size and zinc levels in rats with prostatic hyperplasia induced by testosterone enanthate (Gonzales et al. 2012).

Fertility Enhancing/Aphrodisiac/Sexual Dysfunction Ameliorating Activities

Maca is an Andean plant with multipharmacological functions, but most scientific attention had been focused in the areas of enhancement of sexual drive in humans, increasing overall vigour and energy levels and increasing sexual fertility in humans and domestic livestock (Wang et al. 2007). *Lepidium*

meiyenii had been included in the list of plants with poetical as alternative treatments for female sexual dysfunction (Mazaro-Costa et al. 2010).

In-Vitro Studies

Maca extracts (obtained with different solvents: methanol, ethanol, hexane and chloroform) did not exert direct androgenic activities (Bogani et al. 2006). The extracts were not able to regulate GRE (glucocorticoid response element) activation. They suggested that further studies were needed to elucidate which compound, of the several Maca's components, was responsible for the observed in-vivo effects. Both methanolic and aqueous maca hypocotyl extracts exhibited estrogenic activity comparable with that of silymarin in MCF-7 human breast cell line (Valentova et al. 2006). Maca oestrogenicity was exhibited in the range from 100 to 200 µg of extract per ml. Both extracts did not exhibit cytotoxicity in hepatocyte primary cultures up to 10 mg/mL. Moreover, after 72 hours, both extracts inhibited lactate dehydrogenase and aspartate aminotransferase leakage from the hepatocytes. In contrast, a slight cytoprotective effect, probably not mediated by antioxidant capacity, was noted.

Animal Studies

In-vivo studies in rats by Chacón (1990) and Rea (1992) indicated that feeding female rats with maca extract enhanced fertility probably by stimulating the maturation of the Graaf follicles. In males, maca extract was found to stimulate spermatogenesis (Chacón 1990). Johns (1981) suggested that the fertility-enhancing properties of maca may be due to the presence of biologically active aromatic isothiocyanates derived by hydrolysis of the glucosinolates and specifically due to benzyl isothiocyanate and *p*-methoxybenzyl isothiocyanates. The putative aphrodisiac powers of maca could also be attributed to the presence of prostaglandins and sterols in the hypocotyls (Dini et al. 1994) and to the amides of polyunsaturated fatty acids, which were presumably found to enhance sexual function in rats and mice (Zheng et al. 2000).

Oral administration of a purified lipidic maca extract enhanced the sexual function of mice and rats, as evidenced by an increase in the number of complete intromissions and the number of sperm-positive females in normal mice and a decrease in the latent period of erection in male rats with erectile dysfunction (Zheng et al. 2000). The study suggested an aphrodisiac activity of *L. meyenii* presumably attributable to the presence of amides of polyunsaturated fatty acids in the extract. Studies by Cicero et al. (2001) found both acute and chronic maca oral administration significantly improved sexual performance parameters in male rats. After 15 days of maca treatment, both doses (15 and 75 mg/kg) were able to significantly decrease first mount, first intromission, ejaculation and post-ejaculatory latencies, while the 75 mg/kg dose decreased the intercopulatory interval too. The chronic maca treatment induced an apparently non dose-related increase in rat locomotion. In further studies, they found oral administration of hexanic, methanolic and chloroformic extracts of maca root significantly decreased intromission latency and intercopulatory interval and increased intromission frequency and copulatory efficacy of sexually inexperienced male rats as compared to controls (Cicero et al. 2002). Hexanic and methanolic extracts were able to increase mount frequency (MF), while only hexanic fraction significantly improved mount latency. Overall, only the hexanic fraction significantly improved the majority of the sexual parameters measured.

Oshima et al. (2003) found that progesterone levels increased significantly in mice that received maca, while testosterone levels increased significantly in mice that received maca as well as in those that received both maca and *Jatropha macrantha*. However, there were no marked changes in blood levels of oestradiol-17beta or the rate of embryo implantation. Oral administration of the ethanol maca extract at 48 mg/day or 96 mg/day activated onset and progression of spermatogenesis in rats (Gonzales et al. 2003b). Gonzales et al. (2004) found that treatment of rats with maca at high altitude prevented high altitude-induced spermatogenic disruption. Exposure to high altitude resulted in a reduction in epididymal sperm count after 7 days, and lower values were

maintained up to 21 days. Altitude reduced spermiation (stage VIII) to half and the onset of spermatogenesis (stages IX–XI) to a quarter on days 7 and 14, but treatment with maca (666.6 mg/day) prevented these changes. Data on transillumination and epididymal sperm count in the maca-treated group exposed to high altitude were similar to those obtained at sea level. Furthermore, in the maca-treated group exposed for 21 days to high altitude, epididymal sperm count was higher than in the non-treated group at sea level.

Treatment of male rats with maca resulted in an increase in the weights of testis and epididymis, but not the seminal vesicle weight (Gonzales et al. 2001b). The length and frequency of stages IX–XIV seminiferous tubules, where mitosis occurred, were increased, and stages I–VI were reduced in rats treated with maca. The results indicated that maca invigorated spermatogenesis in male rats by acting on its initial stages. Black maca was found to increase sperm count at epididymal level as early as 1 day after beginning of treatment and to increase in sperm count at the vas deferens of male rats (Gonzales et al. 2006a). Maca treatment enhanced spermatogenesis following spermatogenic damage induced by a single dose of organophosphate insecticide malathion in mice (Bustos-Obregon et al. 2005). Assessment of the relative length of stages of the seminiferous epithelium showed that maca treatment resulted in rapid recovery from the effect of malathion.

Rubio et al. (2006b) reported that maca administration reduced the deleterious effect on daily sperm production of rats caused by lead acetate treatment suggesting that Maca may have potential in the treatment of male infertility associated with lead exposure. Of the maca genotypes, black maca increased daily sperm production and epididymal sperm motility in adult rats (Gonzales et al. 2006b). Red or yellow maca did not alter daily sperm production, and epididymal sperm motility was not affected by treatment with any ecotype of maca. Red maca, however, has no effect on sperm production. However, red maca has been shown to reduce prostate size in rats in which prostate hyperplasia had been induced with testosterone enanthate; yellow maca has shown

moderate effects here, whereas black and yellow maca did not shown any effects. In-vivo studies in rats demonstrated that maca extract in doses up to 5 g/kg (equivalent to the intake of 770 g hypocotyls in a man of 70 kg) was safe and that higher effect on reproductive parameters was elicited with a dose of 1 g extract/kg corresponding to 2.2 g dry maca hypocotyls/kg (Chung et al. 2005). Almost all organ weights were similar in controls and in the maca extract-treated groups.

Acute and short-term administration of maca produced a small effect of male rat sexual behaviour, and long-term administration did not increase anxiety or locomotion (Lentz et al. 2007). An increase in ejaculation latency and post-ejaculatory interval was observed after both acute and 7 days of treatment. Treating male rats by gavage with aqueous extract yellow and black maca increased epididymal sperm count and sperm count in vas deferens after 84 days of treatment without affecting daily sperm production (Gasco et al. 2007a). Maca appeared to act as a modulator of sperm count at the reproductive tract level. In another study, administration of the ethyl acetate fraction from the hydroalcoholic extract of black maca to male rats for 7 days increased daily sperm production and epididymal sperm count suggesting that the compounds related to the beneficial effect on sperm production of black maca were presented in this fraction (Yucra et al. 2008). Antioxidant components could play a role in the effect of increased epididymal sperm concentration observed in the model. Black maca increased stages of spermiation (VII–VIII) and mitosis of germ cells (IX–XI) in male rats, whereas camu camu fruit (*Myrciaria dubia*) increased stages of mitosis (IX–XI) and meiosis (XII) (Gonzales et al. 2013c). Mixture of maca + camu camu increased stages of spermiation, mitosis and meiosis. All treatments increased daily sperm production and epididymal sperm count. Total polyphenols, flavonoids levels and antioxidant activity were higher in camu than in black maca. They concluded that camu camu had potential effects improving spermatogenesis and co-administered with maca increased stages of mitosis, meiosis and spermiation of the spermatogenic cycle of rats. Administration of a hydroalcoholic extract of *Fagara tessmannii* (1 g) and

Lepidium meyenii (black maca) (50 mg) together to rats significantly increased the number of spermatids, epididymis sperm count, daily sperm production and serum testosterone concentration when compared to the control (Lembè et al. 2014). The results indicated that the combination of *Lepidium meyenii* (black maca) with *Fagara tessmannii* could improve male reproductive organs activities in rats.

Administration of aqueous extract of yellow maca to adult female mice increased the litter size (Ruiz-Luna et al. 2005). Moreover, this treatment increased the uterine weight in ovariectomised animals. The results of the study confirmed for the first time some of the traditional uses of maca to enhance female fertility. In another study, administration of maca ethanol extract daily for 7 months ameliorated endocrine disruption after ovariectomy in rats (Zhang et al. 2008). Compared with the ovariectomised control rats, serum follicle-stimulating hormone level decreased markedly after treatment with 1.25 and 0.5 g/kg of maca extract; serum oestradiol level increased with 0.5 g/kg, but the serum testosterone level did not change at the end of 7th month. Also, maca extract decreased serum cholesterol and triglyceride levels at the end of 7th month. Lembè et al. (2012) found that female mice treated with black maca (BM) and *Turraeanthus africanus* (TA) significantly increased embryo implantation in pregnant mice and the uterine weight of non-pregnant mice compared to TA alone and control. The length of the oestrous cycle of BM+TA-treated mice was significantly shorten. At the pro-oestrous stage, the oestradiol level significantly increased in animals treated with BM+TA, and at oestrous stage only the oestradiol level of BM+T-treated animal significantly increased. Recent studies demonstrated that feeding female rats with 50 % maca powder for 7 weeks enhanced the luteinising hormone serum levels (4.5-fold) during the pro-oestrus luteinising hormone surge and follicle-stimulating hormone (19-fold) and acted in a pharmacological, dose-dependent manner (Uchiyama et al. 2014).

In a crossover design lasting for 23 weeks involving seventy-eight 55–84-week-old breeding bulls, maca diet supplementation had no direct effect on body weight, testes

circumference, rectal temperature, mating behaviour and ejaculate volume (Clément et al. 2010b). However, supplementing maca in the first 10-week period increased the number of sperms in the second 10-week period, i.e. when the animals no longer received maca. The DNA fragmentation index and the visually assessed motility of the sperms of bulls, that initially showed a borderline sperm quality, were significantly improved with early maca supplementation.

Clinical Studies

In a study of nine normal adult men, treatment with maca (1,500 or 3,000 mg/day) for 4 months resulted in increased seminal volume, sperm count per ejaculum, motile sperm count and sperm motility (Gonzales et al. 2001a). Serum luteinising hormone, follicle-stimulating hormone, prolactin, testosterone and oestradiol levels were not modified with maca treatment. In a 12-week double-blind, placebo-controlled, randomised, parallel trial of man aged between 21 and 56 years, an improvement in sexual desire was observed with maca after 8 weeks of treatment; however, maca treatment did not affect serum reproductive hormone (luteinising hormone, follicle-stimulating hormone, prolactin, 17- α hydroxyprogesterone, testosterone and 17- β -oestradiol) levels (Gonzales et al. 2002, 2003a). Maca was well tolerated and may also have a beneficial effect on libido. In another double-blind, randomised, placebo clinical trial on 50 adult Caucasian men affected by mild erectile dysfunction, 12 weeks supplementation with maca extract produced a small but significant improvement on subjective perception of general and sexual well-being in the adult patients (Zenico et al. 2009).

In a double-blind, placebo-corrected clinical pilot study of 20 Caucasian healthy early-postmenopausal women, administration of maca organic pre-gelatinised root powder (Maca-GO) capsules, the level of follicle-stimulating hormone (FSH) significantly decreased with a simultaneous significant increase in the luteinising hormone (LH) level, resulting in significant increase in both oestrogen (E2) and progesterone (PG), after 8 months treatment (Meissner et al. 2005, 2006c).

Changes in hormone levels were accompanied by substantially reduced feeling of discomfort associated with menopause. The results showed that in addition to reduction in body weight, blood pressure, triglycerides and cholesterol levels and increasing serum HDL and iron, pre-gelatinised Maca-GO may be a valuable non-hormonal plant preparation for balancing levels of hormones (FSH, E2, PG and adrenocorticotrophic hormone (ACTH)) and alleviating negative physiological and psychological symptoms (frequency of hot flushes, incidence in night sweating, interrupted sleep pattern, nervousness, depression and heart palpitations) experienced by women in perimenopausal stage. It appeared that Maca-GO may act as a toner of hormonal processes, leading to alleviation of discomfort felt by perimenopausal women, hence its potential use as non-hormonal alternative to HRT (hormone replacement therapy) programme. Similar results were obtained with in another double-blind, randomised, 4 months outpatient crossover configuration trial in which total of 34 Caucasian women volunteers participated (Meissner et al. 2006b). Two months application of Maca-GO stimulated production of E2; suppressed blood FSH, thyroid (T3) and ACTH, cortisol and body mass index; increased low-density lipoproteins and blood iron; and alleviated menopausal symptoms. Maca-GO noticeably increased bone density markers. The results suggested that Maca-GO applied to early-postmenopausal women (i) acted as a toner of hormonal processes along the hypothalamus–pituitary–ovarian axis, (ii) balanced hormone levels and (iii) relieved symptoms of menopausal discomfort (hot flushes and night sweating in particular), thus (iv) exhibited a distinctive function peculiar to adaptogens, providing an alternative non-hormonal plant option to reduce dependence on HRT. Similar results were obtained in a larger double-blind, randomised, placebo-corrected, outpatient, multi-centre (five sites) clinical study, in which a total of 168 Caucasian early-postmenopausal women volunteers (age >49 years) participated and 124 completed the study (Meissner et al. 2006a). Maca-GO significantly stimulated production of E2 with a simultaneous suppression of blood FSH, increase) in HDL. Maca-GO significantly reduced both frequency and

severity of individual menopausal symptoms (hot flushes and night sweating in particular) resulting in significant alleviation of Kupperman's Index (from 22 to 10). In another randomised, double-blind, placebo-controlled, crossover trial of 14 postmenopausal women, ingestion of powdered maca (3.5 g/day) for 6 weeks reduced psychological symptoms, including anxiety and depression, and lowered measures of sexual dysfunction in postmenopausal women independent of oestrogenic and androgenic activity (Brooks et al. 2008). In a double-blind, randomised, parallel group pilot dose-finding study of remitted depressed outpatients (17 women) with selective-serotonin reuptake inhibitor (SSRI)-induced sexual dysfunction, maca treatment was found to alleviate SSRI-induced sexual dysfunction in a dose-related manner (Dording et al. 2008).

In a randomised, double-blind, placebo-controlled crossover study of 29 postmenopausal Hong Kong Chinese women, maca treatment did not exert hormonal or immune biological action in the small cohort of patients; however, it appeared to reduce symptoms of depression and improve diastolic blood pressure (Stojanovska et al. 2014). Although results were comparable to previous similar published studies in postmenopausal women, there might be a cultural difference among the Chinese postmenopausal women in terms of symptom reporting.

Review Studies/Case Report/Patents

In a review of clinical evidence for or against the effectiveness of the maca plant as a treatment for sexual dysfunction, Shin et al. (2010) found four randomised clinical trials (RCTs) met all the inclusion criteria. Two RCTs suggested a significant positive effect of maca on sexual dysfunction or sexual desire in healthy menopausal women or healthy adult men, respectively, while the other RCT failed to show any effects in healthy cyclists. An RCT assessed the effects of maca in patients with erectile dysfunction using the International Index of Erectile Dysfunction-5 and showed significant effects. The results of the systematic review conducted by Lee et al. (2011) provided limited evidence for the effectiveness of maca as a

treatment for menopausal symptoms as the total number of trials, the total sample size and the average methodological quality of the primary studies were too limited to draw firm conclusions. Beside, the safety issued has to be proven.

A young female with prolonged intermenstrual bleeding was found to have raised total plasma testosterone of 25.8 nmol/L (normal range <2.9 nmol/L) without clinical features of virulisation (Srikugan et al. 2011). Few months ago, investigations for lethargy and low libido had shown normal total testosterone of 0.8 nmol/L. Further history revealed that she was using maca extract to improve her lethargy and low libido. Reanalysis of the original serum sample using Elecsys testosterone II assay, a higher affinity assay, revealed a total testosterone level of 2.9 nmol/L. They concluded that it was important to exclude assay interference when testosterone level was greater than 5 nmol/L without supportive clinical signs.

An isolated composition obtained by extracting *Lepidium meyenii* roots with aqueous solvent, substantially free of cellulose, comprising benzyl isothiocyanate, *Lepidium* sterol component, *Lepidium* fatty acid component and macamide components, with claims of treating cancer and sexual dysfunction was lodged as separate claims with the US patent office (Zheng et al. 2001, 2002b; He et al. 2011).

Cognitive-Enhancing Activity

Black maca appeared to have more beneficial effects on latent learning in ovariectomised mice in the water finding task (Rubio et al. 2006a). All maca varieties showed antidepressant activity in the forced swimming test, reducing the time of immobility and increased uterine weight in ovariectomised mice. Aqueous and hydroalcoholic extracts of black maca significantly ameliorated the scopolamine-induced memory impairment in ovariectomised mice as measured in both the water Morris maze and the step-down avoidance tests (Rubio et al. 2007). Black maca extracts inhibited acetylcholinesterase activity, whereas monoamine oxidase activity was not affected. The results indicated that black maca improved

scopolamine-induced memory deficits. In a subsequent paper, they reported that black maca aqueous extract improved experimental memory impairment induced by ovariectomy in female mice in the water Morris maze and the step-down avoidance tests, attributed partly to its antioxidant and acetylcholinesterase inhibitory activities (Rubio et al. 2011a). Black maca decreased malondialdehyde and acetylcholinesterase levels in ovariectomised mice. The hydroalcoholic extract of black maca exhibited a dose–response effect in mice orally treated with 20 % ethanol as a model of memory impairment (Rubio et al. 2011b). Additionally, black maca and ascorbic acid ameliorated the deleterious effect of ethanol during the probe trial. The improvement of memory impairment by black maca could be attributed in part to its contents of polyphenolic compounds.

Neuroprotective/CNS Activity

Research showed that (1R,3S)-1-methyl-1,2,3,4-tetrahydro- β -carboline-3-carboxylic acid (MTCA) in maca was not neurotoxic, rather it improved memory and learning in mice (Rubio et al. 2006a, 2007) and had a favourable effect on the experimental mouse model for Alzheimer (Rubio et al. 2007); maca could provide a potential treatment for this pathology. Pentane maca extract exhibited a significant concentration-dependent neuroprotective effect on crayfish neurons subjected to hydrogen peroxide stress (Pino-Figueroa et al. 2010). Maca pentane extract administered intravenously to rats prior to and following middle cerebral artery occlusion decreased infarct volumes at low doses indicating a potential application of maca as a neuroprotectant. Studies by Vu (2012) reported that the pentane extract of maca and its macamides exerted dose-dependent fatty acid amide hydrolase (FAAH) inhibitory activity and may have potential applications as analgesics, antidepressants or anxiolytic agents. Concentration % response curve for the inhibition of human FAAH by maca pentane extract was in the range from 0.3 to 30 $\mu\text{g/mL}$ with $\text{IC}_{50} = 7.5 \mu\text{g/mL}$. FAAH IC_{50} values and maximal inhibitory activity of selected macamides were, respectively, as follows: *N*-benzyl-9Z-octadecenamide 14.18 μM , 761.3 %; *N*-(3-

methoxybenzyl)-9Z-octadecanamide 7.84 μ M, 76.39 %; *N*-benzyl-(9Z,12Z)-octadecadienamide 6.91 μ M, 83.20 %; *N*-(3-methoxybenzyl)-(9Z,12Z)-octadecadienamide 7.24 μ M, 87.50 %; *N*-benzyl-(9Z, 12Z, 15Z)-octadecatrienamide 26.94 μ M, 79.71 %; *N*-(3-methoxybenzyl)-(9Z,12Z,15Z)-octadecatrienamide 11.76 μ M, 82.78 %; and *N*-pyridine-9Z-octadecanamide 6.74 μ M, 901.0 %. Pretreatment of B-35 neuroblastoma cell line with maca pentane extract (5–50 μ g/mL) and its component macamide *N*-(3-methoxybenzyl)palmitamide (1–30 μ M) prior to exposure to a neurotoxic concentration (10 μ M) of amyloid-beta ($A\beta$) (25–35) counteracted the toxicity produced by $A\beta$ (25–35), demonstrating significant increases in cell viability (34 % and 21 %, respectively) (Alquraini et al. 2014). When the tested compounds were evaluated for antioxidant activity and their effects on caspase 3, neither the maca extract nor *N*-(3-methoxybenzyl)palmitamide demonstrated an antioxidant effect or caspase 3 inhibition suggesting that other mechanisms were involved in their neuroprotective action.

N-3-methoxybenzyl-linoleamide, an active maca macamide, displayed significant time-dependent and dose-dependent FAAH activity (Almukadi et al. 2013). The mechanism of inhibition was most likely irreversible or slowly reversible. These results suggested the potential application of macamides isolated from maca as FAAH inhibitors, as they might act on the central nervous system to provide analgesic, anti-inflammatory or neuroprotective effects, by modulating the release of neurotransmitter. Wu et al. (2013) synthesised 11 of the 19 reported macamides in *L. meyenii* and found them to be potential inhibitors of the human enzyme, FAAH. The following four most active macamides inhibited FAAH with IC_{50} values in the 10–14 μ molar range: the *N*-benzylamide of linoleic acid and the *N*-(3 methoxybenzyl)amides of oleic, linoleic and linolenic acids. Somewhat less active were the *N*-benzylamide of oleic acid (IC_{50} = 17 μ molar) and the *N*-benzylamide of linolenic acid (IC_{50} = 42 μ molar). Of the three compounds evaluated in a preincubation time study, two macamides were not irreversible inhibitors of FAAH. The third, a carbamate structurally related to macamides, was

shown to be an irreversible inhibitor of FAAH ($IC_{50} = 0.153 \mu M$).

Of the macamides (N-alkylamides) isolated from maca roots, *N*-(3-methoxybenzyl)-(9*Z*,12*Z*,15*Z*)-octadecatrienamide (5), *N*-benzyl-(9*Z*,12*Z*,15*Z*)-octadecatrienamide (6), and *N*-benzyl-(9*Z*,12*Z*)-octadecadienamide (7), compound 7 showed submicromolar and selective binding affinities for the cannabinoid CB1 receptor (K_i value of $0.48 \mu M$) (Hadju et al. 2014). Notably, compound 7 also exhibited weak fatty acid amide hydrolase (FAAH) inhibition ($IC_{50} = 4 \mu M$) and a potent inhibition of anandamide cellular uptake ($IC_{50} = 0.67 \mu M$). The pronounced endocannabinoid system polypharmacology of compound 7 highlighted the potential involvement of the arachidonoyl-mimicking 9*Z*,12*Z* double-bond system in the linoleoyl group for the overall cannabimimetic action of N-alkylamides in Peruvian maca roots.

In mice exposed to chronic unpredictable mild stress, maca extract (250 and 500 mg/kg) significantly decreased the duration of immobility time in the tail suspension test (Ai et al. 2014). After treatment with maca extract (250 and 500 mg/kg), the granule cell layer in the dentate gyrus appeared thicker. Maca extract (250 and 500 mg/kg) also induced a significant reduction in corticosterone levels in mouse serum. In mouse brain tissue, after 6 weeks of treatment, noradrenaline and dopamine levels were increased by maca extract, and the activity of reactive oxygen species was significantly inhibited. Serotonin levels were not significantly altered. These results demonstrated that maca extract (250 and 500 mg/kg) showed antidepressant-like effects and was related to the activation of both noradrenergic and dopaminergic systems, as well as attenuation of oxidative stress in mouse brain.

Adaptogenic Activity

Animal studies showed that dry maca powder had antifatigue effect (Yu and Jin 2004). It was found to contain various antifatigue substances such as branched-chain amino acids (BCAA), taurine and zinc; and its protein content reached 8.87

%). Maca was found to restore homeostasis impaired by restraint stress (López-Fando et al. 2004). It attenuated or abolished stress-induced ulcers, elevated corticosterone levels, the reduction of glucose and the increase in the weight of adrenal glands produced by stress. It also eliminated the decrease in free fatty acids (FFA) in plasma produced by stress, and a positive result was obtained in the forced swimming test. Supplementation of maca extract increased swimming endurance capacity by increasing the swimming time to exhaustion in rats (Choi et al. 2012). Lipid-soluble maca extract attenuated exercise-induced oxidative stress. Supplementation with 100 mg/kg of maca extract reduced serum lactate dehydrogenase activity and muscle lipid peroxidation and increased hepatic and muscle total glutathione compared with those values in controls.

Aqueous maca extract was found to enhance the energy of mouse in the forced swimming test (Zheng et al. 2002a). Oral administration of aqueous extracts, MacaForce™ AQ-1, AQ-2, AQ-3 and AQ-4, showed that the increase in swim time was directly related to the increase in content of polysaccharides in the aqueous extracts. Increase in serum lactate dehydrogenase (LDH) activity and decrease in the concentration of serum lactic acid were dose related with the content of potential active constituents. Administration of aqueous yellow maca extract (0.8 and 1.2 mg maca/g) to newly weaned male rats for 30 days elicited an adaptogenic effect by enhancing their endurance in the swimming test through reduction of oxidative stress (reducing superoxide dismutase, catalase and lactate dehydrogenase enzyme activities and lipid peroxidation (TBARS)) (Suárez et al. 2009).

In a pilot trial, Stone et al. (2009) found that 14 days maca extract supplementation significantly improved 40 km cycling time trial endurance performance and sexual desire in trained male cyclists.

Anti-hypertriglyceridaemic/Antiatherogenic Activity

Administration of maca extract to hereditary hypertriglyceridaemic (HHTg) rats significantly decreased the levels of VLDL (very low-density lipoproteins), LDL (low-density lipoproteins) and total cholesterol and also the level of TAG (triacylglycerols) in the plasma, VLDL and liver (Vecera et al. 2007). Maca, as well as rosiglitazone (positive control), significantly improved glucose tolerance, as the decrease of AUC (area under the curve) of glucose showed, and lowered levels of glucose in blood. The activity of SOD (superoxide dismutase) in the liver, the GPX (glutathione peroxidase) in the blood and the level of GSH (glutathione) in liver increased in all cases significantly. Results demonstrated that maca appeared to have a potential as a positive influence on chronic human diseases (characterised by atherogenous lipoprotein profile, aggravated antioxidative status and impaired glucose tolerance) and their prevention.

In a randomised placebo-controlled 90-day study of patients suffering from the metabolic syndrome, no adverse effects were found in volunteers using silymarin (0.8 g/day), silymarin+yacon (0.8 g/day) and silymarin+maca (0.6 g/day) for the prevention of diseases with a proatherogenic lipoprotein profile and liver steatosis (Valentová et al. 2008). A moderate AST (aspartate aminotransferase) level and diastolic blood pressure increase were found in volunteers using high doses of maca powder (0.6 g/day), but this effect could be reversed by supplementation with silymarin.

Antidiabetic Activity

Black maca (BM), yacon and the mixture of both extracts reduced glucose levels in streptozotocin-diabetic mice (Gonzales et al. 2013a). Non-diabetic mice treated with BM and yacon showed higher daily sperm production (DSP) than those treated with vehicle. Diabetic mice treated with BM, yacon and the mixture maca/yacon increased DSP and sperm count in vas deferens and epididymis with respect to non-diabetic and diabetic mice treated with vehicle. The combination of two extracts improved glycaemic levels and male reproductive function in diabetic mice. Streptozotocin

increased 1.43 times the liver weight that was reversed with both plants extracts.

Anti-inflammatory Activity

Oral administration of maca extract significantly relieved the symptoms of diarrhoea and rectal bleeding and reduced colonic myeloperoxidase activity in dextran sodium sulfate (DSS)-induced colitis in mice (Cho et al. 2013). Maca extract treatment inhibited expression of several colonic proteins related to inflammatory responses, such as interleukin (IL)-1 β , tumour necrosis factor- α , IL-6 and S100 calcium-binding protein A8, whose expressions were increased significantly by DSS treatment. These results suggested that maca extract could alleviate DSS-induced colitis in mice by modulating colonic inflammatory mediators.

In a Mumbai-based, multi-centre, randomised, double-blind study of 95 subjects, treatments with Reparagen (a polyherbal consisting of 300 mg of *Uncaria guianensis* and 1,500 mg of *Lepidium meyenii*) and glucosamine sulfate, twice daily for up to 8 weeks, produced substantial improvements in pain, stiffness and function in subjects with osteoarthritis with 45–62 % reduction in WOMAC (Western Ontario and McMaster Universities Osteoarthritis Index) or VAS (visual analogue score) scores (Mehta et al. 2007). Response rates were high, and the safety profile was excellent, with significantly less rescue medication use with Reparagen.

Antihypertensive Activity

Maca was one of several medicinal plants used in Latin America, reported to inhibit significantly the hypertension relevant angiotensin I-converting enzyme (ACE) (Ranilla et al. 2010).

Osteoprotective Activity

Studies showed that administration of a high dose of maca ethanol extract (0.28 g/kg) for 28 weeks effective in preventing oestrogen deficient bone loss in ovariectomised rats

(Zhang et al. 2006). Red and black maca exhibited protective effects on bone architecture in ovariectomised rats by reversing the adverse effect of ovariectomy on weight, diameter and width of the femoral bone without showing oestrogenic effects on uterine weight (Gonzales et al. 2010). Maca treatment also reversed the effect of ovariectomy by increasing the trabecular bone area in the second lumbar vertebra. Studies by Wang et al. (2009) found that dietary supplementation of ovariectomised rats for 7 weeks with maca may have potential effects on prevention from postmenopausal lipid abnormality and bone metabolism via a different mechanism from oestrogen.

Immunomodulatory Activity

Supplementation of the diet of mice intraperitoneally inoculated with *Staphylococcus aureus* with maca or uña de gato (*Uncaria tomentosa*) significantly increased the number of peritoneal macrophages and body weight (Guerra et al. 2002). The experimental groups fed with maca or uña de gato had 46.2 % and 52.4 % of active macrophages, respectively, versus 32.8 % in the control group. Oral administration of ethanol maca extract to mice significantly increased the rate of transformation of lymphocyte induced by phytohaemagglutinin, and it also promoted production of haemolysin in serum and antibody-producing cell in the spleen (Zhang et al. 2007). The study suggested that ethanol maca extract may enhance cellular and humoral immunity function in mice. Feeding mice with maca powder and ginsenosides from *Panax ginseng* was found to enhance the immune function (Jin et al. 2007b). Mice fed with powdered maca, ginsenosides or a combination had increases of Con A-induced lymphocyte proliferation and total haemolytic complement value, as well as higher peritoneal macrophage function and NK (natural killer) cell activity.

Photoprotective Activity

Maca extracts were found to protect the skin of rats against UV irradiations and could be suggested as an alternative

means of solar protection (Gonzales-Castañeda and Gonzales 2008). The aqueous extract of maca after a boiling process had better effect than maca extract without a boiling process. A dose–response effect was observed with increasing doses of aqueous extract of maca after a boiling process. Maca extract was found to possess benzyl glucosinolates and polyphenols. Gonzales-Castañeda et al. (2011) reported that leaf extracts of three maca varieties prevented the development of sunburn cells, epidermal hyperplasia, leucocytic infiltration and other alterations produced by UVB radiation in mice. Mice treated with black maca showed the highest superoxide dismutase levels, and mice treated with black and yellow maca showed higher catalase levels in skin, whereas red maca protected the skin and liver against significant increases in the lipid peroxidation activity observed in the unprotected animals.

Cosmetics Uses

Compositions containing papain-treated papaya (*Carica papaya*) powders, papain-treated maca (*L. meyenii*) powders, papain and substantially water-free powders or oils that would be useful as face cleansers, packs and bath preparations with skin-conditioning effects had been lodged with the Japanese Patent Office (Arita and Hirao 2003). A face cleanser prepared from mannitol, soap, kaolin, talc, olive oil, papain, papain-treated papaya powder and papain-treated maca powder with the addition of polyols, mucopolysaccharides, sugars and/or amino acids to the extract was reported to improve the skin-moisturising effect (Hiroshi et al. 2003). Mitsuma and Hirao (2001) had lodged a claim with the Japanese Patent Office pertaining to the skin-lightening, rough skin-treating and moisturising cosmetics containing extract of *Lepidium meyenii*. The water extract of *L. meyenii* inhibited tyrosinase, a key enzyme in the production of the skin pigment melanin, with an IC₅₀ of 150 µg/mL.

Activity of 1-Methyl-1,2,3,4-Tetrahydro-β-Carboline-3-Carboxylic Acid (MTCA)

1-Methyl-1,2,3,4-tetrahydro- β -carboline-3-carboxylic acid (MTCA), a tetrahydro- β -carboline found in maca and other crops, was reported to be both a helpful and harmful compound and was suggested to be co-mutagenic or a precursor to mutagenic compounds, causing neuronal death in-vitro or could be bioactivated giving rise to endotoxins (Gonzales and Gonzales-Castañeda 2009). They found no toxicity on consumption of maca, suggesting that when consumed as multicomponent, MTCA may lose its adversity as drug action. Conflicting observations necessitated research to determine the true actions of MTCA in the human body. Manabe et al. (1996) suggested that accumulation of high MTCA levels in the eyes correlated with the development of cataracts. However, subsequent studies had demonstrated that MTCA had antioxidant capacity greater than that of vitamin E. Pari et al. (2000) found that β -carbolines like MTCA accumulated in human tissues and may serve a protective role against oxidative stress. They quenched singlet oxygen, superoxide and hydroxyl radicals and inhibited the oxidative formation of higher-molecular-weight aggregates of the test protein, eye lens gamma-crystallin. Studies by Ichikawa et al. (2006) found that 1-methyl-1,2,3,4-tetrahydro- β -carboline-3-carboxylic acid (MTCA), also found in aged garlic, demonstrated strong hydrogen peroxide scavenging and inhibited LPS-induced nitrite production preventing the conversion of the MTCA to other non-beneficial metabolites.

Tetrahydro- β -carbolines like 1,2,3,4-tetrahydro- β -carboline-3-carboxylic acid (THCA) and 1-methyl-1,2,3,4-tetrahydro- β -carboline-3-carboxylic acid (MTCA), two diastereoisomers (1S,3S and 1R,3S), were found in $\mu\text{g/g}$ in commercial fruits like citrus, banana, grapes, tomatoes and apples (Herraiz 1999) and fruit juices (Herraiz and Galisteo 2003). Tetrahydro- β -carbolines (THbetaCs) like 6-hydroxy-1-methyl-1,2,3,4-tetrahydro- β -carboline (6OHMTHbetaC), 1,2,3,4-tetrahydro- β -carboline-3-carboxylic acid (THCA), 1-methyl-1,2,3,4-tetrahydro- β -carboline-3-carboxylic acid (MTCA) in both diastereoisomers (1S,3S and 1R,3S) and 1-methyl-1,2,3,4-tetrahydro- β -carboline were also found in dark chocolate, milk chocolate, cocoa and chocolate-containing cereals (Herraiz 2000). These biological active alkaloids had

been reported to accumulate in the mammalian tissues, fluids and brain. Herraiz and Galisteo (2003) found that they acted as antioxidants and free radical scavengers in the ABTS assay when compared with ascorbic acid and Trolox, suggesting that tetrahydro-beta-carboline alkaloids might act as antioxidants when absorbed and accumulated in the body, contributing to the antioxidant effect of fruit products containing these compounds. The mutagenic effect of MTCA on *Salmonella typhimurium* TA100 in the absence of S9 had been described in Japanese soy sauce treated with exogenous nitrites (Wakabayashi et al. 1983, 1984). The mutagen produced from (–)-(1S,3S)-MTCA with nitrite was a minor product(s), the major product being the non-mutagen (–)-(1S,3S)-1-methyl-2-nitroso-1,2,3,4-tetrahydro-β-carboline-3-carboxylic acid [(–)-(1S,3S)-MNTCA. However, MTCA was found not mutagenic on *S. typhimurium* TA100 in the absence of the nitrites, with or without S9 (Ichikawa et al. 2006). Further, Higashimoto demonstrated that the mutagenicity of 1-methyl-1,2,3, 4-tetrahydro-beta-carboline-3-carboxylic acid (MTCCA), a major mutagen precursor in soy sauce on treatment with nitrite and ethanol, was strongly decreased by the addition of hot water extracts of green, black and oolong teas in the reaction mixture. Their findings suggested that the mutagenicity of MTCCA on treatment with nitrite in the presence of ethanol may be decreased by the mixed fractions of lyophilic components such as polyphenols, which have high reducing power such as catechins and the other compounds which have little reducing power including the derivatives of the catechins.

Effect on Health Status and Growth

A nutritional evaluation study of maca in albino mice found that mice given cooked maca had the best growth curve, while mice fed commercial balanced food (CBF) had better growth than the raw maca group (Canales et al. 2000). The serum values of total proteins and albumin were statistically superior for the mice group eating cooked maca than that of the raw maca and CBF groups. No signs of malnutrition nor overweight were observed in any of the groups.

In a survey of the health status of 27 maca consumers and 23 nonconsumers living in the Peruvian Central Highlands, testosterone/oestradiol ratio, interleukin IL-6 and chronic mountain sickness score were lower, whereas the health status score was higher, in maca consumers when compared to nonconsumers (Gonzales et al. 2013b).

Maca and Dyspepsia

A 4-week long treatment with Maca did not produce significant changes on gastric mucosa of patients (29) with functional dyspepsia, neither on *Helicobacter pylori* eradication (Benites Goñi et al. 2014).

Toxicity Studies

Maca had been reported in the scientific literature to have a low degree of acute oral toxicity in animals and low cellular toxicity in-vitro (Valerio and Gonzales 2005). Freeze-dried maca aqueous extract of maca (1 g/kg BW) did not reveal any toxic effect on the normal development of pre-implanted mouse embryos in mice (D'Arrigo et al. 2004).

Traditional Medicinal Uses

Maca has been used traditionally by Andean Indians as a food and an essential folk medicine for thousands of years (Leon 1964; Ochoa 2001; Gonzales 2012). The tuber of the maca has had popular use for hundreds of years for medicinal purposes, to increase fertility in man and animals (Leon 1964). The Kallawaya, travelling healers in the Andes, prescribed the fresh tuber cut into fine slices, in decoction, 3 or 4 days after the last menstrual period for sterile women wishing to become pregnant (Girault 1984). Maca has been prescribed as an adaptogen, an immunostimulant, an anabolic, in menopause and for influence on hormonal balance (Quir'os and Aliaga 1997). Maca has been recommended for treating malabsorption syndrome and protein deficiency disease, during chemotherapy for leukaemia, in AIDS treatment and for alcoholism and menopausal anaemia (Chacón de Popovici

1997). It has also been used to treat chronic polyarthritis, during allergy attacks and as a laxative (Aliaga and Aliaga 1998). Native Indians used Maca to treat anaemia, tuberculosis, sterility and fatigue (Cicero et al. 2001). Maca has traditionally been employed for its purported aphrodisiac and fertility-enhancing properties (Bogani et al. 2006). For generations, people of the rural community in Peru have used Maca, because of their belief that it improves fertility and sexual desire (Lentz et al. 2007). It is also recommended in traditional medicine as an effective agent for cancer prevention and treatment, anaemia, gastritis and depression (Wang et al. 2007). Maca is used to enhance sexual behaviour, fertility and energy and to reduce stress and menopausal symptoms (Cho et al. 2013). In the United States, maca has become known as a libido booster and also known for its effects on energy and endurance (Kilham 2002).

Other Uses

Miscellaneous potential non-edible uses of maca have also been reported.

Maca oil has cyanobactericidal and antitermite activity. The oil of maca aerial parts was selectively toxic towards the cyanobacterium *Oscillatoria perornata* compared to the green alga *Selenastrum capricornutum*, with complete growth inhibition at 100 µg/mL (Tellez et al. 2002). Mortality of the Formosan subterranean termite, *Coptotermes formosanus*, was numerically, but not significantly, higher when held on filter paper treated with maca oil. At 1 % (w/w), maca oil also appeared to act as a feeding deterrent to termites. Several minor components of the essential oil of maca including 3-methoxyphenylacetone nitrile and benzyl thiocyanate were significantly active against the Formosan termite.

Studies by Lee et al. (2005) found that certain compounds in maca meal had growth-enhancing effects in rainbow trout (*Oncorhynchus mykiss*) juveniles. Feed conversion ratio (FCR) and protein efficiency ratio (PER) were also significantly improved in the fish fed maca meal diets.

Studies by Saldaña et al. (2006) showed the potential usefulness of maca to be used as a culture medium for the study of *Trypanosoma cruzi*. They found the inclusion of maca in the culture media facilitated *Trypanosoma cruzi* growth; it was determined that the medium containing blood-enriched maca among its solid components and a maca infusion in the liquid phase had better growth (3.41×10^5 parasites/mL) compared to the other culture media after 5 days.

Comments

Fifty native and 12 naturalised species of *Lepidium* grow in South America (Al-Shehbaz 2010). *Lepidium peruvianum* was one of 17 taxa reduced to synonymy.

Raphanus raphanistrum subsp.
sativus

T. K. Lim¹✉

(1) Canberra, Aust Capital Terr, Australia

Scientific Name

***Raphanus raphanistrum* subsp. *sativus* (L.) Domin**

Synonyms

Raphanistrum gayanum Fisch. & C.A.Mey., *Raphanus acanthiformis* Morel ex L.Sisley, *Raphanus acanthiformis* J.M. Morel ex Sasaki, *Raphanus acanthiformis* var. *raphanistroides* (Makino) Hara, *Raphanus candidus* Vorosch., *Raphanus chinensis* Mill., *Raphanus gayanus* (Fisch. & C.A.Mey.) G.Don, *Raphanus macropodus* H.Lév., *Raphanus niger* Mill., *Raphanus oleifer* Steud., *Raphanus orbicularis* Mill., *Raphanus radícula* Pers., *Raphanus raphanistroides* (Makino) Nakai, *Raphanus raphanistrum* var. *sativus* (L.) Schmalh., *Raphanus raphanistrum* subsp. *sativus* Schmalh., *Raphanus raphanistrum* var. *sativus* (L.) Domin, *Raphanus raphanistrum* var. *sativus* (L.) Beck, *Raphanus rotundus* Mill., *Raphanus sativus* L., *Raphanus sativus* subsp. *esculentus* Metzg., *Raphanus sativus* var. *longipinnatus* L.H.Bailey, *Raphanus sativus* var. *macropodus* (H.Lév.) Makino, *Raphanus sativus* var. *niger* (Mill.) J.Kern., *Raphanus sativus* var. *radícula* Pers., *Raphanus sativus* var. *raphanistroides* (Makino) Makino, *Raphanus sativus* f. *raphanistroides* Makino, *Raphanus sativus* subsp. *sinensis* Sazonova & Stank., *Raphanus sinensis* Thunb. ex Pritz., *Raphanus taquetii* H.Lév.

Family

Brassicaceae

Common/English Names

Chinese Radish, Common Radish, Daikon, Daikon Radish, Fodder Radish, Garden Radish, Japanese Radish, Leafy Daikon, Oriental Radish, Oriental Winter Radish, Radish, Wild Radish

Vernacular Names

Arabic: Fejil, Fijil, Fujl

Azerbaijan: Qırmızı turp, Turp

Brazil: Rabanete

Burmese: Monla

Chinese: Hung Loh Paak Tsai, Hong Luo Bo Zi, Lai Fu, Lai-Fu-Tzu Ts-Ao, Loh Bak, Luo Bo, Ou Zhou Luo Bo

Croatian: Rotkva, Rotkvica

Czech: Øedkvièka, Ředkev Seta

Danish: Haveræddike, Kinaræddike, Ræddike, Radis, Radise, Japanræddike

Dutch: Radijs, Ramenas, Tamme Radÿs

Esperanto: Rafano, Rafano Kultiva, Rafano Manĝebla, Rafaneto

Estonian: Redis

Euskera: Arapa, Erradilla, Erraso, Errasu, Errefau, Errefaun, Erresan, Erresana, Erresauchoa, Erresaun, Erresauna, Erresautxo, Lutxarbi

Finnish: Retiisi, Retikka, Ruokaretikka

French: Petit Radis, Radis, Rave, Radis Cultivé, Radis D'été, Radis Rose

Galician: Labestro, Rábano, Rabão, Rábão, Ravo, Saramago

German: Bierrettich, Bierwurz, Furzwurzel, Garten-Rettich, Monatsrettich, Radi, Radieschen, Rettich, Retwurz

Greek: Rapani

Hebrew: Tznonit

Hornjoserbsce (Upper Sorbian): Zahrodna Rjetkej

Hungarian: Retek

Icelandic: Ætihreðka, Hreðka, Raefla

India: Mulō, Mulla (Bengali), Mooli, Muli, Mūlī, Mulla (Hindi), Mullangi (Malayalam), Mūlaka (Marathi), Mūlī

(Punjabi), Muulaka (Sanskrit), Muulam, Mullangi, Mullanggi

Vietnamese: Củ Cải, Củ Dền, Rađi

Welsh: Heddig, Radys, Redis, Redyns, Rhodri Rhuddygl

Origin/Distribution

The exact origin of radish is unknown because it has been in cultivation for thousands of years. Radish is thought to have originated in the eastern Mediterranean region and has been domesticated in Europe in the pre-Roman times.

DNA sequence study from different organelles by Yang et al. (2000) suggested *Raphanus sativus* to be a hybrid between *B. rapa*/*B. oleracea* and *B. nigra* lineages as proposed by Song et al. (1990).

Agroecology

Radish tolerates a wide range of climatic regimes. Radish flourishes in full sun and in well-drained, light sandy loams with pH of 6.5–7. In temperate areas, radish is usually planted out a few weeks prior to spring before the first frost. In warm weather, they are normally planted out in fall.

Edible Plant Parts and Uses

Radish roots, seed sprouts, leaves, flowers and seeds are edible. Radish roots are eaten raw, baked, roasted or cooked in stews, soups or stir fries, also lightly steamed with olive oil, salt or lemon juice. Radish is eaten raw with a dip or with peanut butter, shredded to salads, pickled in kimchi and made into radish cakes like Japanese diakon mocha. A number of pickled radish products are produced in Korea such as *kaktugi*, *tongchimi*, *chonggak-kimchi*, *seokbakji*, *yolmu-kimchi* dan *moogi kach doo ki gactuki* and *mootsanji*. *Sinki* is a sour pickle prepared from radish taproots and is consumed traditionally in India, Nepal and parts of Bhutan, where it is used as a base for soup or eaten as a pickle.

Young leaves are also eaten raw or cooked as greens. Radish greens are also blended into smoothies. The blossoms are edible, and the seed pods have many uses, eaten raw, cooked, in stir fries to pickles.

Botany

An annual or biennial coarse herb, 30–120 cm tall, glabrous, scabrous or hispid with stout, erect, branched stem. Roots are fleshy; swollen; white, pink, red or black; linear; fusiform; oblong; or globose, 1–100 × 0.5–45 cm, sometimes slender and not fleshy (Plates 1, 2, 3, 4 and 5). Lower leaves are lyrate-pinnatifid, petiolate, sparsely hirsute to glabrous; the lobes are dentate or denticulate (Plates 2 and 6). The uppermost cauline leaves are subsessile, often undivided and dentate. Racemes are elongated, narrowly erect, oblong, glabrous or sparsely hirsute; petals are purplish, pink to nearly white (Plate 7), with dark purple veins, 1.5–2 cm long, broadly obovate with a long narrowed claw; filaments are slender and anthers are sagittate at the base, style, stigma entire. Fruit is indehiscent, silique fusiform, lanceolate and cylindrical to conical, tapering from above base to a narrow beak. Seeds are 2–4, globose or ovoid, somewhat ridged, 2.5–4 mm in diameter.

Nutritive/Medicinal Properties

Nutrients/Phytochemicals: Root

The proximate nutrient composition per 100 g edible portion of raw radish was reported as water 95.2 g, energy 16 kcal (66 kJ), protein 0.68 g, total lipid 0.10 g, ash 0.55 g, carbohydrate 3.4 g and total dietary fibre 1.6; total sugars 1.86 g, sucrose 0.10 g, glucose 1.05 g and fructose 0.71 g; minerals, Ca 25 mg, Fe 0.34 mg, Mg 10 mg, P 20 mg, K 233 mg, Na 39 mg, Zn 0.28 mg, Cu 0.050 mg, Mn 0.069 mg and Se 0.6 µg; vitamins, vitamin C 14.8 mg, thiamine 0.012 mg, riboflavin 0.039 mg, niacin 0.254 mg, pantothenic acid 0.165 mg, vitamin B6 0.071 mg, total folate 25 µg, total choline 12.3 mg, β-carotene 4 µg, vitamin A 7 IU, vitamin K (phylloquinone) 1.3 µg, β-carotene 22 µg, lutein + zeaxanthin 10 µg and phytosterols 7 mg; total saturated fatty acids 0.032 g, 16:0 (palmitic acid) 0.027 g, and 18:0 (stearic acid) 0.004 g; total monounsaturated fatty acids 0.017 g, 18:1 undifferentiated (oleic acid) 0.017 g; and total polyunsaturated fatty acids 0.048 g, 18:2 undifferentiated (linoleic acid) 0.017 g and 18:3 undifferentiated (linolenic acid) 0.031 g; and amino acids, tryptophan 0.009 g, threonine 0.023 g, isoleucine 0.020 g, leucine 0.031 g, lysine 0.033 g, methionine 0.010 g, cystine 0.010 g, phenylalanine 0.036 g, tyrosine 0.009 g, valine 0.035 g, arginine 0.038 g, histidine 0.013 g, alanine 0.26 g, aspartic acid 0.064 g, glutamic acid 0.157 g, glycine 0.026 g, proline 0.022 g and serine 0.278 g (USDA ARS [2013](#)). Radish was also found to contain 0.4–2.11 mg/100 g FW of the flavonol kaempferol FW (Bilyk and Sapers [1985](#); Hertog et al. [1992](#); Lugasi and Hovari [2000](#)). Radish leaves and sprouts were found to contain 7.72 mg/100 g and 13.76–35.128 mg/100 g kaempferol, respectively (Sakakibara et al. [2003](#)).

The proximate value per 100 g edible portion of raw oriental radish was reported as water 94.62 g, energy 18 kcal (76 kJ), protein 0.60 g, total lipid 0.10 g, ash 0.58 g, carbohydrate 4.1 g, total dietary fibre 1.6 and total sugars 2.5 g; minerals, Ca 27 mg, Fe 0.4 mg, Mg 16 mg, P 23 mg, K 227 mg, Na 21 mg, Zn 0.15 mg, Cu 0.115 mg, Mn 0.038 mg and Se 0.7 µg; vitamins, vitamin C 22 mg, thiamine 0.02 mg, riboflavin 0.02 mg, niacin 0.2 mg, pantothenic acid 0.138 mg, vitamin B6 0.046 mg, total folate 7.3 µg, betaine 0.1 mg, total choline 12.3 mg and vitamin K (phylloquinone) 0.3 µg; total saturated fatty acids 0.03 g, 16:0 (palmitic acid) 0.026 g and 18:0 (stearic acid) 0.004 g; total monounsaturated fatty acids 0.017 g, 18:1 undifferentiated (oleic acid) 0.017 g; total polyunsaturated fatty acids

0.045 g, 18:2 undifferentiated (linoleic acid) 0.016 g and 18:3 undifferentiated (linolenic acid) 0.029 g; and amino acids, tryptophan 0.003 g, threonine 0.025 g, isoleucine 0.026 g, leucine 0.031 g, lysine 0.030 g, methionine 0.006 g, cystine 0.005 g, phenylalanine 0.020 g, tyrosine 0.011 g, valine 0.028 g, arginine 0.035 g, histidine 0.011 g, alanine 0.19 g, aspartic acid 0.041 g, glutamic acid 0.113 g, glycine 0.019 g, proline 0.015 g and serine 0.018 g (USDA ARS 2013).

Among the seven Japanese radish cultivars, Koshin, Kouto and Shogoin were the three highest in terms of the total soluble sugar (glucose, fructose, sucrose) content (Hara et al. 2011). Sobutori, which is the most common radish cultivar in Japan, was the lowest. The total organic acid (malate, citrate, ascorbate, lactate and pyruvate) contents varied among the seven cultivars, although they were 5–13 times lower than the total soluble sugar contents. The Koshin cultivar showed the highest amylase activity, with a level approximately six times higher than that of the Sobutori cultivar, which had the lowest (Hara et al. 2009). Cultivars with higher amylase activities showed higher starch contents.

Anthocyanins

The anthocyanin concentrations of the mature radish taproot were significantly greater than in the sprouts of red, pink and purple varieties. The primary anthocyanidins present in the red and pink radish varieties were pelargonidin and delphinidin, while the primary anthocyanidin in the purple radish variety was cyanidin (Hanlon and Barnes 2011). Radish was reported to contain 7.40–128 mg/100 g pelargonidin anthocyanidins (Harnly et al. 2006; Wu et al. 2006). Two novel diacylated anthocyanins, pelargonidin 3-*O*-[2-*O*-(β -glucopyranosyl)-6-*O*-(*trans*-*p*-coumaroyl)- β -glucopyranoside] 5-*O*-(6-*O*-malonyl- β -glucopyranoside) and pelargonidin 3-*O*-[2-*O*-(β -glucopyranosyl)-6-*O*-(*trans*-feruloyl)- β -glucopyranoside] 5-*O*-(6-*O*-malonyl- β -glucopyranoside), were characterised from red radish (Guisti et al. 1998). Two other monoacylated anthocyanins were determined to be pelargonidin 3-*O*-[2-*O*-(β -glucopyranosyl)-6-*O*-(*trans*-*p*-coumaroyl)- β -d-glucopyranoside] 5-*O*-(β -glucopyranoside) and pelargonidin 3-*O*-[2-*O*-(β -glucopyranosyl)-6-*O*-(*trans*-feruloyl)- β -glucopyranoside] 5-*O*-(β -glucopyranoside). Twelve acylated anthocyanins were isolated from the red radish (Otsuki et al. 2002). Six of these were identified as pelargonidin 3-*O*-[6-*O*-(*E*)-feruloyl-2-*O*- β -d-glucopyranosyl]-(1 $\rightarrow$ 2)- β -D-glucopyranoside]-5-*O*-(β -D-glucopyranoside); pelargonidin 3-*O*-[6-*O*-(*E*)-caffeoyl-2-*O*-(6-*E*)-

feruloyl- β -D-GLUCOPYRANOSYL)-(1 $\rightarrow$ 2)- β -D-glucopyranoside]-5-*O*-(β -D-glucopyranoside); pelargonidin 3-*O*-[6-*O*-(*E*)-*p*-coumaroyl-2-*O*-(6-*E*)-caffeoyl- β -D-glucopyranosyl)-(1 $\rightarrow$ 2)- β -D-glucopyranoside]-5-*O*-(β -D-glucopyranoside); pelargonidin 3-*O*-[6-*O*-(*E*)-feruloyl-2-*O*-(6-*E*)-caffeoyl- β -D-glucopyranosyl)-(1 $\rightarrow$ 2)- β -D-glucopyranoside]-5-*O*-(β -D-glucopyranoside); pelargonidin 3-*O*-[6-*O*-(*E*)-*p*-coumaroyl-2-*O*-(6-*E*)-feruloyl- β -D-glucopyranosyl)-(1 $\rightarrow$ 2)- β -D-glucopyranoside]-5-*O*-(β -D-glucopyranoside); and pelargonidin 3-*O*-[6-*O*-(*E*)-feruloyl-2-*O*-(2-*E*)-feruloyl- β -D-glucopyranosyl)-(1 $\rightarrow$ 2)- β -D-glucopyranoside]-5-*O*-(β -D-glucopyranoside). Ten known acylated anthocyanins were isolated from red radish (Liu et al. 2008). The acylated anthocyanins are all based on pelargonidin 3-sophoroside-5-glucoside, acylated with caffeoyl, feruloyl or *p*-coumaroyl moieties. The anthocyanins were pelargonidin 3-*O*-[6-*O*-(*E*)-caffeoyl-2-*O*- β -D-glucopyranosyl)-(1 $\rightarrow$ 2)- β -D-glucopyranoside]-5-*O*-(β -D-glucopyranoside); pelargonidin 3-*O*-[6-*O*-(*E*)-caffeoyl-2-*O*-(6-*E*)-caffeoyl- β -D-glucopyranosyl)-(1 $\rightarrow$ 2)- β -D-glucopyranoside]-5-*O*-(β -D-glucopyranoside); pelargonidin 3-*O*-[6-*O*-(*E*)-caffeoyl-2-*O*-(6-*E*)-feruloyl- β -D-glucopyranosyl)-(1 $\rightarrow$ 2)- β -D-glucopyranoside]-5-*O*-(β -D-glucopyranoside); pelargonidin 3-*O*-[6-*O*-(*E*)-*p*-coumaroyl-2-*O*- β -D-glucopyranosyl)-(1 $\rightarrow$ 2)- β -D-glucopyranoside]-5-*O*-(β -D-glucopyranoside); pelargonidin 3-*O*-[6-*O*-(*E*)-*p*-coumaroyl-2-*O*-(6-*E*)-caffeoyl- β -D-glucopyranosyl)-(1 $\rightarrow$ 2)- β -D-glucopyranoside]-5-*O*-(β -D-glucopyranoside); pelargonidin 3-*O*-[6-*O*-(*E*)-feruloyl-2-*O*- β -D-glucopyranosyl)-(1 $\rightarrow$ 2)- β -D-glucopyranoside]-5-*O*-(β -D-glucopyranoside); pelargonidin 3-*O*-[6-*O*-(*E*)-feruloyl-2-*O*-(6-*E*)-caffeoyl- β -D-GLUCOPYRANOSYL)-(1 $\rightarrow$ 2)- β -D-glucopyranoside]-5-*O*-(β -D-glucopyranoside); pelargonidin 3-*O*-[6-*O*-(*E*)-*p*-coumaroyl-2-*O*-(6-*E*)-feruloyl- β -D-glucopyranosyl)-(1 $\rightarrow$ 2)- β -D-glucopyranoside]-5-*O*-(β -D-glucopyranoside); pelargonidin 3-*O*-[6-*O*-(*E*)-feruloyl-2-*O*-(6-*E*)-feruloyl- β -D-glucopyranosyl)-(1 $\rightarrow$ 2)- β -D-glucopyranoside]-5-*O*-(β -D-glucopyranoside); and pelargonidin 3-*O*-[6-*O*-(*E*)-feruloyl-2-*O*-(2-*E*)-feruloyl- β -D-glucopyranosyl)-(1 $\rightarrow$ 2)- β -D-glucopyranoside]-5-*O*-(β -D-glucopyranoside).

Three new acylated pelargonidin 3-sophoroside-5-glucosides were isolated from the root peels, petioles and flowers of red radish, *Raphanus sativus* ‘Cherry Mate’, in addition to the five known anthocyanins, namely, pelargonidin 3-sophoroside-5-glucoside, pelargonidin 3-[2-(glucosyl)-6-(*trans-p*-coumaroyl)-glucoside]-5-glucoside, pelargonidin 3-[2-(glucosyl)-6-(*trans*-feruloyl)-glucoside]-5-glucoside, pelargonidin 3-[2-(glucosyl)-6-(*trans-p*-coumaroyl)-glucoside]-5-(6-malonylglucoside) and pelargonidin 3-[2-(glucosyl)-6-(*trans*-feruloyl)-glucoside]-5-(6-malonylglucoside).

(Tatsuzawa et al. 2008). The structures of the three new acylated anthocyanins were shown to be pelargonidin 3-*O*-[2-*O*-(β -D-glucopyranosyl)-6-*O*-(*trans*-caffeoyl)- β -D-glucopyranoside]-5-*O*-(6-*O*-malonyl- β -D-glucopyranoside), its demalonyl derivative, and pelargonidin 3-*O*-[2-*O*-(β -D-glucopyranosyl)-6-*O*-(*cis*-*p*-coumaroyl)- β -D-glucopyranoside]-5-*O*-(6-*O*-malonyl- β -D-glucopyranoside). *p*-Coumaroyl anthocyanins were the main pigments found in the root, petioles and flowers. Although the *trans*-*p*-coumaroyl form was abundant in all three plant organs, its *cis* form was present in very low amount within the root but in large amount in the flowers and petioles. Four new acylated cyanidin glycosides were isolated from the purple roots of *Raphanus sativus* 'Benikanmi', along with five known anthocyanins (Tatsuzawa et al. 2010). Two of these pigments were determined to be cyanidin 3-*O*-[2-*O*-(β -glucopyranosyl)-6-*O*-(*trans*-feruloyl)- β -glucopyranoside]-5-*O*-[6-*O*-(malonyl)- β -glucopyranoside] and cyanidin 3-[2-(glucosyl)-6-(*cis*-*p*-coumaroyl)-glucoside]-5-[6-(malonyl)-glucoside]. Two other new pigments were obtained in small quantities and were assigned to be malonyl cyanidin 3-sophoroside-5-glucoside and malonyl cyanidin 3-[2-(glucosyl)-6-(*trans*-caffeoyl)-glucoside]-5-glucoside.

Six new acylated anthocyanins were isolated along with the three known congeners from the fresh roots of red radishes (Tamura et al. 2010). Their chemical structures were elucidated as 3-*O*-[6-*O*-(*E*)-caffeoyl-2-*O*-{6-*O*-(*E*)-caffeoyl- β -D-glucopyranosyl}- β -D-glucopyranosyl]-5-*O*-(6-*O*-malonyl- β -D-glucopyranosyl)pelargonidin; 3-*O*-[6-*O*-(*E*)-*p*-coumaroyl-2-*O*-{6-*O*-(*E*)-caffeoyl- β -D-glucopyranosyl}- β -D-glucopyranosyl]-5-*O*-(6-*O*-malonyl- β -D-glucopyranosyl)pelargonidin; 3-*O*-[6-*O*-(*E*)-feruloyl-2-*O*-{6-*O*-(*E*)-*p*-coumaroyl- β -D-glucopyranosyl}- β -D-glucopyranosyl]-5-*O*- β -D-glucopyranosylpelargonidin; 3-*O*-[6-*O*-(*E*)-feruloyl-2-*O*-{6-*O*-(*E*)-caffeoyl- β -D-glucopyranosyl}- β -D-glucopyranosyl]-5-*O*-(6-*O*-malonyl- β -D-glucopyranosyl)pelargonidin; 3-*O*-[6-*O*-(*E*)-*p*-coumaroyl-2-*O*-{6-*O*-(*E*)-*p*-coumaroyl- β -D-glucopyranosyl}- β -D-glucopyranosyl]-5-*O*-(6-*O*-malonyl- β -D-glucopyranosyl)pelargonidin; and 3-*O*-[6-*O*-(*E*)-feruloyl-2-*O*-{6-*O*-(*E*)-*p*-coumaroyl- β -D-glucopyranosyl}- β -D-glucopyranosyl]-5-*O*-(6-*O*-malonyl- β -D-glucopyranosyl)pelargonidin. Sixty anthocyanins, 14 acylated cyanidin 3-(glucosylacyl)acylsophoroside-5-diglucosides, 24 acylated cyanidin 3-sophoroside-5-diglucosides and 22 acylated cyanidin 3-sophoroside-5-glucosides, were found in purple Bordeaux radish (Lin et al. 2011). The presence of 38 acylated cyanidin 3-

sophoroside-5-diglucosides and around ten acylated cyanidin 3-sophoroside-5-malonylglucosides was found reported in *R. sativus* for the first time.

The light irradiation (fluorescence light, 5,000 lx; at 25 °C) indicated that the red radish extract (in which major anthocyanins were pelargonidin glycosides acylated with a combination of *p*-coumaric, ferulic or caffeic acids) was more stable at lower pH than at higher pH (Matsufuji et al. 2007). The HPLC analyses revealed that diacylated anthocyanins in the extract were more stable to light at pH 3 than monoacylated anthocyanins. No significant difference in degradation rates of acylated anthocyanins at pH 5 was observed, whereas anthocyanins acylated with *p*-coumaric or ferulic acids were more stable at pH 7 than ones with caffeic acids. The stability to heat (at 90–95 °C) showed a tendency similar to that for light. The degradation behaviour of red radish extract to H₂O₂ was almost the same to those of light and heat, depending on the pH. However, HPLC analyses revealed that the stability of individual acylated anthocyanins was independent of the pH. DPPH radical scavenging activity of all acylated anthocyanins was higher than those of pelargonidin and pelargonidin 3-glucoside. The activity of acylated anthocyanins mostly depended on the activity of intramolecular acyl units (caffeic acid > ferulic acid > *p*-coumaric acid). In another study, 17 pigments were tentatively identified as pelargonidin 3-sophoroside-5-glucoside derivatives with multiple acylation of hydroxycinnamic acids in the roots of Chinese radish cultivars (Jing et al. 2012). These Chinese radish cultivars showed high variation in anthocyanins (63.77–160.74 mg/100 g FW). A bright colour (CIELab) of radish anthocyanins was shown at a wide pH range, comparatively stable at pH < 4.2. Those anthocyanins also showed a remarkable thermal stability, following a zero-order kinetics at pH 2.5 with half-lives of 14.5 or 8.7 hours at 90 or 100 °C, respectively. Additionally, those cultivars varied in glucosinolate contents (59.69–163.91 mg/100 g FW), whereas their degradation was sensitive to pH and followed a first-order kinetics at pH 5.8 with half-lives of 11.44 or 7.05 hours at 90 or 100 °C, respectively. However, the stable pH ranges for anthocyanins and glucosinolates were different: pH < 4.2 and pH > 3.6, respectively. In a radish juice model (pH 5.8/2.5), thermal degradation of anthocyanins or glucosinolates was associated closely with media pH values.

Red radish anthocyanins (RRAs) in various fruit juice beverages (apple, grape, peach, pear, pomegranate and lemon) displayed a much faster degradation rate during storage at room temperature ($t_{1/2}$

value ≤ 84.0 days) than did in refrigerated temperature (Liu et al. 2014). During heating, RRAs in peach and pomegranate showed higher stability than others at these temperatures. There was a positive correlation ($R^2 > 0.9128$) between ascorbic acid content of juice beverages (8–36 mg/100 mg) and stability of RRAs at 70–90 °C. It was found that RRAs in apple and pear juice beverages were more stable than in other juice beverages.

Glucosinolates/Isothiocyanates/Nitriles

Intact roots of 109 radish cultivars including oil radishes (subsp. *oleifera*) and food radishes (subsp. *radicola*) from European, European-American, Japanese and Korean markets were found to contain primarily 4-methylthio-3-butenyl glucosinolate (GS) with small amounts of 4-methylsulfinylbutyl GS, 4-methylsulfinyl-3-butenyl GS and 3-indolylmethyl GS (Carlson et al. 1985). Regarding total GSs, 80 % or more of the red European-American radishes had 100–199 $\mu\text{mole}/100\text{ g}$, the Korean 100–299 $\mu\text{mole}/100\text{ g}$ and the Japanese 200–399 $\mu\text{mole}/100\text{ g}$. No correlation was found between root size and 4-methylthio-3-butenyl-, 3-indolylmethyl- or total GSs. Japanese radish peelings contained significantly greater concentrations of these three constituents than did the peeled root. Early radish (Rex and Ostergruss Róžowa) contained the least amount of thiocyanate compounds and winter radish cv. Murzynka the highest amount (Capecka 1998). The content of thiocyanates in leaves was three to five times higher than that in hypocotyl roots in all cultivars including Japanese radish (Tokinashi and Minowase Summer Cross F1) and winter radish (Monachijska Biała and Murzynka). The changes in the thiocyanate content during root growth showed a constant rising tendency in the case of the leaves of all cultivars and the storage organs of Murzynka. Elivra and Tatiana (2012) reported radish to contain thioglycosides sinalbin, sinigrin and glucobrassicin. They found black radish to have higher content of isothiocyanates 37.6 mg/100 g versus green radish 33.7 mg/100 g and higher level of indole compounds 35.91 mg/100 versus 24.41 mg/100 g in green radish.

Trans-4-(methylthio)-3-butenyl glucosinolate (4MTBGLS) was isolated as a potassium salt from radish roots (Visentin et al. 1992). The contents of 4-methylthio-3-butenyl isothiocyanate (MTBITC) in more than half of the commercial Japanese radish cultivars ranged from 200 to 300 $\mu\text{mol}/100\text{ mL}$ juice (Okano et al. 1990). Among the cultivars examined, ‘Karami’ showed the highest content of MTBITC, reaching as much as 1,735 $\mu\text{mol}/100\text{ mL}$, followed by the

‘Shinshu-jidaikon’ group of 400–700 $\mu\text{mol}/100\text{ mL}$. The ‘Ninengo’ and ‘Shiroagari’ groups also exhibited relatively high content averaging more than 300 $\mu\text{mol}/100\text{ mL}$. On the contrary, the ‘Miyashige’ group or Chinese cultivars contained the lowest level of MTBITC ranging from 100 to 200 $\mu\text{mol}/100\text{ mL}$. The result of sensory evaluation on grated radish showed that a cultivar with higher content of MTBITC was proportionately more pungent, supporting the notion that MTBITC was the pungent principle in roots of Japanese radish.

Studies by Ishii and Saijo (1987) found that isothiocyanate (ITC) in daikon roots decreased with days after sowing. The roots harvested in early summer contained a higher level of ITC than those harvested in autumn. ITC was higher in radish roots grown in alluvial soils. Mulching treatment with plastic film increased ITC in roots. ITC in the roots increased linearly with increasing sulfate levels in pots filled with vermiculite. Planting density did not affect ITC in roots. The range and mean of 4-methylthio-3-butenyl glucosinolate (MTBGLS) contents in 20 daikon cultivars were 42–345 $\mu\text{mol}/100\text{ g}$ of fresh weight and 210 $\mu\text{mol}/100\text{ g}$ of fresh weight, respectively (Ishii et al. 1989b). Among the cultivars examined, the highest in total glucosinolate content contained 2.3 times higher than the lowest. The mean content of MTBGLS corresponded to about 80 % of that of total glucosinolate. 4-Methylthio-3-butenyl glucosinolate, the predominant glucosinolate in daikon root, was quantitatively determined after myrosinase enzymatic conversion to its isothiocyanate (Ishii et al. 1989a).

The major volatile components in the oil of the roots of black, white and red radish in respective sequence were hexadecanoic acid (palmitic acid) (32.2, 30.3, 49.9 %), methyl linolenate (21.7, 13.7, 8.5 %), 4-(methylthio)butyl isothiocyanate (erucin) (21.5, 25.7, 17.9 %), 5-(methylthio)-4-pentenitrile (6.9, 5.3, tr%), dimethyl trisulfide (1.1, 1.3, 3.8 %), 5-(methylthio)pentyl isothiocyanate (berteroin) (0.5, 2.0, 0.6 %), 4-(methylthio)-3-butenyl isothiocyanate (0.2, 1.7, 0.7 %) and 2-phenylethyl isothiocyanate (1.0, 1.5, 0.1 %) (Blažević and Mastelić 2009). Other isothiocyanates and nitriles included 4-methylpentyl isothiocyanate (0.1, 0.1, 0 %), benzenepropanenitrile (tr, tr, 0 %), 3-(methylthio)propyl isothiocyanate (iberiverin) (tr, 0.5, 0.7 %) and benzyl isothiocyanate (tr, 0.5, tr %). Alkanes identified in the roots were undecane (0.1, 0.3, tr%), dodecane (0.1, 1.1, 1.4 %), tridecane (0.4, 0.5, 1.2 %), tetradecane (tr, 0, 0.7 %), heneicosane (0, 2.5, 0 %), tricosane (0, 2.3, 0 %) and tetracosane (0, 1.2, 0 %). Other aliphatic alcohols and carbonyls identified in the roots were (*Z*)-3-hexen-1-ol (tr, 0.7, 0 %), (*E,E*)-2,4-

heptadienal (0.1, 0, 0.1 %), 2-phenylacetaldehyde (0.1, tr, 0 %), 4-ethylbenzaldehyde (0, tr, 0 %), 6,10,14-trimethyl-2-pentadecanone (0.1, 0, 0 %), isobutyl phthalate (0, 0.1, 0.3 %) and dibutyl phthalate (0.1, 0.7, 1.1 %). Other fatty acids and esters identified were (Z)-3-hexenyl acetate (tr, tr, tr%), dodecanoic acid (lauric acid) (tr, 0, 0.5 %), benzyl benzoate (0.1, 0, 0 %), tetradecanoic acid (myristic acid) (1.9, 0.5, 0 %) and pentadecanoic acid (0.2, 0, 0 %). Other sulfur and/or nitrogen compounds identified were dimethyl disulfide (1.8, tr, 1.3 %), 2-acetylthiazole (tr, 0, 0 %), 1-(methylthio)-3-pentanone (0.1, 0.3, 0 %) and dimethyl tetrasulfide (0, 0, 0.5 %). Terpenes identified were β -caryophyllene (tr, 0, tr) and neophytadiene (0.1, tr, 0 %). Miscellaneous compound identified included 4-vinyl-2-methoxyphenol (tr, 0, tr%).

Glucoraphasatin an atypical glucosinolate mainly found in *Raphanus sativus* roots and sprouts and its corresponding isothiocyanate, 4-methylsulfanyl-3-butenyl isothiocyanate, had been found to upregulate enzymes involved in the detoxification of carcinogens with the potential to be used as chemopreventive agents (Montaut et al. 2010). Six glucosinolates were identified and quantified in the black radish-based dietary supplements: glucoraphasatin (0.2–0.48 mg/g), glucosisaustriacin (0.37–0.91 mg/g), glucoraphenin (0.84–1.27 mg/g), glucoputrajivin (0.14–0.28 mg/g), glucosisymbrin (0.70–0.99 mg/g) and gluconasturtiin (0.06–0.12 mg/g) (Ediage et al. 2011). Glucoraphenin was the most abundant glucosinolate in all samples.

Four radish glucosinolates (glucoraphenin, dehydroerucin, glucobrassicin and glucoerucin) were identified from root extracts, and dehydroerucin was found to be the major glucosinolate in red radish roots (Gao et al. 2014). Application of chitosan with 76 %, 83 % or 89 % deacetylation in radish extracts attributed to 26 %, 35 % or 43 % adsorption rate for glucosinolates and 28 %, 26 % or 22 % for anthocyanins, respectively. It was found that the concentration of volatile compounds decreased by 70 %, resulting in the loss of odorous compounds. The changes in chitosan spectra before/after adsorption and after desorption at 1,590 and 3,360 cm^{-1} and at broad bands from 2,600 to 2,000 cm^{-1} suggested that the dominant adsorption mechanisms of glucosinolates on chitosan may be electrostatic attractions, including hydrogen bonds and charge neutralisation.

The steam-volatile constituents of fresh radish of Japanese and Kenyan origin identified included 4-methylthio-3-butenyl isothiocyanate and its parent glucosinolate, dimethyl disulfide,

methyl methanethiol sulfinat, pentyl isothiocyanate, 4-methylpentyl isothiocyanate, hexyl isothiocyanate, 5-(methylthio)-4-pentenitrile, 3-methylthiopropyl isothiocyanate, benzyl isothiocyanate, 4-methylthiobutyl isothiocyanate, 5-methylthiopentyl isothiocyanate, (*E*)-2-hexenal, (*Z*)-3-hexenol, 1-methylthio-3-penta-none, 5-hexenyl isothiocyanate, 5-(methylthio)-pentane nitrile and 2-phenylethyl isothiocyanate (Kjaer et al. 1978).

The six heirloom Japanese radish varieties produced 2.0–11.5 times higher levels of 4-methylthio-3-butenyl isothiocyanate (MTBITC) as compared to the widely consumed conventional variety, Aokubi (Nakamura et al. 2008). The myrosinase, a cytosolic plant enzyme that hydrolyses 4-methylthio-3-butenyl glucosinolate (MTBGLS) into the natural pungent agent 4-methylthio-3-butenyl isothiocyanate (MTBITC), was located exclusively in the outer epidermal layer in Aokubi daikon, while 4-methylthio-3-butenyl glucosinolate (MTBGLS) was widely distributed throughout the root tissue. Despite the skin being a potentially rich source of myrosinase in Aokubi, the skin is usually peeled off in the current practice of preparing daikon for cooking. Thus, new practices were therefore proposed for the preparation of daikon tubers that eliminated the peeling of the skin to avoid removing the enzyme needed to convert MTBGLS to the health-beneficial MTBITC.

A total of eight glucosinolates were identified in different tissues of radish, including five aliphatic glucosinolates (4-methylsulfinyl-3-butenyl glucosinolate, 2-hydroxy-3-butenyl glucosinolate, ethyl glucosinolate, 4-methylthio-3-butenyl glucosinolate and 6-heptenyl glucosinolate) and three indole glucosinolates (1-methoxyindol-3-ylmethyl glucosinolate, indol-3-ylmethyl glucosinolate, 4-hydroxyindol-3-ylmethyl glucosinolate) (Li et al. 2008). The contents of total glucosinolates in the edible roots and sprouts were higher than that in the leaves. The major glucosinolate in edible roots and sprouts was 4-methylthio-3-butenyl glucosinolate, accounting for 75.5 % and 71.5 % of the total glucosinolates, respectively. Indol-3-ylmethyl GS was the major glucosinolate in radish leaves, accounting for 57.1 % of the total leaf glucosinolates.

Other Phytochemicals

The contents of phenolic acids (hydroxycinnamic acids and hydroxybenzoic acids) in radish roots were much smaller than in the corresponding leaves (Stöhr and Herrmann 1975). In small radishes, *p*-coumaric acid and, in radishes, ferulic acid dominated after hydrolysis. Small radishes showed higher concentrations of phenolic

acids in outer tissue layers. In contrary to hydroxycinnamic acid derivatives, the contents of hydroxybenzoic acid derivatives (*p*-hydroxybenzoic, vanillic, salicylic and gentisic acid) mostly were small. Partially, hydroxycoumarins (aesculetin and scopoletin) were also identified. *N*-methylphenethylamine, a secondary amine with indirect sympathomimetic action (Marquardt et al. 1976), and phenethylamine (Gutiérrez and Perez 2004) were found in radish root.

Alkaloids, saponins and flavonoids and the following constituents were detected in the swollen radish root: 11 long-chain alkyl esters, 3-methyl-5-propylnonane, 5-(hydroxymethyl)undecane, 4,6-dimethyldodecane, *n*-tetradecane; *n*-hexadecane, *n*-heneicosane; 2,6,10,14-tetramethylhexadecane; *n*-eicosane, methyl *n*-tetradecanoate; 2,6,10,15-tetramethylheptadecane; *n*-tricosane; *n*-hexadecanoic acid methyl ester; tritetracontane; 10-octadecenoic acid methyl ester; 9-octadecenoic acid ethyl ester; 2 aromatic ketones, diphenyl-benzophenone and 1-phenyl-pent-4-en-1-one; a benzyl halide, *a*-iodotoluene; an aryl ether, 1-methoxy-4-(prop-2-en-1-yl)benzene; a quinone, 2,6-di-*tert*-butylquinone; an aromatic aldehyde, 2-benzylideneoctanal; a long-chain aromatic alkane, 6-phenyldodecane; and a long-chain alkyl nitrile, 9-octadecenitrile (San Jaun et al. 2012).

The enzyme cysteine synthase comprising of two identical subunits of molecular weight 33,000 was isolated from radish roots (Tamura et al. 1976). Radish root was found to contain phospholipase D (Rakhimov et al. 1981). Phospholipase D displayed a more pronounced specificity for lecithin as substrate and was weakly active in the reaction with cephalin. An addition of Ca²⁺ increases the enzymatic affinity for the substrate in all cases studied. Two cationic isoperoxidases (designated C1 and C3) and four anionic isoperoxidases (designated A1, A2, A3n and A3) from Korean radish root were purified (Lee and Kim 1994). All six isoperoxidases were glycoproteins composed of a single polypeptide chain. The MW of C1, C3, A1 and A2 were ca 44,000, while anionic isoperoxidases A3n and A3 had MW of 31,000 and 50,000, respectively. Deglycosylated A2 and C3 by trifluoromethanesulfonic acid treatment showed MWs of 37,000 and 40,000, respectively, suggesting that the carbohydrate contents for these isoenzymes were 14 and 9 %, respectively. Two chitin-binding proteins with lysozyme activity, named as CBP1 and CBP2, were purified to homogeneity with the molecular weights of 26.9 kD and 24.8 kD, respectively, from radish roots (Lai et al. 2006). CBP1 and CBP2 were found to be bifunctional enzymes with activities of lysozyme and chitinase, but

without chitosanase activity. A unique acidic calcium-binding protein RVCaB, rich in glutamic acid and proline and lacking aromatic amino acid residues, was found in radish vacuoles and may be involved in the vacuole Ca(2+) storage function (Ishijima et al. 2007). RVCaB was found to be predominantly an unstructured protein with a polyproline type II helix.

Arabinogalactan proteins (AGPs) were isolated from primary and mature radish roots (Tsumuraya et al. 1988). These root AGPs were composed mainly of L-arabinose and D-galactose but were distinguishable from each other in their contents of L-fucose as well as of protein and hydroxyproline. The structures of the carbohydrate moieties of the root AGPs were essentially similar to those of AGPs isolated from seeds and mature leaves in that they consisted of consecutive (1→3)-linked β-D-galactosyl backbone chains having side chains of (1→6)-linked β-D-galactosyl residues, to which α-L-arabinofuranosyl residues were attached in the outer regions. Three ferredoxin isoproteins (R-Fd A, R-Fd B-1 and R-Fd B-2) were purified from white roots of radish (*Raphanus sativus* L. var. *acantiformis* cultivar Miyashige) (Wada et al. 1989). 1-*O*-sinapoyl-β-glucose:L-malate *O*-sinapoyl-transferase (SMT) from cotyledons of red radish was purified to apparent homogeneity with a 2,100-fold enrichment and a 4 % recovery (Gräwe et al. 1992). Apparent molecular mass of 52 and 51, respectively, were determined. On isoelectric focusing, the SMT resolved into two isoforms which showed slightly different molecular mass (SMT I, Mr/isoelectric point = 51/5.75; SMT II, Mr/isoelectric point = 51.5/5.9). The enzyme accepted all the hydroxycinnamic acid glucose esters tested with relative ratios of initial velocity values of 100:85:45:26:2.6 of 1-*O*-sinapoyl-, 1-*O*-feruloyl-, 1-*O*-caffeoyl-, 1,2-di-*O*-sinapoyl- and 1-*O*-(4-coumaroyl)-β-glucose.

Genes involved in anthocyanin biosynthesis in radish include phenylalanine ammonia lyase (PAL), cinnamate 4-hydroxylase (C4H), 4-coumarate-CoA ligase (4CL), chalcone synthase (CHS), chalcone isomerase (CHI), flavanone 3-hydroxylase (F3H), dihydroflavonol reductase (DFR) and anthocyanidin synthase (ANS). RsDFR and RsANS were found to accumulate in the flesh or skin of two radish cultivars (Man Tang Hong and Hong Feng No. 1) (Park et al. 2011). Radish skin contained higher CHS, CHI and F3H transcript levels than radish flesh in all three cultivars. In red radish, 16 anthocyanins were separated and identified. Some of them were acylated with coumaroyl, malonyl, feruloyl and caffeoyl moieties. Furthermore, (-)-epicatechin and ferulic acid were also identified in the three cultivars.

Myrosinase was found to accumulate in myrosin cells and in other non-specialised cells in the seeds, seedling and other organs of radish plant (Phelan et al. 1984). Two myrosinase isoenzymes were extracted and purified from radish root tissues with M_r s 28,800 and 58,900 (Jwanny et al. 1995). The most active one (120 U/mg) was identified and characterised. The yield of the purified myrosinases was 21 mg (2,398 U) of pure enzymes from 100 g of dry root tissues. Myrosinase (thioglucoside glucohydrolase), a plant enzyme that hydrolyses glucosinolates, principally to isothiocyanates, was purified to homogeneity in good yield from 8-day-old daikon seedlings (Shikita et al. 1999). The purified enzyme was resolved into two subunits with molecular masses of 61 and 62 kDa. Ascorbic acid activated the purified enzyme more than 100-fold. The enzyme also had β -glucosidase activity and hydrolysed *p*-nitrophenyl- β -D-glucopyranoside. Two myrosinase isoenzymes were extracted and purified from radish root tissues with M_r s 28,800 and 58,900 (Jwanny et al. 1995). The most active one (120 U/mg) was identified and characterised. The yield of the purified myrosinases was 21 mg (2,398 U) of pure enzymes from 100 g of dry root tissues. Two cDNA clones of myrosinase (thioglucoside glucohydrolase) were isolated from radish (*Raphanus sativus*) seedlings (Hara et al. 2000). Both clones were identified as MB (B type myrosinase). The tissue distribution of gene expression and enzyme activity of myrosinase corresponded well to the site of glucosinolate accumulation in different tissues of radish. The myrosinase–glucosinolate system was localised in the cotyledons in the seedlings and in the peel of the root in the mature plant. Myrosinase mRNA and activity were localised in the epidermis and vascular cambium that were present in the peripheral part of the root, but few signals were detected in the parenchyma inside of the vascular cambium. Since the myrosinase–glucosinolate system is known to be a defence system in higher plants, the localisation of the myrosinase–glucosinolate system in the peel of the root may act to protect the sink organ from the attack of herbivores or pathogens in soil.

In radish, the concentrations of individual polycyclic aromatic hydrocarbons (PAHs) and phthalic acid esters (PAEs) varied from undetectable to 803 μ g/kg dry weight (DW) and from undetectable to 2,048 μ g/kg DW, respectively (Cai et al. 2008). Compared to the control, higher application rates of sewage sludge resulted in pronounced increases in radish shoot, root and soil concentrations of PAHs and PAEs. PAE concentrations in radish grown in latosolic red soil spiked with sludge compost were higher, while the PAH concentrations were comparable to those receiving 10 g/kg of sewage

sludge. However, the root biomass of radish in soil amended with compost was significantly higher, and the shoot-to-root ratio was significantly lower than in the other treatments. The bioconcentration factors (BCFs, the ratio of contaminant concentration in plant tissue to the soil concentration) of di-n-butyl phthalate and di(2-ethylhexyl) phthalate in both shoots and roots and of total PAH concentrations in roots were less than 1.0, but some BCFs for individual PAHs were high with a maximum value of 80.

Phytochemicals in Leaf/Stem

In radish leaves, the anaerobic accumulation of alanine was accompanied by a loss of aspartate, and these changes preceded gamma-aminobutyrate accumulation and glutamate loss (Streeter and Thompson 1972). Accumulation of gamma-aminobutyrate was due to acceleration of glutamate decarboxylation and arrest of gamma-aminobutyrate transamination. Changes in keto acid content did not appear to be the cause of amino acid changes. Most of the aspartate may be converted anaerobically to alanine via oxaloacetate and pyruvate. Regarding phenolic acids (hydroxycinnamic acid compounds), leaves of radish (*Raphanus sativus* var. *sativus* and var. *niger*) mainly contained compounds of caffeic and *p*-coumaric acid (Schmidtlein and Herrmann 1975). In the group of hydroxybenzoic acid derivatives, traces of salicylic and gentisic acid and frequently vanillic acid were also found. Caffeic, *p*-coumaric, ferulic and sinapic acid esters of malic acid and the enzyme(s) involved in their syntheses were found in the vacuoles of radish leaf protoplasts (Strack and Sharma 1985). The flavonoid kaempferol 3,7-di-*O*- α -l-rhamnopyranoside (lespedin) was identified in radish leaves (Muminova et al. 2006). The following polyphenolic compounds catechin, protocatechuic acid, syringic acid, vanillic acid, ferulic acid, sinapic acid, *o*-coumaric acid, myricetin, and quercetin were found in radish leaves and stem (Beevi et al. 2010b). Oriental radish (Longipinnatus group) was reported to contain the flavonol kaempferol 0.34 mg/100 g (Arai et al. 2000). Quercetin, rutin and kaempferol were determined in radish leaves by liquid chromatography–tandem mass spectrometry (Devaraj et al. 2011).

Radish leaf was characterised chiefly by indole glucosinolates, largely 3-indolylmethyl-glucosinolate (glucobrassicin) with traces of 4-methoxy-3-indolylmethyl-glucosinolate (4-methoxyglucobrassicin) and 4-hydroxy-3-indolylmethyl-glucosinolate (4-hydroxybrassicin) (Sang et al. 1984). Hydroxylated cinnamic acid malate esters, namely, 2-*O*-(*p*-coumaroyl)-L-malate, 2-*O*-caffeoyl-L-malate and 2-

O-feruloyl-L-malate, were found to be quantitatively predominating compounds in the fraction of carboxylic acids isolated from radish leaves and inflorescences (Nielsen et al. 1984). The esters of *p*-coumaric, ferulic and caffeic acid with malic acid were isolated from the leaves, the ester of sinapic acid with malic acid from cotyledons of *R. sativus* (Brandl et al. 1984). The flavonoid kaempferol 3,7-di-*O*- α -L-rhamnopyranoside (lespedin) was isolated from radish leaves (Muminova et al. 2006).

The major volatile components found in the oil of leaves of black, white and red radish in respective sequence were phytol (65.3, 69.7, 65.9 %), hexadecanoic acid (palmitic acid) (14.3, 2.5, 8.5 %), methyl linolenate (11.1, 8.9, 2.1 %) and (*Z*)-3-hexen-1-ol (0.7, 0.7, 6.9 %) (Blažević and Mastelić 2009). Corresponding aliphatic or aromatic glucosinolate compounds identified in the leaves constituted only 0.3–5.7 % of the isolated volatiles. They were 4-methylpentyl isothiocyanate (0, 0.1, 0 %), 5-(methylthio)-4-pentenitrile (tr, 2.2, 0.3 %), 4-(methylthio)butyl isothiocyanate erucin (0.3, 1.7, tr %), 2-phenylethyl isothiocyanate (tr, 0.4, 0 %), 4-(methylthio)-3-butenyl isothiocyanate (0, tr, 0 %), benzenepropanenitrile (0, tr, 0 %), 3-(methylthio)propyl isothiocyanate (iberiverin) (0, tr, 0 %), benzyl isothiocyanate (tr, 0, 0 %) and 2-phenylethyl isothiocyanate (tr, 0.4, 0 %). Alkanes identified in the leaves were undecane (tr, 0.2, 0.2 %), dodecane (0.3, 1.1, 0.8 %), tridecane (0.1, 0.3, 0.3 %), tetradecane (tr, tr, 0.1 %), tricosane (0.2, 0.3, 0.5 %) and tetracosane (0.1, 0.2, 0.2 %). Other aliphatic alcohols and carbonyls identified in the leaves were (*E*)-2-hexenal (tr, tr, 0.8 %), nonanal (0, tr, 0.2 %), (*E,E*)-2,4-heptadienal (0.1, 0, 0 %), benzaldehyde (tr, 0, 0 %), 2-phenylacetaldehyde (tr, 0.2, 0.2 %), 4-ethylbenzaldehyde (0, 0, 0.1 %), isobutyl phthalate (0, 0.3, 0 %) and dibutyl phthalate (0.4, 1.1, 1.0 %). Other fatty acids and esters identified were tetradecanoic acid (myristic acid) (tr, 0, 0 %) and methyl palmitate (0.1, 0, 0 %). Other sulfur and/or nitrogen compounds identified were dimethyl trisulfide (tr, 0.4, 0.2 %) and 1-(methylthio)-0-3-pentanone (0, tr, 1.1 %). Besides phytol, terpenes identified were (*E*)- β -ionone (0.5, 1.3, 1.4 %) and neophytadiene (1.5, 1.1, 1.3 %). Miscellaneous compound identified included 4-vinyl-2-methoxyphenol (0.5, 1.3, 1.0 %), 2,3-dihydrobenzofuran (coumaran) (0.1, tr, 0.4 %), β -cyclocitral (0, tr, tr), β -damascone (0, 0.1, 0 %) and 1H-indole (0.1, 1.8, 0.2 %). Nineteen volatile aglycones were identified for the first time in the leaves of all three varieties of radish. The main aglycones in the leaves of black, white and red radish were, respectively, eugenol (29.2, 30.2, 37.1 %), 2-phenylethanol (23.5, 2.0, 11.8 %), 4-vinyl-2-methoxyphenol (2.7,

12.4, 2.4 %), (Z)-3-hexen-1-ol (6.2, 2.6, 10.4 %), methyl vanillate (0, 10.0, 6.3 %), 1H-indole (6.8, 2.2, 0.7 %), benzyl alcohol (4.2, 1.4, 1.8 %), vanillin (3.7, 3.5, 6.3 %) and methyl salicylate (3.4, 0.8, 0 %). Other aglycones included benzaldehyde (0.1, 1.4, 0 %), 2-phenylacetaldehyde (0, 0.9, 0 %), 1-phenylethyl alcohol (0.2, 0.1, 0.2 %), 2-methoxyphenol (guaiacol) (0.6, 1.7, 0 %), 2-methoxy-4-methylphenol (0, 2.2, 0 %), phenol (0, 2.3, 0 %), 4-ethyl-2-methoxyphenol (2.6, 2.3, 0 %), 2,4-dimethylphenol (0, 3.2, 0.3 %), 4-keto- α -ionol (0.5, 2.9, 2.1 %) and 3-hydroxy- β -ionone (0, 2.4, 1.1 %).

Two isoproteins (L-Fd A and L-Fd B) were isolated from radish leaves (Wada et al. 1989).

Three ferredoxin components, a, b and c, were found in the green shoots of Japanese radish seedlings and mature leaves (Obata et al. 1995). Component a was further separated into two components, a1 and a2. They found that the primary structures of components a1, a2 and b were all found in 12 possible structures of L-Fd A, one the two leaf ferredoxins, L-Fds A and B, isolated by Wada et al. (1989). They concluded that L-Fd A was a mixture of three ferredoxins corresponding to components a1, a2 and b.

Two L-arabino-D-galactan-containing glycoproteins having a potent inhibitory activity against eel anti-H agglutinin were isolated from mature radish leaves and characterised to have a similar monosaccharide composition that consisted of L-arabinose, D-galactose, L-fucose, 4-O-methyl-D-glucuronic acid and D-glucuronic acid residues (Tsumuraya et al. 1984). Two isoproteins (L-Fd A and L-Fd B) were isolated from (*Raphanus sativus* L. var. *acanthiformis* cultivar Miyashige) leaves (Wada et al. 1989). Two induced radish leaf proteins (designated Rs-AFP3 and Rs-AFP4) were purified and shown to be homologous to seed Rs-AFPs and to exert similar antifungal activity in-vitro (Terras et al. 1995). A chimeric Rs-AFP2 gene under the control of the constitutive cauliflower mosaic virus 35S promoter conferred enhanced resistance to the foliar pathogen *Alternaria longipes* in transgenic tobacco. The term 'plant defensins' was proposed to denote these defence-related proteins. On the basis of molecular weight and their antifungal properties, the protein samples from the *Alternaria alternata*- and *Fusarium oxysporum*-infected radish leaves were found to be PR2 (glucanase) and PR3 (chitinase) (Khanal et al. 2014).

Gibberellins (GA₁, GA₃, GA₇) were reported to play a direct role in the bolting of 'Miyashige-sofuto' radish but were probably not directly functional in initiating flowering (Suge and Rappaport

1968). The concentrations of putative active GAs (GA_1 and GA_4) and their precursors (GA_9 and GA_{20}) in both the stems and leaves of *R. sativus* grown without cold treatment were higher in the long-day condition than the short-day condition (Nakayama et al. 1995). The concentrations of the above four GAs in the stems and leaves generally tended to decrease during the cold treatment, although GA_1 in the stems was at almost the same level before and after the cold treatment. These results suggested that the GA biosynthesis was promoted by the long-day condition rather than cold treatment. Considering that application of GAs after the cold treatment as well as cultivation in the long-day condition after cold treatment induced the bolting of *R. sativus*, both the cold treatment and activation of GA biosynthesis by cultivation in the long-day condition appeared to be essential to bolting. A series of GAs belonging to either the early-13-hydroxylation or early-non-hydroxylation pathway were identified in four cultivars of Japanese radish (*Raphanus sativus* L. cvs. Sofutori-Miyashige, Wakayama, Hanashirazu-Hayafutori-Tokinashi and Wase-Shijunichi), which varied greatly in their cold requirement for bolting (or stem elongation) and flowering, suggesting that the endogenous active GAs were GA_1 and GA_4 (Nishijima et al. 1995). The concentration of GA_1 increased in the stem and decreased in the leaf during bolting in all the cultivars.

Two anti-migraine compounds were isolated from radish roots and elucidated as *cis*-(1-methylazetidin-2-yl)methanol and cyclo- (4-methyl-val-4-methyl-val) (Wu et al. 2014).

Foliar applications of brassinosteroids (polyhydroxyl steroidal phytohormones), namely, 28-homobrassinolide and 24-epibrassinolide, to the radish plants resulted in substantial increment (65 %) in soluble protein contents and nucleic acids DNA and RNA (Vardhini et al. 2012). Increased levels of carbohydrates in terms of reducing sugars, nonreducing sugars and starch were also observed.

Seed Phytochemicals

The major active compounds in radish seeds reported were alkaloids, glucosinolates, brassinosteroids and flavonoids (Sham et al. 2013). Two fructooligosaccharides, sucrose, glucose and galactose were identified in radish and *Brassica napus* seed ethanol extracts (Orlovskaya et al. 2013).

The thiocyanate (SCN)[−] content in radish seeds prior to planting was negatively correlated with the SCN[−] content in marketable roots

of five white cultivars (Chong and Bible 1975). On the contrary, there was a corresponding positive correlation for eight red cultivars. Although larger seeds resulted in larger radishes, there was no difference in SCN– content in the root of plants grown from different seed sizes. Studies by Sang et al. (1984) found that the only indole glucosinolate present in the radish seed meal was 4-hydroxy-3-indolylmethyl GS (4-hydroxyglucobrassicin) with the dominant glucosinolate being 4-methylsulfinylbut-3-enyl GS (glucoraphenin), which contained an unsaturated sulfinyl R group. Ten isothiocyanates, seven aliphatic hydrocarbons and some other volatile substances were characterised in *Raphanus sativus* var. *niger* seeds (Afsharypuor and Balam (2005). The main isothiocyanates were hexyl isothiocyanate (18.4 %), 4-methylthiobutyl isothiocyanate (17 %), 4-methylpentyl isothiocyanate (8.4 %), 4-methylthio-(3*E*)-butenyl isothiocyanate (5.2 %), 4-methylthio-(3*Z*)-butenyl isothiocyanate (4.7 %) and isoamyl isothiocyanate (2.4 %). Seven 4-methylthio-butanyl derivatives were identified in the radish seed methanol extract: sinapoyl desulfoglucoraphenin, (*E*)-5-(methylsulfinyl)pent-4-enoxylimidic acid methyl ester, (*S*)-5-((methylsulfinyl)methyl)pyrrolidine-2-thione, 5-(methylsulfinyl)-4-pentenitrile, 5-(methylsulfinyl)-pentanenitrile, sulforaphene and sulforaphane (Kim et al. 2014).

Radish seeds contained two major types of storage protein aggregates which could be separated by gel filtration into 12 and 1.7 Svedberg fractions (Laroche et al. 1984). Radish 12 Svedberg particles comprised a series of nine major polypeptides ranging from 33 to 30 kDa and composed of six subunits approximately 55 kDa. Each subunit is a couple of two polypeptides linked by a disulfide bridge. The 1.7 Svedberg particle is composed of two polypeptides of 10 and 12 kDa and smaller peptides of approximately 7 kDa. Twelve and 1.7 Svedberg particles also differed in their amino acid composition, the 1.7 Svedberg being particularly rich in glutamic acid and proline. An L-arabino-D-GALACTAN and an L-arabino-D-galactan-containing proteoglycan were isolated from radish seeds (Tsumuraya et al. 1987). The proteoglycan consisted of 86 % of a polysaccharide component containing β -L-arabinose and D-galactose as major sugar constituents, together with small proportions of D-xylose, D-glucose and uronic acids and 9 % of a hydroxyproline-containing protein. Raphanuside, an unusual oxathiane-fused thioglycoside isolated from *Raphanus sativus* seeds, was synthesised giving 11 % overall yield (Yang et al. 2010). Two novel sulfur compounds *S*-6-(methylsulfinyl)methyl-1,3-thiazinan-2-thione and *O*-ethyl *N*-(*E*)-4-(methylsulfinyl)but-3-enylcarbamothioate were

isolated from the seeds (Zhang et al. 2010). A novel compound rasatiol was isolated from radish seed used as Korean herbal medicine, 'NaBokJa' (Roh et al. 2013).

A basic β -galactosidase (β -Galase) with an apparent molecular mass of 45 kDa was purified 281-fold from imbibed radish seeds (Sekimata et al. 1989). The enzyme was maximally active at pH 4.0 on *p*-nitrophenyl β -D-galactoside and β -1,3-linked galactobiose. Radish seed and leaf arabinosyl-3,6-galactan proteins were resistant to β -Galase alone but could be partially degraded by the enzyme after the treatment with a fungal α -L-arabinofuranosidase leaving some oligosaccharides consisting of D-galactose, uronic acid, L-arabinose and other minor sugar components besides D-galactose as the main product. α -L-arabinofuranosidase was purified 1,043-fold from radish seeds (Hata et al. 1992). The purified enzyme was a homogeneous glycoprotein consisting of a single polypeptide with an apparent molecular weight of 64,000 and an isoelectric point value of 4.7. The enzyme characteristically catalyses the hydrolysis of *p*-nitrophenyl α -L-arabinofuranoside and *p*-nitrophenyl β -D-xylopyranoside. The enzyme was shown to split off α -L-arabinofuranosyl residues in sugar beet arabinan, soybean arabinan-4-galactan and radish seed and leaf arabinogalactan proteins. Arabinose and xylose were released by the action of the enzyme on oat-spelt xylan. Synergistic action of α -L-arabinofuranosidase and β -D-galactosidase on radish seed arabinogalactan protein resulted in the extensive degradation of the carbohydrate moiety. Radish seeds were found to contain two homologous, small, 5 kD, cysteine-rich oligomeric proteins designated *Raphanus sativus* antifungal protein 1 (Rs-AFP1) and Rs-AFP2; they were found in the cell wall occurring predominantly in the outer cell layers lining different seed organs (Terras et al. 1992a, 1995). The radish 2S storage albumins in the seeds were identified as the second novel class of antifungal proteins. An α -L-arabinofuranosidase/ β -D-xylosidase was cloned from immature seeds of radish by reverse transcriptase-PCR (Kotake et al. 2006). It hydrolysed α -L-arabinofuranosyl residues of the carbohydrate moieties of arabinogalactan proteins (AGPs). The gene, designated RsAra1, was found to encode a bifunctional α -L-arabinofuranosidase/ β -D-xylosidase and the results suggested that RsAra1 was involved in the hydrolysis of the carbohydrate moieties of AGPs in immature radish seeds. *Raphanus sativus* antifungal protein 1 (Rs-AFP1), a 51 amino acid residue plant defensin, was isolated from radish seeds (Fant et al. 1998). Cationic peroxidase Cs with molecular mass of 44 kDa was purified to apparent homogeneity and characterised from Korean radish seeds (Kim and

Lee 2005). The cationic peroxidase Cs showed the peroxidase activities for native substrates, such as coumaric acid, ferulic acid and scopoletin. This result suggested that cationic peroxidase Cs may play an important role in plant cell wall formation during seed germination. Rs-AFP2 (*Raphanus sativus* antifungal peptide 2), an antifungal plant defensin, was isolated from radish seed (Aerts et al. 2007). Karri and Bharadwaja (2013) linked two plant defensins, namely, *Trigonella foenum-graecum* defensin 2 (Tfgd2) and *Raphanus sativus* antifungal protein 2 (Rs-AFP2) genes, by a linker peptide sequence (occurring in the seeds of *Impatiens balsamina*) and made into a single-fusion gene construct with enhanced antifungal activity.

Eleven gibberellins (GAs) were identified in extracts of mature seed of radish (*Raphanus sativus* cv. Taibiyosobutori) (Nakayama et al. 1990). These GAs comprised seven 13-hydroxy GAs [GA₁, 3-*epi*-GA₁, GA₈, GA₁₇, GA₁₉, GA₂₀ and a new GA, 12 α -hydroxy GA₂₀ (GA₇₇)] and four non-13-hydroxy GAs [GA₉, GA₂₄, 12 β -hydroxy GA₂₄ (tentative) and GA₂₅]. The major GAs were GA₈, GA₂₀, GA₂₄ and GA₇₇.

During the first 48 hours after imbibition of water by quiescent radish seeds, the changes in ATP concentrations, oxygen utilisation and fresh weights followed a triphasic time course, characterised by a rapid initial increase, which extended from 0 to approximately 1.5 hours, a lag phase from 1.5 to 16 hours and a sharp linear increase from 16 to 48 hours (Moreland et al. 1974). After imbibition of water by the quiescent seeds, for 1 hour, the ATP concentration had increased to 2.5, and ADP and AMP concentrations had decreased to 0.3 and 0.1 nmole/seed, respectively. In unimbibed seeds, the concentrations of ATP, ADP and AMP were <0.1, 0.9, and 2.2 nmoles/seed, respectively. Oxidative phosphorylation was estimated to have contributed 15, 20 and 65 % of the pool ATP at 1.5, 16 and 48 hours, respectively.

Phytochemicals in Seedlings and Sprouts

In dark-grown radish seedlings, the level of phenylalanine transaminase was higher in cotyledons than in the root and hypocotyls (Tomè et al. 1975). The maximum activity of phenylalanine ammonia lyase (PAL) was found in the root. Only PAL was significantly increased by light. Continuous far-red light (active phytochrome P fr) stimulated the synthesis of all prenyl chains (C40 carotenoids; C45 in plastoquinone-9; C20 phytyl in

chlorophylls, α -tocopherol and vitamin K1) in plastids of etiolated radish seedlings but had no or only little effect on the dark pattern of the prenyl chain formation (Lichtenthaler and Becker 1975). White light enhanced the accumulation of prenyl chains to a much higher degree than does far-red light. Two separate enzyme activities for the formation of the 7- and 9-glucopyranosyl derivatives of the cytokinin 6-benzylaminopurine (BAP) were found in soluble extracts of expanded cotyledons of radish and purified (Entsch and Letham 1979). Each activity resulted in the formation of both glucosides, and the enzymes use UDP-glucose as the source of the glucose residue.

Nucleoside polyphosphates, namely, nucleoside triphosphates, nucleoside tetraphosphates, pentaphosphates and hexaphosphates were found in labelled RNA preparations from radish seedlings (Aspart-Pascot et al. 1976). Polyadenylic and polyadenylated ribonucleic acids were found in radish seedlings (Aspart et al. 1979). Two lifetime classes of polyadenylic acid were determined in these seedlings: a short-lived component with a half-life of 30 minutes which represented 60 % of poly(A) and a more stable component with varying half-lives of which the majority range from 4 to 10 hours and a few were considerably longer. Anti-bolting activity was detected in an extract of rosette shoots of radish plants by an assay using seedlings cultured in-vitro (Yoshida et al. 2010). The causal compound that strongly inhibited bolting was isolated and identified as α -(7Z,10Z,13Z)-hexadecatrienoic acid monoglyceride (16:3 monoglyceride). The compound disappeared completely after vernalisation, and bolting occurred thereafter. A membrane-bound 3-hydroxy-3-methylglutaryl-coenzyme A reductase was characterised from 4-day-old, dark-grown radish seedlings (Bach et al. 1986).

The specificity of binding and the complete precipitation of β -fructosidase activity by the insolubilised lectin implied that all β -fructosidase activity measured in *Raphanus sativus* seedling extracts was linked to (a) glycoprotein form(s) of this enzyme (Faye and Berjonneau 1979). When 36-hour-old dark-grown radish seedlings were transferred to far-red light, there was a decrease in glycoprotein cytoplasmic β -fructosidase (betaF) and an increase in cell wall betaF compared to the dark controls (Faye et al. 1986). Cytoplasmic and cell wall-bound β -fructosidase exhibited high antigenic similarities but differed according to charge heterogeneity and carbohydrate microheterogeneity. Growth of radish seedlings in the presence of tunicamycin resulted in a partial inhibition of betaF glycosylation, but nonglycosylated betaF still accumulated in the cell wall under far-red light. The nonglycosylated cytoplasmic and cell wall betaF forms have the same relative molecular mass, but glycosylated forms

had different oligosaccharide side chains, with respect to size and susceptibility to α -mannosidase and endoglycosidase D digestion. An inhibitor of Ca^{2+} -calmodulin (Cam)-dependent brain phosphodiesterase was present in the soluble fraction of embryo axes from ungerminated radish seeds (Cocucci and Negrini 1988). During the early phases of germination, the fresh weight and the levels of DNA and RNA of embryo axes increased, the level of the inhibitor decreased and the level of Cam increased. It was found that the Ca^{2+} -calmodulin system was activated in early germination of radish seeds by an increase in Cam and a decrease in the inhibitor levels; that fusicoccin, probably through the activation of membrane functions, increased Cam level; and that the abscisic acid (ABA) inhibition on germination was not mediated by the Ca^{2+} -Cam system. The peptide-N4-(N-acetyl- β -D-glucosaminyl) asparagine amidase (PNGase) activity was found in dry radish seeds, and its level was constant during germination and postgermination (Berger et al. 1995). The endo-N-acetyl-beta-D-glucosaminidase (ENGase) activity was first detected about 18 hours after the start of imbibition (HAI) and displayed a maximum level at 36 HAI. After 36 HAI, the production of both enzymes was constant until days 4–5. Both enzymes displayed substrate specificities corresponding to the potential glycoprotein substrates found in plants.

In radish hypocotyl, 4-hydroxy-3-indolylmethyl glucosinolate (4-hydroxybrassicin), 4-methoxy-3-indolylmethyl glucosinolate (4-methoxygluco-brassicin) and 3-indolylmethyl glucosinolate (glucobrassicin) were present with the major glucosinolate being 4-methylthio-3-butenyl glucosinolate (glucoraphasatin) (Sang et al. 1984). In comparison to daikon seeds, glucoraphenin (4-methylsulfinyl-3-butenyl Gs, GRE) content in daikon sprouts decreased from about 90 to about 12 $\mu\text{mol/g}$ of dry weight (DW), whereas a 25-fold increase from about 3 to 76 $\mu\text{mol/g}$ DW of the glucoraphasatin (4-methylthio-3-butenyl Gs, GRH) content was determined (Barillari et al. 2005). An efficient pure GRH gram-scale production process from *R. sativus* (kaiware daikon) sprouts resulted in significant yield improvement of up to 2.2 % (DW basis). Radish sprouts contained significantly greater concentrations of glucosinolates (3.8-fold) and isothiocyanates (8.2-fold) than the mature radish taproot and also contained significantly greater concentrations of phenolics on average 6.9-fold (Hanlon and Barnes 2011).

Malate, which plays many essential roles in plant metabolism, was found to be a potent in-vitro inhibitor of the cytosolic enzyme

phosphoenolpyruvate carboxylase in radish root hair cytoplasm (Bodson et al. 1991). A novel α -L-fucosyltransferase capable of transferring L-fucose (L-Fuc) from GDP-L-Fuc to the O-2 of α -L-arabinofuranosyl residue (GDP-L-Fuc- α -L-arabinofuranoside 2- α -L-fucosyltransferase) was found in the microsomal fraction of primary roots from 6-day-old radish seedlings (Misawa et al. 1996). Soluble and cell wall-bound gamma-glutamyl transferases (GGTs) were purified from radish cotyledons (Nakano et al. 2006). Soluble GGTs (GGT I and II) had the same M(r) of 63,000, and were composed of a heavy subunit (M(r), 42,000) and a light one (M(r), 21,000). The properties of GGT I and II were similar. Both soluble and bound GGTs utilised glutathione, gamma-L-glutamyl-p-nitroanilide, oxidised glutathione and the conjugate of glutathione with monobromobimane as substrates and were inhibited by acivicin, but soluble GGTs were also distinguished from bound GGTs with regard to these properties. Two forms of RD21 (responsive to desiccation-21), an Arabidopsis cysteine protease, were identified from cotyledons of daikon radish, consisting of an intermediate form (iRD21) containing a granulin domain and a mature form (mRD21) lacking this domain (Kikuchi et al. 2008). A cathepsin B-like cysteine protease (CBCP) that was reported to play a role in disease resistance and in protein remobilisation during germination was purified from daikon radish cotyledons (Tsuji et al. 2008). The molecular mass of the enzyme was estimated to be 28 kDa. The best synthetic substrate for CBCP was t-butyloxycarbonyl Leu-Arg-Arg-4-methylcoumaryl 7-amide. Daikon CBCP exhibited both endopeptidase and exopeptidase activities. In addition, CBCP was found to display carboxymonopeptidase activity against the substrate o-aminobenzoyl-Phe-Arg-Phe(4-NO₂).

Three acidic and three neutral growth inhibitors were detected in Sakurajima radish hypocotyls grown in light (Hasegawa and Miyamoto 1978). Among them, all of the acidic and one of the neutral inhibitors increased with the time period of illumination, whereas the other two neutral substances remained almost unchanged in the light but decreased in the dark. Thus, the levels of all six inhibitors were higher in light-grown seedlings than in dark-grown ones. A neutral growth inhibitor named raphanusol A was isolated as a colourless powder from light-grown radish seedlings and partially characterised as a phenolic compound (Hasegawa and Miyamoto 1980). Raphanusol A, isolated from an acetone extract of light-exposed seedlings of Sakurajima radish, was characterised as 1- β ,4-di-O-(4-hydroxy-3,5-dimethoxycinnamoyl) gentiobiose (Hase and Hasegawa 1982). Another growth inhibitor, designated raphanusol B,

was isolated in crystalline form from light-grown Sakurajima radish seedlings and has been shown to be 1-sinapoylglucose (Hasegawa and Hase 1981). Raphanusol B inhibited the growth of intact and excised hypocotyls of etiolated radish seedlings. The raphanusol B content of the radish seedlings increased greatly under red light but decreased in the dark. Another neutral growth inhibitor, designated raphanusanin, was isolated in crystalline form from light-exposed Sakurajima radish (*Raphanus sativus* var. *hortensis* f. *gigantissimus* Makino) seedlings and identified as a new compound, 3-methoxy-4-methylthio-2-piperithione (Hasegawa et al. 1982). Applied raphanusanin inhibited the hypocotyl growth of etiolated radish and lettuce seedlings at concentrations higher than 1.5×10^{-6} M. A new growth inhibitor isolated from an acetone extract of light-exposed seedlings of Sakurajima radish was characterised as 2-thioxothiazolidine-4-carboxylic acid (Hase et al. 1983). Three growth inhibitors which might be involved in phototropism of Sakurajima radish (*Raphanus sativus* var. *hortensis* f. *gigantissimus* Makino) hypocotyls were isolated as crystalline forms from light-exposed radish seedlings and identified as *cis*- and *trans*-raphanusanins and 6-methoxy-2,3,4,5-tetrahydro-1,3-oxazepin-2-one (designated raphanusamide) (Hasegawa et al. 1986). The *cis*- and *trans*-raphanusanins inhibited the growth of etiolated radish hypocotyls at concentrations higher than 1.5 μ molar, raphanusamide at concentrations higher than 20 μ molar. Studies found that *cis*- and *trans*-raphanusanins caused growth inhibition by suppressing the action of auxin and/or cytokinin (Sakoda et al. 1991). A new growth inhibitor was isolated from light-grown radish seedlings and its structure determined as 3-(*E*)-(methylthio)methylene-2-pyrrolidinethione (Sakoda et al. 1990). Above concentrations of 30 mg/L, it inhibited hypocotyl growth in the etiolated cress seedling test.

During radish germination, there was a wide fluctuation of soluble sinapic acid esters. Two major constituents were rapidly degraded in the imbibition phase, and during cotyledon growth, new soluble sinapic acid esters appeared, from which three major components exhibited considerable quantitative changes in opposing directions (Strack 1977). Sinapine esterase that catalysed sinapine (a major phenolic compound in radish seeds) into sinapate and choline during seed germination was found in radish cotyledons (Nurmann and Strack 1979). Sinapine was isolated from radish seeds (Liu et al. 2002). The mean recovery rate for sinapine thiocyanate from radish seeds was 99.75 % and the amount ranged from 1.696 to 16.96 (Li and Jing 2010). The following components were identified in the

metabolic pathway of sinapic acid and its ester derivatives in radish cotyledons: sinapoylglucose, sinapine (sinapoylcholine), sinapoylmalate and disinapoylglucose (Linscheid et al. 1980). Protein preparations from radish cotyledons converted the sinapoyl moiety of 1-sinapoylglucose to L-malate to form sinapoyl-L-malate via a sinapoyltransferase (Tkotz and Strack 1980). During the development of radish seedlings, transconjugation reactions of sinapine (*O*-sinapoylcholine) via transiently accumulating the intermediate 1-*O*-sinapoyl- β -D-glucose in the cotyledons led to accumulation of *O*-sinapoyl-L-MALATE (Strack 1982). The first committed enzyme in sinapate ester biosynthesis was established as a glucosyltransferase (UDP-glucose–sinapate glucosyltransferase) that transferred the glucose moiety from UDP-glucose to the carboxyl group of sinapate (Strack 1982). The resulting β -acetal ester 1-*O*-sinapoyl- β -D-glucose (sinapoylglucose) served as acyl donor in subsequent transacylation reactions thus providing an alternative to CoA-dependent pathways (Mock and Strack 1993). A uridine 5'-diphosphoglucose–hydroxycinnamic acid acyl-glucosyltransferase (HCA-GT) catalysing the formation of 1-*O*-sinapoyl- β -glucose (EC 2.4.1.120) in seedlings of *Raphanus sativus* was partially purified (Mock and Strack 1993). The enzymes channelling sinapoylglucose into the major accumulating sinapate ester compounds had been defined as sinapoylglucose–malate sinapoyltransferase (SMT) and sinapoylglucose–choline sinapoyltransferase (SCT), respectively (Tkotz and Strack 1980; Strack et al. 1986). L-phenylalanine ammonia lyase (PAL) was not involved in sinapoyl derivative metabolism in radish (Strack et al. 1978). In-vivo inhibition of PAL activity with α -aminooxy- β -phenylpropionic acid (AOP) did not affect the accumulation of sinapoylglucose, whereas the formation of anthocyanins, flavonols and a feruloyl derivative was severely depressed. Administration of AOP to the intact seedling revealed I_{50} values to be 0.14 mM for pelargonidin, 0.16 mM for kaempferol and 0.18 mM for the feruloyl derivative. Biosynthesis of phosphatidylcholine in young radish seedlings was supplied with choline from degradation of the seed constituent sinapine (sinapoylcholine) (Strack 1981). During seedling development, the quantity of labelled sinapine rapidly decreased as a result of sinapine degradation with a concomitant label increase in free choline, phosphorylcholine and phosphatidylcholine. Approximately 50 % of the choline liberated from sinapine was consumed in the biosynthesis of phosphatidylcholine. Seedlings of red radish accumulated high amounts of free malic acid and sinapoylmalate, when grown on nitrate as the sole N-source (Dahlbender and Strack 1984). In the

presence of ammonium ($\text{NO}_3^-/\text{NH}_4^+-\text{N}$, 1:2), both metabolites failed to accumulate, and the levels of arginine, asparagine, glutamine, histidine and serine were greatly increased. Sinapic acid esters, namely, 1-sinapoylglucose, sinapoylmalate, 6,3'-disinapoylsucrose and 1,2-disinapoylglucose from crude methanolic extracts from cotyledons of 6-day-old *R. sativus* seedlings, cultured on nutrient solution with $\text{NO}_3^-/\text{NH}_4^+-\text{N}$, were higher than when cultured on NO_3^--N . The extractable activity of 1-sinapoylglucose–L-malate sinapoyltransferase, an enzyme which plays a key role in channelling malic acid into the sinapic-acid metabolism of this plant, was positively correlated with the malic acid level in the cotyledons. From the results, it was proposed that free malic acid might be the likely candidate for regulating the activity of 1-sinapoylglucose–L-malate sinapoyltransferase. L-malate, sinapic acid esters and 1-sinapoylglucose–L-malate sinapoyltransferase (SMT) catalysing the synthesis of sinapoyl-L-malate were found in the vacuoles of protoplasts obtained from cotyledons of red radish (Sharma and Strack 1985). The epidermis and mesophyll tissues of radish cotyledons were found to contain sinapic acid esters (1-sinapoylglucose, sinapoyl-L-malate, 6,3'-disinapoylsucrose), kaempferol glycosides, free malic acid and enzyme involved in the synthesis of sinapoyl-L-malate, 1-sinapoylglucose–L-malate sinapoyltransferase (SMT) (Strack et al. 1985). The kaempferol glycosides were mainly localised in the upper epidermis of radish seedling cotyledons, while the sinapoyl esters were found in all tissues but differed markedly in their concentrations. Disinapoylsucrose was localised predominantly in the mesophyll, while most sinapoylmalate was found in the epidermal layers, as was most 1-sinapoylglucose–L-malate sinapoyltransferase (SMT) activity. Epidermal sinapoyl esters were restricted to guard cells and to guard mother cells and adjacent epidermal cells. Strack et al. (1986) afforded evidence indicating that the 1-sinapoylglucose–L-malate sinapoyltransferase (SMT) activity in radish cotyledons might be related to the metabolism of malic acid.

Sinapoyl glucose was found in radish sprouts (Herrmann 1989). Methyl sinapate, 1,2-disinapoyl- β -D-glucopyranoside and β -D-(3,4-disinapoyl)fructofuranosyl- α -D-(6-sinapoyl)-glucopyranoside were isolated from radish sprouts (Takaya et al. 2003). The main phenolic acids represented in *R. sativus* grown in hydroponic culture in excess copper were chlorogenic, vanillic, caffeic, syringic, *p*-coumaric and ferulic acids, whereas the least represented were gallic, protocatechuic and *p*-hydroxybenzoic acids (Sgherri et al. 2003). The

Cu contents increased with the treatment in both shoots and roots, maintaining in the roots a value eight- to tenfold higher than in the shoots. In both parts, phytochelatin-SH content reached the maximum at 5 μ M copper and then decreased, reaching at 15 μ M copper the control value in the roots and a value fivefold higher than the control value in the shoots. The phenolic acids as well as the total and reduced ascorbate contents increased with the intensification of copper treatment. Notwithstanding these changes, total ascorbate remained 35 % higher in the shoots than in the roots.

Phytochemicals in Flowers

Radish stigma diffusates were found to contain many protein bands; the molecular weights of some of the major fractions were estimated to be 15,000, 30,000–46,000 and 70,000 Da (Zhang et al. 1983). Glycine, glutamic acid, serine and aspartic acid were some of the predominant amino acids. The carbohydrate fraction of the glycoprotein consisted of arabinose 17.3 %, galactose 19.1 %, xylose 8.1 %, mannose 5.4 %, glucose 23.7 %, rhamnose and/or fucose 26.4 %. In the stigma surface diffusates, the content of protein was estimated to be 16 % and that carbohydrate was 11 %.

Antioxidant/Redox Activity

The antioxidative activity of hot water extract of daikon was higher than that of the ambient water extract (Katsuzaki et al. 2004). One of the antioxidants was isolated as L-tryptophan which changed to 5-hydroxytryptophan, another antioxidant in the rat liver microsome. Radish root extract reduced the levels of thiobarbituric acid reactive substance significantly in all treated albino rats as compared to the experimental control group (Chaturvedi 2008). It also increased the levels of reduced glutathione and increased the activity of catalase. The extract also inhibited in-vitro cumene hydroperoxide-induced lipid peroxidation. The results suggested that radish root extract afforded protection by strengthening the antioxidants like glutathione and catalase.

Among the different extraction solvents, methanolic extract of the leaves and stem showed potent reductive capacity, significantly inhibited linoleic acid peroxidation and displayed metal chelating activity (Beevi et al. 2010b). Additionally, they scavenged free radicals effectively with IC₅₀ of 31 and 42 μ g/mL for DPPH radical, 23 and 52 μ g/mL for superoxide radical, 67 and 197 μ g/mL for hydrogen peroxide and 56 and 62 μ g/mL for nitric oxide,

respectively. The leaves showed the most potent antioxidant and radical scavenging activity as compared to the stem, attributable to the higher polyphenolic content. The methanolic radish root extract showed significant ferric reducing ability, moderate metal chelating activity and strong radical scavenging activity (Beevi et al. 2012). Polyphenolic content in radish was estimated to be in the range 13.18–63.54 mg/g dry weight, with a considerable amount being obtained with polar solvents. Catechin was found to be the most abundant phenolic compound in water extract and sinapic acid, the predominant phenolic compound in methanolic, ethyl acetate and hexane extracts.

Red radish extract in which the major compounds were acylated pelargonidin derivatives appeared to form a complex with Fe^{3+} or Cu^{2+} (Wang et al. 2010). It displayed a concentration-dependant reducing power and scavenging effect against 2,2'-azino-bis-(3-ethylbenzothiazoline-6-sulfonic acid) radicals (with $\text{IC}_{50} = 1.74$ mM). It could promote the cleavage of plasmid DNA with $\text{Cu(II)/H}_2\text{O}_2$ or Cu(II) alone. The extract also showed growth inhibition of Bel-7402 cells at lower concentration. The results suggested that the formation of reactive oxygen species might be involved in the mechanism of DNA damage. The acylated pelargonidin derivatives extracted from red radish could act as antioxidant and pro-oxidant, and their antioxidant and pro-oxidant properties were relative to the reaction conditions.

Hydrogen peroxide oxidation of glucoraphasatin (4-methylthio-3-butenyl GS) readily resulted in complete transformation into glucoraphenin (4-methylsulfinyl-3-butenyl GS). ABTS^{•+} radical caused complete decay of the glucosinolate in radish sprouts (Barillari et al. 2005). Even though not directly related to its radical scavenging activity, the assessed reducing capacity of glucoraphenin suggests that *R. sativus* sprouts might possess potential for health benefits. Spraying exogenous plant hormone methyl jasmonate (MeJA) upon radish sprout significantly increased the total phenolic content that resulted in the increased DPPH[•] (2,2-diphenyl-1-picrylhydrazyl) free radical scavenging capacity (Kim et al. 2006). In addition, the phenylalanine ammonia lyase activity also increased by 60 % at 24 hours after MeJA treatment. However, the same treatment decreased the amount of 4-methylthio-3-butenyl isothiocyanate (MTBITC), a major isothiocyanate in radish sprout, and the activity of myrosinase, an enzyme related to produce isothiocyanates.

Glucoraphasatin (GRH) and its corresponding isothiocyanate (ITC), 4-methylthio-3-butenyl isothiocyanate (GRH-ITC), from

radish sprouts, were able to quench the 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical, with second-order rate constants of 14.0 and 43.1 M⁻¹ s⁻¹, respectively (at 298 K in methanol), whereas the corresponding value measured for the reference antioxidant α -tocopherol was 425 M⁻¹ s⁻¹ (Papi et al. 2008). GRH reacted with H₂O₂ and *tert-butyl* hydroperoxide in water (pH 7.4) at 37 °C, with rate constants of 1.9 × 10⁻² and 9.5 × 10⁻⁴ M⁻¹ s⁻¹ (paralleling recently developed synthetic antioxidants) being quantitatively (>97 %) converted to glucoraphenin.

Radish sprouts were between 9- and 59-fold more potent than the corresponding mature taproot at activating the antioxidant response element (ARE) in a stably transfected hepatoma cell line (Hanlon and Barnes 2011). The ARE activity of the radish sprouts and mature taproots was significantly correlated with the total isothiocyanate concentration of the radishes.

Among the 11 kinds of commonly available vegetables, the methanol extract of radish sprout (Japanese name ‘kaiware daikon’) exhibited the highest hydroxyl radical scavenging potency using the bleomycin–Fe method (1.8 times as L-ascorbic acid) (Takaya et al. 2003). Several sinapinic acid esters and flavonoids were isolated with high radical scavenging potency, which may contribute substantially to the activity. Black radish root juice exhibited significant antioxidant properties (Lugasi et al. 2005). Supplementation of the lipid-rich diet (20 % sunflower oil, 2 % cholesterol, 0.5 % cholic acid in normal chow) with black radish juice resulted in a significant improvement of antioxidant enzyme activities and the free radical scavenging capacity in hyperlipidaemic rats.

Anticancer Activity

The methanol extract of radish sprouts induced quinone reductase activity in a dose-dependent manner in the concentration range of 0.2–1.6 mg/mL with a maximum of a 3.5-fold increase in induction in murine Hepa1c1c7 cells (Lee and Lee 2006). The induction of quinone reductase by the extract was regulated at the transcriptional level. The dichloromethane (CH₂Cl₂) fraction of the extract showed the highest induction potency, while the other fractions were less potent. The results indicated that radish sprouts could be regarded as a safe and promising new dietary source for decreasing the risk of developing cancer as quinone reductase is known to play critical

roles in protection against chemical carcinogens and other toxic xenobiotics.

Isothiocyanates from radish sprouts, 4-methylthio-3-butenyl isothiocyanate (GRH-ITC) and 4-methylsulfinyl-3-butenyl isothiocyanate (GRE-ITC), reduced cell proliferation in a dose-dependent manner and induced apoptosis in three human colon carcinoma cell lines (LoVo, HCT-116 and HT-29) (Papi et al. 2008). The compounds significantly increased Bax and decreased Bcl-2 protein expression, as well as produce caspase-9 and PARP-1 cleavage after 3 days of exposure in the three cancer cell lines. GRH-ITC treatment was shown to have no toxicity with regard to normal human lymphocytes (–15 %) in comparison with sulforaphane from broccoli (complete growth inhibition). GRH and GRH-ITC were able to quench the 2,2-diphenyl-1-picrylhydrazyl radical. Barillari et al. (2008) found that administration of kaiware daikon extract (KDE), in combination with myrosinase at doses corresponding to 50 μ M 4-methylthio-3-butenyl isothiocyanate (GRH-ITC) plus 15 μ M 4-methylsulfinyl-3-butenyl isothiocyanate (GRE-ITC) (50 μ M KDE-ITC) to three human cancer cell lines (LoVo, HCT-116 and HT-29), significantly reduced cell growth by 94–96 % of control in 6 days, outperforming pure GRH-ITC or GRE-ITC at the same dose. In contrast, the same treatment had no significant toxicity on normal human T lymphocytes. A 50 μ M concentration of KDE-ITC had relevant apoptosis induction in all tested cancer cell lines. Unlike pure GRH or GRH-ITC, KDE also had significant chain-breaking antioxidant activity, retarding the 2,2'-azobis-(2-amidinopropane hydrochloride) (AAPH)-initiated autoxidation of methyl linoleate in sodium dodecyl sulfate (SDS) micelles at concentrations as low as 4.4 ppm (–50 % in oxygen consumption rate), and induced very fast quenching of DPPH radical. In another study, Kim et al. (2011) reported that the ethanol extract of radish leaves inhibited cell proliferation of MDA-MB-231 human breast cancer cells after 48 hours of incubation via the ErbB–Akt pathway. The extract significantly decreased protein expression and mRNA of ErbB-3 (epidermal growth factor receptor) and mRNA expression of Akt (protein kinase B); it increased significantly protein and mRNA expression of Bax and Bcl-2 (apoptosis regulators). Seven 4-methylthio-butenyl derivatives from radish seeds showed antiproliferative activity against the HCT-15 cancer cell, with IC₅₀ values of 8.49–23.97 μ M (Kim et al. 2014).

Nitrogen mustards *cis*-1-methoxy-2-deoxy-2-[*N,N*-bis(2 - chloroethyl)amino]spirobrassinol and *trans*-1-methoxy-2-deoxy-2-

[*N,N*-bis(2 -chloroethyl)amino]spirobrassinol derived from 1-methoxyspirobrassinol, an indole phytoalexin produced by the Japanese radish, were designed as prospective dual-action compounds with DNA-alkylating effect and glutathione-depleting effects that may sensitise cancer cells to alkylating agents (Mezencev et al. 2009). Both new compounds demonstrated cytostatic/cytotoxic effects on various leukaemia and ovarian cancer cell lines and dsDNA-destabilising effects in-vitro. The *cis* isomer was the more promising of the two compounds, exerting earlier onset of anticancer effects on Jurkat cells via induction of apoptosis compared to the traditional alkylating anticancer agent melphalan. Additionally, it demonstrated higher potency on ovarian cancer OVCAR3 cell line and lower fold resistance between Jurkat and Jurkat-M cells selected for the resistance to melphalan. Mustard oil in ‘Shibori Daikon’ a variety of Japanese radish selectively inhibited the proliferation of H-ras-transformed derivative of rat fibroblast HR-3Y1-2, but not 3Y1 rat fibroblasts after 24 hours of treatment (Yamasaki et al. 2009). The selective inhibition was associated with transient oxidative stress via reduced glutathione (GSH) depletion and cell cycle G2/M arrest. The mustard oil extract was found to contain 95.6 % of 4-methylthio-3-butenyl isothiocyanate and 4.4 % of 4-methylthiobutyl isothiocyanate.

Hexane extract of radish root inhibited cell proliferation and induced apoptosis in human cancer cells by upregulation of pro-apoptotic genes and downregulation of antiapoptotic genes along with activation of Caspase-3 (Beevi et al. 2010a). The presence of several isothiocyanates (ITCs) such as 4-(methylthio)-3-butenyl isothiocyanate (MTBITC), 4-(methylthio)-3-butyl isothiocyanate (erucin), 4-methylpentyl isothiocyanate, 4-pentenyl isothiocyanate and sulforaphene was detected in the hexane extract. 4-(methylthio)-3-butenyl isothiocyanate (MTBITC) extracted from *Raphanus sativus* significantly inhibited nitroblue tetrazolium reduction by superoxide radicals in a nonenzymatic superoxide generating system, to scavenge free radicals and to cause a decrease in murine leukaemia cell line (L1210) cell growth (Salah-Abbès et al. 2010b). It also counteracted zearalenone oxidative stress to BALB/c mice keratinocyte cell line (C5-O) through caspase-8 inhibition of apoptosis.

A low transformation of selenium into organic forms was observed in radish plants grown in Se(VI)-enriched culture media (Pedrero et al. 2006). On the contrary, in those plants exposed to selenite, >95 % of the total selenium was found as selenocysteine (SeCys2), selenomethionine (SeMet) and Se-methylselenocysteine

(SeMetSeCys). The concentrations of these compounds in fresh samples remained almost unaltered after a simulated gastrointestinal digestion. Therefore, a high selenium content of Se-methylselenocysteine (65 %), previously reported as a cancer chemopreventive species, remained in the potentially bioabsorbable fraction. The results suggested that radish enriched in selenite could be a good choice as an organoselenium supplement for the human diet and animal feed.

Antimutagenic Activity

A correlation was found between the potency of antimutagenicity and the amount of 4-(methylthio)-3-butenyl isothiocyanate (MTBITC) in the n-hexane extracts of eight strains of daikon (Nakamura et al. 2001). Because the pure MTBITC also showed antimutagenicity, MTBITC was presumed to be the active antimutagen principle in n-hexane extracts of daikon. In addition, phenethyl isothiocyanate was found in a lesser amount (5–33 nmol/100 g) in eight strains of daikon, and allyl isothiocyanate and benzyl isothiocyanate were not detectable in any strains (<3 nmol/100 g). The amount of total isothiocyanate in grated daikon was 7.0 times higher than that in cut daikon measured after 30 minutes of cooking. Through eating habits, humans might be able to consume substantial amounts of the antimutagen MTBITC from dishes using the grated form of wild strains of daikon. 4-(methylthio)-3-butenyl isothiocyanate (MTBITC) extracted from Tunisian radish was found to prevent genotoxicity and clastogenicity of zearalenone in BALB/c mice and in in-vitro (Salah-Abbès et al. 2009c).

Antidiabetic Activity

Normal rats fed with a diet containing Japanese radish sprout (JRS) had lower plasma levels of total cholesterol (TC), triglycerides (TG), phospholipids (PL), fructosamine, glucose and insulin and higher plasma levels of low-density lipoprotein cholesterol, whereas the JRS-fed streptozotocin-induced diabetic rats showed lower plasma levels of fructosamine, glucose and insulin without changes in the plasma lipid parameters (Taniguchi et al. 2006). JRS also decreased the hepatic TC, TG and PL levels in the normal rats and the TG level in the diabetic rats. The results showed that JRS had a hypoglycaemic activity in both the normal and diabetic rats and partly improved lipid metabolism in the normal rats. JRS also had the potential to alleviate hyperglycaemia in cases of diabetes and may

serve in the primary prevention of diabetes mellitus. In subsequent study, they found that the water-soluble (WSE) and fat-soluble extracts (FSE) from Japanese radish sprouts exerted dierring effects on carbohydrate and lipid metabolism in normal and streptozotocin-induced diabetic rats (Taniguchi et al. 2007). FSE suppressed insulin secretion and improved lipid metabolism in the normal rats. The effect of WSE was different from that of the FSE as it decreased blood glucose levels without increasing insulin secretion and also lowered glycoalbumin and fructosamine levels in the streptozotocin (STZ)-induced diabetic rats.

Radish root juice extract at a dose of 300 mg/kg BW was identified as the most effective dose lowering blood glucose level (BGL) by 33.4 % at 6 hours during fasting blood glucose studies in normal rats (Shukla et al. 2011a). However, the glucose tolerance test (GTT) revealed the maximum reduction of 15.9 % in BGL at 3 hours in normal rats with the same dose, whereas the reduction observed was by 23.8 and 28.3 % in streptozotocin (STZ)-induced sub- and mild-diabetic rats, respectively, at the same interval of time. The data suggested that radish root juice had hypoglycaemic potential coupled with antidiabetic efficacy.

Anti-inflammatory Activity

The 4-methylthio-butanyl derivative, sinapoyl desulfoglucoraphenin, isolated from radish seeds, exhibited anti-neuroinflammatory effect in lipopolysaccharide-stimulated murine microglia BV-2 cells (Kim et al. 2014). It significantly inhibited nitrite oxide production with IC_{50} values of 45.36 μ M. Moreover, it also reduced the protein expression of inducible nitric oxide synthase.

After treatment with granules from black radish root, all of the histopathological changes and parameters of the redox state (epithelial lining disruption, reduction in the number of enterocytes and goblet cells and the presence of inflammatory cells) caused by the fat-rich diet were improved (Sipos et al. 2002). The structure of the epithelial cells was similar to the controls, the number of goblet cells increased and no inflammation was observed.

Both radish leaf juice and root juice significantly reduced carrageenan- and formalin-induced paw oedema in rats, but radish leaf juice compared to root juice produced more significant anti-inflammatory effect in both acute and chronic models of inflammation (Kamble et al. 2013). However, the anti-inflammatory

effect of radish leaf juice was less than the standard drug diclofenac sodium.

Spasmogenic Activity

Aqueous extract of radish seeds containing terpenes, flavonoids, phenols, alkaloids and saponins showed a spasmogenic effect in isolated rabbit jejunum and ileum, rat stomach fundus and ileum and guinea pig ileum and jejunum (Ghayur et al. 2005). The extract was around ten times more potent in the guinea pig tissues, and this effect was resistant to atropine, pyrilamine or SB203186, while the spasmogenic effect in the rat and rabbit tissues was atropine sensitive. The extract exhibited atropine-sensitive GI (gastrointestinal) prokinetic and laxative effects in-vivo in mice. In the atropinised rabbit jejunum, radish seed extract produced a spasmolytic effect independent of Ca^{2+} or K^{+} channels and adrenergic or opioid receptor involvement. Activity-directed fractionation of the extract yielded four fractions, all showing effects similar to that of the parent extract. The extract and its fractions were found to be nonlethal up to 10 g/kg in mice for 24 hours, except for the petroleum fraction, which showed 50 % mortality at high doses. Some known radish compounds (spermine, spermidine, putrescine and sinigrin) were also tested and found to be devoid of any activity. A mild relaxant effect was also observed in rabbit jejunum at the lower doses (0.1–0.3 mg/mL) but not against K^{+} -induced contractions, ruling out a calcium channel-blocking effect. In guinea pig ileum, radish leaf extract exhibited a stimulant effect resistant to atropine while sensitive to pyrilamine pretreatment. The findings suggested the presence of species-dependent gastrointestinal effects of radish mediated partially through cholinergic receptors in rabbit and rat tissues but through histaminergic activation in the guinea pig. The crude radish leaf extract exhibited a dose-dependent (0.03–5.0 mg/mL) spasmogenicity in guinea pig ileum and colon (Gilani and Ghayur 2004). The effect was insensitive to atropine pretreatment but was completely abolished by pyrilamine indicating involvement of histaminergic ($\text{H}(1)$) receptors. The contractile effect at high doses (3.0–5.0 mg/mL) was followed by relaxation. The extract also enhanced the transit of charcoal meal in mice at 30–100 mg/kg. The petroleum spirit, chloroform and aqueous fractions all showed histaminergic activity in the ileum, aqueous fraction being more potent. The results indicated the presence of a histaminergic component(s) along with a weak spasmolytic factor thus providing sound mechanistic basis for the traditional use of the plant in

constipation. In subsequent studies, they found that administration of radish and betel nut extracts to isolated rabbit gall bladder tissues modulated gall bladder contractility in a concentration-dependent manner similar to carbachol, a muscarinic receptor agonist (Ghayur and Gilani 2012). The stimulant effect of the extract, as well as that of carbachol, was completely blocked in the presence of atropine, a muscarinic antagonist, indicating similarity in the mechanism of action of the extracts with carbachol. The result showed the potential of these extracts to contract the gall bladder and to subsequently increase bile secretion.

Hepatoprotective Activity

Acute and chronic administration of radish leaf powder, its water and ethanol extracts significantly decreased the elevated activity of serum glutamate oxaloacetate transaminase (SGOT), serum glutamate aspartate transaminase (SGPT), serum lactate dehydrogenase (SLDH), serum alkaline phosphatase (SAP) and serum total bilirubin in paracetamol-induced hepatotoxicity in rabbits (Anwar and Ahmad 2006). Crude radish leaf powder, its water and ethanol extracts produced nonsignificant effect on total protein contents. In a separate study, administration of radish root methanol extract to albino rats exerted a protective effect on paracetamol-induced hepatotoxicity in a dose-dependent manner (Chaturvedi et al. 2007; Chaturdevi and Machacha 2007). Radish extract reduced the levels of thiobarbituric acid reactive substances (TBARS), SGOT and SGPT and increased the level of GSH and reduced glutathione (GSH) and catalase. The extract reduced lipid peroxidation induced by paracetamol and reverted the levels of SGOT and SGPT to normal, indicating liver recovery. It also restored GSH levels and recovery of catalase activity. Oral administration of radish extract of 200 and 400 mg/kg body weight protected Wistar albino rats against carbon tetrachloride-induced hepatotoxicity (Mohammed et al. 2008). The extract inhibited the increase in serum aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP) and bilirubin concentrations besides adverse histopathological changes induced by CCL₄. Studies found that oral administration of the sulfur-radish extract and of sulforaphane after CCL₄-induced liver injury in mice both decreased the serum level of alanine aminotransferase, reduced the necrotic zones, inhibited lipid peroxidation and induced phase 2 enzymes without affecting cytochrome P450 2E1 (CYP2E1) (Baek et al. 2008). The results suggested that the administration of the sulfur-radish extract and of

sulforaphane may partially prevent CCL₄-induced hepatotoxicity, possibly by indirectly acting as an antioxidant by improving the detoxification system.

Administration of radish extract enhanced the antioxidant status and protected against oxidative stress in the liver and kidney induced by zearalenone (a nonsteroidal oestrogenic mycotoxin) in BALB/c mice (Salah-Abbès et al. 2008b). Co-treatment of male BALB/c mice with *R. sativus* extract plus zearalenone prevented the hepatotoxic damage effects of zearalenone (Salah-Abbès et al. 2009b). Radish extract succeeded in reversing hepatotoxic condition back to normal levels for all studied parameters.

Radish enzyme extract showed hepatoprotective activity on tacrine-induced cytotoxicity in HepG2 cells with EC₅₀ value of 1,250 µg/mL (Lee et al. 2012). Oral administration of the extract at doses of 50 and 100 mg/kg and silymarin at a dose of 50 mg/kg significantly reduced the elevated levels of serum enzyme markers induced by CCL₄.

Enzyme Detoxification Activity

The crude aqueous extract from 0.3 to 3 mg of dry Spanish black radish material (SBR) increased the activity of the phase II detoxification enzyme quinone reductase in the human hepatoma HepG2 cell line with a maximal effect at a concentration of 1 mg/mL (Hanlon et al. 2007). Treatment of HepG2 cells with the crude aqueous extract of 1 mg of SBR per mL also significantly induced the expression of mRNA corresponding to the phase I detoxification enzymes, cytochrome P450 (CYP)1A1, CYP1A2 and CYP1B1, as well as the phase II detoxification enzymes, quinone reductase, haem oxygenase 1 and thioredoxin reductase 1. They showed that while glucoraphasatin addition was ineffective, the isothiocyanate metabolite of glucoraphasatin, 4-methylthio-3-butenyl isothiocyanate (MIBITC), significantly induced phase II detoxification enzymes at a concentration of 10 µM. Further, Hanlon et al. (2009) demonstrated that the crude aqueous extract of Spanish black radish and the isothiocyanate metabolite of glucoraphasatin, 4-methylthio-3-butenyl isothiocyanate (MIBITC), were potent inducers of phase I detoxification enzymes, cytochrome P450 (CYP)1A1, CYP1A2 and CYP1B1, as well as the phase II detoxification enzymes, quinone reductase, haem oxygenase 1 and thioredoxin reductase 1 in the HepG2 cell line.

In HepG2 cells, raphasatin induced quinone reductase activity and the RNA expression of several phase 1 and 2 detoxification enzymes by a significantly greater amount than the degradation products of raphasatin (Scholl et al. 2011). Raphasatin, but not its degradation products, activated the antioxidant response element (ARE) in a stably transfected reporter cell line. Mice fed a diet consisting of 20 % freeze-dried radishes for 2 weeks had significantly higher liver expression of cytochrome P450 (CYP)1A1, 1A2, quinone reductase, microsomal epoxide hydrolase and glutathione S-transferase α 2 than mice fed with a nutritionally matched control diet.

In an animal study, N'jai et al. (2012) found expression of phase I and II detoxification enzymes was significantly greater for mice fed with Spanish black radishes than control diet. Six hours after 7,12-dimethylbenz(a)anthracene (DMBA) administration, the blood levels of DMBA in mice fed with the radish diet were significantly lower than mice fed with a control diet. DMBA reduced bone marrow cells in mice fed with a control diet to a significantly greater extent than mice fed with the black radish diet. Colony-forming assays demonstrated that mice on black radish diet had (1) less reduction in lymphoid CFU-preB progenitor cells, (2) greater recovery of CFU-preB progenitor cells at 168 hours and (3) less reduction of CFU-GM progenitor cells at 6 hours. Thus, mice fed with a 20 % black radish diet for 2 weeks had greater expression of detoxification enzymes, faster metabolism of DMBA and a reduction in DMBA-induced bone marrow toxicity.

Antihypertensive Activity

Radish seed extract tested positive for the presence of saponins, flavonoids, tannins, phenols and alkaloids and caused a dose-dependent (0.1–3 mg/kg) fall in blood pressure and heart rate of rats that was mediated via an atropine-sensitive pathway (Ghayur and Gilani 2006). In isolated guinea pig atria, the extract showed dose-dependent (0.03–3.0 mg/mL) inhibition of force and rate of contractions. In the atropine-treated tissues, the inhibitory effect was abolished and a cardiac stimulant effect was unmasked which was resistant to adrenergic and serotonergic receptor blockade. In the endothelium-intact rat aorta, the extract inhibited phenylephrine-induced contractions, which was blocked by atropine and Nomega-Nitro-L-arginine methyl ester hydrochloride which was also absent in the endothelium-denuded preparations. The data showed that the cardiovascular inhibitory effects of the plant were mediated through

activation of muscarinic receptors thus possibly justifying its use in hypertension. Administration of soluble alkaloids of Raphani Semen significantly lowered the blood pressure of spontaneously hypertensive rats (SHR) and improved the process of cardiovascular remodelling (Li et al. 2007). Laiju extract (LJE) from Raphani Semen and Flos Chrysanthemi exhibited antihypertensive effect in renal hypertensive rat (RHR) and spontaneous hypertensive rat (SHR) (Chen et al. 2007). Compared with saline control, blood pressure was significantly lowered at 6 and 5 hours in high and moderate LJE, respectively, in both RHR and SHR groups. However, blood pressure was significantly lowered at 2 and 3 hours in low LJE in both RHR and SHR groups, respectively. Compared with saline control, blood pressure remained significantly lower in SHR in all dosage groups with a single daily dose for 28 days of study. The results suggested that LJE had potential in the preventive management of hypertension.

The flavonoid kaempferol 3,7-di-*O*- α -l-rhamnopyranoside (lespedin) isolated from radish leaves was found to have hypotensor activity (Muminova et al. 2006).

Antiatherosclerotic Activity

The abnormal growth of vascular smooth muscle cells (VSMC) is a prominent feature of vascular disease, including atherosclerosis and restenosis after angioplasty. Treatment with Korean white radish extract decreased the viability of VSMC by 35 % after 24 hours treatment (Suh et al. 2006). Radish extract showed potent inhibitory effects on the DNA synthesis of cultured VSMC. In addition, radish extract induced apoptosis using cell death ELISA assay. These inhibitory effects were associated with G1 cell cycle arrest. Four active isothiocyanate (ITC) were isolated from the hexane radish extract 4-(methylthio)-3-butenyl isothiocyanate (MTBITC), allyl isothiocyanate (AITC), benzyl isothiocyanate (BITC) and phenethyl isothiocyanate (PEITC). When the VSMC were treated with ITC, the cell viability was significantly decreased.

Antimicrobial Activity

An antibacterial principle designated raphanin was isolated from radish seeds (Ivanovics and Horvath 1947). It was inhibitory to the growth of *Staphylococcus* and coliform bacteria. The crude juices of *Raphanus sativus* was found to be strongly inhibitory in-vitro against *Escherichia coli*, *Pseudomonas pyocyaneus*, *Salmonella typhi* and

Bacillus subtilis (Abdou et al. 1972). An antifungal nonspecific lipid transfer protein composed of two 9 kD subunits and possessing 43 amino acids was isolated from radish seed (Terras et al. 1992b). In low ionic strength medium, it exhibited in-vitro antifungal activity with IC₅₀ values of 48 µg/mL for *Alternaria brassicicola*, 41 µg/mL for *Alternaria pisi*, 45 µg/mL for *Botrytis cinerea*, 25 µg/mL for *Colletotrichum lindemuthianum*, 20 µg/mL for *Fusarium culmorum*, 54 µg/mL for *Fusarium oxysporum* f.sp. *lycopersici*, 58 µg/mL for *Fusarium oxysporum* f.sp. *lisi*, 100 µg/mL for *Nectria haematococca*, 18 µg/mL for *Phoma betae*, 10 µg/mL for *Pyricularia oryzae*, 30 µg/mL for *Trichoderma hamatum* and 7 µg/mL for *Verticillium dahliae*. Two homologous, 5 kD, cysteine-rich proteins designated *Raphanus sativus* antifungal protein 1 (Rs-AFP1) and 2 (Rs-AFP2) from radish seeds were found to exhibit potent antifungal activity in-vitro (Terras et al. 1992b, 1995). Their antibiotic activity showed a high degree of specificity to filamentous fungi. The radish 2S storage albumins in the seeds were identified as the second novel class of antifungal proteins. All isoforms inhibit the growth of different plant pathogenic fungi and some bacteria. However, their antimicrobial activities were strongly antagonised by cations. Two induced radish leaf proteins (designated Rs-AFP3 and Rs-AFP4) were purified and shown to be homologous to seed Rs-AFPs and to exert similar antifungal activity in-vitro (Terras et al. 1995). Rs-AFP2, a 51 amino acid cysteine-rich peptide isolated from radish seeds, exhibited potent inhibitory activity against filamentous fungi (Alves et al. 1994). A cDNA clone encoding the Rs-AFP2 preprotein was modified by recombinant DNA methods to allow expression in the yeast *Saccharomyces cerevisiae*.

4-methylthio-3-butenyl isothiocyanate (MTBI), the pungent principle in radish, exhibited antimicrobial activity in-vitro (Uda et al. 1993b). Among the tested Gram-negative bacterial strains (*Escherichia coli*, *Enterobacter cloacae*, *Salmonella typhimurium*, *Proteus vulgaris*), the growth of *E. cloacae* was most strongly affected; the growth inhibition of the other Gram-negative bacterial strains was relatively lower. In contrast, the Gram-positive strains (*Staphylococcus aureus* S-6, *Staphylococcus epidermidis*, *Bacillus subtilis*, *Bacillus cereus* var. *mycoides*) were more sensitive to 2.5–7.5 µmol MTBI. Growth of *B. cereus* was highly inhibited, and *S. aureus* was also relatively sensitive. At 2.5–7.5 µmol, MTBI inhibited the growth of the yeasts (*Candida valida*, *Debaryomyces hansenii*, *Hansenula anomala*) and fungi (*Alternaria helianthi*, *Cladosporium colocasiae*, *Eurotium chevalieri*, *Penicillium frequentans*, *Mucor racemosus* f. *racemosus*) far more strongly than

that of the bacteria. Especially, the growth of *A. helianthi* and *C. colocasiae* was almost completely inhibited by 5.0–7.5 μmol of MTBI. A strong inhibitory effect was also observed in *E. chevalieri* and the yeast *C. valida*. Two antimicrobial components were found in the water-soluble products obtained by degradation of 4-methylthio-3-butenyl isothiocyanate, the pungent principle of radish, of which the major one was isolated and indentified to be 2-thioxo-3-pyrrolidinecarbaldehyde (TPC) (Uda et al. 1993a). The identified compound exhibited prominent growth inhibition on the fungi (*Alternaria helianthi*, *Cladosporium colocasiae*, *Eurotium chevalieri*, *Mucor racemosus* f. *racemosus*, *Penicillium frequentans*, *Penicillium expansum*, *Penicillium martensii*, *Aspergillus candidus*, *Aspergillus fumigatus*) and Gram-positive bacteria (*Staphylococcus aureus* S-6, *Staphylococcus epidermidis*, *Bacillus subtilis*, *Bacillus cereus* var. *mycoides*, *Streptococcus faecalis*). The inhibitory effect on the yeasts (*Candida valida*, *Candida lactis-condensi*, *Debaryomyces hansenii*, *Hansenula anomala*, *Zygosaccharomyces rouxii*) and Gram-negative bacteria (*Enterobacter cloacae*, *Salmonella typhimurium*, *Proteus vulgaris*, *Pseudomonas aeruginosa*) except for *Escherichia coli* was the least among the tested microorganisms. The minimum inhibitory concentration (MIC) of 2-thioxo-3-pyrrolidinecarbaldehyde (TPC) was determined by strains of microbes (Matsuoka et al. 1997). MICs of 100 $\mu\text{g/mL}$ were obtained for the fungi *Alternaria helianthi*, *Aspergillus candidus* and *Aspergillus fumigatus*; MICs of 200 $\mu\text{g/mL}$ for *Cladosporium colocasiae*, *Eurotium chevalieri*, *Neurospora crassa*; and MICs of 400 $\mu\text{g/mL}$ for *Mucor racemosus* f. *racemosus*, *Penicillium frequentans*, *Penicillium expansum* and *Penicillium martensii*. Yeasts were less sensitive with MICs of 400 $\mu\text{g/mL}$ for *Candida albicans* and *Saccharomyces bayanus* and 800 $\mu\text{g/mL}$ for *Candida valida*, *Debaryomyces hansenii* and *Hansenula anomala*. MICs obtained for Gram-negative bacteria were 200 $\mu\text{g/mL}$ for *Enterobacter cloacae*, *Pseudomonas aeruginosa* and *Salmonella typhimurium* and 100 $\mu\text{g/mL}$ for *Escherichia coli* and *Proteus vulgaris*. For the Gram-positive bacteria, the most sensitive was *Bacillus subtilis* with MIC of 50 $\mu\text{g/mL}$, followed by *Staphylococcus aureus* and *Staphylococcus epidermidis* at 100 $\mu\text{g/mL}$ and *Bacillus cereus* and *Enterococcus faecalis* at 200 $\mu\text{g/mL}$. The antifungal and antibacterial actions of TPC were due to the sporicidal and bactericidal activities. In *S. epidermidis*, a dose-dependent inhibition of the uptakes of both oxygen and radioactive precursors was observed, suggesting that TPC caused damage to the mitochondrial functions and biosynthetic systems. The ethanol and methanol extracts of radish seeds exhibited in-vitro antibacterial activity

against *Escherichia coli*, *Klebsiella pneumonia*, *Proteus vulgaris*, *Pseudomonas aeruginosa*, *Staphylococcus aureus*, *Shigella sonnei*, *Salmonella typhi* and *Salmonella paratyphi* (Ahmad et al. 2013).

Rs-AFP2 (*Raphanus sativus* antifungal peptide 2), an antifungal plant defensin isolated from radish seed, was found to interact with glucosylceramides (GlcCer) in membranes of susceptible yeast and fungi and induced membrane permeabilisation and fungal cell death (Aerts et al. 2007). It was shown that Rs-AFP2 induced reactive oxygen species (ROS) in *Candida albicans* wild type in a dose-dependent manner, but not at all in an Rs-AFP2-resistant Deltags *C. albicans* mutant that lacked the Rs-AFP2-binding site in its membranes. The findings indicated that upstream binding of Rs-AFP2 to GlcCer was essential for ROS production leading to yeast cell death. They also demonstrated that deletion of *C. albicans* metacaspase 1, encoding the only reported (putative) caspase in *C. albicans*, significantly affected caspase activation by the apoptotic stimulus acetic acid, but not by Rs-AFP2 (Aerts et al. 2009). Their data indicated the existence of at least two different types of caspases or caspase-like proteases in *C. albicans*.

The acetone and hexane fractions of radish root, stem and leaf exhibited selective antibacterial activity against *Bacillus subtilis*, *Staphylococcus aureus*, *Staphylococcus epidermidis*, *Enterococcus faecalis*, *Salmonella typhimurium*, *Enterobacter aerogenes*, *Enterobacter cloacae* and *Escherichia coli* (Beevi et al. 2009). Antibacterial activity was strongest in the acetone fraction of root with larger zone of inhibition and lower minimum inhibitory concentration. The results obtained were comparable to that with standard antibiotics. Of the different parts of *R. sativus* studied, root tended to be more active than the stem and leaf extracts in inhibiting the bacterial growth. Five different ITCs such as allyl isothiocyanate (AITC), phenyl isothiocyanate (PITC), benzyl isothiocyanate (BITC), phenethyl isothiocyanate and 4-(methylthio)-3-butenyl isothiocyanate (MTBITC) were identified in different parts of the plant. The low linear correlation between the total ITC content and antibacterial activity implied that bacterial growth inhibitory ability of *R. sativus* was not dependent on the total ITC content. However, the antibacterial activity of *R. sativus* was well correlated with AITC, PITC and BITC for all organisms except for *Enterococcus faecalis*, whose inhibitory effect was more related to MTBITC.

Radish root juice exhibited considerable antimicrobial activity in-vitro against five bacterial strains, viz., *Klebsiella pneumoniae*, *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Enterococcus*

faecalis and *Escherichia coli* with minimum inhibitory concentration (MIC) ranging from 0.078 to 0.625 mg/mL (Shukla et al. 2011b). Ethanolic and ethyl acetate extracts of radish root peels were the most effective of all extracts against bacterial strains tested (Janjua et al. 2013). Ethyl acetate extract of radish root peels was most effective against *Staphylococcus aureus*, *Bacillus subtilis*, *Salmonella typhi* and *Klebsiella pneumonia*. The ethanol extract had the highest zone of inhibition against *Micrococcus luteus*, *Pseudomonas aeruginosa*, *Bordetella bronchiseptica* and *Enterobacter aerogenes*.

Antiviral Activity

Administration of black radish aqueous extract by intranasal instillations to mice before inoculation of the influenza virus A/PR 8/34 (H1N1) strain protected against the experimental influenza infection (Prahoveanu and Eşanu 1987, 1990). A significant decrease of the haemagglutinin titre of the mouse lung homogenate was noted, as well as a decrease of the mortality rate and a significant increase of the rate of survival as compared to the untreated control.

Antilithiatic and Diuretic Activities

Administration of the aqueous extract of radish bark to rats with artificially induced urolithiasis significantly decreased the weight of stones compared to untreated urolithiatic rats (Vargas et al. 1999). This extract showed an increase in the 24 hour urine volume as compared to the control. After treatment with black radish root juice for 6 days of female C57BL/6 mice with induced gall bladder lithiasis, cholesterol gallstones were eradicated significantly in the gall bladder of mice; cholesterol and triglycerides levels were decreased, and there was also an increase in levels of HDL (Castro-Torres et al. 2012, 2014).

Immunoprotective Activity

Administration of radish extract was effective in protecting against zearalenone-induced immunological disorders in BALB/c mice (Salah-Abbès et al. 2008a). Mice treated with radish extract (5, 10 or 15 mg/kg) for 7 days before, during or after zearalenone treatment showed a significant improvement in lymphocyte, immunoglobulin profile, T-cell subtypes, B cells and proinflammatory cytokines. Moreover, treatment with the highest dose of radish extract (15 mg/kg) enhanced the release of tumour necrosis factor-alpha and

interleukin 1beta, but the other parameters were comparable with those of the control. Radish extract was found to be effective for the protection of high-dose zearalenone immunotoxication in BALB/c mice (Salah-Abbès et al. 2010a). The extract at 15 and 30 mg/kg BW reduced the deleterious effects in immunological parameters of high subchronic doses of 40 and 80 mg of zearalenone/kg BW on modulation of lipopolysaccharide (LPS). Radish extract was found to be effective for the protection of high-dose zearalenone immunotoxication in BALB/c mice (Salah-Abbès et al. 2010a). The extract at 15 and 30 mg/kg BW reduced the deleterious effects in immunological parameters of high subchronic doses of 40 and 80 mg of zearalenone/kg BW on modulation of lipopolysaccharide (LPS).

Salah-Abbès et al. (2014) found that radish extract prevented cadmium-induced immunotoxic and biochemical alterations in rats. Treatment with CdCl₂ alone resulted in significant decreases in plasma levels of total protein, triglycerides, creatine kinase, creatinine, IgG and IgA, T-lymphocyte subtypes (CD4⁺, CD3⁺, CD56⁺ and CD8⁺) and thymic and hepatic indices (relative weights). Conversely, CdCl₂ treatment caused significant increases in serum LDH, AST and ALT, in the formation/release of proinflammatory cytokines (IL-1 and TNF-α) and in the relative weights of host spleen and kidneys. Rats treated with radish extract alone had no discernable changes compared to the controls with regard to all test parameters. Combined treatment of CdCl₂ and radish extract at any dose resulted in a significant improvement of all test parameters compared to those seen with cadmium alone.

Choleretic Activity

Studies showed that administration of 1.5 g/kg of body weight radish sprouts (Kaiware Daikon) extract (containing 10.5 % w/w glucosinolate glucoraphasatin) for four consecutive days had antioxidant properties and significantly induced bile flow in rats (Barillari et al. 2006).

Gastroprotective Activity

Oral administration of freshly squeezed radish juice (FRJ) in doses of 2 and 4 mL/200 g BW significantly inhibited gastric ulcer formation induced by necrotising agents (ethanol, sodium hydroxide and sodium chloride), hypothermic restraint stress and indomethacin (Algasoumi et al. 2008). The FRJ also replenished the ethanol-induced depleted gastric wall mucus secretion and nonprotein

sulfhydryl (NPSH) concentrations in rats. Phytochemical screening showed the presence of flavonoids, anthocyanins and sulfurated constituents.

Studies by Ahn et al. (2013) found that pretreatment with purple Bordeaux radish (PBR) extract at doses of 500 and 1,000 mg/kg, but not 250 mg/kg, significantly ameliorated ethanol-induced gastric haemorrhages in rats. The immunoreactivities of inducible nitric oxide (iNOS) and its by-product nitrotyrosine in the gastric mucosa of ethanol-treated rats pretreated with 500 mg/kg PBR extract were significantly reduced, as compared with rats treated with ethanol alone, the findings suggested that the gastroprotective effect of PBR could be mediated partly by the antioxidative activity of the extract.

Antidiarrhoeal Activity

Sinapine at 300 and 600 mg/Kg reduced the frequency or incidence of purging induced by castor oil or senna in mice, in a dose-dependent manner (Zhang and Shen 1996). Sinapine inhibited the gastrointestinal propellant rate of charcoal ink in normal mice, but the inhibition was weak and was not enhanced in a dose-dependent manner.

Skin Anti-ageing/Whitening Activity

The freeze-dried radish root juice showed higher potency of tyrosinase inhibition ($IC_{50} = 3.09$ mg/mL) than the methanolic extract ($IC_{50} = 9.62$ mg/mL) (Jakmatakul et al. 2009). Also, the scavenging effects of the freeze-dried juice on DPPH radical, superoxide anion radical and singlet oxygen were greater than the methanolic extract, with the respective IC_{50} values of 0.64, 4.20 and 1.42 mg/mL for the freeze-dried juice and 1.25, 6.28 and 2.40 mg/mL for the methanolic extract. The contents of total phenolics, total flavonoids and L-ascorbic acid (as per 1 mg of the dried extract) were found to be 10.09, 0.51 and 24.11 μ g for the freeze-dried juice and 6.59, 0.33 and 8.28 μ g for the methanolic extract, respectively. The higher contents of phenolic compounds and L-ascorbic acid in the freeze-dried juice appeared to be responsible for its greater antityrosinase and antioxidant activities. The extract of *R. sativus* root appeared to be a good candidate for application as a natural skin whitening/skin anti-ageing agent due to its abilities to inhibit tyrosinase and scavenge several types of reactive oxygen species.

Rasatiol, isolated from radish seed, accelerated dermal fibroblast growth in a dose-dependent manner and increased the production of type 1 collagen, fibronectin and elastin (Roh et al. 2013). Phosphorylation of p42/44 extracellular signal-regulated kinase, p38 mitogen-activated protein kinase and Akt was remarkably increased by rasatiol, indicating that enhanced extracellular matrix production was linked to the activation of intracellular signalling cascades. The results indicated that rasatiol stimulated the fibrous components of production and may be applied to the maintenance of skin texture.

Reproductive Toxicity Protective Activity

Radish extract, rich in many antioxidant compounds, was safe and succeeded in counteracting the oxidative stress and protected against zearalenone-induced toxicological effects (decreased sperm number, testosterone level and antioxidant enzyme status) in male BALB/c mice (Salah-Abbès et al. 2009a). The extract also exhibited antigenotoxic effect in germ cells.

Laxative Activity

Administration of radish leaf aqueous extract and radish leaf juice to Wistar rats exerted significantly increased faecal output in loperamide-induced constipation and laxative activity test (Dande et al. 2014). Both the extract and the juice increased the distance covered in charcoal meal test and increased the water–ion secretion in electrolyte secretion test indicating laxative activity of *Raphanus sativus* leaf.

Antithyroid Activity

Makhkamov and Latipov (1965) reported a decrease in thyroid hormone in rats fed with radish. Upon hydrolysis, 3-indolylmethyl glucosinolate was reported to produce the thiocyanate (SCN) ion which, when administered over a prolonged period, will reduce the iodine available to the thyroid for incorporation into the thyroid hormone (Greer 1950).

Boiled extracts of radish showed maximum inhibition of thyroid peroxidase activity in-vitro followed by cooked and raw extracts (Chandra et al. 2004). After chronic radish feeding, increased weight of thyroid gland, decreased thyroid peroxidase activity, reduced thyroid hormone profiles and elevated level of thyrotropin were observed in albino rats resembling a relative state of hypoactive

thyroid gland in comparison to control even after supplementation of adequate iodine (Chandra et al. 2006).

Food Safety Studies

Biogenic amines putrescine, cadaverine, histamine, tyramine, spermidine and spermine increased during broccoli and radish sprout production although these levels were below those permitted by legislation (5 mg/100 g of edible food) (Martínez-Villaluenga et al. 2008). Broccoli and radish sprouts contained numbers of mesophilic, psychrotrophic, total and faecal coliform bacteria which were the usual counts for minimally processed germinated seeds. They found that broccoli and radish sprouts demonstrated no toxic effects on proliferation and viability of HL-60 cells and should be included in our diets as healthy and safe fresh foods. Raphani Semen processed by roasting was reported to exhibit some adverse effects on mice (Sham et al. 2013). Additionally, erucic acid, the main fatty acid in Raphani Semen, was shown to enhance the toxicity of doxorubicin. Thus, Raphani Semen has a potential risk of causing toxicity and drug interaction.

Allergy Issues

A case of allergic contact dermatitis from the radish was reported in a waitress aged 38 years (Mitchell and Jordan 1974). The mixture of sinigrin, the thioglucoside of allyl isothiocyanate, mixed in petrolatum with the enzyme myrosinase produced a positive patch test reaction. A more recent case of generalised urticaria after ingestion of radish was reported by Damiani et al. 2011).

Traditional Medicinal Uses

Almost all parts of radish plant including leaves, seeds and roots are utilised in medicine (Mayer 1981; Stuart 2013). The fresh juice obtained from leaves is diuretic, laxative, and used for diarrhoea, dropsy and general anasarca. Roots are considered stimulant, carminative and corrective, antiscorbutic and used for urinary complaints, haemorrhoids, gastrodynia pains and various gastric ailments. Roots are crushed and applied locally as dressing or poultice for burns, scalds, ecchymoses or foetid or smelly feet. Root decoction is employed for fever and to bring out the rash in eruptive fevers. Seeds are considered expectorant, digestive, diuretic, laxative, stimulant, carminative and lithotriptic and used to promote the flow

of urine, bowel movements and menstruation. Flowers are considered cholagogue.

Lai fu zi (radish) is employed in traditional Chinese medicine (TCM) for treatment of gastrointestinal disorder and as expectorant in China (Zhang et al. 2010). Radish is a preventive and cure for stone (in the bladder or kidney) (Abdou et al. 1972). It cures readily bronchial troubles and whooping cough (so common among infants in the East). Radish is reputed to be highly diuretic. Radish is a cruciferous vegetable that has been traditionally used in South Asia for different gastrointestinal, gall bladder and hepatic diseases (Ghayur and Gilani 2012). In Mexico, black radish is employed for the treatment of gallstones and for decreasing lipid serum levels (Castro-Torres et al. 2012, 2014).

Dried ripe radish seed (Raphani Semen) is listed in Pharmacopoeia of the People's Republic of China to be commonly used in TCM for promoting digestion, relieving distension, directing 'Qi' downwards and dissipating phlegm (Chinese Pharmacopoeia Commission 2010; Tan et al. 2005). Raphani Semen is traditionally used to treat food dyspeptic retention, distending pain in the epigastrium and abdomen, constipation, diarrhoea and dysentery, panting and cough with phlegm congestion clinically in combination with other TCM herbs. For example, Raphani Semen is one of the three important ingredients of San-Zi-Yang-Qin-Tang, which is a common TCM formula for relieving cough and asthma, dissipating phlegm and promoting digestion. Radish root has been used as a traditional anti-migraine drug in China for hundreds of years (Wu et al. 2014).

Other Uses

Raphanus sativus root was found to have potential in removal of phenolic compounds from phenol-contaminated water (Naghibi et al. 2003). Sliced radish or its juice was added separately as enzyme source to phenol solution, and after 3 hours, more than 90 % of phenol were removed in both cases.

Domingos et al. (2008) employed response surface methodology (RSM) to determine the optimum condition for the ethanolysis of *R. sativus* crude oil. Three process variables were evaluated at two levels (2(3) experimental design): the ethanol–oil molar ratio (6:1 and 12:1), the catalyst concentration in relation to oil mass (0.4 and 0.8 wt.% NaOH) and the alcoholysis temperature (45 and 65 °C). Radish press cake, a solid residue from biodiesel processing, could be used to produce adsorbents by microwave thermal activation for the removal of cationic dyes from wastewaters (Nunes et al. 2011). Both the removal efficiency and the removal capacity decreased with an increase in temperature, pointing towards the exothermic nature of the removal process.

Karri and Bharadwaja (2013) linked two plant defensins, namely, *Trigonella foenum-graecum* defensin 2 (Tfgd2) and *Raphanus sativus* antifungal protein 2 (Rs-AFP2) genes, by a linker peptide sequence (occurring in the seeds of *Impatiens balsamina*) and made into a single-fusion gene construct. This method produced biologically active recombinant His6-tagged fusion protein, which exhibited potent antifungal action towards the plant pathogenic fungi (*Botrytis cinerea*, *Fusarium moniliforme*, *Fusarium oxysporum*, *Phaeoisariopsis personata* and *Rhizoctonia solani* along with an oomycete pathogen *Phytophthora parasitica* var. *nicotianae*) at lower concentrations under in-vitro conditions. This strategy of combining activity of two defensin genes into a single-fusion gene may have promising utility for biotechnological applications.

Comments

Radish plants are propagated primarily from seeds.

Codonopsis javanica

T. K. Lim¹✉

(1) Canberra, Aust Capital Terr, Australia

Scientific Name

Codonopsis javanica (Blume) Hook.f. & Thomson

Synonyms

Campanula javanica (Blume) D. Dietr., *Campanumoea javanica* Blume basionym, *Codonopsis javanica* subsp. *javanica* (Blume) Miq.

Family

Campanulaceae

Common/English Names

Bastard ginseng, Bellflower, Bonnet Flower, Javanese Bluebell

Vernacular Names

Chinese: Dǎngshēn, Jin Qian Bao, Tu Dang Shen

Laos: Man Kha Kai

Vietnam: Dàng Sâm, Cây Dùi Gà, Man Rày Cay (Tay),
Co Nhà Dòi (Thai), Cang Hô (H'mông)

Origin/Distribution

E. Asia – subtropical to temperate areas in China Japan, Vietnam, Laos, northern Thailand, Myanmar to Nepal, Bhutan, North east India. In China it is found up to 2,400 m altitude in Anhui, Fujian, Guangdong, Guangxi, Guizhou, Hubei, Hunan, Jiangxi, Sichuan, Yunnan, Zhejiang and also in Taiwan. In Vietnam it occurs in the mountainous areas of 14 provinces of North Vietnam, particularly in Cao Bang, Lang Son, Lao Cai, Ha Giang, Lai Chau and Son La at altitudes of 500–1,600 m and in the highland in South Vietnam Lam Dong, Kon Tum and Quang Nam at an elevation of 1,500 m.

Agroecology

A cool climate species, hygrophilous and partially shade enduring. Optimum temperature for growth and development and is 18–20 °C but will tolerate temperatures up to 30 °C and low temperatures. It requires an annual mean precipitation of 1,500 mm. It prefers well-drained, friable, fertile soil rich in humus. It grows wild in meadows, by streams and forest edge in mountainous areas. It grows well on sloping hillside and upland fields.

Edible Plant Parts and Uses

Codonopsis javanica or *Dang Sam* has edible fruit and roots, and the leaves can be used for soup and fried food (Anonymous 2013). Dried roots are used in a special herbal *Dang Sam* chicken soup.

Botany

A deciduous, slender, perennial twining herb that grows to 1.0 m high by 0.5 m wide (Plate 1) with cylindrical tuberous roots reaching 2 cm diameter (Plates 2 and 3). All parts of the plant have milky latex. Stems are greenish and often tinted purplish. Leaves are pale green, 3–8 cm by 2–4 cm, opposite, cordate, margins entire wavy or slightly denticulate. Flower solitary, axillary, with five-toothed calyx and campanulate corolla, ivory yellow and purple veined inside. Five stamens; stigma 4 or 5 fid. Capsule globose, 1–2 cm diameter, with persistent calyx, reddish violet when ripe with numerous lustrous, yellowish, reticulate textured seeds.

Plate 1 Twining dang sam plant

Plate 2 Dried dang sam roots

Plate 3 Close-up of dried dang sam roots

Nutritive/Medicinal Properties

The root was reported to contain an essential oil, glucose, fatty substances, the glucoside scutellarin and a small amount of alkaloids (Nguyen and Doan 1989). The presence of quaternary ammonium alkaloids codotubulosines A and B, adenosine and 5-(hydroxymethyl)furfural in the roots of *C. javanica* was determined using nuclear magnetic resonance (Li et al. 2009).

Antidiabetic Activity

Studies found that *C. javanica* treatment of fructose-treated rats significantly improved significantly attenuated the hyperinsulinaemia with correspondingly improved glucose tolerance and antioxidant enzyme activities, including superoxide dismutase, glutathione peroxidase and glutathione reductase in the liver (Chen et al. 2013).

The root contains an essential oil, glucose, fatty substances, the glucoside scutellarin and a small amount of alkaloids.

Neuroprotective Activity

Polysaccharides from *C. javanica* were found to have a protective effect on cerebral ischemia–reperfusion injury in mice (Zhang et al. 2011). The polysaccharides alleviated ischemic–reperfusion injuries of neurons in hippocampus CA1 and reduced the brain tissue content of malondialdehyde and nitric oxide, but had no significant effect on superoxide dismutase (SOD), glutathione activity. Its neuroprotective activity may be related to neurotrophic, antioxidant, metabolic control, as well as reduced acetylcholinesterase activity.

Insecticidal Activity

Studies reported that an aqueous extract of roots of *Codonopsis javanica* displayed significant inhibitory activity against the pupae of *Aedes albopictus*, Asian tiger mosquito

vector of dengue fever with 75 % mortality both at 12.79 % and 6.39 % concentration of the decoction but poor or little activity against the larvae (Macchioni et al. 2004).

Traditional Medicinal Uses

Codonopsis javanica roots are pounded and liquid drunk to overcome vitamin deficiency and help new mother bring on milk by Akha hill tribals in Northern Thailand (Anderson 1986). The root is used in the treatment of a wide range of conditions, including general debility, fatigue, anaemia, jaundice, dyspepsia, diarrhoea, nephritis, haemorrhoids, oedema and diseases of the lymphatic system (Nguyen and Doan 1989). In Vietnam, *Dang Sam* root is employed in treating digestive and respiratory disorders, anorexia, diarrhoea, fatigue, thirst, general debility or senility after prolonged illness, haemorrhoids, uterine prolapse, metrorrhagia, menorrhagia, anaemia, jaundice, leucocytosis, nephritis, albuminuria and painful oedema in the legs (Le and Nguyen 1999). It is also used as gastric tonic, diuretic, antitussive and expectorant. *Dang Sam* mixed with other herbs are used to treat cough, tuberculosis, lumbago and arthralgia micturition and as general tonic. In Vietnam, the root decoction is used in traditional medicine as tonic and for treating leukaemia, inflammation and hepatitis (Ueda et al. 2002).

Other Uses

Dried roots are used principally for medicine. The Xo Dang people of Tu Mo Rong District in the Central Highlands province of Kon Tum in Vietnam can make easy money from farming *Dang Sam* (a kind of “wide ginseng”) in their gardens (Anonymous 2013).

Comments

The plant is usually propagated from seeds, and being a twining climber, support frames or live supports (trees) should be provided.

Codonopsis lanceolata

T. K. Lim¹✉

(1) Canberra, Aust Capital Terr, Australia

Scientific Name

***Codonopsis lanceolata* (Siebold. & Zucc.) Benth. & Hook.f.
ex Trautv.**

Synonyms

Campanumoea japonica Sieb. ex Morr., *Campanumoea lanceolata* Siebold & Zucc. basionym, *Codonopsis bodinieri* Lev., *Codonopsis lanceolata* var. *amuræ* T. Koyama, *Codonopsis lanceolata* var. *emaculata* Honda, *Codonopsis lanceolata* f. *emaculata* (Honda) H. Hara, *Codonopsis ussuriensis* f. *viridiflora* J. Ohara, *Codonopsis yesoensis* Nakai, *Glosocomia hortensis* Rupr., *Glosocomia lanceolata* (Siebold & Zucc.) Rupr.

Family

Campanulaceae

Common Names

Bonnet Bell Flower, Lance Asia Bell, Todok

Vernacular Names

Chinese: Shen hai lou, Yang Ru

Eastonian: Süstjas väänkellukas

Korean: Deodeok

Japanese: Tsuru-ninjin

Swedish: prickig porslinsklocka

Origin/Distribution

The species is native to northeast China (Anhui, Fujian, Hebei, Henan, Hubei, Hunan, Jiangsu, Shandong, Shanxi, Zhejiang), Eastern Russia, Korea and Japan.

Agroecology

The plant flourishes in a cold temperate area, on well-drained sandy to loamy, acid to near neutral soils (pH 4.8–6.4) in full sun or partial shade but is frost intolerant. In its native range it grows in thin thickets on hill and mountain slopes and forest margins, shrublands, broad-leaved forests subalpine or mountain forest from 200–1,500 m.

Edible Plant Parts and Uses

Codonopsis lanceolata is equally well known as a culinary and medicinal herb in Korea. The thick tuberous roots are eaten raw or cooked, roasted, dried and sliced or pan-fried. The roots are used in Korean salads, cold soups, pan-fried, as dried or fried vegetables and as vegetables soaked in Korean sauces or as mixed vegetables with spices (Kim et al. 2006b). Roots are eaten as a tonic when boiled with chicken and old ginseng roots. They are used as health food when preserved in alcohol. Roots are also used to prepare *Codonopsis* wine (light yellow coloured wine) by immersing the roots in *soju* (sweet potato liquor) and consumed for health reasons. Young shoots or leaves are parboiled to make seasoned vegetables or used in soups. The deodeok roots are used in Korean dishes such as *deodeok jeon*, *deodeok-saengchae*, *changui* and *namul*. *Saengchae* is a kind of salad dish except it is seasoned with hot chilli pepper, salt, garlic and green onion. Sometimes, soy sauce is used instead of hot chilli pepper. *Namul* is a variety of steamed vegetables seasoned with hot pepper, garlic, green onion, salt and sesame or perilla oil. Typical vegetables include spinach, daikon, royal fern, bracken, zucchini, mung bean sprouts, *deodeok*, bamboo shoots, etc. *Codonopsis* roots are also an ingredient of *deodeok gui* – root marinated in *gochujang* sauce and grilled over charcoal. Other main ingredients include chicken, liver, beef, fish, mushrooms and vegetables like *dureup* (young shoots of *Aralia elata*). Another popular dish is *Changui*: cold roast of liver and deodeok root. *Deodeok* is also made into *deodeok kimchi*. Its leaves are also edible.

Botany

The plant is a perennial, herbaceous, twining vine up to 1.5–2 m in length, with milky sap, and glabrous. The tap root thickened, fusiform, 10–20 cm long, 1–4 cm in diameter (Plate 1). Leaves are small, alternate on the long main stem, two to four opposite or in a whorl towards the apex of branches. Leaf lamina is rhombic-ovate or narrowly ovate to elliptic, 3–10 cm long and 1.3–4.5 cm wide, apex acute or obtuse, base cuneate, entire or very remotely serrate; petiole 1–5 mm long. Leaves are green on the upper surface and whitish on the lower surface. Flowers are solitary or in pairs, terminal on branches; pedicels 1–9 cm long; calyx tube is about 1 mm long, adnate to middle of ovary, with five ovate–triangular lobes, 1.3–3 cm long. The corolla is campanulate (bell shaped), 2–4 cm long, 2–3.5 in diameter, five deltoid lobes, greenish yellow outside, dark purple patches or stripes inside; stamens 5; ovary half-inferior. Fruit is a cone-shaped capsule, 2–2.5 cm in diameter with numerous winged, brown, ellipsoid seeds.

Plate 1 Tuberous deodeok roots

Nutritive/Medicinal Properties

Root Phytochemicals

The roots were found to contain α -spinasterol, Δ^7 -stigmasterol, oleanolic acid, echinocystic acid and an unidentified triterpene acid (Yang et al. 1975). Four β -carboline alkaloids are isolated from the roots: norharman, perlolyrine, 1-carbomethoxy- β -carboline and N9-formylharman (Chang et al. 1986).

Colonoside B was isolated as the main triterpene glycoside from *C. lanceolata* (Alad'ina et al. 1988). Its aglycone was echinocystic acid and the carbohydrate moiety consisted of D-glucose, D-xylose, L-rhamnose, L-arabinose and D-glucuronic acid residues. Its structure was elucidated as echinocystic acid 3-*O*- β -D-glucopyranuronoside 28-*O*-[*O*- β -D-xylo-pyranosyl-(1 $\rightarrow$ 4)-*O*- α -L-rhamnopyranosyl-(1 $\rightarrow$ 4)-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 2)- α -L-arabinopyranoside] (Alad'ina et al. 1989).

The roots of *Codonopsis* species including *C. lanceolata* were found to contain hydrophobic constituents β -Sitosterol, α -spinasterol and taraxerol (Wang et al. 1995). From the roots were isolated four compounds, identified as shikimic acid, succinic acid, syringaresinol and tectorigenin-7-glucoside (Mao et al. 2000). 1, 2, 3, 4-tetrahydro- β -carboline-3-carboxylic acid (0.0012 %) was isolated from the roots and found to be adequate as an analytical marker for the plant (Yoo et al. 2002). Total ash content in the roots was 5.0 % and loss on drying was 11.9 %. A saponin named codonoposide was isolated from *Codonopsis lanceolata* roots and characterised as 3-*O*-[β -D-xylopyranosyl(1 $\rightarrow$ 3)- β -D-glucuronopyranosyl]-3 β ,16 α -dihydroxyolean-28-oic acid 28-*O*-[β -D-xylopyranosyl (1 $\rightarrow$ 3)- α -L-rhamnopyranosyl (1 $\rightarrow$ 2)- α -L-arabinopyranosyl] ester (Lee et al. 2002). Complete hydrolysis of codonoposide produced a sapogenin (1a), and the partial hydrolysis and further isolation afforded two prosapogenins (1b, 1c). The structures of 1a, 1b and 1c were found to be 3 β , 16 α -dihydroxyolean-28-oic acid (echinocystic acid), 3-*O*- β -D-glucuronopyranoside of echinocystic acid and 3-*O*- β -D-xylopyranosyl (1 $\rightarrow$ 3)- β -D-glucuronopyranoside of

echinocystic acid. Jung et al. (2006) isolated tangshenoside and β -adenosine from the roots. A triterpenoid saponin, named codonolaside V, was isolated from the root (Yuan and Liang 2006; Zhang et al. 2009). Two unknown compounds 10 and 11 were proposed to be asterogenic acid derivatives containing uronic acid at the C-3 position and a trisaccharide (two pentoses and deoxyhexose) and a disaccharide (pentose and deoxyhexose), respectively, at the C-28 position. Two triterpenoid saponins named codonolaside I and codonolaside II were isolated from the ethanol root extract (Li et al. 2007). Their structures were determined to be 3-*O*-[β -D-xylopyranosyl (1 $\rightarrow$ 3)-(6'-*O*-methyl)- β -D-glucuronopyranosyl]-3 β , 16 α -dihydroxyolean-12-ene-28-oic acid 28-*O*-[β -D-xylopyranosyl (1 $\rightarrow$ 4)- α -L-rhamnopyranosyl (1 $\rightarrow$ 2)- α -L-arabinopyranosyl] ester and 3 β , 16 α -dihydroxyolean-12-ene-28-oic acid 28-*O*-[β -D-xylopyranosyl (1 $\rightarrow$ 3)- β -D-xylopyranosyl (1 $\rightarrow$ 4)- α -L-rhamnopyranosyl (1 $\rightarrow$ 2)- α -L-arabinopyranosyl] ester, respectively.

Bioactive constituents of the polar fraction of the roots of *C. lanceolata* included six triterpene saponins, lancemasides B, C, D, E, F and G, along with the known saponin lancemaside A and phenylpropanoid glycosides tangshenoside I, tangshenoside II and syringin (Ushijima et al. 2008). Compound 11 was identified as tryptophan. Hot water extraction of *C. lanceolata* roots yielded saponins lancemaside A, foetidissimoside A and astersaponin Hb in their pure forms (Shirota et al. 2008). Six triterpenoid saponins, including a new compound named codonolaside III, were isolated from *Codonopsis lanceolata* roots of (Xu et al. 2008a). The structure of codonolaside III was elucidated as 3-*O*-[β -D-xylopyranosyl -(1 $\rightarrow$ 3)- β -D-glucuronopyranosyl]-3 β , 16 α -dihydroxyolean-12-ene-28-oic acid 28-*O*-[β -D-xylopyranosyl-(1 $\rightarrow$ 4)- α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)][β -D-glucopyranosyl-(1 $\rightarrow$ 4)]- α -L-arabinopyranosyl ester. Seven 3, 28-bidesmosidic triterpenoid saponins were identified in the roots of *Codonopsis lanceolata*: lancemaside A, lancemaside B, lancemaside C, lancemaside E, lancemaside G, foetidissimoside A and aster saponin Hb (Ichikawa et al. 2008, 2009). The overall recoveries of all saponins were 92–116 %. Lancemaside A was the most abundant saponin in the root

samples from Korea, ranging from 2.65 to 3.64 mg/g dry root. However, the maximum content of lancemaside A among Japanese samples was 0.101 mg/g dry root.

The presence of quaternary ammonium alkaloids codotubulosine A and B, adenosine and 5-(hydroxymethyl)furfural in the roots of *C. lanceolata* was determined using nuclear magnetic resonance (Li et al. 2009). Three benzofuranylpropanoids, lanceolones A–C, were isolated from the roots of *Codonopsis lanceolata* (Hu et al. 2012). A symmetrical phenylpropanoid glycoside, tangshenoside VIII, together with six known tangshenosides were isolated from the roots (Ren et al. 2013). A new cerebroside, namely, codonocerebroside A and lobetyolin were isolated from the roots (Zhao et al. 2013).

A total of 50 components were identified in the volatile oil of *Codonopsis lanceolata* root including 16 terpene and terpene alcohols, 13 hydrocarbons, 5 alcohols, 6 aldehyde and ketones, 6 acids, 2 esters and 2 miscellaneous components (Park et al. 1989a, b). The major components were *trans*-2-hexen-1-ol (29.4 % of total volatile oil), *trans*-2-hexenal (24.9 %), *n*-hexanol (19.8 %), *n*-hexanal (7.3 %) and *cis*-3-hexen-1-ol (5.6 %). Thirty-five volatile flavour components were identified from *C. lanceolata* by GC-MS (gas chromatography–mass spectrometry) (Kim et al. 1992). *Trans*-2-hexenal, *cis*-3-hexen-1-ol, *trans*-2-hexen-1-ol and *n*-hexanol were considered key components of the green note, while 1-octen-3-ol is the component of the fresh note. Esters, including amyl propionate, appeared to be responsible for the sweet note characteristic of *C. lanceolata*. The other compounds identified included 2-methyl octane, nitrocyclohexane, 3-methyl-2-heptanol, 4-carene, butyl butyrate, 1-8-cineole, phenylacetaldehyde, limonene, 2-ethyl hexanol, 2,9-dimethyl decane, 2-methyl dodecane, linalyl isobutyrate, 2-methyl tridecane, 2-octenal, 2,3-decadienal, 3-dodecanol, citronellyl acetate, *cis*-3-hexenyl caproate, 3-decen-1-ol, humulene, octadecyl benzene, hexadecanoic acid, 9-octadecenal, eicosane, octadecanamide, tetracosane, 1, 2-diisooctyl benzenedicarboxylic acid, hexacosane and heptacosane.

Six compounds were isolated from the plant and identified as syringin, shikimic acid, friedelin, α -spinasterol, stigmasterol and stigmasta-7-dien-3 β -ol (Wang et al. 2011b). Transgenic hairy roots of *C. lanceolata* were found to be richer in triterpenoids (lancemaside A, foetidissimoside A and aster saponin Hb) than non-transformed roots (Kim et al. 2011). Transgenic plants regenerated from the hairy roots via somatic embryogenesis were found to contain plants having higher triterpenoid levels than wild-type plants. They showed phenotypic alterations such as shortened shoots and an increased number of axillary buds and adventitious roots.

C. lanceolata roots were found to be rich in polysaccharides (Sun 2007). The polysaccharide content was 12.45 %, and the rate of recovery was 99.12 %.

Zhou et al. (2010) found the content of polysaccharides in *C. lanceolata* root from Mount Taishan was highest in 4-year-old plants. The contents of polysaccharide in 2-year-old, 3-year-old and 4-year-old plants were 8.82 %, 10.47 % and 11.32 %, respectively. The average recovery rate was 96.09 %. Zhu et al. (2014) found that the content of triterpene decreases as the plant aged, but the relative content of saccharides initially increased and decreased significantly afterwards. Specifically, the content of polysaccharides accumulated in the root of 2-year-old plant was the lowest, 4-years-old was the highest, and then the content decreased gradually. Sixteen kinds of amino acids were identified in *Codonopsis lanceolata* comprised of 5.70 % hydrolysed amino acids and 4.17 % free amino acids (Xu et al. 2008b).

Other Plant Parts Phytochemicals

Three flavonoids, namely, luteolin, luteolin 5-*O*- β -D-glucopyranoside and luteolin 7-*O*- β -D-glucopyranoside, were isolated from the leaves (Whang et al. 1994). The content of tangshenoside I and saponins (tentatively named saponins A and B) in the parent plants and in the regenerated tissue cultured plants were almost the same (Isoda et al. 1995). A cDNA clone containing a fructose-1, 6-bisphosphate aldolase (ALD) gene, and encoding a precursor protein of 358 amino

acid residues, designated ClAldC, was isolated from *Codonopsis lanceolata* (Purev et al. 2008).

The application of a fermentation process was found to effectively improve the biological and pharmacological activities of high-pressure extraction (HPE) of *C. lanceolata* by increasing the extraction efficacy and inducing probiotic conversion (He et al. 2011b). The results suggest that the combined treatment of HPE and a fermentation process could be used as alternative extraction method over conventional extraction. Compared to conventional extraction without fermentation (6.69 mg GAE/g), the phenol amounts of HPE *Bifidobacterium longum* fermentation (HPE-BF) and HPE *Lactobacillus rhamnosus* fermentation (HPE-LRF) were significantly increased to more than 8 mg GAE/g, while the lowest flavonoid contents were observed for HPE-BLF (0.44 mg RE/mL) and HPE-LRF (0.45 mg RE/mL). Cinnamic acid was the most abundant phenolic acid in the fermented *C. lanceolata*.

Antioxidant Activity

The antioxidant activity of the ethanol deodeok extract in soybean oil was significantly stronger compared with that of ginseng in terms of peroxide values and thiobarbituric acid values (Maeng and Park 1991). Antioxidative activities of *Codonopsis lanceolata* were also compared from the electron-donating activity. Fresh *C. lanceolata* had about 70 % of electron-donating activity. Independent of cultivation area, electron-donating activity dropped to 19–74 % (wild *C. lanceolata*) and 27–59 % (cultivated *C. lanceolata*) during 15 days storage. But after 30 days storage, antioxidant activities were higher than 15 days-stored samples or the fresh samples. The results suggested that *Codonopsis lanceolata* could maintain antioxidant activities most strongly with low-density polyethylene (LDPE) film and chilled condition (2–4 °C). The antioxidative activity of *C. lanceolata* was 87 %; addition of salt to *C. lanceolata* did not affect its antioxidative activity (Oh and Kim 2006). In spite of fourfold addition of *Codonopsis lanceolata* to *Cornus officinalis*, the antioxidative activity was conserved at 90 %. Oral administration of the

ethanol and aqueous extracts of *C. lanceolata* to mice was found to enhance the antioxidative ability of mice (Wang et al. 2008). The superoxide dismutase, glutathione peroxidase and glutathione levels were enhanced significantly, and the malondialdehyde levels were reduced markedly in the serum, liver and brain homogenate of mice treated with 20 g/kg of both extracts.

The antioxidant activity (1, 1-diphenyl-2-picrylhydrazyl (DPPH) radical scavenging) of the leaf and root extracts of transgenic *C. lanceolata* plants was higher (IC₅₀ 12–17.33 and 408–524 µg/mL, respectively) than that of control plant leaf and root extracts (18 and 529 µg/mL, respectively) (Ghimire et al. 2011). Analysis of phenolic compounds confirmed an increase in the levels of 12 major phenolic acids and flavonoids in the leaf and root extracts of transgenic plants compared to control plants. Also, the rate of photosynthesis was 48 % higher in transgenic plants than in control plants. Based on these results, the authors suggested that increases in the α-tocopherol level in transgenic *C. lanceolata* plants may result in increases in the photosynthetic performance and antioxidant metabolism of these plants.

High-pressure water treatment was found to have an effect on the extraction of total phenols, flavonoids and phenolic acids from deodeok (He et al. 2011a). The optimising conditions for the pressure-assisted water extraction (PAWE) of *deodeok* as a function of pressure level and extraction time were 385 MPa and 25 minutes for total phenols (633 µg GAE/mL) and 405 MPa and 24 minutes for flavonoids (124 µg RE/mL). The PAWE significantly increased the amount of vanillic acid (41 µg/mL) in *deodeok* extract compared to the conventional extraction (CE, 17 µg/mL). The highest radical scavenging activity (81 %) of *deodeok* extract was achieved at the treatment of 500 MPa and 30 minutes. The application of a fermentation process was found to effectively improve the biological and pharmacological activities of high-pressure extraction (HPE) of *C. lanceolata* by increasing the extraction efficacy and inducing probiotic conversion (He et al. 2011b). The highest DPPH scavenging activities were observed for HPE- *Bifidobacterium longum* fermentation (HPE-BF) and

HPE- *Lactobacillus rhamnosus* fermentation (HPE-LRF), with minimum EC₅₀ values of 1.26 and 1.18 mg/mL, respectively. The highest amounts of total phenols and flavonoids were observed in chloroform fraction from nonfermented (NF) deodeok (72 and 31 mg RE/g) and *Lactobacillus rhamnosus* fermented (LRF) (79 and 24 mg RE/g) deodeok (Jung et al. 2012b). The ferric reducing antioxidant power (FRAP) values were highly correlated with the DPPH scavenging activity, showing that the highest FRAP values were observed in chloroform fractions from NF (35 mM Fe(II)/g) and LRF (50 mM Fe(II)/g).

The nonfermented *C. lanceolata* samples extracted with high pressure (NF-HPE) had the highest total phenolic content (13.3 mg of GAE/g) (He et al. 2010). The lowest effective concentrations (EC₅₀ and EC_{0.5}) were 4.55 and 1.76 mg/mL, respectively, for NF-HPE extracts, indicating its highest antioxidant activity.

The total polyphenol content of the heat treatment of fermented *Codonopsis lanceolata* tea for 15 minutes at 200 °C was increased to about 4.5 times of 713.71 mg/100 mL as compared to the control group (Park et al. 2013). From the results of the antioxidant activity test, as both the heating temperature and time increased, the antioxidant activity was increased for DPPH radical scavenging activity, FRAP and reducing its power. In the case of the samples treated with heat for 15 minutes at 200 °C in the DPPH radical scavenging ability, it increased about twice more than control 45.17–85.40 %, and the reducing power and FRAP were increased to approximately two or three times more than the control group.

Anti-inflammatory Activity

Several studies confirmed that the root of *C. lanceolata* had anti-inflammatory activity.

The xylene-induced mouse ear oedema inhibitory effect assay revealed codonolaside and codonolasides I–III as the major anti-inflammatory constituents in *Codonopsis lanceolata* roots (Xu et al. 2008a). Lee et al. (2007) reported

that the methanol extracts of fresh leaves or roots of *Codonopsis lanceolata* significantly suppressed the production of proinflammatory mediators, nitric oxide [NO] and tumour necrosis factor [TNF- α] without altering mRNA levels and also strongly blocked Raf-ERK signalling pathway, which was involved in regulation of post-translational modification of proinflammatory gene products. The expression of interleukin (IL)-3 and IL-6, however, was strongly diminished. The surface levels of the co-stimulatory molecules (CD80 and CD86) of RAW264.7 cells were also enhanced by these extracts. The leaf extract also diminished functional activation and the surface level of dectin-1, but not toll-like receptor (TLR)-2. The results suggested that *Codonopsis lanceolata* may have the ability to modulate macrophage-mediated immune responses, thus contributing to its anti-inflammatory activity. Another study reported that the ethanolic root extract of *Codonopsis lanceolata* displayed significant anti-inflammatory activity of 51.82 % inhibition at 200 mg/kg at 3 hours using the carrageenan-induced rat hind paw oedema model (Li et al. 2007). Further isolation of the extract yielded two triterpenoid saponins, named codonolaside I (1) and codonolaside II (2). Saponin fraction from *Codonopsis lanceolata* was found to have potent anti-inflammatory activity (Byeon et al. 2009a). The fraction suppressed the release of nitric oxide (NO) and tumour necrosis factor (TNF)- α , but not prostaglandin E2 (PGE2). The anti-inflammatory activities on NO production appeared to be due to inhibition of nuclear factor (NF)- κ B activation signalling, since it blocked the phosphorylation of inhibitor of kappaB (IkappaB) alpha as well as inducible NO synthase (iNOS) expression. In another study, lancemaside A isolated from *Codonopsis lanceolata* suppressed the production of proinflammatory cytokines, TNF- α and IL-1 β , in-vitro and in-vivo (Joh and Kim 2010b). Lancemaside A also downregulated inducible nitric oxide synthase (iNOS) and cyclooxygenase-2 (COX-2), as well as the inflammatory mediators, nitric oxide (NO) and PGE(2). Lancemaside A also inhibited the expression of IL-1 receptor-associated kinase-4 (IRAK-4), the phosphorylation of IKK- β and I κ B- α , the nuclear translocation of NF- κ B and the activation of mitogen-activated protein kinases in LPS-

stimulated peritoneal macrophages. Furthermore, lancemaside A inhibited the interaction between LPS and toll-like receptor 4 (TLR4), as well as IRAK-4 expression in peritoneal macrophages. Orally administered lancemaside A, isolated from *C. lanceolata*, was metabolised echinocystic acid which was absorbed into the blood and found to ameliorate lung inflammation in mice and in alveolar macrophages by inhibiting the binding of lipopolysaccharide to toll-like receptor 4 (TLR4) in nuclear factor-kappaB (NF-κB) and mitogen-activated protein kinase (MAPK) pathways (Joh et al. 2012).

Among *Codonopsis lanceolata* rhizome extracts, the BuOH extract inhibited LPS-induced IL-1β, IL-6 and TNF-α expression, as well as NF-κB activation most potently in lipopolysaccharide (LPS)-stimulated peritoneal macrophages (Hyam et al. 2013). BuOH extract also inhibited colon shortening and myeloperoxidase activity in 2,4,6-trinitrobenzene sulfonic acid (TNBS)-induced colitic mice. Among lancemaside A and its metabolites (lancemaside X, echinocystic acid-3-*O*-β-D-glucopyranoside and echinocystic acid), echinocystic acid inhibited the expression of the proinflammatory cytokines, IL-1β, IL-6 and TNF-α, as well as the phosphorylation of IKKβ and p65 in LPS-stimulated peritoneal macrophages most potently. Echinocystic acid also potently inhibited the binding of LPS to TLR4 on peritoneal macrophages. Lancemaside A and its metabolite, echinocystic acid, inhibited TNBS-induced colonic inflammation, including colon shortening, increased myeloperoxidase activity and proinflammatory cytokine expression and NF-κB activation in mice. Joh et al. (2014) found that topically administered echinocystic acid potently suppressed 12-*O*-tetra decanoylphorbol-13-acetate (TPA)-induced ear swelling in mice. Echinocystic acid also inhibited TPA-induced myeloperoxidase activity, as well as COX-2, iNOS, TNF-α and IL-1β expressions. Echinocystic acid inhibited NF-κB in TPA-treated mouse ears, as well as in lipopolysaccharide-stimulated peritoneal macrophages.

Anticancer Activity

Codonopsis lanceolata had also been reported to possess cytotoxic and antitumour activities. A new saponin named codonoposide (1) from the roots of *Codonopsis lanceolata* on hydrolysis yielded sapogenin (1a) and two prosapogenins (1b, 1c) (Lee et al. 2002). Using MTT (3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide) assay, sapogenin 1a showed marginal cytotoxic activity, whereas prosapogenin 1b exhibited more cytotoxicity than sapogenin 1a. The result indicated that glycoside linkage of glucuronic acid at C-3 enhanced the cytotoxicity of sapogenin (1a), and additive glycosylation of xylose to 1b strongly enhanced the cytotoxicity of 3-*O*-monosaccharides (1b). Therefore, true forms of codonoposide for the cytotoxicity were affirmed to be sapogenins or prosapogenins. Studies demonstrated that β -d-xylopyranosyl-(1 $\rightarrow$ 3)- β -D-glucuronopyranosyl echinocystic acid (codonoposide 1c), a biologically active compound isolated from the roots of *Codonopsis lanceolata*, was cytotoxic to cancer cells. Additional investigations by Lee et al. (2005) revealed that codonoposide 1c was a potent inducer of apoptosis in HL-60 human promyelocytic leukaemia cells and facilitated its activity via Bid cleavage and translocation to mitochondria, Bax reduction in cytosol, release of cytochrome c and Smac/DIABLO (second mitochondria-derived activator of caspases/direct inhibitor of apoptosis-binding protein with a low isoelectric point) into the cytosol, and subsequently caspase activation, providing a potential mechanism for the cytotoxic activity of codonoposide 1c.

Studies showed that the Fr I fraction containing <1,000 MW of crude polysaccharide from deodeok had the highest total sugar contents, total protein contents, total phenolic compounds content, as well as the greatest growth inhibitory activity against stomach carcinoma SNU-1 and Hela cells, ACE (angiotensin-converting enzyme) inhibitory activity and DPPH (diphenyl picrylhydrazyl) radical scavenging effect (Kim et al. 2006a). The Fr II (1,000 MW < fraction < 3,000 MW) fraction exhibited lower physiological activity than Fr I but showed higher activity than those of fraction of above 3,000 MW, but there was no significant ACE inhibitory activity. The fraction Fr III (3,000 MW < fraction < 10,000 MW) exhibited the lowest yield, total sugar contents, total

protein contents and total phenolic contents, as well as the least growth inhibitory activity against SNU-1, Hela, ACE inhibitory activity and DPPH radical scavenging effect.

The n-butanol fraction of *C. lanceolata* significantly inhibited human colon cancer HT-29 cell growth in a dose- and time-dependent manner by inducing G0/G1 phase arrest and apoptosis (Wang et al. 2011a). The inhibition was associated with intracellular ROS generation and polyamine depletion. The methanol extracts of *Codonopsis lanceolata* inhibited tumour growth of HSC-2 human oral cancer cells by inducing apoptosis (Shin et al. 2012). It also increased Bak protein expression, while Bax, Bcl-XL and Mcl-1 were not affected.

Antimicrobial Activity

The probiotic *Bifidobacterium longum*-fermented *C. lanceolata* samples extracted by high pressure (BLF-HPE) exhibited the highest antimicrobial activity (MIC<14 mg/mL) against *Listeria monocytogenes*, *Staphylococcus aureus*, *Shigella boydii* and *Salmonella typhimurium* (He et al. 2010). The application of a fermentation process was found to effectively improve the biological and pharmacological activities of high-pressure extraction (HPE) of *C. lanceolata* by increasing the extraction efficacy and inducing probiotic conversion (He et al. 2011b). The HPE-*Bifidobacterium longum* fermentation (HPE-BF) and HPE-*Lactobacillus rhamnosus* fermentation (HPE-LRF) samples exhibited the most noticeable antimicrobial activities against *Staphylococcus aureus*, *Listeria monocytogenes*, *Salmonella typhimurium* and *Shigella boydii* (MICs<15 mg/mL). *Staphylococcus aureus* biofilm cells were highly susceptible to chloroform fraction of deodeok, showing 1.8 log reductions (Jung et al. 2012b).

Antimutagenic Activity

The *Bifidobacterium longum*-fermented *C. lanceolata* samples extracted by high pressure (BLF-HPE) and *Lactobacillus rhamnosus*-fermented *C. lanceolata* samples extracted by high

pressure (LRF-HPE) exhibited the highest antimutagenic activities in *Salmonella typhimurium* TA 100, which were 82 % and 83 % inhibition, respectively (He et al. 2010).

Adaptogenic Activity

Codonopsis lanceolata root extract and its bioactive constituent lancemaside A were reported to inhibit the reduction of blood testosterone levels induced by immobilisation stress in mice (Sekita et al. 2005). The positive responses of ClAldC (a cDNA clone containing a fructose-1, 6-bisphosphate aldolase (ALD) gene isolated from *C. lanceolata*) to the three abiotic stimuli suggested that *C. lanceolata* ClAldC may help to protect against abiotic environmental stresses such as anoxia, chilling and oxidative stress (Purev et al. 2008).

A dehydrin gene designated as ClDhn was isolated from *C. lanceolata* (Pulla et al. 2008). The full-length cDNA of ClDhn was 813 bp and contained a 477 bp open reading frame (ORF) encoding a polypeptide of 159 amino acids. RT-PCR analysis showed that different abiotic stresses such as salt, wounding, chilling and light triggered a significant induction of ClDhn at different time points within 4–48 hours posttreatment. This study revealed that ClDhn assisted *C. lanceolata* in becoming resistant to dehydration.

In the course of the development of new designer foods using the roots of *C. lanceolata*, Japanese scientists found that hot water extracts of *C. lanceolata* recovered decreased testosterone levels in the blood and accelerated the restoration of reproductive dysfunction induced by hyperthermic treatment in male mice (Ushijima et al. 2008). One of the bioactive constituents tangshenoside I accelerated the restoration of reproductive dysfunction induced by hyperthermic treatment in male mice.

The aqueous extract of *C. lanceolata* root at the dose of 20 g/kg reduced the cumulative oxygen consumption at different times and prolonged survival time of mice with hypoxia, the loaded swimming time and the rotational stick endurance time in mice (Wang et al. 2007). In another study, the purified

polysaccharide from 4-year-old *C. lanceolata* roots, at the dose of 1.5 g/kg, reduced oxygen consumption and prolonged the survival time of mice in hypoxia condition (Zhao et al. 2011). It also prolonged the loaded swimming time of mice indicating its antifatigue effect.

Hepatoprotective Activity

Han and Cho (1997) found that hepatic cytochrome P450 content and activity of superoxide dismutase in rats were decreased by carbon tetrachloride but was significantly increased by *Codonopsis lanceolata* water extract. Significant decrease in hepatic xanthine oxidase activity was found in rats treated with *Codonopsis lanceolata* water extract. Contents of glutathione and lipid peroxide and the activity of glutathione peroxidase elevated by carbon tetrachloride were significantly decreased by *Codonopsis lanceolata* water extract. The activities of catalase and glutathione S-transferase were not significantly influenced by *Codonopsis lanceolata* water extract. Studies by Zhang et al. (2007) reported that administration of *C. lanceolata* extract protected against alcohol-induced hepatic injury in mice possibly by enhancing its radical scavenging ability to inhibit lipid peroxidation in mice liver. Superoxide dismutase, glutathione peroxidase activity and selenium levels were significantly higher in extract-treated mice compared to control mice.

Kim et al. (2009) found that the saponin fraction from *Codonopsis lanceolata* exerted a protective effect against water immersion stress-induced liver damage and radical generation. It decreased the elevated levels of serum glutamate-oxaloacetate transaminase and glutamate-pyruvate-transaminase induced by water-immersed stress conditions, and Griess and DPPH assays revealed that Cl-SF significantly suppressed both radical generation in sodium nitroprusside-treated RAW264.7 cells and nitric oxide production in LPS-treated RAW264.7 cells. Among the three different fractions prepared from the *C. lanceolata* root, the methanol extract exhibited the most remarkable attenuation of alcohol-induced fatty liver in mice with respect to various parameters such as hepatic free fatty acid concentration, body weight loss and

hepatic accumulations of triglyceride and cholesterol (Cha et al. 2012). The beneficial effects of the extract against alcoholic fatty livers of mice appeared to be with adenosine- and adiponectin-mediated regulation of hepatic steatosis and toll-like receptor (TLR)-mediated modulation of hepatic proinflammatory responses.

In-vivo studies showed that supplementation of *C. lanceolata* root water extract to rats appeared to be protective against alcoholic fatty liver caused by chronic alcohol consumption, through the down-regulation of tumour necrosis factor- α (TNF- α), liver X receptor α (LXR α), sterol regulatory element-binding protein (SREBP)-1c, fatty acid synthase, acetyl-coenzyme A carboxylase α (ACC), stearoyl-coenzyme A desaturase 1, 3-hydroxy-3-methylglutaryl-coenzyme A reductase (HMGCR), and low-density lipoprotein receptor (LDLR) genes and by the phosphorylation of phospho-5'-AMP-activated protein kinase (AMPK) α and acetyl-coenzyme A carboxylase α which were implicated in lipid metabolism (Cho et al. 2009).

Neuroprotective Activity

Yoo et al. (2011) found that ethyl acetate extracts of raw and steamed *Codonopsis lanceolata* protected against ischemic damage in gerbil hippocampal CA1 region after an ischemic insult by reducing ischemic neuronal loss potentially by maintaining superoxide dismutase 1 (SOD1) and brain-derived neurotrophic factor (BDNF) immunoreactivity in the ischemic hippocampal CA1 region.

Antihyperlipidaemic/Anti-obesity Activity

Oral administration of *Codonopsis lanceolata* water extract to rats fed a high fat diet significantly reduced the elevated level of serum total lipid, serum triglyceride and total cholesterol (Han et al. 1998). The levels of serum HDL-cholesterol and phospholipid were slightly increased by *C. lanceolata* water extract. Studies showed that fermented milk supplement containing *Codonopsis lanceolata* roots had an anti-hyperlipidemic effect on the blood lipid profiles in

ovariectomised (OVX) rats (Chang and Cheong 2007). Serum triglyceride, total cholesterol and LDL-cholesterol levels in ovariectomised Sprague-Dawley female rats fed fermented milk supplement containing *C. lanceolata* (CL) roots) were significantly lower than the OVX group. The ratio of HDL-cholesterol to total cholesterol was significantly higher and the ratio of LDL-cholesterol to HDL-cholesterol was significantly lower.

Animal studies by Choi et al. (2013) indicated *C. lanceolata* to have great potential as a functional food with anti-obesity effects and as a therapeutic alternative in the treatment of obesity. The body weight gains of rats administered high fat diet (HFD) + *C. lanceolata* were lower than those of the rats fed with only the HFD. Additionally, the weight of adipose pads and the serum levels of triglycerides, total cholesterol and low-density lipoprotein cholesterol in the group administered HFDL + *C. lanceolata* were significantly lower than in the HFD group. Treatment of 3T3-L1 cells with *C. lanceolata* inhibited lipid accumulation and expression of C/EBP α and PPAR γ .

Antidiabetic Activity

The α -glucosidase inhibitory activities of *Codonopsis lanceolata* was 25 % and the addition of salt slightly decreased its α -glucosidase inhibitory activity (Oh and Kim 2006). On addition of *Cornus officinalis* to *Codonopsis lanceolata*, the α -glucosidase inhibitory activities of the resulting mixture was highly increased. Tangshenoside and β -adenosine were isolated as α -glucosidase inhibitors from the roots (Jung et al. 2006). They exerted weak α -glucosidase inhibitory activities in-vitro with IC₅₀ of 1.4 and 9.3 mM, respectively.

Administration of *C. lanceolata* root polysaccharides to alloxan-induced diabetic mice significantly reduced the level of fasting plasma glucose and malondialdehyde content; and improved antioxidant activity by increasing serum and pancreatic gland superoxide dismutase activity (Zhang et al. 2010). In a subsequent study, they reported that *C. lanceolata* root polysaccharides decreased the level of fasting blood

glucose in diabetic mellitus rats, and significantly improved cellular immune function (Zhang et al. 2012). Also, thymus index was enhanced significantly and lymphocyte proliferation stimulated.

The application of a fermentation process was found to effectively improve the biological and pharmacological activities of high-pressure extraction (HPE) of *C. lanceolata* by increasing the extraction efficacy and inducing probiotic conversion (He et al. 2011b). The HPE- *Bifidobacterium longum* fermentation (HPE-BF) and HPE-*Lactobacillus rhamnosus* fermentation (HPE-LRF) samples effectively inhibited α -glucosidase and tyrosinase activities and potentially improved a scopolamine-induced memory deficit in mice.

Anti-colic Activity

Oral administration of lancemaside A (10 and 20 mg/kg), from *C. lanceolata*, inhibited colon shortening and myeloperoxidase activity in 2, 4, 6-trinitrobenzene sulfonic acid (TNBS)-induced colitic mice and also decreased colonic expression of interleukin IL-1beta, IL-6 and TNF-alpha (Joh et al. 2010). Lancemaside A inhibited NF-kappaB activation induced by TNBS, as well as the expression of cyclooxygenase 2 and TLR-4. Lancemaside A also reduced the activity of intestinal bacterial β -glucuronidase that was induced by TNBS.

Cognitive Enhancing Activity

Han et al. (1999) found that old mice ingesting *C. lanceolata* extract, 4 and 8 g/kg, learned faster than those drinking water. Lipid peroxide level in red blood cells were decreased and superoxide dismutase increased by ingestion of the extract.

Lancemaside A, active ingredient in *C. lanceolata* rhizome, orally administered to mice 5 hours before scopolamine treatment. Significantly reversed scopolamine-induced memory and learning deficits (Jung et al. 2012a). Lancemaside A and its metabolite echinocystic acid which was absorbed into the blood significantly reversed

scopolamine-induced memory and learning deficits on the Y-maze and Morris water maze tasks. Echinocystic acid more potently reversed it than lancemaside A. Both inhibited AChE activity and increased the expression of brain-derived neurotrophic factor (BDNF) and phosphorylated cAMP response element-binding protein (p-CREB). Fermented *C. lanceolata* extract (500 mg/kg body weight, p.o.) significantly shortened the escape latency times that were increased by scopolamine on the fourth day of trial sessions in the Morris water maze task (Weon et al. 2013a, b). Additionally, it exerted longer step-through latency times than those of the scopolamine-treated group in the passive avoidance test. Steamed and fermented *C. lanceolata* extract showed a relative protection ratio of 59.62 % at 500 µg/mL on glutamate-induced neurocytotoxicity in HT22 cells.

Anticholinesterase Activity

The highest anticholinesterase activity was observed in chloroform and ethyl acetate fractions from *Lactobacillus rhamnosus* fermented *deodeok* ($1.5 \text{ mg/mL} < \text{EC}_{50} < 2.5 \text{ mg/mL}$) (Jung et al. 2012b).

Fibrinolytic/Blood Flow Stimulating Activity

The fibrinolytic activity of *Codonopsis lanceolata* was 0.78 plasmin unit/mL and addition of salt decreased its fibrinolytic activity (Oh and Kim 2006). A mixture (3:1) of *Codonopsis lanceolata* and *Cornus officinalis* exhibited a 21 % increase in activity. Fibrinolytic activity of fresh *Codonopsis lanceolata* cultivated in the mountain or field was 0.8 unit (plasmin unit/mL) or 7.3 units, respectively (Kim et al. 2005). In descending order, the activities of wild *Codonopsis lanceolata* stored for 15 days were as followed; low-density polyethylene (LDPE)-RE (refrigerated 2–4 °C) (0.70 unit), woven polypropylene (WP)-RO (room temperature 18–20 °C) (0.52 unit), WP-RE (0.45 unit) and LDPE-RO (0.30 unit). After 30 days, fibrinolytic activities of them decreased to 0.47 unit (LDPE-RE), 0.28 unit (WP-RO), 0.21 unit (WP-RE) and 0.30

unit (LDPE-RO). Considering from the point of fibrinolytic activity, the optimal storage condition of wild *C. lanceolata* was packing with LDPE film and storing at 4 °C. The fibrinolytic activities of 30-day-stored samples were maintained better than the wild *C. lanceolata*. Fibrinolytic activity of wild *C. lanceolata* was increased by heating for 5 minutes at 100 °C and decreased by addition of salt.

Animal studies by Xu et al. (2008a) found that administration of the alcohol extract of *C. lanceolata* exhibited effects of invigorating energy, stimulating blood flow and resolving blood stasis in rats and anti-ageing in mice. The extract enhanced red blood cell electrodeposition time and decreased significantly whole blood viscosity (high shear, middle shear, low shear), plasma viscosity, aggregation indices of red blood cells and packed red blood cells in rats with Qi deficiency and blood stasis syndrome. The extract at high dose extended the time of antianoxia significantly on the 7th day and 14th day, while the group receiving low dose of extract extended the time of antianoxia significantly on the 14th day. Both of the group of high-dose and low-dose extract increased thymus weights of mice significantly on the 7th day and 14th day and spleen weights of mice on the 14th day.

Immunomodulatory Activity

Codonopsis lanceolata water extract increased the proliferation of thymocytes in-vivo and accelerated the activation of helper T cells in thymocytes (Suh 1996; Kim et al. 1996). The extract inhibited the production of nitric oxide from peritoneal macrophages and increased the phagocytosis of human polymorphonuclear cells. The results suggested that *Codonopsis lanceolata* had immunoregulatory action in-vivo.

Oral administration of the active component (MW 3,500 above) separated from the water fraction of *C. lanceolata* root methanol extract to mice for 7 days enhanced the proliferation of thymocyte, the population of CD⁴–CD8⁺ single-positive cells and phagocytic activity in macrophage (Suh and Eun 1998). Studies showed that oral administration of *C. lanceolata* water extract for 4 weeks to old BALB/c mice

significantly enhanced immune function by increasing the splenocyte proliferation and enhance the immune function through regulating cytokine production capacity (Ryu et al. 2009). Cytokine production was more significantly enhanced at the lower supplementation (50 mg/kg BW) group rather than at the higher concentration (500 mg/kg BW) compared to the control group.

Results of studies by Byeon et al. (2009b) suggested that the ethnopharmacological role of *Codonopsis lanceolata* on the recovery of blood loss and spleen QI may be due to its upregulatory effect of granulocyte–macrophage-colony stimulating factor (GM-CSF) expression via activating relevant signalling cascades.

Androgen Deficiency Alleviation Activity

Root extract of *C. lanceolata* had been reported to inhibit the reduction of blood testosterone levels induced by psychological stress in mice (Sekita et al. 2005). Lancemaside A, its active constituent, had been reported to contribute to the recovery of decreased testosterone levels in the blood. A supplement containing the root extracts of *C. lanceolata* was found to alleviate partial androgen deficiency of the ageing male (PADAM)-like symptoms (Morales and Lunenfeld 2002; Ushijima et al. 2007).

Pharmacokinetic Studies

When lancemaside A (3-*O*- β -D-glucuronopyranosyl-3 β , 16 α -dihydroxyolean-12-en-28-oic acid 28-*O*- β -D-xylopyranosyl(1 $\rightarrow$ 3)- β -D-xylopyranosyl-(1 $\rightarrow$ 4)- α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)- α -L-arabinopyranosyl ester) (60 mg/kg) was orally administered to mice, echinocystic acid was detected in the blood (Joh and Kim 2010a). Orally administered lancemaside A was metabolised to lancemaside X (3 β , 16 α -dihydroxyolean-12-en-28-oic acid 28-*O*- β -D-xylopyranosyl(1 $\rightarrow$ 3)- β -D-xylopyranosyl-(1 $\rightarrow$ 4)- α -L-rhamnopyranosyl-(1 $\rightarrow$ 2)- α -L-arabinopyranosyl ester) by intestinal microflora in mice, which was metabolised to echinocystic acid by intestinal microflora and/or intestinal

tissues. Human intestinal microflora also metabolised lancemaside A to echinocystic acid via lancemaside X. In another study, after oral administration of lancemaside A at 100 mg/kg body weight, the unmetabolised compound appeared rapidly in murine plasma ($t_{\max} = 0.5$ hour) (Komoto et al. 2010). Lancemaside A had a low bioavailability (1.1 %) because of its metabolism by intestinal bacteria and its poor absorption in the gastrointestinal tract. In addition, four metabolites were identified from the cecum of mice after oral administration of lancemaside A: codonolaside II, echinocystic acid, echinocystic acid 28-*O*- β -D-xylopyranosyl-(1 $\rightarrow$ 4)- α -L-rhamno-pyranosyl-($\rightarrow$ 2)- α -L-arabinopyranosyl ester and echinocystic acid 28-*O*- α -L-rhamnopyranosyl-($\rightarrow$ 2)- α -L-arabinopyranosyl ester. Among these metabolites, codonolaside II and echinocystic acid were detected in plasma, and their $t_{\max}$ values were 4 and 8 hours, respectively.

Allergic Activity

A case of serious anaphylactic reaction in an 18-year-old student following ingestion of *C. lanceolata* roots was confirmed (Hur et al. 2008). Severe systemic reactions including hypotension (90/40 mmHg), chest discomfort, dyspnoea, diaphoresis and generalised urticaria developed within 30 minutes following ingestion of 20 g of *C. lanceolata*. The reaction probably resulted via a direct histamine-releasing mechanism.

Traditional Medicinal Uses

The roots of *C. lanceolata* have been used in traditional medicines as an anti-inflammatory agent and for bronchitis and for cough (Lee et al. 2002; Xu et al. 2008a). In Korea, *deodeok* has been used as a traditional *qi* tonic herb to aid those who are weakened by blood loss or other injury (Byeon et al. 2009b). Weon et al. (2013a, b) reported that *C. lanceolata* has been traditionally used to treat lung inflammatory diseases, such as asthma, tonsillitis and pharyngitis in Korea. In Korea, the roots are used for coughs, fevers, furuncles, bronchitis, leucorrhoea, and lymph

tuberculosis, detoxification, and as expectorant, tonic and for milk reduction (Kim et al. 2006b; Ahn 1998). *Codonopsis lanceolata* has long been used as traditional folk medicine in Korea, Japan and China for the treatment of lung inflammatory diseases (Lee et al. 2007; Hur et al. 2008). *C. lanceolata* root, a traditional Chinese herbal medicine, has a long history in China, and some other Asian countries and is reported to be used to treat lung ailments, rheumatism, menstrual disturbance and bruises with (Zhu et al. 2014). Dried roots of *Codonopsis lanceolata* is used as a tonic in oriental medicine to strengthen Yin and its sap as anti-ageing properties. The root is aphrodisiac, anticancer, depurative, emmenagogue and galactagogue. It has medicinal efficacies for asthma, convulsions, chillness and fever, strengthening respiratory organs' function, tonsillitis, pharyngitis, cough, expectoration, discharge of phlegm, discharge of pus and furuncles. It also has been used to treat oedema, lung abscess, malignant tumour, peptic ulcer and kidney stones. A decoction is used in the treatment of lung abscesses, milk-flow obstruction, amenorrhoea, acute and inflamed boils and abscesses and lymphadenopathy.

Other Uses

Besides being eaten, *deodeok* is widely used as natural herbal medicine in Korea.

Comments

The plant is grown commercially in Hoengseong County and Gangwon Province, South Korea, where it is an important part of the local agriculture.

Author's Blurb

TK Lim (Tong Kwee Lim) obtained his bachelor's and master's degrees in Agricultural Science from the University of Malaya and his PhD (Botanical Sciences) from the University of Hawaii. He worked in the Agricultural University of Malaysia for 20 years as a Lecturer and Associate Professor; as Principal Horticulturist for 9 years for the Department of Primary Industries and Fisheries, Darwin, Northern Territory; for 6 years as Manager of the Asia and Middle East Team in Plant Biosecurity Australia, Department of Agriculture, Fisheries and Forestry, Australia, and for 4 years as Research Program Manager with the Australian Centre for International Agriculture Research (ACIAR), Department of Foreign Affairs and Trade, Australia, before he retired from public service. He has published over a hundred scientific papers and several books: 'Guava in Malaysia: Production, Pest and Diseases', 'Durian Diseases and Disorders', 'Diseases of Mango in Malaysia'; chapters in books, international refereed journals, conference proceedings (as editor) and technical bulletins in the areas of plant pathology, crop protection, horticulture, agronomy and quarantine science. He was also a reviewer of scientific papers for several international scientific journals. As Principal Horticulturist in Darwin, he and his team were instrumental in establishing the horticultural industry in Northern Territory, Australia, especially on tropical fruit, vegetables, culinary herbs, spices/medicinal herbs and tropical flowers. During his tenure with Plant Biosecurity, he led a team responsible for conducting pest risk analyses and quarantine policy issues dealing with import and export of plants and plant products into and out of Australia from and for the Middle East and Asian region. During his time with ACIAR, he oversaw and managed international research and development programs in plant protection and horticulture, covering a wide array of crops that included fruit, plantation crops, vegetables, culinary and medicinal herbs and spices mainly in southeast Asia and the Pacific. In the course of his four decades of working career, he has travelled extensively worldwide to many

countries in South Asia, East Asia, Southeast Asia, Middle East, Europe, the Pacific Islands, USA and England and also throughout Malaysia and Australia. Since his tertiary education days, he always had a strong passion for crops and took an avid interest in edible and medicinal plants. Over the four decades, he has taken several thousands of photographs of common, known and lesser known edible, medicinal and non-medicinal plants; amassed local literature, local indigenous knowledge and books and has developed and established a close rapport with many local researchers, scientists, growers and farmers during the course of his work and travels. All relevant available and up-to-date information collated on more than 1,000 species of edible, medicinal and non-medicinal plants will be provided in a comprehensive reference series fully illustrated with coloured images to help in plant identification. This work will cover scientific names, synonyms, common and vernacular names, origin and distribution, agroecology, edible plant parts and uses, plant habit/description, nutritive and medicinal value, other uses and selected current references. Additional information is provided on the medicinal uses and pharmacological properties of plants. This work will be of significant interest to scientists, researchers, practitioners (medical practitioners, pharmacologists, ethnobotanists, horticulturists, food nutritionists, agriculturists, botanists, herbalogists, herbologists, naturalists, conservationists, extension scientists, teachers and lecturers), students and the general public.

Glossaries

Medical Glossary

AAD

Allergic airway disease, an inflammatory disorder of the airways caused by allergens.

AAPH

2,2'-azobis (2-amidinopropane) dihydrochloride, a water-soluble azo compound used extensively as a free-radical

generator, often in the study of lipid peroxidation and the characterisation of antioxidants.

Abeta aggregation

Amyloid beta protein (Abeta) aggregation is associated with Alzheimer's disease (AD); it is a major component of the extracellular plaque found in AD brains.

Abdominal distension

Referring to generalised distension of most or all of the abdomen. Also referred to as stomach bloating often caused by a sudden increase in fibre from consumption of vegetables, fruit and beans.

Ablation therapy

The destruction of small areas of myocardial tissue, usually by application of electrical or chemical energy in the treatment of some tachyarrhythmias.

Abortifacient

A substance that causes or induces abortion.

Abortivum

A substance inducing abortion.

Abscess

A swollen, infected, inflamed area filled with pus in body tissues.

ABTS

2,2-azino-bis(3-ethylthiazoline-6-sulfonic acid), a type of mediator in chemical reaction kinetics of specific enzymes.

ACAT

Acyl CoA: cholesterol acyltransferase.

ACE

See angiotensin-converting enzyme.

ACTH (Adrenocorticotrophic hormone)

Also known as ‘corticotropin’, it is a polypeptide tropic hormone produced and secreted by the anterior pituitary gland.

Acetogenins

Natural products from the plants of the family Annonaceae, they are very potent inhibitors of the NADH-ubiquinone reductase (Complex I) activity of mammalian mitochondria.

Acetyl-CoA carboxylase (ACC)

Enzyme that catalyses the biotin-dependent carboxylation of acetyl-CoA to produce malonyl-CoA.

Acetylcholinesterase (AChE)

Is an enzyme that degrades (through its hydrolytic activity) the neurotransmitter acetylcholine, producing choline.

Acne vulga'ris

Also known as chronic acne, usually occurring in adolescence, with comedones (blackheads), papules (red pimples), nodules (inflamed acne spots) and pustules (small inflamed pus-filled lesions) on the face, neck and upper part of the trunk.

Acidosis

Increased acidity, an excessively acid condition of body fluids.

Acquired immunodeficiency syndrome (AIDS)

An epidemic disease caused by an infection by the human immunodeficiency virus (HIV-1, HIV-2), a retrovirus that causes immune system failure and debilitation and is often accompanied by infections such as tuberculosis.

Acridone

An organic compound based on the acridine skeleton with a carbonyl group at the 9 position.

ACTH

Adrenocorticotrophic hormone (or corticotropin), a polypeptide tropic hormone produced and secreted by the anterior

pituitary gland. It plays a role in the synthesis and secretion of gluco- and mineralo-corticosteroids and androgenic steroids.

Activating transcription factor (ATF)

A protein (gene) that binds to specific DNA sequences regulating the transfer or transcription of information from DNA to mRNA.

Activator protein-1 (AP-1)

A heterodimeric protein transcription factor that regulates gene expression in response to a variety of stimuli including cytokines, growth factors, stress and bacterial and viral infections. AP-1 in turn regulates a number of cellular processes including differentiation, proliferation and apoptosis.

Actoprotective

Increasing the body's physical performance.

Actoprotectors

Preparations that increase the mental performance and enhance body stability against physical loads without increasing oxygen consumption. Actoprotectors are regarded as a subclass of adaptogens that hold a significant capacity to increase physical performance.

Acute otitis media (AOM)

See otitis media.

Acyl-CoA dehydrogenases

A group of enzymes that catalyses the initial step in each cycle of fatty acid β -oxidation in the mitochondria of cells.

Adaptogen

A term used by herbalists to refer to a natural herb product that increases the body's resistance to stresses such as trauma, stress and fatigue.

Adaptogenic

Increasing the resistance of the body to stress.

Addison's disease

Is a rare endocrine disorder. It occurs when the adrenal glands cannot produce sufficient hormones (corticosteroids). It is also known as chronic adrenal insufficiency, hypocortisolism or hypocorticism.

Adenocarcinoma

A cancer originating in glandular tissue.

Adenoma

A benign tumour from a glandular origin.

Adenoidectomy

Surgical removal of the adenoids.

Adenopathy

Abnormal enlargement or swelling of the lymph node.

Adenosine receptors

A class of purinergic, G-protein-coupled receptors with adenosine as endogenous ligand. In humans, there are four adenosine receptors. A₁ and A_{2A} receptors play roles in the heart, regulating myocardial oxygen consumption and coronary blood flow, while the A_{2A} receptor also has broader anti-inflammatory effects throughout the body. These two receptors also have important roles in the brain, regulating the release of other neurotransmitters such as dopamine and glutamate, while A_{2B} and A₃ receptors are located mainly peripherally and are involved in inflammation and immune responses.

ADH

See alcohol dehydrogenase.

Adipocyte

A fat cell involved in the synthesis and storage of fats.

Adipocytokine

Bioactive cytokines produced by adipose tissues.

Adiponectin

A protein in humans that modulates several physiological processes such as metabolism of glucose and fatty acids and immune responses.

Adipose tissues

Body fat, loose connective tissue composed of adipocytes (fat cells).

Adoptogen

Containing smooth pro-stressors which reduce reactivity of host defense systems and decrease damaging effects of various stressors due to increased basal level of mediators involved in stress response.

Adrenal glands

Star-shaped endocrine glands that sit on top of the kidneys.

Adrenalectomised

Having had the adrenal glands surgically removed.

Adrenergic

Having to do with adrenaline (epinephrine) and/or noradrenaline (norepinephrine).

Adrenergic receptors

A class of G protein-coupled receptors that are targets of the noradrenaline (norepinephrine) and adrenaline (epinephrine).

Adulterant

An impure ingredient added into a preparation.

Advanced Glycation End products (AGEs)

Resultant products of a chain of chemical reactions after an initial glycation reaction. AGEs may play an important adverse role in the process of atherosclerosis, diabetes, aging and chronic renal failure.

Aegilops

An ulcer or fistula in the inner corner of the eye.

Afferent

Something that so conducts or carries towards, such as a blood vessel, fibre or nerve.

Agammaglobulinaemia

An inherited disorder in which there are very low levels of protective immune proteins called immunoglobulins. *cf.* x-linked agammaglobulinaemia.

Agalactia

Lack of milk after parturition (birth).

Age-related macular degeneration (AMD)

A medical condition of elderly adults that results in a loss of vision in the center of the visual field (the macula) because of damage to the retina.

Agglutinin

A protein substance, such as an antibody, that is capable of causing agglutination (clumping) of a particular antigen.

Agglutination

Clumping of particles.

Agonist

A drug that binds to a receptor of a cell and triggers a response by the cell.

Ague

A fever (such as from malaria) that is marked by paroxysms of chills, fever and sweating and that recurs at regular intervals.

AHR

AhR, aryl hydrocarbon receptor, a cytosolic protein transcription factor.

AIDS

See acquired immunodeficiency syndrome.

Akathisia

A movement disorder in which there is an urge or need to move the legs to stop unpleasant sensations. Also called restless leg syndrome, the disorder is often caused by long-term use of antipsychotic medications.

AKT

Serine/threonine kinase (also known as protein kinase B or PKB) plays a critical regulatory role in diverse cellular processes including cancer progression and insulin metabolism.

Akt signaling pathway

Akts are protein kinases involved in mammalian cellular signaling that inhibits apoptotic processes.

Akt/FoxO pathway

Cellular processes involving Akt and FoxO transcription factors that play a role in angiogenesis and vasculogenesis.

Akt/GSK-3 β /eNOS phosphorylation

Amplifies serotonin 5-HT_{2B} receptor blockade-mediated anti-hypertrophic effects.

Alanine transaminase (ALT)

Also called Serum Glutamic Pyruvate Transaminase (SGPT) or Alanine aminotransferase (ALAT), an enzyme present in hepatocytes (liver cells). When a cell is damaged, it leaks this enzyme into the blood.

ALAT, (Alanine aminotransferase)

See alanine transaminase.

Albumin

Water-soluble proteins found in egg white, blood serum, milk, various animal tissues and plant juices and tissues.

Albuminaria

Excessive amount of albumin in the urine, a symptom of severe kidney disease.

Aldose reductase, aldehyde reductase

An enzyme in carbohydrate metabolism that converts glucose to sorbitol.

Alexipharmic

An antidote remedy for poison.

Alexiteric

A preservative against contagious and infectious diseases and the effects of poisons.

Alcohol dehydrogenase (ADH)

An enzyme involved in the breakdown of alcohol.

Algesic

Endogenous substances involved in the production of pain that is associated with inflammation, e.g. serotonin, bradykinin and prostaglandins.

Alkaline phosphatase (ALP)

An enzyme in the cells lining the biliary ducts of the liver. ALP levels in plasma will rise with large bile duct obstruction, intrahepatic cholestasis or infiltrative diseases of the liver. ALP is also present in bone and placental tissues.

Allergenic

Having the properties of an antigen (allergen), immunogenic.

Allergic

Pertaining to, caused by, affected with or of the nature of allergy.

Allergic conjunctivitis

Inflammation of the tissue lining the eyelids (conjunctiva) due to allergy.

Allergy

A hypersensitivity state induced by exposure to a particular antigen (allergen) resulting in harmful immunologic reactions on subsequent exposures. The term is usually used to refer to hypersensitivity to an environmental

antigen (atopic allergy or contact dermatitis) or to drug allergy.

Allodynia

A painful response to a normally innocuous stimulus.

Allogeneic

Cells or tissues which are genetically different because they are derived from separate individuals of the same species. Also refers to a type of immunological reaction that occurs when cells are transplanted into a genetically different recipient.

Allografts

Or homografts, a graft between individuals of the same species but of different genotypes.

Alloknesis

Itch produced by innocuous mechanical stimulation.

Allostasis

The process of achieving stability, or homeostasis, through physiological or behavioural change.

Alopecia

Is the loss of hair on the body.

Alopecia areata

Type of hair loss that typically causes patches of baldness.

ALP

See Alkaline phosphatase.

Alpha-adrenoceptor

Receptors postulated to exist on nerve cell membranes of the sympathetic nervous system in order to explain the specificity of certain agents that affect only some sympathetic activities (such as vasoconstriction, relaxation of intestinal muscles and contraction of smooth muscles).

Alpha amylase (α -amylase)

A major form of amylase found in humans and other mammals that cleaves alpha bonds of large, alpha-linked polysaccharides such as starch and glycogen yielding glucose and maltose.

ALT

See Alanine transaminase.

Alterative

A medication or treatment which gradually induces a change and restores healthy functions without sensible evacuations.

Alveolar macrophage

A vigorously phagocytic macrophage on the epithelial surface of lung alveoli that ingests carbon and other inhaled particulate matter. Also called coniphage or dust cell.

Alzheimer's disease

A degenerative, organic, mental disease characterised by progressive brain deterioration and dementia usually occurring after the age of 50.

Amastigote

Refers to a cell that does not have any flagella, used mainly to describe a certain phase in the life cycle of trypanosome protozoans.

Amenorrhea

The condition when a woman fails to have menstrual periods.

Amidolytic

Cleavage of the amide structure.

Amoebiasis

State of being infected by amoeba such as *Entamoeba histolytica*.

Amoebicidal

Lethal to amoeba.

AMPK (5' AMP-activated protein kinase)

Or 5' adenosine monophosphate-activated protein kinase,
enzyme that plays a role in cellular energy homeostasis.

Amygdalitis

Inflammation of one or both tonsils, tonsilitis.

Amyloid beta ($A\beta$ or Abeta)

A peptide of 39–43 amino acids that appears to be the main
constituent of amyloid plaques in the brains of
Alzheimer's disease patients.

Amyloidosis

A disorder that results from abnormal deposition of the protein
amyloid in various tissues of the body.

Amyotrophic lateral sclerosis

Or ALS, is a disease of the motor neurons in the brain and
spinal cord that control voluntary muscle movement.

Amyotrophy

Progressive wasting of muscle tissues. *adj* . amyotrophic.

Anaemia

A blood disorder in which the blood is deficient in red blood
cells and in haemoglobin.

Anaesthesia

Condition of having sensation temporarily suppressed.

Anaesthetic

A substance that partially or totally decreases the nerve sense
of pain.

Analeptic

A central nervous system (CNS) stimulant medication.

Analgesia

Term describing relief, reduction or suppression of pain. *adj* .
analgetic.

Analgesic

A substance that relieves or reduces pain.

Anaphoretic

An antiperspirant.

Anaphrodisiac

Or antiaphrodisiac, is something that reduces or blunts the libido.

Anaphylaxis

A severe, life-threatening allergic response that may be characterised by symptoms such as reduced blood pressure, wheezing, vomiting or diarrhoea.

Anaphylactic

Adj . See anaphylaxis.

Anaphylotoxins

Are fragments (C3a, C4a or C5a) that are produced during the pathways of the complement system. They can trigger release of substances of endothelial cells, mast cells or phagocytes, which produce a local inflammatory response.

Anaplasia

A reversion of differentiation in cells, is characteristic of malignant neoplasms (tumours).

Anaplastic

Adj . See anaplasia.

Anasarca

Accumulation of a great quantity of fluid in body tissues.

Anencephaly

A cephalic disorder that results from a neural tube defect that occurs when the cephalic (head) end of the neural tube fails to close, resulting in the absence of a major portion of the brain, skull and scalp.

Androgen

Male sex hormone in vertebrates. Androgens may be used in patients with breast cancer to treat recurrence of the disease.

Androgenic alopecia

Hair loss in men and women.

Android adiposity

Centric fat distribution patterns with increased disposition towards the abdominal area, visceral fat – apple-shaped *cf.* gynoid adiposity.

Andrology

Branch of medicine concerned with reproductive diseases in men.

Aneugen

An agent that affects cell division and the mitotic spindle apparatus, causing the loss or gain of whole chromosomes, thereby inducing aneuploidy. *adj.* aneugenic.

Angina pectoris, Angina

Chest pain or chest discomfort that occurs when the heart muscle does not get enough blood.

Angioedema

Rapid swelling of the dermis, subcutaneous tissues, mucosa and submucosal tissues caused by small blood vessels leaking fluid into these tissues.

Angiogenic

Adj. See angiogenesis.

Angiogenesis

A physiological process involving the growth of new blood vessels from pre-existing vessels.

Angiotensin

An oligopeptide hormone in the blood that causes blood vessels to constrict and drives blood pressure up. It is part of the renin–angiotensin system.

Angiotensin-converting enzyme (ACE)

An exopeptidase, a circulating enzyme that participates in the body's renin–angiotensin system (RAS), which mediates extracellular volume (i.e. that of the blood plasma, lymph and interstitial fluid) and arterial vasoconstriction.

Angioplasty

Medical procedure used to open obstructed or narrowed blood vessels resulting usually from atherosclerosis.

Anguillulosis

A parasitosis caused by the intestinal nematode *Strongyloides stercoralis* (round worm).

Anisakiasis

A human parasitic infection of the gastrointestinal tract caused by the consumption of raw or undercooked seafood containing larvae of the nematode *Anisakis simplex*.

Anisonucleosis

A morphological manifestation of nuclear injury characterised by variation in the size of cell nuclei.

Ankylosing spondylitis (AS)

Is a type of inflammatory arthritis that targets the joints of the spine.

Annexin V

Or Annexin A5, is a member of the annexin family of intracellular proteins that binds to phosphatidylserine (PS) in a calcium-dependent manner.

Annexitis

Also called adnexitis, a pelvic inflammatory disease involving the inflammation of the ovaries or fallopian tubes.

Anodyne

A substance that relieves or soothes pain by lessening the sensitivity of the brain or nervous system. Also called an analgesic.

Anoikis

Apoptosis that is induced by inadequate or inappropriate cell–matrix interactions.

Anorectal

Relating to the rectum and anus.

Anorectics

Appetite suppressants, substances which reduce the desire to eat. Used on a short-term basis clinically to treat obesity. Also called anorexigenics.

Anorexia

Lack or loss of desire to eat.

Anorexic

Having no appetite to eat.

Anorexigenics

See anorectics.

Anosmia

Inability to perceive odour, reduced sense of smell.

Anoxia

Absence of oxygen supply.

Antagonist

A substance that acts against and blocks an action.

Antalgic

A substance used to relieve a painful condition.

Antecubital vein

This vein is located in the antecubital fossa —the area of the arm in front of the elbow.

Anterior uveitis

Is the most common form of ocular inflammation that often causes a painful red eye.

Anthelmintic

An agent or substance that is destructive to worms and used for expulsion of internal parasitic worms in animals and humans.

Anthocyanins

A subgroup of antioxidant flavonoids, they are glucosides of anthocyanidins, which are beneficial to health. They occur as water-soluble vacuolar pigments that may appear red, purple or blue according to pH in plants.

Anthrax

A bacterial disease of cattle and sheep that can be transmitted to man through unprocessed wool.

Anthropometric

Pertaining to the study of human body measurements.

Antiamoebic

A substance that destroys or suppresses parasitic amoebae.

Anti-amyloidogenic

Compounds that inhibit the formation of Alzheimer's β -amyloid fibrils (fA β) from amyloid β -peptide (A β) and destabilise fA β .

Antianaphylactic

Agent that can prevent the occurrence of anaphylaxis (life-threatening allergic response).

Antiangiogenic

A drug or substance used to stop the growth of tumours and progression of cancers by limiting the pathological formation of new blood vessels (angiogenesis).

Antiarrhythmic

A substance to correct irregular heartbeats and restore the normal rhythm.

Antiasthmatic

Drug that treats or ameliorates asthma.

Antiatherogenic

That protects against atherogenesis, the formation of atheromas (plaques) in arteries.

Antibacterial

Substance that kills or inhibits bacteria.

Antibiliary

An agent or substance which helps remove excess bile from the body.

Antibiotic

A chemical substance produced by a microorganism which has the capacity to inhibit the growth of or to kill other microorganisms.

Antiblenorrhagic

A substance that treats blenorrhagia, a conjunctival inflammation resulting in mucous discharge.

Antibody

A gamma globulin protein produced by a kind of white blood cell called the plasma cell in the blood used by the immune system to identify and neutralise foreign objects (antigen).

Anticarcinomic

A substance that kills or inhibits carcinomas (any cancer that arises in epithelium/tissue cells).

Anticephalalgic

Headache-relieving or preventing.

Anticestodal

A chemical destructive to tapeworms.

Anticholesterolemic

A substance that can prevent the build-up of cholesterol.

Anticlastogenic

Having a suppressing effect of chromosomal aberrations.

Anticoagulant

A substance that thins the blood and acts to inhibit blood platelets from sticking together.

Antidepressant

A substance that suppresses depression or sadness.

Antidiabetic

A substance that prevents or alleviates diabetes. Also called antidiabetogenic.

Antidiarrhoeal

Having the property of stopping or correcting diarrhoea, an agent having such action.

Antidote

A remedy for counteracting a poison.

Antidopaminergic

A term for a chemical that prevents or counteracts the effects of dopamine.

Antidrepanocytary

Anti-sickle cell anaemia.

Antidysenteric

An agent used to reduce or treat dysentery and diarrhoea.

Antidyslipidemic

Agent that will reduce the abnormal amount of lipids and lipoproteins in the blood.

Anti-oedematous

Reduces or suppresses oedema.

Antiemetic

An agent that stops vomiting and nausea.

Anti-epileptic

A drug used to treat or prevent convulsions, anticonvulsant.

Antifebrile

A substance that reduces fever, also called antipyretic.

Antifeedant

Preventing something from being eaten.

Antifertility

Agent that inhibits formation of ova and sperm and disrupts the process of fertilisation (antizygotic).

Antifibrosis

Preventing/retarding the development of fibrosis i.e. excessive growth and activity of fibroblasts.

Antifilarial

Effective against human filarial worms.

Antifungal

An agent that kills or inhibits the growth of fungi.

Antigen

A substance that prompts the production of antibodies and can cause an immune response. *adj* . antigenic.

Antigenotoxic

An agent that inhibits DNA adduct formation, stimulates DNA repair mechanisms and possesses antioxidant functions.

Antiganacratia

Antimenstruation.

Antigastralgie

Preventing or alleviating gastric colic.

Antihematic

Agent that stops vomiting.

Antihemorrhagic

An agent which stops or prevents bleeding.

Antihepatotoxic

Counteracting injuries to the liver.

Antiherpetic

Having activity against herpes simplex virus (HSV).

Antihistamine

An agent used to counteract the effects of histamine production in allergic reactions.

Antihyperalgesia

The ability to block enhanced sensitivity to pain usually produced by nerve injury or inflammation or to nociceptive stimuli. *adj* . antihyperalgesic.

Antihypercholesterolemia

Term to describe lowering of cholesterol level in the blood or blood serum.

Antihypercholesterolemic

Agent that lowers cholesterol level in the blood or blood serum.

Antihyperlidemic

Promoting a reduction of lipid levels in the blood or an agent that has this action.

Antihypersensitive

A substance used to treat excessive reactivity to any stimuli.

Antihypertensive

A drug used in medicine and pharmacology to treat hypertension (high blood pressure).

Anti-inflammatory

A substance used to reduce or prevent inflammation.

Antileishmanial

Inhibiting the growth and proliferation of *Leishmania* , a genus of flagellate protozoans that are parasitic in the tissues of vertebrates.

Antileprotic

Therapeutically effective against leprosy.

Antilithiatic

An agent that reduces or suppresses urinary calculi (stones) and acts to dissolve those already present.

Antileukaemic

Anticancer drugs that are used to treat leukaemia.

Antilithogenic

Inhibiting the formation of calculi (stones).

Antimalarial

An agent used to treat malaria and/or kill the malaria-causing organism, *Plasmodium* spp.

Antimelanogenesis

Obstruction of production of melanin.

Antimicrobial

A substance that destroys or inhibits growth of disease-causing bacteria, viruses, fungi and other microorganisms.

Antimitotic

Inhibiting or preventing mitosis.

Antimutagenic

An agent that inhibits mutations.

Antimycotic

Antifungal.

Antineoplastic

Said of a drug intended to inhibit or prevent the maturation and proliferation of neoplasms that may become malignant by targeting the DNA.

Antineuralgic

A substance that stops intense intermittent pain, usually of the head or face, caused by neuralgia.

Antinociception

Reduction in pain: a reduction in pain sensitivity produced within neurons when an endorphin or similar opium-

containing substance (opioid) combines with a receptor.

Antinociceptive

Having an analgesic effect.

Antioxytotic

Inhibiting premature labour,. *cf.* tocolytic.

Antinutrient

Are natural or synthetic compounds that interfere with the absorption of nutrients and are commonly found in food sources and beverages.

Antioestrogen

A substance that inhibits the biological effects of female sex hormones.

Antiophidian

Antivenom.

Antiosteoporotic

Substance that can prevent osteoporosis.

Antioviulatory

Substance suppressing ovulation.

Antioxidant

A chemical compound or substance that inhibits oxidation and protects against free radical activity and lipid oxidation such as vitamin E, vitamin C or beta-carotene (converted to vitamin A), carotenoids and flavonoids which are thought to protect body cells from the damaging effects of oxidation. Many foods including fruit and vegetables contain compounds with antioxidant properties.

Antioxidants may also reduce the risks of cancer and age-related macular degeneration (AMD).

Antipaludic

Antimalarial.

Antiperiodic

Substance that prevents the recurrence of symptoms of a disease e.g. malaria.

Antiperspirant

A substance that inhibits sweating. Also called antisudorific, anaphoretic.

Antiphlogistic

A traditional term for a substance used against inflammation, anti-inflammatory.

Antiplatelet agent

Drug that decreases platelet aggregation and inhibits thrombus formation.

Antiplasmodial

Suppressing or destroying plasmodia.

Antiproliferative

Preventing or inhibiting the reproduction of similar cells.

Antiprostatic

Drug to treat the prostate.

Antiprotozoal

Suppressing the growth or reproduction of protozoa.

Antipruritic

Alleviating or preventing itching.

Antipyretic

A substance that reduces fever or quells it. Also known as antithermic.

Antirheumatic

Relieving or preventing rheumatism.

Antiscorbutic

A substance or plant rich in vitamin C that is used to counteract scurvy.

Antisecretory

Inhibiting or diminishing secretion.

Antisense

Refers to an antisense RNA strand because its sequence of nucleotides is the complement of message sense. When mRNA forms a duplex with a complementary antisense RNA sequence, translation of the mRNA into the protein is blocked. This may slow or halt the growth of cancer cells.

Antiseptic

Preventing decay or putrefaction, a substance inhibiting the growth and development of microorganisms.

Antisickling agent

An agent used to prevent or reverse the pathological events leading to sickling of erythrocytes in sickle-cell conditions.

Antispasmodic

A substance that relieves spasms or inhibits the contraction of smooth muscles, smooth muscle relaxant, muscle relaxer.

Antispermatogetic

Preventing or suppressing the production of semen or spermatozoa.

Antisudorific

See antiperspirant.

Antisymphilitic

A drug (or other chemical agent) that is effective against syphilis.

Antithermic

A substance that reduces fever and temperature. Also known as antipyretic.

Antithrombotic

Preventing or interfering with the formation of thrombi.

Antitoxin

An antibody with the ability to neutralise a specific toxin.

Antitumoral

Substance that acts against the growth, development or spread of a tumour.

Antitussive

A substance that depresses coughing.

Antiulcerogenic

An agent used to protect against the formation of ulcers or used for the treatment of ulcers.

Antivenin

An agent used against the venom of a snake, spider or other venomous animal or insect.

Antivinous

An agent or substance that treats addiction to alcohol.

Antiviral

Substance that destroys or inhibits the growth and viability of infectious viruses.

Antivomitive

A substance that reduces or suppresses vomiting.

Antizygotic

See antifertility.

Anuria

Absence of urine production and excretion. *adj* . anuric.

Anxiogenic

Substance that causes anxiety.

Anxiolytic

A drug prescribed for the treatment of symptoms of anxiety.

APAF-1

Apoptotic protease activating factor 1.

Apelin

Also known as APLN, a peptide which in humans is encoded by the APLN gene.

Aperient

A substance that acts as a mild laxative by increasing fluids in the bowel.

Aperitif

An appetite stimulant.

Aphonia

Loss of the voice resulting from disease, injury to the vocal cords or various psychological causes such as hysteria.

Aphrodisiac

An agent that increases sexual activity and libido and/or improves sexual performance.

Aphthae

White, painful oral ulcer of unknown cause.

Aphthous ulcer

Also known as a canker sore, it is a type of oral ulcer which presents as a painful open sore inside the mouth or upper throat.

Aphthous stomatitis

A canker sore, a type of painful oral ulcer or sore inside the mouth or upper throat, caused by a break in the mucous membrane. Also called aphthous ulcer.

Apnoea

Suspension of external breathing.

Apoprotein

The protein moiety of a molecule or complex, as of a lipoprotein.

Apolipoprotein A-I (APOA1)

A major protein component of high-density lipoprotein (HDL) in plasma. The protein promotes cholesterol efflux from

tissues to the liver for excretion.

Apolipoprotein B (APOB)

Is the primary apolipoprotein of low-density lipoproteins (LDL or 'bad cholesterol'), which is responsible for carrying cholesterol to tissues.

Apolipoprotein E (APOE)

The apolipoprotein found on intermediate-density lipoprotein and chylomicron that binds to a specific receptor on liver and peripheral cells.

Apoplexy

Unconsciousness or incapacity of the brain to function, resulting from a cerebral haemorrhage or stroke.

Apoptogenic

Ability to cause death of cells.

Apoptosis

Death of cells.

Appendicitis

Is a condition characterised by inflammation of the appendix. Also called epityphlitis.

Appetite stimulant

A substance to increase or stimulate the appetite. Also called aperitif.

aPTT (Activated Partial Thromboplastin Time)

A blood test, a measure of the part of the blood-clotting pathway.

Apurinic lyase

A DNA enzyme that catalyses a chemical reaction.

Arachidonate cascade

Includes the cyclooxygenase (COX) pathway to form prostanoids and the lipoxygenase (LOX) pathway to

generate several oxygenated fatty acids collectively called eicosanoids.

ARE

Antioxidant response element, is a transcriptional control element that mediates expression of a set of antioxidant proteins.

Ariboflavinosis

A condition caused by the dietary deficiency of riboflavin that is characterised by mouth lesions, seborrhea and vascularisation.

Aromatase

An enzyme involved in the production of oestrogen that acts by catalysing the conversion of testosterone (an androgen) to estradiol (an oestrogen). Aromatase is located in oestrogen-producing cells in the adrenal glands, ovaries, placenta, testicles, adipose (fat) tissue and brain.

Aromatic

Having a pleasant fragrant odour.

Aromatherapy

A form of alternative medicine that uses volatile liquid plant materials such as essential oils and other scented compounds from plants for the purpose of affecting a person's mood or health.

ARPE-19 cells

A human retinal pigment epithelial cell line with differentiated properties.

Arrhythmias

Abnormal heart rhythms that can cause the heart to pump less effectively. Also called dysrhythmias.

Arsenicosis

See arsenism.

Arsenism

An incommunicable disease resulting from the ingestion of groundwater containing unsafe levels of arsenic, also known as arsenicosis.

Arteriogenic erectile dysfunction

A penis dysfunction caused by the narrowing of the arteries in the penis decreasing blood inflow to it, thus making erection impossible.

Arteriosclerosis

Imprecise term for various disorders of arteries, particularly hardening due to fibrosis or calcium deposition, often used as a synonym for atherosclerosis.

Arthralgia

Is pain in the joints from many possible causes.

Arthritis

Inflammation of the joints of the body.

Arthrodynia

An affection characterised by pain in or about a joint.

Arthus reaction

An allergic reaction of the immediate hypersensitive type that results from the union of antigen and antibody, with complement present, in blood vessel walls.

Aryl hydrocarbon receptor (AhR)

A ligand-activated transcription factor best known for mediating the toxicity of dioxin and other exogenous contaminants and responsible for their toxic effects including immunosuppression.

ASAT or AST

Aspartate aminotransferase, see aspartate transaminase.

ASBT

Apical sodium-dependent bile acid transporter belongs to the solute carrier family (SLC) of transporters and is an important carrier protein expressed in the small intestine.

Ascaris

A genus of parasitic intestinal roundworms.

Ascites

Abnormal accumulation of fluid within the abdominal or peritoneal cavity.

Ascorbic acid

See vitamin C.

Aspartate transaminase (AST)

Also called Serum Glutamic Oxaloacetic Transaminase (SGOT) or aspartate aminotransferase (ASAT), it is similar to ALT in that it is another enzyme associated with liver parenchymal cells. It is increased in acute liver damage but is also present in red blood cells and cardiac and skeletal muscle and is therefore not specific to the liver.

Asphyxia

Failure or suppression of the respiratory process due to obstruction of airflow to the lungs or to the lack of oxygen in inspired air.

Asphyxiation

The process of undergoing asphyxia.

Asthenia

A nonspecific symptom characterised by loss of energy and strength and feeling of weakness.

Asthenopia

Weakness or fatigue of the eyes usually accompanied by headache and dimming of vision. *adj* . asthenopic.

Asthma

A chronic illness involving the respiratory system in which the airway occasionally constricts, becomes inflamed and is lined with excessive amounts of mucus often in response to one or more triggers.

Astringent

A substance that contracts blood vessels and certain body tissues (such as mucous membranes) with the effect of reducing secretion and excretion of fluids and/or has a drying effect.

Astrocytes

Collectively called astroglia, they are characteristic star-shaped glial cells in the brain and spinal cord.

Ataxia

(Loss of coordination) results from the degeneration of nerve tissue in the spinal cord and of nerves that control muscle movement in the arms and legs.

Ataxia telangiectasia and Rad3-related protein (ATR)

Also known as Serine/threonine-protein kinase ATR, FRAP-related protein 1 (FRP1) is an enzyme encoded by the ATR gene. It is involved in sensing DNA damage and activating the DNA damage checkpoint leading to cell cycle arrest.

Atelectasis

The collapse or closure of the lung resulting in reduced or absent gas exchange.

ATF-2

Activating transcription factor 2.

Athlete's foot

A contagious skin disease caused by parasitic fungi affecting the foot and hands, causing itching, blisters and cracking. Also called dermatophytosis.

Atherogenic

Having the capacity to start or accelerate the process of atherogenesis.

Atherogenesis

The formation of lipid deposits in arteries.

Atheroma

A deposit or degenerative accumulation of lipid-containing plaques on the innermost layer of the wall of an artery.

Atherosclerosis

The condition in which an artery wall thickens as the result of a build-up of fatty materials such as cholesterol.

Atherothrombosis

Medical condition characterised by an unpredictable, sudden disruption (rupture or erosion/fissure) of an atherosclerotic plaque, which leads to platelet activation and thrombus formation.

Athymic mice

Laboratory mice lacking a thymus gland.

Atonic

Lacking normal tone or strength.

Atony

Insufficient muscular tone.

Atopic dermatitis

An inflammatory, non-contagious, pruritic skin disorder of unknown aetiology, often called eczema.

Atresia

A congenital medical condition in which a body orifice or passage in the body is abnormally closed or absent.

Atretic follicle

Follicular atresia is the breakdown of ovarian follicles.

Atretic ovarian follicle

An involuted or closed ovarian follicle.

Atrial fibrillation

Is the most common cardiac arrhythmia (abnormal heart rhythm) and involves the two upper chambers (atria) of the heart; the most serious consequence of atrial fibrillation is ischaemic stroke.

Atrioventricular node

A node of specialised heart muscle located in the septal wall of the right atrium receives impulses from the sinoatrial node and directs them to the walls of the ventricles.

Attention deficit hyperactivity disorder (ADHD, ADD or AD/HD)

Is a neurobehavioural developmental disorder primarily characterised by the co-existence of attentional problems and hyperactivity.

Auditory brainstem response (ABR)

Also called brainstem evoked response (BSER), it is an electrical signal evoked from the brainstem of a human by the presentation of a sound such as a click.

Augmerosen

A drug that may kill cancer cells by blocking the production of a protein that makes cancer cells live longer. Also called bcl-2 antisense oligonucleotide.

Auricular

Of or relating to the auricle or the ear in general.

Aurones

[2-benzylidenebenzofuran-3(2H)-ones] are the secondary plant metabolites and are a subgroup of flavonoids. See flavonoids.

Autoantibodies

Antibodies manufactured by the immune system that mistakenly target and damage specific tissues and organs of the body.

Autolysin

An enzyme that hydrolyses and destroys the components of a biological cell or a tissue in which it is produced.

Autonomic disorder

A neurological disease in which the autonomic nervous system ceases to function properly.

Autophagy

Digestion of cell contents by enzymes in the same cell.

Autopsy

Examination of a cadaver to determine or confirm the cause of death.

Avenanthramides

Low-molecular weight, soluble phenolic compounds found in oats.

Avidity index

Describes the collective interactions between antibodies and a multivalent antigen.

Avulsed tooth

Is a tooth that has been knocked out.

Ayurvedic

Traditional Hindu system of medicine based largely on homeopathy and naturopathy.

Azoospermia

Is the medical condition of a male not having any measurable level of sperm in his semen.

Azotaemia

A higher-than-normal blood level of urea or other nitrogen-containing compounds in the blood.

B-cell activating factor (BAFF)

Also called tumor necrosis factor ligand superfamily member 13B. It plays an important role in the proliferation and differentiation of B cells.

Babesia

A protozoan parasite (malaria-like) of the blood that causes a hemolytic disease known as Babesiosis.

Babesiosis

Malaria-like parasitic disease caused by Babesia, a genus of protozoal piroplasms.

Back tonus

Normal state of balanced tension in the tissues of the back.

Bactericidal

Lethal to bacteria.

BAFF

A cytokine that belongs to the tumor necrosis factor (TNF) ligand family.

Balanitis

Is an inflammation of the glans (head) of the penis.

BALB/c mice

The balb/c mouse was developed in 1923 by McDowell. It is a popular strain and is used in many different research disciplines but most often in the production of monoclonal antibodies.

Balm

Aromatic oily resin from certain trees and shrubs used in medicine.

Baroreceptor

A type of interoceptor that is stimulated by pressure changes, as those in blood vessel walls.

Barrett's oesophagus (Barrett oesophagitis)

A disorder in which the lining of the oesophagus is damaged by stomach acid.

Basophil

A type of white blood cell with coarse granules within the cytoplasm and a bilobate (two-lobed) nucleus.

Bax/Bad

Proapoptotic proteins.

BCL-2

A family of apoptosis regulatory proteins in humans encoded by the B-cell lymphoma 2 (BCL-2) gene.

BCL-2 antisense oligonucleotide

See augmereson.

BCR/ABL

A chimeric oncogene from a fusion of BCR and ABL cancer genes associated with chronic myelogenous leukaemia.

Bechic

A remedy or treatment of cough.

Bed nucleus of the stria terminalis (BNST)

Acts as a relay site within the hypothalamic–pituitary–adrenal axis and regulates its activity in response to acute stress.

Belching, or burping

Refers to the noisy release of air or gas from the stomach through the mouth.

Beriberi

Is a disease caused by a deficiency of thiamine (vitamin B₁) that affects many systems of the body including the muscles, heart, nerves and digestive system.

Beta-carotene

Naturally occurring retinol (vitamin A) precursor obtained from certain fruit and vegetables with potential antineoplastic and chemopreventive activities. As an antioxidant, beta-carotene inhibits free-radical damage to DNA. This agent also induces cell differentiation and apoptosis of some tumour cell types, particularly in early stages of tumorigenesis, and enhances immune system activity by stimulating the release of natural killer cells, lymphocytes, and monocytes.

Beta-catenin

Is a multifunctional oncogenic protein that contributes fundamentally to cell development and biology; it has been

implicated as an integral component in the Wnt signaling pathway.

Beta cells

A type of cell in the pancreas in areas called the islets of Langerhans.

Beta glucans

Polysaccharides of D -glucose monomers linked by β -glycosidic bonds, (1 $\rightarrow$ 3), (1 $\rightarrow$ 4)- β - D -glucan, soluble, viscous component of fibres found in cereals like oats.

Beta-thalassemia

An inherited blood disorder that reduces the production of haemoglobin.

Beta-lactamases

Enzymes produced by some bacteria that are responsible for their resistance to beta-lactam antibiotics like penicillins.

BHT

Butylated hydroxytoluene (phenolic compound), an antioxidant used in foods, cosmetics, pharmaceuticals and petroleum products.

BID

The only known Bcl-2 family member that can function as an agonist of proapoptotic Bcl-2-related proteins such as Bax and Bak.

Bifidobacterium

Is a genus of gram-positive, non-motile, often branched anaerobic bacteria. Bifidobacteria are one of the major genera of bacteria that make up the gut flora. Bifidobacteria aid in digestion, are associated with a lower incidence of allergies and also prevent some forms of tumour growth. Some bifidobacteria are being used as probiotics.

Bifidogenic

Promoting the growth of (beneficial) bifidobacteria in the intestinal tract.

Bile

Fluid secreted by the liver and discharged into the duodenum, where it is integral in the digestion and absorption of fats.

Bilharzia, bilharziosis

See Schistosomiasis.

Biliary

Relating to the bile or the organs in which the bile is contained or transported.

Biliary infections

Infection of organ(s) associated with bile, comprising (a) acute cholecystitis: an acute inflammation of the gallbladder wall; (b) cholangitis: inflammation of bile ducts.

Biliousness

Old term used in the eighteenth and nineteenth centuries pertaining to bad digestion, stomach pains, constipation and excessive flatulence.

Bilirubin

A breakdown product of heme (a part of haemoglobin in red blood cells) produced by the liver that is excreted in bile, which causes a yellow discoloration of the skin and eyes when it accumulates in those organs.

Biotin

Also known as vitamin B7. See vitamin B7.

Bitter

A medicinal agent with a bitter taste used as a tonic, alterative or appetiser.

Blackhead

See comedone.

Blackwater fever

Dangerous complication of malaria whereby red blood cells burst in the bloodstream (haemolysis), releasing haemoglobin directly into the blood.

Blain

See chilblain.

Blastocyst

Blastocyst is an embryonic structure formed in the early embryogenesis of mammals after the formation of the morula but before implantation.

Blastocystotoxic

Agent that suppresses further development of the blastocyst through to the ovum stage.

Blebbing

Bulging, e.g. membrane blebbing, also called membrane bulging or ballooning.

Bleeding diathesis

Is an unusual susceptibility to bleeding (haemorrhage) due to a defect in the system of coagulation.

Blennorrhagia

Gonorrhea.

Blennorrhea

Inordinate discharge of mucus, especially a gonorrheal discharge from the urethra or vagina.

Blepharitis

Inflammation of eyelids.

Blepharospasm

Involuntary twitching, blinking closure or squeezing of eyelids.

Blister

Thin vesicle on the skin containing serum and caused by rubbing, friction or burn.

Blood–brain barrier (BBB)

Is a separation of circulating blood and cerebrospinal fluid (CSF) in the central nervous system (CNS). It allows essential metabolites such as oxygen and glucose to pass from the blood to the brain and central nervous system (CNS) but blocks most molecules that are more massive than about 500 Da.

Blood stasis syndrome

Blood stagnation or slowing of blood, an important underlying pathology of many disease processes according to traditional Chinese medicine.

BMPs (bone morphogenetic proteins)

A family of secreted signaling molecules that can induce ectopic bone growth.

BNIP3

A pro-apoptotic BH3-only protein which is associated with mitochondrial dysfunction and cell death.

Boil

Localised pyrogenic, painful infection originating in a hair follicle.

Borborygmus

Rumbling noise caused by the muscular contractions of peristalsis, the process that moves the contents of the stomach and intestines downwards.

Bowman Birk inhibitors

Type of serine proteinase inhibitor.

Bouillon

A broth in French cuisine.

Bradycardia

As applied to adult medicine, it is defined as a resting heart rate of under 60 beats per minute.

Bradyphrenia

Referring to the slowness of thought common to many disorders of the brain.

Brain-derived neurotrophic factor (BDNF)

A protein member of the neurotrophin family that plays an important role in the growth, maintenance, function and survival of neurons. The protein molecule is involved in the modulation of cognitive and emotional functions and in the treatment of a variety of mental disorders.

Bright's disease

Chronic nephritis.

Bronchial inflammation

See bronchitis.

Bronchiectasis

A condition in which the airways within the lungs (bronchial tubes) become damaged and widened.

Bronchitis

Is an inflammation of the main air passages (bronchi) to the lungs.

Bronchoalveolar lavage (BAL)

A medical procedure in which a bronchoscope is passed through the mouth or nose into the lungs and fluid is squirted into a small part of the lung and then recollected for examination.

Bronchopneumonia

Or bronchial pneumonia; inflammation of the lungs beginning in the terminal bronchioles.

Bronchopulmonary

Relating to the bronchi and lungs.

Bronchospasm

Is a difficulty in breathing caused by a sudden constriction of muscles in the walls of the bronchioles as occurs in asthma.

Brown fat

Brown adipose tissue (BAT) in mammals; its primary function is to generate body heat in animals or newborns that do not shiver.

Bubo

Inflamed, swollen lymph node in the neck or groin.

Buccal

Of or relating to the cheeks or the mouth cavity.

Bulbectomy

Removal of the olfactory bulb.

Bullae

Blisters; circumscribed, fluid-containing, elevated lesions of the skin usually more than 5 mm in diameter.

Bursa

A fluid-filled sac or saclike cavity situated in areas subject to friction.

Bursitis

Condition characterised by inflammation of one or more bursae (small sacs) of synovial fluid in the body.

C fibres

Afferent fibres found in the nerve of the somatic sensory system.

c-FOS

A cellular proto-oncogene belonging to the immediate early gene family of transcription factors.

C-jun NH(2)-terminal kinase

Enzymes that belong to the family of the MAPK superfamily of protein kinases. These kinases mediate a plethora of cellular responses to such stressful stimuli including apoptosis and production of inflammatory and immunoregulatory cytokines in diverse cell systems. *cf*: MAPK.

c-Jun-I (Ser 73)

Substrate of JNK-1 activated by phosphorylation at Ser73.

c-Jun II (Ser 63)

Substrate of JNK-1 activated by phosphorylation at Ser63.

C-reactive protein

A protein found in the blood, the levels of which rise in response to inflammation.

c-Src

A cellular non-receptor tyrosine kinase.

CAAT element-binding proteins-alpha (c/EBP-alpha)

Regulates gene expression in adipocytes in the liver.

Cachexia

Physical wasting with loss of weight, muscle atrophy, fatigue and weakness caused by disease.

Caco-2 cell line

A continuous line of heterogeneous human epithelial colorectal adenocarcinoma cells.

Cadaver

A dead body, corpse.

Ca²⁺ ATPase

(PMCA) is a transport protein in the plasma membrane of cells that serves to remove calcium (Ca²⁺) from the cell.

Calcitonin gene-related peptide

(CGRP) is a 37-amino acid neuropeptide that is abundant in the sensory neurons which innervate bone.

Calcium (Ca)

Is the most abundant mineral in the body found mainly in bones and teeth. It is required for muscle contraction, blood vessel expansion and contraction, secretion of hormones and enzymes and transmitting impulses throughout the nervous system. Dietary sources include

milk, yoghurt, cheese, Chinese cabbage, kale, broccoli, some green leafy vegetables, fortified cereals, beverages and soybean products.

Calcium ATPase

Is a form of P-ATPase which transfers calcium after a muscle has contracted.

Calcium channel blockers (CCBs)

A class of drugs and natural substances that disrupt the calcium (Ca^{2+}) conduction of calcium channels.

Calciuria

Abnormal presence of calcium in urine.

Calculosis

The tendency or deposition to form calculi or stones.

Calculus (calculi)

Hardened, mineral deposits that can form a blockage in the urinary system.

Calculi infection

Most calculi arise in the kidney when urine becomes supersaturated with a salt that is capable of forming solid crystals. Symptoms arise as these calculi become impacted within the ureter as they pass towards the urinary bladder.

Caligo

Dimness or obscurity of sight dependent upon a speck on the cornea.

Calmodulin

Is a calcium-modulated protein that can bind to and regulate a multitude of different protein targets, thereby affecting many different cellular functions.

cAMP-dependent pathway

Cyclic adenosine monophosphate is a G protein-coupled receptor-triggered signaling cascade used in cell communication in living organisms.

CAMP factor

Diffusible, heat-stable, extracellular protein produced by Group B *Streptococcus* that enhances the hemolysis of sheep erythrocytes by *Staphylococcus aureus*. It is named after Christie, Atkins and Munch-Peterson, who described it in 1944.

Campylobacteriosis

Is a gastrointestinal disease (gastroenteritis) caused by bacteria called *Campylobacter* which is frequently associated with the consumption of contaminated poultry.

Cancer

A malignant neoplasm or tumour in any part of the body.

Candidiasis

Infections caused by members of the fungus genus *Candida* that range from superficial such as oral thrush and vaginitis to systemic and potentially life-threatening diseases.

Canker

See chancre.

Cannabinoid receptor family

Includes CB1 cannabinoid receptors found predominantly in the brain and nervous system and CB2 cannabinoid receptors mainly associated with immune tissues and expressed at low levels in the brain.

Cannabinoid receptor type 2 (CB 2 receptor)

A G protein-coupled receptor from the cannabinoid receptor family that is mainly expressed on T cells of the immune system, on macrophages and B cells and in hematopoietic cells.

Carboxypeptidase

An enzyme that hydrolyses the carboxy-terminal (C-terminal) end of a peptide bond. It is synthesised in the pancreas and secreted into the small intestine.

Carbuncle

Is an abscess larger than a boil, usually with one or more openings draining pus onto the skin.

Carcinogenesis

Production of carcinomas. *adj* . carcinogenic.

Carcinoma

Any malignant cancer that arises from epithelial cells.

Carcinosarcoma

A rare tumour containing carcinomatous and sarcomatous components.

Cardiac

Relating to, situated near or affecting the heart.

Cardiac asthma

Acute attack of dyspnoea with wheezing resulting from a cardiac disorder.

Cardiac hypertrophy

Is a thickening of the heart muscle (myocardium) resulting in a decreased chamber size including the left and right ventricles. Common causes of cardiac hypertrophy include high blood pressure (hypertension) and heart valve stenosis.

Cardialgia

Heartburn.

Cardinolides

Cardiac glycosides with a five-membered lactone ring in the side chain of the steroid aglycone.

Cardinolide glycoside

Cardenolides that contain structural groups derived from sugars.

Cardioactive

Having an effect on the heart.

Cardiogenic shock

Is characterised by a decreased pumping ability of the heart that causes a shock-like state associated with an inadequate circulation of blood due to primary failure of the ventricles of the heart to function effectively.

Cardiomyocytes

Cardiac muscle cells.

Cardiomyopathy

Heart muscle disease.

Cardiopathy

Disease or disorder of the heart.

Cardioplegia

Stopping the heart so that surgical procedures can proceed in a still and bloodless field.

Cardiotonic

Something which strengthens, tones or regulates heart functions without overt stimulation or depression.

Cardiovascular

Pertaining to the heart and blood vessels.

Caries

Tooth decay, commonly called cavities.

Cariogenic

Leading to the production of caries.

Carminative

Substance that stops the formation of intestinal gas and helps expel gas that has already formed, relieving flatulence: relieving flatulence or colic by expelling gas.

Carnitine palmitoyltransferase I (CPT1)

Also known as carnitine acyltransferase I or CAT1, it is a mitochondrial enzyme involved in converting long-chain fatty acid into energy.

Carotenes

Are a large group of intense red and yellow pigments found in all plants; these are hydrocarbon carotenoids (subclass of tetraterpenes), and the principal carotene is beta-carotene, which is a precursor of vitamin A.

Carotenoids

A class of natural fat-soluble pigments found principally in plants, belonging to a subgroup of terpenoids containing eight isoprene units forming a C₄₀ polyene chain. Carotenoids play an important potential role in human health by acting as biological antioxidants. See also carotenes.

Carotenodermia

Yellow skin discoloration caused by excess blood carotene.

Carpopedal spasm

Spasm of the hand or foot or of the thumbs and great toes.

Capases

Cysteine-aspartic acid proteases are a family of cysteine proteases which play essential roles in apoptosis (programmed cell death), necrosis and inflammation.

Catalase (CAT)

Enzyme in living organism that catalyses the decomposition of hydrogen peroxide to water and oxygen.

Catalepsy

Indefinitely prolonged maintenance of a fixed body posture seen in severe cases of catatonic schizophrenia.

Catamenia

Menstruation.

Cataplasia

Degenerative reversion of cells or tissue to a less differentiated form.

Cataplasm

A medicated poultice or plaster. A soft moist mass, often warm and medicated, that is spread over the skin to treat an inflamed, aching or painful area to improve circulation.

Cataractogenesis

Formation of cataracts.

Catarrh, Catarrhal

Inflammation of mucous membranes especially of the nose and throat.

Catechins

Are polyphenolic antioxidant plant metabolites. They belong to the family of flavonoids; tea is a rich source of catechins. See flavonoids.

Catecholamines

Hormones that are released by adrenal glands in response to stress.

Cathartic

Is a substance which accelerates defecation.

Caustic

Having a corrosive or burning effect.

Cauterisation

A medical term describing the burning of the body to remove or close a part of it.

Caveolae

Tiny (50–100 nm) invaginations of the plasma membrane of the cell.

CB-1 receptor

Cannabinoid receptor type 1 held to be one of the most widely expressed G protein-coupled receptors in the brain.

CCAAT/enhancer-binding proteins (C/EBP)

Family of transcription factors that interact with CCAAT (cytidine-cytidine-adenosine-adenosine-thymidine) box

motif.

CCAAT/enhancer-binding protein (C/EBP) α

A key adipogenic transcription factor.

cdc2 Kinase

A member of cyclin-dependent protein kinases (CDKs).

CDKs

Cyclin-dependent protein kinases, a family of serine/threonine kinases that mediate many stages in mitosis.

CD4T cell

Helper T cell with CD4 receptor that recognises antigens on the surface of a virus-infected cell and secretes lymphokines that stimulate B cells and killer T cells.

CD 28

Is one of the molecules expressed on T cells that provide co-stimulatory signals, which are required for T-cell (lymphocytes) activation.

CD31

Also known as PECAM-1 (platelet endothelial cell adhesion molecule-1), a member of the immunoglobulin superfamily that mediates cell-to-cell adhesion.

CD36

An integral membrane protein found on the surface of many cell types in vertebrate animals.

CD40

An integral membrane protein found on the surface of B lymphocytes, dendritic cells, follicular dendritic cells, hematopoietic progenitor cells, epithelial cells and carcinomas.

CD68

A glycoprotein expressed on monocytes/macrophages which binds to low-density lipoprotein.

Cecal ligation

Tying up the cecum.

Celiac disease

An autoimmune disorder of the small intestine triggered in genetically susceptible individuals by ingested gluten from wheat, rye, barley and other closely related cereal grains. Peptides resulting from partially digested gluten of wheat, barley or rye cause inflammation of the small intestinal mucosa.

Cell adhesion molecules (CAM)

Glycoproteins located on the surface of cell membranes involved with binding of other cells or with the extracellular matrix.

Cellular respiration

Is the set of the metabolic reactions and processes that take place in organisms' cells to convert biochemical energy from nutrients into adenosine triphosphate (ATP) and then release waste products. The reactions involved in respiration are catabolic reactions that involve the oxidation of one molecule and the reduction of another.

Cellulitis

A bacterial infection of the skin that tends to occur in areas that have been damaged or inflamed.

Central nervous system

Part of the vertebrate nervous system comprising the brain and spinal cord.

Central venous catheter

A catheter placed into the large vein in the neck, chest or groin.

Cephalagia

Pain in the head, a headache.

Cephalic

Relating to the head.

Ceramide oligosides

Oligosides with an N-acetyl-sphingosine moiety.

Cercariae

A free-swimming larva of the parasitic schistosome worm that has a tail and suckers on its head for penetration into a host.

Cerebral embolism

A blockage of blood flow through a vessel in the brain by a blood clot that formed elsewhere in the body and traveled to the brain.

Cerebral ischaemia

Is the localised reduction of blood flow to the brain or parts of the brain due to arterial obstruction or systematic hyperfusion.

Cerebral infarction

Is the ischaemic kind of stroke due to a disturbance in blood vessels supplying blood to the brain.

Cerebral tonic

Substance that can alleviate poor concentration and memory, restlessness, uneasiness and insomnia.

Cerebrosides

Are glycosphingolipids which are important components in animal muscle and nerve cell membranes.

Cerebrovascular disease

Is a group of brain dysfunctions related to disease of blood vessels supplying the brain.

Cerumen

Ear wax, a yellowish waxy substance secreted in the ear canal of humans and other mammals.

cFLIP

Cellular FLICE-inhibitory protein, an inhibitor of death ligand-induced apoptosis.

cGMP

Cyclic guanosine monophosphate is a cyclic nucleotide derived from guanosine triphosphate (GTP). cGMP is a common regulator of ion channel conductance, glycogenolysis and cellular apoptosis. It also relaxes smooth muscle tissues.

CGRP calcitonin gene-related peptide

A vasodilator neuropeptide that is expressed in a subgroup of small neurons in the dorsal root, trigeminal and vagal ganglia. This neuropeptide has been postulated to play a role in the pathophysiology of migraine.

Chalcones

A subgroup of flavonoids.

Chancres

A painless lesion formed during the primary stage of syphilis.

Chaperones

Are proteins that assist the non-covalent folding or unfolding and the assembly or disassembly of other macromolecular structures.

Chemoembolisation

A procedure in which the blood supply to the tumour is blocked surgically or mechanically and anticancer drugs are administered directly into the tumour.

Chemokines

Are chemotactic cytokines which stimulate migration of inflammatory cells towards tissue sites of inflammation.

Chemoreceptors

Nociceptors or sensory peripheral neurons that are sensitive to chemical stimuli.

Chemotherapeutic

A drug that makes tumour cells more sensitive to the effects of chemotherapy.

Chemosis

Oedema of the conjunctiva of the eye.

Chickenpox

Is also known as varicella, a highly contagious illness caused by primary infection with varicella zoster virus (VZV).

The virus causes red, itchy bumps on the body.

Chilblains

Small, itchy, painful lumps that develop on the skin. They develop as an abnormal response to cold. Also called perniosis or blain.

Chlorosis

Iron deficiency anaemia characterised by a greenish yellow colour.

Cholagogue

Is a medicinal agent which promotes the discharge of bile from the system.

Cholecalcifereol

A form of vitamin D also called vitamin D3. See vitamin D.

Cholecyst

Gall bladder.

Cholecystitis

Inflammation of the gall bladder.

Cholecystokinine

A peptide hormone that plays a key role in facilitating digestion in the small intestine.

Cholera

An infectious gastroenteritis caused by enterotoxin-producing strains of the bacterium *Vibrio cholera* and characterised by severe, watery diarrhoea.

Choleretic

Stimulation of the production of bile by the liver.

Cholestasis

A condition caused by rapidly developing (acute) or long-term (chronic) interruption in the excretion of bile from the liver to the duodenum.

Cholesterol

A soft, waxy steroid substance found among lipids (fats) in the bloodstream and in all our body's cells.

Cholethiasis

Presence of gall stones (calculi) in the gall bladder.

Choline

A water-soluble organic compound usually grouped within the Vitamin B complex. It is an essential nutrient and is needed for physiological functions such as structural integrity and signaling roles for cell membranes and cholinergic neuro-transmission (acetylcholine synthesis).

Cholinergic

Activated by or capable of liberating acetylcholine especially in the parasympathetic nervous system.

Cholinergic system

A system of nerve cells that uses acetylcholine in transmitting nerve impulses.

Cholinomimetic

Having an action similar to that of acetylcholine, also called parasympathomimetic.

Chronotropic

Affecting the time or rate, as the rate of contraction of the heart.

Choriocarcinoma

A quick-growing, malignant, trophoblastic, aggressive cancer that occurs in a woman's uterus (womb).

Chromium (Cr)

Is required in trace amounts in humans for sugar and lipid metabolism. Its deficiency may cause a disease called

chromium deficiency. It is found in cereals, legumes, nuts and animal sources.

Chromoblastomycosis

A chronic fungal infection of the skin and subcutaneous tissue caused by traumatic inoculation of a specific group of dematiaceous fungi (such as *Fonsecaea pedrosoi*, *Phialophora verrucosa* and *Fonsecaea compacta*) through the skin.

Chromosome

Long pieces of DNA found in the centre (nucleus) of cells.

Chronic

Persisting over extended periods.

Chronic Obstructive Pulmonary Disease (COPD)

A progressive disease that makes it hard to breathe.

Chronic venous insufficiency (CVI)

A medical condition where the veins cannot pump enough oxygen-poor blood back to the heart.

Chronotropic

Affecting the rate of rhythmic movements (e.g. heartbeat).

Chyle

A milky bodily fluid consisting of lymph and emulsified fats or free fatty acids.

Chylomicrons

Are large lipoprotein particles that transport dietary lipids from the intestines to other locations in the body.

Chylomicrons are one of the five major groups of lipoproteins (chylomicrons, VLDL, IDL, LDL, HDL) that enable fats and cholesterol to move within the water-based solution of the bloodstream.

Chylorus

Milky (having fat emulsion).

Chyluria

Also called chylous urine, it is a medical condition involving the presence of chyle (emulsified fat) in the urine stream, which results in urine appearing milky.

Chymase

Member of the family of serine proteases found primarily in mast cells.

Chymopapain

An enzyme derived from papaya used in medicine and to tenderise meat.

Cicatrisant

The term used to describe a product that promotes healing through the formation of scar tissue.

C-Kit receptor

A protein-tyrosine kinase receptor that is specific for stem cell factor. This interaction is crucial for the development of hematopoietic, gonadal and pigment stem cells.

Cirrhosis

Chronic liver disease characterised by replacement of liver tissue by fibrous scar tissue and regenerative nodules/lumps leading progressively to loss of liver function.

Clastogen

Is an agent that can cause one of two types of structural changes, breaks in chromosomes that result in the gain, loss or rearrangements of chromosomal segments. *adj* . clastogenic.

Claudication

Limping, impairment in walking.

Climacterium

Refers to menopause and the bodily and mental changes associated with it.

Clonic seizures

Consist of rhythmic jerking movements of arms and legs, sometimes on both sides of the body.

Clonus

A series of involuntary muscular contractions and relaxations.

Clyster

Enema.

C-myc

Codes for a protein that binds to the DNA of other genes and is therefore a transcription factor.

CNS depressant

Anything that depresses or slows the sympathetic impulses of the central nervous system (i.e. respiratory rate, heart rate).

Coagulopathy

A defect in the body's mechanism for blood clotting, causing susceptibility to bleeding.

Cobalamin

Vitamin B12. See vitamin B12.

Co-carcinogen

A chemical that promotes the effects of a carcinogen in the production of cancer.

Cold

An acute inflammation of the mucous membrane of the respiratory tract especially of the nose and throat caused by a virus and accompanied by sneezing and coughing.

Collagen

Protein that is the major constituent of cartilage and other connective tissue; comprises the amino acids hydroxyproline, proline, glycine and hydroxylysine.

Collagenases

Enzymes that break peptide bonds in collagen.

Colibacillosis

Infection with *Escherichia coli* .

Colic

A broad term which refers to episodes of uncontrollable, extended crying in a baby who is otherwise healthy and well fed.

Colitis

Inflammatory bowel disease affecting the tissue that lines the gastrointestinal system.

Collyrium

A lotion or liquid wash used as a cleanser for the eyes, particularly in diseases of the eye.

Colorectal

Relating to the colon or rectum.

Coma

A state of unconsciousness from which a patient cannot be aroused.

Comedone

A blocked, open sebaceous gland where the secretions oxidise, turning black. Also called blackhead.

Comitogen

Agent that is considered not to induce cell growth alone but to promote the effect of the mitogen.

Concoction

A combination of crude ingredients that are prepared or cooked together.

Condyloma, condylomata acuminata

Genital warts, venereal warts, anal wart or anogenital wart, a highly contagious sexually transmitted infection caused by epidermotropic human papillomavirus (HPV).

Conglutination

Becoming stuck together.

Conjunctival hyperemia

Enlarged blood vessels in the eyes.

Conjunctivitis

Sore, red and sticky eyes caused by eye infection.

Constipation

A very common gastrointestinal disorder characterised by the passing of hard, dry bowel motions (stools) and difficulty of bowel motion.

Constitutive androstane receptor (CAR, NR113)

Is a nuclear receptor transcription factor that regulates drug metabolism and homoeostasis.

Consumption

Term used to describe wasting of tissues including but not limited to tuberculosis.

Consumptive

Afflicted with or associated with pulmonary tuberculosis.

Contraceptive

An agent that reduces the likelihood of or prevents conception.

Contraindication

A condition which makes a particular treatment or procedure inadvisable.

Contralateral muscle

Muscle of opposite limb (leg or arm).

Contralateral rotation

Rotation occurring or originating in a corresponding part on an opposite side.

Contusion

Another term for a bruise. A bruise, or contusion, is caused when blood vessels are damaged or broken as the result of a blow to the skin.

Convulsant

A drug or physical disturbance that induces convulsion.

Convulsion

Rapid and uncontrollable shaking of the body.

Coolant

That which reduces body temperature.

Copper (Cu)

Is essential in all plants and animals. It is found in a variety of enzymes including the copper centres of cytochrome C oxidase and the enzyme superoxide dismutase (containing copper and zinc). In addition to its enzymatic roles, copper is used for biological electron transport. Because of its role in facilitating iron uptake, copper deficiency can often produce anaemia-like symptoms. Dietary sources include curry powder, mushroom, nuts, seeds, wheat germ, whole grains and animal meat.

Copulation

To engage in coitus or sexual intercourse. *adj* . copulatory.

Cor pulmonale

Or pulmonary heart disease, is enlargement of the right ventricle of the heart as a response to high blood pressure or increased resistance in the lungs.

Cordial

A preparation that is stimulating to the heart.

Corn

Or callus, is a patch of hard, thickened skin on the foot that is formed in response to pressure or friction.

Corpora lutea

A yellow, progesterone-secreting body that forms from an ovarian follicle after the release of a mature egg.

Corticosteroids

A class of steroid hormones that are produced in the adrenal cortex, used clinically for hormone replacement therapy, for suppressing ACTH secretion, for suppression of immune response and as anti-neoplastic, anti-allergic and anti-inflammatory agents.

Corticosterone

A 21-carbon steroid hormone of the corticosteroid type produced in the cortex of adrenal glands.

Cortisol

Is a corticosteroid hormone made by adrenal glands.

Cornification

Is the process of forming an epidermal barrier in stratified squamous epithelial tissue.

Coryza

A word describing the symptoms of a head cold. It describes the inflammation of mucous membranes lining the nasal cavity which usually gives rise to the symptoms of nasal congestion and loss of smell, among other symptoms.

COX-1

See cyclooxygenase -1.

COX-2

See cyclooxygenase-2.

CpG islands

Genomic regions that contain a high frequency of CpG sites.

CpG sites

The cytosine-phosphate-guanine nucleotide that links two nucleosides together in DNA.

cPLA(2)

Cytosolic phospholipases A2; these phospholipases are involved in cell-signalling processes such as inflammatory response.

CPY1B1, CPY1A1

A member of the cytochrome P450 superfamily of heme-thiolate monooxygenase enzymes.

Corticosterone

A 21-carbon corticosteroid hormone produced in the cortex of adrenal glands that functions in the metabolism of carbohydrates and proteins.

Creatin

A nitrogenous organic acid that occurs naturally in vertebrates and helps to supply energy to muscles.

Creatine phosphokinase (CPK, CK)

Enzyme that catalyses the conversion of creatine and consumes adenosine triphosphate (ATP) to create phosphocreatine and adenosine diphosphate (ADP).

CREB

cAMP response element-binding, a protein that is a transcription factor that binds to certain DNA sequences called cAMP response elements.

Crohn disease

An inflammatory disease of the intestines that affects any part of the gastrointestinal tract.

CRP (C-reactive protein)

A substance produced by the liver that increases in the presence of inflammation in the body.

Crossover study

A longitudinal balance study in which participants receive a sequence of different treatments or exposures.

Croup

Is an infection of the throat (larynx) and windpipe (trachea) that is caused by a virus (also called laryngotracheobronchitis).

Cryptococcal meningitis

A fungal infection of the membranes covering the brain and spinal cord (meninges).

Cryptorchidism (cryptorchism)

A developmental defect characterised by the failure of one or both testes to move into the scrotum as the male fetus develops.

Curettage

Surgical procedure in which a body cavity or tissue is scraped with a sharp instrument or aspirated with a cannula.

Cutaneous

Pertaining to the skin.

CXC8

Also known as interleukin 8, IL-8.

Cyanogenesis

Generation of cyanide. *adj* . cyanogenetic.

Cyclooxygenase (COX)

An enzyme that is responsible for the formation of prostanoids – prostaglandins, prostacyclins and thromboxanes that are each involved in inflammatory response. Two different COX enzymes existed, now known as COX-1 and COX-2.

Cyclooxygenase-1 (COX-1)

Is known to be present in most tissues. In the gastrointestinal tract, COX-1 maintains the normal lining of the stomach. The enzyme is also involved in kidney and platelet function.

Cyclooxygenase-2 (COX-2)

Is primarily present at sites of inflammation.

Cysteine proteases

Are enzymes that degrade polypeptides possessing a common catalytic mechanism that involves a nucleophilic cysteine thiol in a catalytic triad. They are found in fruit like papaya, pineapple and kiwifruit.

Cystitis

A common urinary tract infection that occurs when bacteria travel up the urethra, infect the urine and inflame the bladder lining.

Cystorrhea

Discharge of mucus from the bladder.

Cytochrome bc-1 complex

Ubiquinol:cytochrome c oxidoreductase.

Cytochrome P450 3A CYP3A

A very large and diverse superfamily of heme-thiolate proteins found in all domains of life. This group of enzymes catalyses many reactions involved in drug metabolism and synthesis of cholesterol, steroids and other lipids.

Cytokine

Non-antibody proteins secreted by certain cells of the immune system which carry signals locally between cells. They are a category of signalling molecules that are used extensively in cellular communication.

Cytopathic

Any detectable degenerative changes in the host cell due to infection.

Cytoprotective

Protecting cells from noxious chemicals or other stimuli.

Cytosolic

Relates to the fluid of the cytoplasm in cells.

Cytostatic

Preventing the growth and proliferation of cells.

Cytotoxic

Of or relating to substances that are toxic to cells, cell-killing.

D - galactosamine

An amino sugar with unique hepatotoxic properties in animals.

Dandruff

Scurf, dead, scaly skin among the hair.

Dartre

Condition of dry, scaly skin

Debility

Weakness, relaxation of muscular fibre.

Debridement

Is the process of removing non-living tissue from pressure ulcers, burns and other wounds.

Debriding agent

Substance that cleans and treats certain types of wounds, burns and ulcers.

Deciduogenic

Relating to the uterus lining that is shed off at childbirth.

Deciduoma

Decidual tissue induced in the uterus (as by trauma) in the absence of pregnancy.

Deciduomata

Plural of deciduoma.

Decidual stromal cells

Like endometrial glands and endothelium, they express integrins that bind basement components.

Decoction

A medical preparation made by boiling the ingredients.

Decongestant

A substance that relieves or reduces nasal or bronchial congestion.

Deep venous thrombosis

Is a blood clot that forms in a vein deep inside a part of the body.

Defibrinated plasma

Blood whose plasma component has had fibrinogen and fibrin removed.

Degranulation

Cellular process that releases antimicrobial cytotoxic molecules from secretory vesicles called granules found inside some cells.

Delayed afterdepolarisations (DADs)

Abnormal depolarisation that begins during phase 4 – after repolarisation is completed, but before another action potential would normally occur.

Delirium

Is common, sudden severe confusion and rapid changes in brain function that occur with physical or mental illness; it is reversible and temporary.

Demulcent

An agent that soothes internal membranes. Also called emollient.

Dendritic cells

Are immune cells and form part of the mammalian immune system, functioning as antigen-presenting cells.

Dentition

A term that describes all of the upper and lower teeth collectively.

Deobstruent

A medicine which removes obstructions, also called an aperient.

Deoxyypyridinoline (Dpd)

A cross-link product of collagen molecules found in bone and excreted in urine during bone degradation.

Depilatory

An agent for removing or destroying hair.

Depressant

A substance that diminishes functional activity, usually by depressing the nervous system.

Depurative

An agent used to cleanse or purify the blood, it eliminates toxins and purifies the system.

Dermatitis

Inflammation of the skin causing discomfort, such as eczema.

Dermatitis herpetiformis

An autoimmune chronic blistering skin disorder characterised by blisters filled with a watery fluid.

Dermatophyte

A parasitic fungus on the skin.

Dermatosis

Is a broad term that refers to any disease of the skin, especially one that is not accompanied by inflammation.

Dermonecrotic

Pertaining to or causing necrosis of the skin.

Desquamation

The shedding of the outer layers of the skin.

Desquamative gingivitis

Red, painful, glazed and friable gingivae which may be a manifestation of some mucocutaneous conditions such as lichen planus or vesiculobullous disorders.

Detoxifier

A substance that promotes the removal of toxins from a system or organ.

Diabetes

A metabolic disorder associated with inadequate secretion or utilisation of insulin and characterised by frequent urination and persistent thirst. See diabetes mellitus.

Diabetes mellitus (DM)

Sometimes called ‘sugar diabetes’, it is a set of chronic, metabolic disease conditions characterised by high blood sugar (glucose) levels that result from defects in insulin secretion, action or both. Diabetes mellitus appears in two forms.

Diabetes mellitus type I

Formerly known as juvenile-onset diabetes, it is caused by deficiency of the pancreatic hormone insulin as a result of destruction of insulin-producing beta cells of the pancreas. Lack of insulin causes an increase of fasting blood glucose that begins to appear in the urine above the renal threshold.

Diabetes mellitus type II

Formerly called non-insulin-dependent diabetes mellitus or adult-onset diabetes, the disorder is characterised by high blood glucose in the context of insulin resistance and relative insulin deficiency in which insulin is available but cannot be properly utilised.

Diabetic foot

Any pathology that results directly from diabetes mellitus or any long-term or chronic complication of diabetes mellitus.

Diabetic neuropathy

A neuropathic disorder that is associated with diabetes mellitus. It affects all peripheral nerves including pain fibres, motor neurons and the autonomic nervous system.

Diabetic retinopathy

Damage to the retina caused by complications of diabetes mellitus, which can eventually lead to blindness.

Diads

Two adjacent structural units in a polymer molecule.

Dialysis

Is a method of removing toxic substances (impurities or wastes) from the blood when the kidneys are unable to do so.

Diaphoresis

Is profuse sweating commonly associated with shock and other medical emergency conditions.

Diaphoretic

A substance that induces perspiration. Also called sudorific.

Diaphyseal

Pertaining to or affecting the shaft of a long bone (diaphysis).

Diaphysis

The main or mid-section (shaft) of a long bone.

Diarrhoea

A profuse, frequent and loose discharge from the bowels.

Diastolic

Referring to the time when the heart is in a period of relaxation and dilatation (expansion). *cf.* systolic.

Dieresis

Surgical separation of parts.

Dietary fibre

Is a term that refers to a group of food components that pass through the stomach and small intestine undigested and reach the large intestine virtually unchanged. Scientific evidence suggests that a diet high in dietary fibre can be of value for treating or preventing such disorders as constipation, irritable bowel syndrome, diverticular disease, hiatus hernia and haemorrhoids. Some components of dietary fibre may also be of value in reducing the level of cholesterol in blood and thereby decreasing a risk factor for coronary heart disease and the development of gallstones. Dietary fibre is beneficial in the treatment of some diabetics.

Digalactosyl diglycerides

Are major lipid components of chloroplasts.

Diosgenin

A steroid-like substance that is involved in the production of the hormone progesterone, extracted from roots of *Dioscorea* yam.

Dipsia

Sensation of dryness in the mouth and throat related to a desire to drink.

Dipsomania

Pathological use of alcohol.

Discussant

An agent (as a medicinal application) which serves to disperse morbid matter.

Disinfectant

An agent that prevents the spread of infection, bacteria or communicable disease.

Distal sensory polyneuropathy (DSPN)

Or peripheral neuropathy, is the most common neurological problem in HIV disease. DSPN also represents a complex symptom that occurs because of peripheral-nerve damage related to advanced HIV disease.

Diuresis

Increased urination.

Diuretic

A substance that increases urination (diuresis).

Diverticular disease

Is a condition affecting the large bowel or colon and thought to be caused by eating too little fibre.

Diverticulitis

Common, sometimes painful digestive disease which involves the formation of pouches (diverticula) within the bowel

wall.

DMBA

7,12-Dimethylbenzanthracene. A polycyclic aromatic hydrocarbon found in tobacco smoke, which is a potent carcinogen.

DNA

Deoxyribonucleic acid, a nucleic acid that contains the genetic instructions used in the development and functioning of all known living organisms.

DOCA

Desoxycorticosterone acetate – a steroid chemical used as replacement therapy in Addison's disease.

Dopamine

A catecholamine neurotransmitter that occurs in a wide variety of animals including both vertebrates and invertebrates.

Dopaminergic

Relating to or activated by the neurotransmitter dopamine.

Double blind

Refers to a clinical trial or experiment in which neither the subject nor the researcher knows which treatment any particular subject is receiving.

Douche

A localised spray of liquid directed into a body cavity or onto a part.

DPPH

2,2 diphenyl -1- picryl-hydrazyl – a crystalline, stable free radical used as an inhibitor of free-radical reactions.

Dracunculiasis

Also called guinea worm disease (GWD), is a parasitic infection caused by the nematode *Dracunculus medinensis*.

Dropsy

An old term for the swelling of soft tissues due to the accumulation of excess water. *adj* . dropsical.

Drug-metabolising enzymes

Play central roles in the biotransformation, metabolism and/or detoxification of xenobiotics or foreign compounds that are introduced into the human body.

Drusen

Tiny yellow or white deposits of extracellular materials in the retina of the eye or on the optic nerve head.

DT diaphorase

Also called DTD or NAD(P)H:quinone oxidoreductase, is an obligate two-electron reductase which bioactivates chemotherapeutic quinones.

Dysarthria

Is a motor speech disorder.

Dysbiosis

Also called dysbacteriosis, refers to a condition with microbial imbalances on or inside the body.

Dysentery

Formerly known as flux or the bloody flux, is a disorder of the digestive system that results in severe diarrhoea containing mucus and blood in the feces. It is caused usually by a bacterium called *Shigella* .

Dysesthesia

An unpleasant abnormal sensation produced by normal stimuli.

Dysgeusia

Distortion of the sense of taste.

Dyshomeostasis

An imbalance or other breakdown of a homeostasis system.

Dyskinesia

The impairment of the power of voluntary movement resulting in fragmentary or incomplete movements. *adj* . dyskinetic.

Dyslipidemia

Abnormality in or abnormal amount of lipids and lipoproteins in the blood.

Dysmenorrhea

Is a menstrual condition characterised by severe and frequent menstrual cramps and pain associated with menstruation.

Dysmotility syndrome

A vague descriptive term used to describe diseases of the muscles of the gastrointestinal tract (oesophagus, stomach and small and large intestines).

Dysosmia

Qualitative alteration or distortion of the perception of smell.

Dyspareunia

Painful sexual intercourse.

Dyspepia

Indigestion followed by nausea.

Dyspepsia

Refers to a complex symptom of epigastric pain or discomfort. It is often defined as chronic or recurrent discomfort centred in the upper abdomen and can be caused by a variety of conditions. *cf* . functional dyspepsia.

Dysphagia

Difficulty in swallowing.

Dysphonia

A voice disorder, an impairment in the ability to produce voice sounds using vocal organs.

Dysplasia

Refers to abnormality in development.

Dyspnoea

Shortness of breath, difficulty in breathing.

Dysrhythmias

See arrhythmias.

Dystocia

Abnormal or difficult childbirth or labour.

Dystonia

A neurological movement disorder characterised by prolonged, repetitive muscle contractions that may cause twisting or jerking movements of muscles.

Dysuria

Refers to difficult and painful urination.

E-cadherin

Has traditionally been categorised as a tumour suppressor.

E-selectin

Also known as endothelial leukocyte adhesion molecule-1 (ELAM-1), CD62E, a member of the selectin family. It is transiently expressed on vascular endothelial cells in response to IL-1 beta and TNF alpha.

EC 50

Median effective concentration that produces desired effects in 50% of the test population.

Ecbolic

A drug (as an ergot alkaloid) that tends to increase uterine contractions and that is used especially to facilitate delivery.

Ecchymosis

Skin discoloration caused by the escape of blood into the tissues from ruptured blood vessels.

ECG

See electrocardiography.

EC-SOD

Extracellular superoxide dismutase, a tissue enzyme mainly found in the extracellular matrix of tissues. It participates in the detoxification of reactive oxygen species by catalysing the dismutation of superoxide radicals.

Ectopic heartbeats

Small changes in an otherwise normal heartbeat that lead to extra or skipped heartbeats.

Ectrodactyly

Involves the absence of one or more central digits of the hand or foot.

Eczema

Is broadly applied to a range of persistent skin conditions.

These include dryness and recurring skin rashes which are characterised by one or more of these symptoms: redness, skin oedema, itching and dryness, crusting, flaking, blistering, cracking, oozing or bleeding.

Eczematous rash

Dry, scaly, itchy rash.

ED 50

Is defined as the dose producing a response that is 50 % of the maximum obtainable.

Oedema

Formerly known as dropsy or hydropsy, is characterised by swelling caused by abnormal accumulation of fluid beneath the skin or in one or more cavities of the body. It usually occurs in the feet, ankles and legs, but it can involve the entire body.

Oedematogenic

Producing or causing oedema.

EGFR proteins

Epidermal growth factor receptor (EGFR) proteins – Protein kinases are enzymes that transfer a phosphate group from a

phosphate donor onto an acceptor amino acid in a substrate protein.

EGR-1

Early growth response 1, a human gene.

Eicosanoids

Are signaling molecules made by oxygenation of arachidonic acid, a 20-carbon essential fatty acid, includes prostaglandins and related compounds.

Elastase

A serine protease that also hydrolyses amides and esters.

Electrocardiography

Or ECG, is a transthoracic interpretation of the electrical activity of the heart over time captured and externally recorded by skin electrodes.

Electromyogram (EMG)

A test used to record the electrical activity of muscles. An electromyogram (EMG) is also called a myogram.

Electuary

A medicinal paste composed of powders or other medical ingredients incorporated with sweeteners to hide the taste, suitable for oral administration.

Elephantiasis

A disorder characterised by chronic thickened and oedematous tissue on the genitals and legs due to various causes.

Embrocation

Lotion or liniment that relieves muscle or joint pains.

Embryonation

Formation of embryo in the egg.

Embryotoxic

Term that describes any chemical which is harmful to an embryo.

Emesis

Vomiting, throwing up.

Emetic

An agent that induces vomiting, *cf*: antiemetic.

Emetocathartic

Causing vomiting and purging.

Emmenagogue

A substance that stimulates, initiates and/or promotes menstrual flow. Emmenagogues are used in herbal medicine to balance and restore the normal function of the female reproductive system.

Emollient

An agent that has a protective and soothing action on the surface of the skin and membranes.

Emphysema

A long-term progressive disease of the lungs that primarily causes shortness of breath.

Emulsion

A preparation formed by the suspension of very finely divided oily or resinous liquid in another liquid.

Encephalitis

Inflammation of the brain caused by a virus.

Encephalocele

Protrusion of brain tissue through a congenital fissure in the skull.

Encephalomalacia

Cerebral softening, a localised softening of the brain substance due to haemorrhage or inflammation.

Encephalopathy

A disorder or disease of the brain.

Endocrine

Adj . Of or relating to endocrine glands or hormones secreted by them.

Endocytosis

Is the process by which cells absorb material (molecules such as proteins) from outside the cell by engulfing it with their cell membrane.

Endometrial cancer

Cancer that arises in the endometrium, the lining of the uterus (womb).

Endometriosis

Is a common and often painful disorder of the female reproductive system in which the endometrium, the tissue that normally lines the womb (uterus), grows outside the uterus. The two most common symptoms of endometriosis are pain and infertility.

Endometritis

Refers to inflammation of the endometrium, the inner lining of the uterus.

Endometrium

The inner lining of the uterus.

Endoplasmic reticulum

Is a network of tubules, vesicles and sacs around the nucleus that are interconnected.

Endostatin

A naturally occurring 20-kDa C-terminal protein fragment derived from type-XVIII collagen. It is reported to serve as an anti-angiogenic agent that inhibits the formation of blood vessels that feed cancer tumours.

Endosteum

The thin layer of cells lining the medullary cavity of a bone.

Endosteal

Pertaining to the endosteum.

Endothelial progenitor cells

Population of rare cells that circulate in the blood with the ability to differentiate into endothelial cells, cells that make up the lining of blood vessels.

Endothelin

Any of a group of vasoconstrictive peptides produced by endothelial cells that constrict blood vessels and raise blood pressure.

Endotoxemia

The presence of endotoxins in the blood, which may result in shock. *adj* . endotoxemic.

Endotoxin

Toxins associated with certain bacteria unlike an 'exotoxin' that is not secreted in soluble form by live bacteria but is a structural component in bacteria which is released mainly when bacteria are lysed.

Enema

Liquid injected into the rectum either as a purgative or medicine, also called clyster.

Enophthalmos

A condition in which the eye falls back into the socket and inhibits proper eyelid function.

eNOS (Endothelial nitric oxide synthase)

The enzyme responsible for most of the vascular nitric oxide produced.

Enteral

Term used to describe the intestines or other parts of the digestive tract.

Enteralgia

Pain in the intestines, intestinal colic.

Enteral administration

Involves the oesophagus, stomach and small and large intestines (i.e. the gastrointestinal tract).

Enteritis

Refers to inflammation of the small intestine.

Enterocolic disorder

Inflamed-bowel disease.

Enterocytes

Tall columnar cells in the small intestinal mucosa that are responsible for the final digestion and absorption of nutrients.

Enterohaemorrhagic

Causing bloody diarrhoea and colitis, said of pathogenic microorganisms.

Enterohepatonephropathy

Hepatorenal lesions accompanied by renal failure.

Enterolactone

A lignin formed by the action of intestinal bacteria on lignan precursors found in plants, acts as a phytoestrogen.

Enteropooling

Increased fluids and electrolytes within the lumen of the intestines due to increased levels of prostaglandins.

Enterotoxigenic

Of or being an organism containing or producing an enterotoxin.

Enterotoxin

Is a protein toxin released by a microorganism in the intestine.

Entheogen

A substance taken to induce a spiritual experience.

Enuresis

Bed-wetting, a disorder of elimination that involves the voluntary or involuntary release of urine into bedding, clothing or other inappropriate places.

Envenomation

Is the entry of venom into a person's body, and it may cause localised or systemic poisoning.

Eosinophilia

The state of having a high concentration of eosinophils (eosinophil granulocytes) in the blood.

Eosinophils

Or, less commonly, acidophils, are white blood cells that are one of the immune-system components.

Epidermal growth factor receptor (EGFR)

Belongs to the ErbB family of receptor tyrosine kinases (RTK). EGFRs are involved in the pathogenesis and progression of different carcinoma types.

Epididymis

A structure within the scrotum attached to the backside of the testis and whose coiled duct provides storage, transit and maturation of spermatozoa.

Epididymitis

A medical condition in which there is inflammation of the epididymis.

Epidural haematoma

Accumulation of blood in the potential space between dura and bone, may be intracranial or spinal.

Epigastralgia

Pain in the epigastric region.

Epigastric discomfort

Bloated abdomen, swelling of abdomen, abdominal distension.

Epilepsy

A common chronic neurological disorder that is characterised by recurrent unprovoked seizures.

Epileptiform

Resembling epilepsy or its manifestations. *adj* . epileptiformic.

Epileptogenesis

A process by which a normal brain develops epilepsy, a chronic condition in which seizures occur. *adj* . epileptogenic.

Episiotomy

A surgical incision through the perineum made to enlarge the vagina and assist childbirth.

Epithelial–mesenchymal transition or transformation (EMT)

A process by which epithelial cells lose their cell polarity and cell–cell adhesion and gain migratory and invasive properties to become mesenchymal cells.

Epithelioma

A usually benign skin disease most commonly occurring on the face, around the eyelids and on the scalp.

Epitope

A single antigenic site on a protein against which an antibody reacts.

Epitrochlearis

The most superficial muscle of the arm's anterior surface.

Epistaxis

Acute haemorrhage from the nostril, nasal cavity or nasopharynx (nosebleed).

Epstein–Barr virus

Herpes virus that is the causative agent of infectious mononucleosis. It is also associated with various types of human cancers.

ORbeta

Oestrogen receptor beta, a nuclear receptor which is activated by the sex hormone oestrogen.

Ergocalciferol

A form of vitamin D also called vitamin D2. See vitamin D.

Ergogenic

Increasing capacity for bodily or mental labour especially by eliminating fatigue symptoms.

Ergonic

Increasing capacity for bodily or mental labour especially by eliminating fatigue symptoms.

ERK (extracellular signal-regulated kinases)

Widely expressed protein kinase intracellular signaling molecules which are involved in functions including the regulation of meiosis, mitosis and post-mitotic functions in differentiated cells.

Eructation

The act of belching or of casting up wind from the stomach through the mouth.

Eruption

A visible rash or cutaneous disruption.

Eryptosis

Suicidal death of erythrocytes characterised by cell shrinkage, membrane blebbing, activation of proteases and phosphatidylserine exposure at the outer membrane leaflet.

Erysipelas

Is an intensely red *Streptococcus* bacterial infection that occurs on the face and lower extremities.

Erythema

Abnormal redness and inflammation of the skin due to vasodilation.

Erythema multiforme

Is a skin disorder due to an allergic reaction or infection characterised by fever, general ill feeling, skin itching, joint aches and multiple skin lesions.

Erythematous

Characterised by erythema.

Erythroleukoplakia

An abnormal patch of red and white tissue that forms on mucous membranes in the mouth and may become cancer. Tobacco (smoking and chewing) and alcohol may increase the risk of erythroleukoplakia.

Erythropoiesis

Is the process whereby erythroid precursor cells proliferate and differentiate into red blood cells.

Erythropoietin (EPO)

A hormone produced by the kidney that promotes the formation of red blood cells (erythrocytes) in bone marrow.

Eschar

A slough or piece of dead tissue that is cast off from the surface of the skin.

Escharotic

Capable of producing an eschar, a caustic or corrosive agent.

Estradiol

Is the predominant sex hormone present in females, also called oestradiol.

Oestrogen

Female hormone produced by the ovaries that plays an important role in the oestrous cycle in women.

Oestrogen receptor (ER)

Is a protein found in high concentrations in the cytoplasm of breast, uterus, hypothalamus and anterior hypophysis cells;

ER levels are measured to determine a breast CA's potential for response to hormonal manipulation.

Oestrogen receptor positive (ER+)

Means that oestrogen is causing the tumour to grow and that the breast cancer should respond well to hormone suppression treatments.

Oestrogen receptor negative (ER-)

Tumour is not driven by oestrogen and needs another test to determine the most effective treatment.

Oestrogenic

Relating to oestrogen or producing oestrus.

Oestrus

Sexual excitement or heat of female; the period of this is characterised by changes in sex organs.

Euglycaemia

Normal blood glucose concentration.

Eupeptic

Conducive to digestion.

Exanthema

Sudden widespread rash.

Exanthematous

Characterised by or of the nature of an eruption or rash.

Excitotoxicity

Is the pathological process by which neurons are damaged and killed by glutamate and similar substances.

Excipient

A pharmacologically inert substance used as a diluent or vehicle for active ingredients of a medication.

Exfoliative cheilitis

Is a reactive process in which upper, lower or both lips become chronically inflamed, crusted and sometimes fissured.

Exocytosis

The cellular process by which cells excrete waste products or chemical transmitters.

Exophthalmos or exophthalmia or proptosis

Is a bulging of the eye anteriorly out of the orbit. *adj.* exophthalmic.

Exotoxin

A toxin secreted by a microorganism and released into the medium in which it grows.

Expectorant

An agent that increases bronchial mucous secretion by promoting liquefaction of the sticky mucus and expelling it from the body.

Experimental allergic encephalomyelitis (EAE)

Is an animal model of brain inflammation.

Exteroceptive

Responsiveness to stimuli that are external to an organism.

Extrapyramidal side effects

Are a group of symptoms (tremor, slurred speech, akathisia, dystonia, anxiety, paranoia and bradyphrenia) that can occur in persons taking antipsychotic medications.

Extravasation

Discharge or escape as of blood from the vein into surrounding tissues, discharge or escape from a vessel or channel.

Eyelid oedema

Swollen eyelid caused by inflammation or excess fluid.

Fabry disease

Is a rare X-linked (inherited) lysosomal storage disease caused by alpha-galactosidase. A deficiency which can cause a wide range of systemic symptoms such as pain in the extremities, papules on the lower body parts, cornea clouding, fatigue, neuropathy and renal and cardiac complications.

FAC chemotherapy

Fluorouracil, doxorubicin (adriamycin) and cyclophosphamide chemotherapy.

FADD

Fas-associated protein with death domain; the protein encoded by this gene is an adaptor molecule which interacts with other death cell surface receptors and mediates apoptotic signals.

Familial amyloid polyneuropathy (FAP)

Also called Corino de Andrade's disease, a neurodegenerative autosomal dominant genetically transmitted, fatal, incurable disease.

Familial adenomatous polyposis (FAP)

Is an inherited condition in which numerous polyps form mainly in the epithelium of the large intestine.

Familial dysautonomia

A genetic disorder that affects the development and survival of autonomic and sensory nerve cells.

Fanconi syndrome

Is a disease of the proximal renal tubes in which certain substances normally absorbed into the bloodstream by the kidneys are released into the urine instead.

FasL or CD95L

Fas ligand is a type-II trans-membrane protein that belongs to the tumour necrosis factor (TNF) family.

FAS: fatty acid synthase (FAS)

A multi-enzyme that plays a key role in fatty acid synthesis.

Fas molecule

A member of the tumour necrosis factor receptors that mediates apoptotic signals in many cell types.

Fauces

The passage leading from the back of the mouth into the pharynx.

Favus

A chronic skin infection, usually of the scalp, caused by the fungus *Trichophyton schoenleinii* and characterised by the development of thick yellow crusts over hair follicles. Also termed tinea favosa.

Febrifuge

An agent that reduces fever. Also called an antipyretic.

Febrile

Pertaining to or characterised by fever.

Febrile neutropenia

The development of fever, often with other signs of infection, in an individual with neutropenia, an abnormally low number of neutrophil granulocytes in the blood.

Felon

A purulent infection in the bulbous distal end of a finger.

Fetotoxic

Toxic to the fetus.

Fibrates

Hypolipidemic agents primarily used for decreasing serum triglycerides while increasing high-density lipoprotein (HDL).

Fibril

A small slender fibre or filament.

Fibrin

Insoluble protein that forms the essential portion of the blood clot.

Fibrinolysis

A normal ongoing process that dissolves fibrin and results in the removal of small blood clots.

Fibrinolytic

Causing the dissolution of fibrin by enzymatic action.

Fibroblast

Type of cell that synthesises the extracellular matrix and collagen, the structural framework (stroma) for animal tissues, and plays a critical role in wound healing.

Fibrogenic

Promoting the development of fibres.

Fibromyalgia

A common and complex chronic body-wide pain disorder that affects people physically, mentally and socially. Symptoms include debilitating fatigue, sleep disturbance and joint stiffness. Also referred to as FM or FMS.

Fibronectin

A high-molecular weight (~440 kDa) glycoprotein of the extracellular matrix (ECM) that adheres to membrane-spanning receptor proteins called integrins.

Fibrosarcoma

A malignant tumour derived from fibrous connective tissue and characterised by immature proliferating fibroblasts or undifferentiated anaplastic spindle cells.

Fibrosis

The formation of fibrous tissue as a reparative or reactive process.

Filarial

Pertaining to a thread-like nematode worm.

Filariasis

A parasitic and infectious tropical disease that is caused by thread-like filarial nematode worms in the superfamily *Filarioidea* .

Fistula

An abnormal connection between two organs inside the body.

Fistula-in-ano

A track connecting the internal anal canal to the skin surrounding the anal orifice.

5'-Nucleotidase

5'-ribonucleotide phosphohydrolase, an intrinsic membrane glycoprotein present as an ectoenzyme in a wide variety of mammalian cells, hydrolyses 5'-nucleotides to their corresponding nucleosides.

5-HT1A receptor

A serotonin protein that binds to 5-hydroxytryptamine (5-HT) with high affinity to exert subtle control over emotion and behaviour.

Flash electroretinogram or Flash ERG (fERG)

Is a test which measures the electrical response of the eye's light-sensitive cells (rods and cones). It also checks other cell layers in the retina.

Flatulence

Is the presence of a mixture of gases known as flatus in the digestive tract of mammals expelled from the rectum. Excessive flatulence can be caused by lactose intolerance, certain foods or a sudden switch to a high fibre.

Flavans

A sub-group of flavonoids. See flavonoids.

Flavanols

A subgroup of flavonoids, are a class of flavonoids that use the 2-phenyl-3,4-dihydro-2H-chromen-3-ol skeleton. These compounds include catechins and catechin gallates. They

are found in chocolate, fruit and vegetables. See flavonoids.

Flavanones

A sub-group of flavonoids, constitute >90 % of total flavonoids in citrus. The major dietary flavanones are hesperetin, naringenin and eriodictyol.

Flavivirus

A family of viruses transmitted by mosquitoes and ticks that cause some important diseases including dengue, yellow fever, tick-borne encephalitis and West Nile fever.

Flavones

A sub-group of flavonoids based on the backbone of 2-phenylchromen-4-one (2-phenyl-1-benzopyran-4-one). Flavones are mainly found in cereals and herbs.

Flavonoids

Or bioflavonoids are a group of polyphenolic antioxidant compounds that occur in plants as secondary metabolites. They are responsible for the colour of fruit and vegetables. Twelve basic classes (chemical types) of flavonoids have been recognised: flavones, isoflavones, flavans, flavanones, flavanols, flavanolols, anthocyanidins, catechins (including proanthocyanidins), leucoanthocyanidins, chalcones, dihydrochalcones and aurones. Apart from their antioxidant activity, flavonoids are known for their ability to strengthen capillary walls, thus assisting circulation and helping to prevent and treat bruising, varicose veins, bleeding gums and nosebleeds and heavy menstrual bleeding and are also anti-inflammatory.

Fluorine

F is an essential chemical element that is required for maintenance of healthy bones and teeth and to reduce tooth decay. It is found in sea weeds, tea, water, seafood and dairy products.

Fluorosis

A dental health condition caused by a child receiving too much fluoride during tooth development.

Flux

An excessive discharge of fluid.

FMD (flow-mediated dilation)

A measure of endothelial dysfunction which is used to evaluate cardiovascular risk. Also called FMVD (flow-mediated vasodilation).

Focal adhesion kinase (FAK)

Is a protein tyrosine kinase which is recruited at an early stage to focal adhesions and which mediates many of the downstream regulatory responses.

follicle-stimulating hormone (FSH)

A hormone produced by the pituitary gland. In women, it helps control the menstrual cycle and the production of eggs by the ovaries.

Follicular atresia

The breakdown of ovarian follicles.

Fomentation

Treatment by the application of warm, moist substance.

Fontanelle

Soft spot on an infant's skull.

Forkhead box-O transcription factors (FOXOs)

Are a family of transcription factors that play important roles in regulating the expression of genes involved in cell growth, proliferation, differentiation and longevity. It also plays an important role in tumour suppression by regulating the expression of genes involved in stress resistance, DNA damage repair, cell cycle arrest and apoptosis.

Framboesia

See yaws.

FRAP

Ferric reducing ability of plasma, an assay used to assess antioxidant property.

Friedreich's ataxia

Is a genetic inherited disorder that causes progressive damage to the nervous system resulting in symptoms ranging from muscle weakness and speech problems to heart disease. *cf.* ataxia.

Fulminant hepatitis

Acute liver failure.

Functional dyspepsia

A non-ulcer condition that causes an upset stomach or pain or discomfort in the upper belly near the ribs.

Functional food

Is any fresh or processed food claimed to have a health-promoting or disease-preventing property beyond the basic function of supplying nutrients. Also called medicinal food.

Furuncle

Is a skin disease caused by the infection of hair follicles usually caused by *Staphylococcus aureus* resulting in the localised accumulation of pus and dead tissue.

Furunculosis

Skin condition characterised by persistent, recurring boils.

G protein-coupled receptor kinases (GRKs, GPCRKs)

A family of protein kinases which regulate the activity of G protein-coupled receptors (GPCRs) by phosphorylating their intracellular domains after their associated G proteins have been released and activated.

GABA

Gamma aminobutyric acid required as an inhibitory neurotransmitter to block the transmission of an impulse from one cell to another in the central nervous system,

which prevents over-firing of nerve cells. It is used to treat both epilepsy and hypertension.

GADD 152

A pro-apoptotic gene.

Galactifuge

Or lactifuge, causing the arrest of milk secretion.

Galactagogue

A substance that promotes the flow of milk.

Galactophoritis

Inflammation of milk ducts.

Galactopoietic

Increasing the flow of milk, milk-producing.

Gall bladder

A small, pear-shaped muscular sac located under the right lobe of the liver in which bile secreted by the liver is stored until needed by the body for digestion. Also called cholecyst, cholecystis.

gallic acid equivalent (GAE)

Measures the total phenol content in terms of the standard gallic acid by the Folin–Ciocalteu assay.

Galphai proteins or G alpha I proteins

Are heterotrimeric guanine nucleotide-regulatory (G) proteins associated with a variety of intracellular membranes and specific plasma membrane domains.

Gamma GT (GGT)

Gamma-glutamyl transpeptidase, a liver enzyme.

Gastralgia (Heart Burn)

Pain in the stomach or abdominal region. It is caused by excess acid or an accumulation of gas in the stomach.

Gastric

Pertaining to or affecting the stomach.

Gastric emptying

Refers to the speed at which food and drink leave the stomach.

Gastritis

Inflammation of the stomach.

Gastrocnemius muscle

The big calf muscle at the rear of the lower leg.

Gastrodynia

Pain in the stomach.

Gastroprokinetic

See prokinetic.

Gastrotonic (gastroprotective)

Substance that strengthens, tones or regulates gastric functions (or protects from injury) without overt stimulation or depression.

Gavage

Forced feeding.

Gene silencing

Suppression of the expression of a gene.

Genotoxic

Describes a poisonous substance which harms an organism by damaging its DNA, thereby capable of causing mutations or cancer.

Genotoxin

A chemical or other agent that damages cellular DNA resulting in mutations or cancer.

Geriatrics

Is a sub-specialty of internal medicine that focuses on health care of elderly people.

Gestational hypertension

Development of arterial hypertension in a pregnant woman after 20 weeks gestation.

Ghrelin

A gastrointestinal peptide hormone secreted by epithelial cells in the stomach lining; it stimulates appetite and gastric emptying and increases cardiac output.

Gingival index

An index describing the clinical severity of gingival inflammation as well as its location.

Gingivitis

Refers to gingival inflammation induced by bacterial biofilms (also called plaque) adherent to tooth surfaces.

Gin-nan sitotoxism

Toxicity caused by ingestion of ginkgotoxin and characterised mainly by epileptic convulsions, paralysis of the legs and loss of consciousness.

GIP

Gastric inhibitory polypeptide, also known as glucose-dependent insulintropic peptide, a member of the secretin family of hormones.

Glaucoma

A group of eye diseases in which the optic nerve at the back of the eye is slowly destroyed, leading to impaired vision and blindness.

Gleet

A chronic inflammation (as gonorrhoea) of a bodily orifice usually accompanied by an abnormal discharge.

Glial cells

Support, non-neuronal cells in the central nervous system that maintain homeostasis, form myelin and provide protection for the brain's neurons.

Glioma

Is a type of tumour that starts in the brain or spine. It is called a glioma because it arises from glial cells.

Glioblastoma

Common and most lethal form of brain tumour.

Glioblastoma multiforme

Most common and most aggressive type of primary brain tumour in humans involving glial cells.

Glomerulonephritis (GN)

A renal disease characterised by inflammation of the glomeruli, or small blood vessels in the kidneys. Also known as glomerular nephritis. *adj* . glomerulonephritic.

Glomerulosclerosis

A hardening (fibrosis) of the glomerulus in the kidney.

Glossal

Pertaining to the tongue.

GLP-1

Glucagon-like peptide-1.

Glucagon-like peptide-1 (GLP-1)

Is derived from the transcription product of the proglucagon gene, reduces insulin requirement in diabetes mellitus and promotes satiety.

Gluconeogenesis

A metabolic pathway that results in the generation of glucose from non-carbohydrate carbon substrates such as lactate. *adj* . gluconeogenic.

Glucose-6-phosphate dehydrogenase (G6PD or G6PDH)

Is a cytosolic enzyme in the pentose phosphate metabolic pathway.

Glucose transporter type 4 (GLUT 4)

Insulin-regulated glucose transporter found in adipose tissues and striated muscles that modulates insulin-related

translocation into the cell.

Glucose transporters

GLUT or SLC2A family are a family of membrane proteins found in most mammalian cells.

Glucosuria or glycosuria

Is the excretion of glucose into urine.

Glucosyltransferase

An enzyme that enables the transfer of glucose.

Glucuronidation

A phase II detoxification pathway occurring in the liver in which glucuronic acid is conjugated with toxins.

Glutamic oxaloacetate transaminase (GOT)

Catalyses the transfer of an amino group from an amino acid (Glu) to a 2-keto-acid to generate a new amino acid and the residual 2-keto-acid of the donor amino acid.

Glutamic pyruvate transaminase (GPT)

See Alanine aminotransferase.

Glutathione (GSH)

A tripeptide produced in the human liver, plays a key role in intermediary metabolism, immune response and health. It plays an important role in scavenging free radicals and protects cells against several toxic oxygen-derived chemical species.

Glutathione peroxidase (GPX)

The general name of an enzyme family with peroxidase activity whose main biological role is to protect the organism from oxidative damage.

Glutathione S-transferase (GST)

A major group of detoxification enzymes that participate in the detoxification of reactive electrophilic compounds by catalysing their conjugation to glutathione.

Glycaemic index (GI)

Measures carbohydrates according to how quickly they are absorbed and raise the glucose level of the blood.

Glycaemic load (GL)

Is a ranking system for carbohydrate content in food portions based on their glycaemic index and the amount of available carbohydrate, i.e. $GI \times \text{available carbohydrate} / 100$. Glycaemic load combines both the quality and quantity of carbohydrates in one 'number'. It is the best way to predict blood glucose values of different types and amounts of food.

Glycation or glycosylation

A chemical reaction in which glycosyl groups are added to a protein to produce a glycoprotein.

Glycogenolysis

Is the catabolism of glycogen by removal of a glucose monomer through cleavage with inorganic phosphate to produce glucose-1-phosphate.

Glycometabolism

Metabolism (oxidation) of glucose to produce energy.

Glycosuria

Or glucosuria, is an abnormal condition of osmotic diuresis due to excretion of glucose by the kidneys into the urine.

Glycosylases

A family of enzymes involved in base excision repair.

Goitre

An enlargement of the thyroid gland leading to swelling of the neck or larynx.

Goitrogen

Substance that suppresses the function of the thyroid gland by interfering with iodine uptake causing enlargement of the thyroid, i.e. goitre.

Goitrogenic

Adj . causing goitre.

Gonadotroph

A basophilic cell of the anterior pituitary specialised to secrete a follicle-stimulating hormone or luteinising hormone.

Gonatotrops

Protein hormones secreted by gonadotrope cells of the pituitary gland of vertebrates.

Gonorrhoea

A common sexually transmitted bacterial infection caused by the bacterium *Neisseria gonorrhoeae* .

Gout

A disorder caused by a build-up of a waste product, uric acid, in the bloodstream. Excess uric acid settles in joints causing inflammation, pain and swelling.

G-protein-coupled receptors (GPCRs)

Constitute the largest family of cell-surface molecules involved in signal transmission. These receptors play key physiological roles, and their dysfunction results in several diseases.

Granulation

The condition or appearance of being granulated (becoming grain-like).

Gravel

Sand-like concretions of uric acid, calcium oxalate and mineral salts formed in the passages of the biliary and urinary tracts.

Gripe water

Is a home remedy for babies with colic, gas, teething pain or other stomach ailments. Its ingredients vary and may include alcohol, bicarbonate, ginger, dill, fennel and chamomile.

Grippe

An epidemic catarrh; older term for influenza.

GSH

See Glutathione.

GSH-Px

Glutathione peroxidase, general name of an enzyme family with peroxidase activity whose main biological role is to protect the organism from oxidative damage.

GSSG

Glutathione disulfides are biologically important intracellular thiols, and alterations in the GSH/GSSG ratio are often used to assess exposure of cells to oxidative stress.

GSTM

Glutathione S transferase M1, a major group of detoxification enzymes.

GSTM 2

Glutathione S transferase M2, a major group of detoxification enzymes.

G2-M cell cycle

The phase where the cell prepares for mitosis and where chromatids and daughter cells separate.

Guillain–Barre syndrome

Is a serious disorder that occurs when the body's defense (immune) system mistakenly attacks part of the nervous system leading to nerve inflammation, muscle weakness and other symptoms.

Gynecomastia

Enlargement of the gland tissue of the male breast resulting from an imbalance of hormones.

Gynecopathy

Any or various diseases specific to women.

Gynoid adiposity

Fat distribution mainly to the hips and thighs, pear shaped.

Haemagogic

Promoting a flow of blood.

Haematemesis

Is the vomiting of blood.

Haematinic

Improving the quality of blood, its haemoglobin level and the number of erythrocytes.

Haematochezia

Passage of stools containing blood.

Haematochyluria

The discharge of blood and chyle (emulsified fat) in urine, see also chyluria.

Haematoma

A localised accumulation of blood in a tissue or space composed of clotted blood.

Haematometra

A medical condition involving bleeding of or near the uterus.

Haematopoiesis

Formation of blood cellular components from haematopoietic stem cells.

Haematopoietic

Adj . Relating to the formation and development of blood cells.

Haematuria

Is the presence of blood in urine. Haematuria is a sign that something is causing abnormal bleeding in a person's genitourinary tract.

Haeme oxygenase

(HO-1, encoded by Hmox1) is an inducible protein activated in systemic inflammatory conditions by oxidant stress, an enzyme that catalyses degradation of haem.

Haemochromatosis

Iron overload in the body with a hereditary or primary cause.

Haemodialysis

A method for removing waste products such as potassium and urea as well as free water from blood when the kidneys are in renal failure.

Haemolysis

Lysis of red blood cells and the release of haemoglobin into surrounding fluid (plasma). *adj* . haemolytic.

Haemoptysis

Is the coughing up of blood from the respiratory tract. The blood can come from the nose, mouth, throat and airway passages leading to the lungs.

Haemorrhage

Bleeding, discharge of blood from blood vessels.

Haemorrhoids

A painful condition in which the veins around the anus or lower rectum are enlarged, swollen and inflamed. Also called piles.

Haemostasis

A complex process which causes the bleeding process to stop.

Haemostatic

Something that stops bleeding.

Halitosis

(Bad breath) a common condition caused by sulphur-producing bacteria that live within the surface of the tongue and in the throat.

Hallucinogen

Drug that produces hallucination.

Hallucinogenic

Inducing hallucinations.

Hallux abducto valgus

Commonly called bunion, is an abnormal bending of the big toe towards the other toes of the foot.

Haplotype

A set of alleles of closely linked loci on a chromosome that tend to be inherited together.

Hapten

A small molecule that can elicit an immune response only when attached to a large carrier such as a protein.

HATs

Histone acetyl transferases, enzymes that regulate the acetylation of histones and transcription factors, playing a major role in the growth and differentiation of cells.

HbA1c

Glycosylated haemoglobin.

HBeAg

Hepatitis B e antigen.

HBsAg

Hepatitis B s antigen.

HBD-2 (human β -defensin 2)

A member of the defensin family of antimicrobial peptides that plays important roles in the innate and adaptive immune system of both vertebrates and invertebrates.

Heartburn

Burning sensation in the stomach and oesophagus caused by excessive acidity of stomach fluids.

Heat rash

Any condition aggravated by heat or hot weather such as intertrigo.

Heat shock chaperones (HSC)

Ubiquitous molecules involved in the modulation of protein conformational and complexation states associated with heat stress or other cellular stress response.

Heat shock proteins (HSP)

A group of functionally related proteins, the expression of which is increased when cells are exposed to elevated temperatures or other cellular stresses.

Haeminthiasis

A disease in which a part of the body is infested with worms such as pinworm, roundworm or tapeworm.

Haemagglutination

A specific form of agglutination that involves red blood cells.

Haemagglutination inhibition test

Measures the ability of soluble antigen to inhibit the agglutination of antigen-coated red blood cells by antibodies.

Haemagglutinin

Refers to a substance that causes red blood cells to agglutinate.

Haemangioma

Blood vessel.

Haematocrit

Is a blood test that measures the percentage of the volume of whole blood that is made up of red blood cells.

Haematopoietic

Pertaining to the formation of blood or blood cells.

Haematopoietic stem cell

Is a cell isolated from blood or bone marrow that can renew itself and differentiate to a variety of specialised cells.

Haem oxygenase-1 (HO-1)

An enzyme that catalyses the degradation of haem, an inducible stress protein, confers cytoprotection against oxidative stress in-vitro and in-vivo.

Haemoglobinopathies

Genetic defects that produce abnormal haemoglobins and anaemia.

Haemolytic anaemia

Anaemia due to haemolysis, the breakdown of red blood cells in blood vessels or elsewhere in the body.

Haemorheology

Study of blood flow and its elements in the circulatory system.
adj . haemorheological.

Haemorrhagic colitis

An acute gastroenteritis characterised by overtly bloody diarrhoea that is caused by *Escherichia coli* infection.

Haemolysin

Certain proteins and lipids that cause lysis of red blood cells by damaging their cell membranes.

Haemolytic–uremic syndrome

Is a disease characterised by haemolytic anaemia, acute renal failure (uremia) and a low platelet count.

Hepa-1c1c7

A type of hepatoma cells.

Hepatalgia

Pain or discomfort in the liver area.

Hepatomegaly

Condition of enlarged liver.

Hepatectomy

The surgical removal of part or all of the liver.

Hepatic

Relating to the liver.

Hepatic cirrhosis

Affecting the liver, characterised by hepatic fibrosis and regenerative nodules.

Hepatic fibrosis

Is overly profuse wound healing in which excessive connective tissue builds up in the liver.

Hepatitis

Inflammation of the liver.

Hepatitis A

Formerly known as infectious hepatitis, is an acute infectious disease of the liver caused by the hepatovirus hepatitis A virus.

Hepatocarcinogenesis

Represents a linear and progressive cancerous process in the liver in which successively more aberrant monoclonal populations of hepatocytes evolve.

Hepatocellular carcinoma (HCC)

Also called malignant hepatoma, is a primary malignancy (cancer) of the liver.

Hepatocytolysis

Cytotoxicity (dissolution) of liver cells.

Hepatoma

Cancer of the liver.

Hepatopathy

A disease or disorder of the liver.

Hepatoprotective

Liver protector, a substance that helps protect the liver from damage by toxins, chemicals or other disease processes.

Hepatoregenerative

A compound that promotes hepatocellular regeneration and repairs and restores liver function to optimum performance.

Hepatotonic

Liver tonic, a substance that is tonic to the liver – usually employed to normalize liver enzymes and function.

Hernia

Occurs when part of an internal organ bulges through a weak area of muscle.

HER- 2

Human epidermal growth factor receptor 2, a protein giving higher aggressiveness in breast cancer, also known as ErbB-2, ERBB2.

Herpes

A chronic inflammation of the skin or mucous membrane characterised by the development of vesicles on an inflammatory base.

Herpes circinatus

Dermatitis herpetiformis (resembling herpes).

Herpes simplex virus 1 and 2 – (HSV-1 and HSV-2)

Are two species of the herpes virus family which cause a variety of illnesses/infections in humans such as cold sores, chickenpox or varicella, shingles or herpes zoster (VZV), cytomegalovirus (CMV) and various cancers and can cause brain inflammation (encephalitis). HSV-1 is commonly associated with herpes outbreaks of the face known as cold sores or fever blisters, whereas HSV-2 is more often associated with genital herpes. They are also called human herpes virus 1 and 2 (HHV-1 and HHV-2) and are neurotropic and neuroinvasive viruses; they enter and hide in the human nervous system, accounting for their durability in the human body.

Herpes zoster

Or simply zoster, commonly known as shingles and also known as zona, is a viral disease characterised by a painful skin rash with blisters.

Herpes zoster ophthalmicus (HZO)

Is a viral ocular disease characterised by a painful skin rash in one or more dermatome distributions of the fifth cranial nerve, shared by the eye and orbit.

Heterophobia

Term used to describe irrational fear of, aversion to or discrimination against heterosexuals.

HDL-C (HDL cholesterol)

High-density lipoprotein cholesterol, also called ‘good cholesterol’. See also high-density lipoprotein.

Hiatus hernia

Occurs when the upper part of the stomach pushes its way through a tear in the diaphragm.

High-density lipoprotein (HDL)

Is one of the five major groups of lipoproteins which enable cholesterol and triglycerides to be transported within the water-based bloodstream. HDL can remove cholesterol from atheroma within arteries and transport it back to the liver for excretion or re-utilisation – which is the main reason why HDL-bound cholesterol is sometimes called ‘good cholesterol’, or HDL-C. A high level of HDL-C seems to protect against cardiovascular diseases. *cf.* LDL.

HGPRT, HPRT (hypoxanthine-guanine phosphoribosyl transferase)

An enzyme that catalyses the conversion of 5-phosphoribosyl-1-pyrophosphate and hypoxanthine, guanine or 6-mercaptopurine to the corresponding 5'-mononucleotides and pyrophosphate. The enzyme is important in purine biosynthesis as well as central nervous system functions.

Hippocampus

A ridge in the floor of each lateral ventricle of the brain that consists mainly of grey matter.

Hippocampal

Pertaining to the hippocampus.

Hirsutism

A condition where women have excess facial and body hair that is dark and coarse.

Histaminergic

Liberated or activated by histamine, relating to the effects of histamine at histamine receptors of target tissues.

Histaminergic receptors

Are types of G-protein-coupled receptors with histamine as their endogenous ligand.

Histone acetyltransferases (HATs)

Are enzymes that acetylate conserved lysine amino acids on histone proteins by transferring an acetyl group from acetyl CoA to form e-N-acetyl lysine. HATs act as transcriptional co-activators.

Histone lysine demethylases (KDMs)

Enzymes that play a key role in the amplification of hypoxia-inducible-factor signalling and expression of pro-angiogenic genes in cancer and neurological disorders.

HIV

See Human immunodeficiency virus.

Hives

(Urticaria) is a skin rash characterised by circular wheals of reddened and itching skin.

HLA

Human leukocyte antigen system, name of the major histocompatibility complex (MHC) in humans.

HLA-DQB1

Human leucocyte antigen beta chain.

HLA-DR

A major histocompatibility complex (MHC) class II cell surface receptor encoded by the human leukocyte antigen complex on chromosome 6 region 6p21.31.

HMG-CoAr

3-hydroxy-3-methyl-glutaryl-CoA reductase or (HMGCR) is the rate-controlling enzyme (EC 1.1.1.88) of the mevalonate pathway.

HMG-CoA

3-hydroxy-3-methylglutaryl-coenzyme A, an intermediate in the mevalonate pathway.

Hodgkin's disease

Disease characterised by enlargement of the lymph glands and spleen and by anaemia.

Homeodomain transcription factor

A protein domain encoded by a homeobox. Homeobox genes encode transcription factors which typically switch on cascades of other genes.

Homeostasis

The maintenance of a constant internal environment of a cell or an organism despite fluctuations in the external.

Homeotherapy

Treatment or prevention of disease with a substance similar but not identical to the causative agent of the disease.

Homocysteine

An amino acid in the blood.

Homograft

See allograft.

Hormesis

A term used by toxicologists to refer to a biphasic dose response to an environmental agent characterised by a low-dose stimulation or beneficial effect and a high-dose inhibitory or toxic effect.

Hormonal (female)

Substance that has a hormone-like effect similar to that of oestrogen and/or a substance used to normalise female hormone levels.

Hormonal (male)

Substance that has a hormone-like effect similar to that of testosterone and/or a substance used to normalise male hormone levels.

HRT

Hormone replacement therapy, the administration of the female hormones oestrogen and progesterone and sometimes testosterone.

HSF-1 factor

Major regulator of heat shock protein transcription in eukaryotes.

HSP27

Is an ATP-independent, 27 kDa heat shock protein chaperone that confers protection against apoptosis.

HSP70

Heat shock protein chaperone that confers protection against heat-induced apoptosis.

HSP90

A 90 kDa heat shock protein chaperone that has the ability to regulate a specific subset of cellular signalling proteins that have been implicated in disease processes.

HSPD 1

Heat shock 60 kDa protein 1

hTERT – (TERT)

Telomerase reverse transcriptase is a catalytic sub-unit of the enzyme telomerase in humans. It exerts a novel protective function by binding to mitochondrial DNA, increasing respiratory chain activity and protecting against oxidative stress–induced damage.

HT29 cells

Are human intestinal epithelial cells which produce the secretory component of immunoglobulin A (IgA) and carcinoembryonic antigen (CEA).

Human cytomegalovirus (HCMV)

A DNA herpes virus which is the leading cause of congenital viral infection and mental retardation.

Human factor X

A coagulation factor also known by the eponym Stuart–Prower factor or as thrombokinase, is an enzyme involved in blood coagulation. It is synthesised in the liver and requires vitamin K for its synthesis.

Human immunodeficiency virus (HIV)

A retrovirus that can lead to acquired immunodeficiency syndrome (AIDS), a condition in humans in which the immune system begins to fail, leading to life-threatening opportunistic infections.

Humoral immune response (HIR)

Is the aspect of immunity that is mediated by secreted antibodies (as opposed to cell-mediated immunity, which involves T lymphocytes) produced in the cells of the B lymphocyte lineage (B cell).

HUVEC

Human umbilical vein endothelial cells.

Hyaluronidase

Enzymes that catalyse the hydrolysis of certain complex carbohydrates like hyaluronic acid and chondroitin sulphates.

Hydatidiform

A rare mass or growth that forms inside the uterus at the beginning of pregnancy.

Hydrocele

Abnormal accumulation of fluid inside the scrotum.

Hydrocholeretic

An agent that stimulates an increased output of bile of low specific gravity.

Hydrogogue

A purgative that causes an abundant watery discharge from the bowel.

Hydronephrosis

Is distension and dilation of the renal pelvis and calyces usually caused by obstruction of the free flow of urine from the kidney.

Hydrophobia

A viral neuro-invasive disease that causes acute encephalitis (inflammation of the brain) in warm-blooded animals. Also called rabies.

Hydropsy

See dropsy.

Hydrothorax

Accumulation of serous fluid in the pleural cavity.

Hyperaemia

The increase of blood flow to different tissues in the body.

Hyperalgesia

An increased sensitivity to pain (enhanced pricking pain) which may be caused by damage to nociceptors or peripheral nerves.

Hyperammonaemia

A metabolic disturbance characterised by an excess of ammonia in the blood.

Hypercalciuria

(*Idiopathic*) presence of excess calcium in the urine without obvious cause.

Hypercholesterolemia

High levels of cholesterol in the blood that increase a person's risk for cardiovascular disease leading to stroke or heart attack.

Hyperemia

Is the increased blood flow that occurs when tissue is active.

Hyperemesis

Severe and persistent nausea and vomiting (morning sickness) during pregnancy.

Hyperfibrinogenemia

Excessive fibrinogen in the blood.

Hyperglycaemia

High blood sugar; is a condition in which an excessive amount of glucose circulates in the blood plasma.

Hyperglycaemic

A substance that raises blood sugar levels.

Hyperhomocysteinemia

Is a medical condition characterised by an abnormally large level of homocysteine in the blood.

Hyperinsulinemia

A condition in which there are excess levels of circulating insulin in the blood; also known as pre-diabetes.

Hyperkalemia

Is an elevated blood level of the electrolyte potassium.

Hyperkeratosis

Abnormal thickening of the outer layer of the skin. adj
hyperkeratotic.

Hyperknesis

Enhanced itch to pricking.

Hyperleptinemia

Increased serum leptin level.

Hyperlipoproteinemia

A metabolic disorder characterised by abnormally elevated concentrations of lipid/lipoprotein in the plasma; also known as hyperlipidemia and hyperlipemia.

Hypermenorrhoea

Abnormally heavy or prolonged menstruation.

Hypermethylation

An increase in the inherited methylation of cytosine and adenosine residues in DNA.

Hyperoxaluria

An excessive urinary excretion of oxalate.

Hyperphagia

Or polyphagia, abnormally large ingestion of food beyond that needed for basic energy requirements.

Hyperpiesia

Persistent and pathological high blood pressure for which no specific cause can be found.

Hyperplasia

Increased cell production in a normal tissue or organ.

Hyperprebeta-lipoproteinaemia

Increased concentrations of pre-beta-lipoproteins in the blood.

Hyperpropulsion

Using water pressure as a force to move objects; used to dislodge calculi in the urethra.

Hyperpyrexia

Is an abnormally high fever.

Hypertension

Commonly referred to as 'high blood pressure' or HTN, is a medical condition in which the arterial blood pressure is chronically elevated.

Hypertensive

Characterised or caused by increased tension or pressure as abnormally high blood pressure.

Hypertonia

Abnormal increase in muscle tension and a reduced ability of the muscle to stretch.

Hypertriglyceridaemia or hypertriglycemia

A disorder that causes high triglycerides in the blood.

Hypertrophy

Enlargement or overgrowth of an organ.

Hyperuricemia

Is a condition characterised by abnormally high levels of uric acid in the blood.

Hypoadiponectinemia

The state of having too low levels of adiponectin, a major metabolic endocrine, responsible for regulating things like glucose uptake and lipolysis (the breakdown of fat deposits); low adiponectin is a risk factor for both type II diabetes and metabolic syndrome.

Hypoalbuminemia

A medical condition where levels of albumin in blood serum are abnormally low.

Hypocalcemic tetany

A disease caused by an abnormally low level of calcium in the blood and characterised by hyperexcitability of the neuromuscular system and results in carpopedal spasms.

Hypochlorhydria

Refers to states where the production of gastric acid in the stomach is absent or low.

Hypocholesterolemic

Cholesterol reducer, a substance that lowers blood cholesterol levels.

Hypocitraturia

Low amount of citrate in the urine, an important risk factor for kidney stone formation.

Hypocorticism

See Addison's disease.

Hypocortisolism

See Addison's disease.

Hypoesthesia

Or hypesthesia, refers to a reduced sense of touch or sensation or a partial loss of sensitivity to sensory stimuli.

Hypoglycemic

An agent that lowers the concentration of glucose (sugar) in the blood.

Hypogonadism syndrome

Characterised by defects of the gonads.

Hypoperfusion

Decreased blood flow through an organ characterised by an imbalance of oxygen demand and oxygen delivery to tissues.

Hypophagic

Under-eating.

Hypophysectomy

The surgical removal of the hypophysis (pituitary gland).

Hypospadias

An abnormal birth defect in males in which the urethra opens on the under surface of the penis.

Hypotensive

Characterised by or causing diminished tension or pressure as abnormally low blood pressure.

Hypothermia

A condition in which an organism's temperature drops below that required for normal metabolism and body functions.

Hypothermic

Relating to hypothermia, with subnormal body temperature.

Hypoxaemia

Is the reduction of oxygen specifically in the blood.

Hypoxia

A shortage of oxygen in the body. *adj* . hypoxic.

Hypoxia-inducible factors (HIFs)

Transcription factors that respond to changes in available oxygen in the cellular environment, specifically to deficiency in oxygen.

ICAM-1 (inter-cellular adhesion molecule 1)

Also known as CD54 (cluster of differentiation 54), is a protein that in humans is encoded by the ICAM1 gene.

IC₅₀

The median maximal inhibitory concentration; a measure of the effectiveness of a compound in inhibiting biological or biochemical function.

I.C.V. (intra-cerebroventricular)

Injection of chemical into the right lateral ventricle of the brain.

Iceterus

Jaundice, yellowish pigmentation of the skin.

Ichthyotoxic

A substance which is poisonous to fish.

Icteric hepatitis

An infectious syndrome of hepatitis characterised by jaundice, nausea, fever, right-upper-quadrant pain, enlarged liver and transaminitis (increase in alanine aminotransferase (ALT) and/or aspartate aminotransferase (AST)).

Icterus neonatorum

Jaundice in newborn infants.

Idiopathic

Of no apparent physical cause.

Idiopathic mesenteric phlebosclerosis (IMP)

A rare disease, characterised by thickening of the wall of the right hemicolon with calcification of mesenteric veins.

Idiopathic sudden sensorineural hearing loss (ISSHL)

Is sudden hearing loss where clinical assessment fails to reveal a cause.

I.g.

Gastric intubation, insertion of Levin tube through the nasal passage to the stomach.

IgE

Immunoglobulin E – a class of antibody that plays a role in allergy.

IGFs

Insulin-like growth factors, polypeptides with high sequence similarity to insulin.

IgG

Immunoglobulin G – the most abundant immunoglobulin (antibody) and one of the major activators of the complement pathway.

IgM

Immunoglobulin M – primary antibody against A and B antigens on red blood cells.

IKAP

Is a scaffold protein of the IkarosKappaBeta kinase complex and a regulator for kinases involved in pro-inflammatory cytokine signalling.

IKappa B

Or Ikb-beta, a protein of the NF-Kappa-B inhibitor family.

Ileus

A temporary disruption of intestinal peristalsis due to non-mechanical causes.

Immune modulator

A substance that affects or modulates the functioning of the immune system.

Immunodeficiency

A state in which the immune system's ability to fight infectious disease is compromised or entirely absent.

Immunogenicity

The property enabling a substance to provoke an immune response, *adj* . immunogenic.

Immunoglobulin class switching, Ig class switching

A biological mechanism that changes a B cell's production of antibody from one class to another.

Immunomodulatory

Capable of modifying or regulating one or more immune functions.

Immunoreactive

Reacting to particular antigens or haptens.

Immunostimulant

Agent that stimulates an immune response.

Immunosuppression

Involves a process that reduces the activation or efficacy of the immune system.

Immunotoxin

A man-made protein that consists of a targeting portion linked to a toxin.

Impaired glucose tolerance (IGT)

A pre-diabetic state of dysglycaemia associated with insulin resistance, increased risk of cardiovascular pathology and also a risk factor for mortality.

Impetigo

A contagious bacterial skin infection characterised by blisters that may itch, caused by a *Streptococcus* bacterium or *Staphylococcus aureus* and mostly seen in children.

Impotence

A sexual dysfunction characterised by the inability to develop or maintain an erection of the penis.

Incontinence (fecal)

The inability to control bowel movement.

Incontinence (urine)

The inability to control urine excretion.

Incretin

A group of gastrointestinal hormones that cause an increase in the amount of insulin released from beta cells of the islets of Langerhans after a meal; members include GIP and GLP-1.

Index of structural atypia (ISA)

Index of structural abnormality.

Induration

Hardened, as a soft tissue that becomes extremely firm, sclerosis.

Infarct

An area of living tissue that undergoes necrosis as a result of obstruction of local blood supply.

Infarction

Is the process of tissue death (necrosis) caused by blockage of the tissue's blood supply.

Inflammasomes

Are large intracellular caspase-1 activating multiprotein complexes that play a central role in innate immunity.

Inflammation

A protective response of the body to infection, irritation or other injury, aimed at destroying or isolating injuries and characterised by redness, pain, warmth and swelling.

Influenza

A viral infection that affects mainly the nose, throat, bronchi and, occasionally, lungs.

Infusion

A liquid extract obtained by steeping something (e.g. herbs) that are more volatile or dissolve readily in water to release their active ingredients without boiling.

Inguinal hernia

A hernia into the inguinal canal of the groin.

Inhalant

A medicinal substance that is administered as a vapour into the upper respiratory passages.

iNOS, inducible nitric oxide synthases

Through its product, nitric oxide (NO), may contribute to the induction of germ cell apoptosis. It plays a crucial role in early sepsis-related microcirculatory dysfunction.

Inotropic

Affecting the force of muscle contraction.

Insecticide

An agent that destroys insects. *adj* . insecticidal.

Insomnia

A sleeping disorder characterised by the inability to fall asleep and/or the inability to remain asleep for a reasonable amount of time.

Insulin

A peptide hormone composed of 51 amino acids produced in the islets of Langerhans in the pancreas, causes cells in the liver, muscle and fat tissue to take up glucose from the blood, storing it as glycogen in the liver and muscles. Insulin deficiency is often the cause of diabetes, and exogenous insulin is used to control diabetes.

Insulin homeostasis

Blood sugar regulation.

Insulin-like growth factors (IGFs)

Polypeptides with high sequence similarity to insulin. They are part of a complex system that cells employ to communicate with their physiological environment.

Insulin-mimetic

To act like insulin.

Insulin resistance

A condition where the natural hormone insulin becomes less effective at reducing blood sugars.

Insulinogenic

Associated with or stimulating the production of insulin.

Insulinotropic

Stimulating or affecting the production and activity of insulin.

Integrase

An enzyme produced by a retrovirus (such as HIV) that enables its genetic material to be integrated into the DNA of the infected cell.

Interferons (IFNs)

Are natural cell-signalling glycoproteins known as cytokines produced by the cells of the immune system of most vertebrates in response to challenges such as viruses, parasites and tumour cells.

Interleukins

A group of naturally occurring proteins and a subset of a larger group of cellular messenger molecules called cytokines, which are modulators of cellular behaviour.

Interleukin-1 (IL-1)

A cytokine that could induce fever, control lymphocytes, increase the number of bone marrow cells and cause degeneration of bone joints. Also called endogenous pyrogen, lymphocyte activating factor, haemopoietin-1 and mononuclear cell factor, amongst others IL-1 is composed of two distinct proteins, now called IL-1 α and IL-1 β .

Interleukin 1 beta (IL-1 β)

A cytokine protein produced by activated macrophages, cytokine is an important mediator of the inflammatory response and is involved in a variety of cellular activities including cell proliferation, differentiation and apoptosis.

Interleukin 2 (IL-2)

A type of cytokine immune system signalling molecule that is instrumental in the body's natural response to microbial infection.

Interleukin-2 receptor (IL-2R)

A heterotrimeric protein expressed on the surface of certain immune cells such as lymphocytes that binds and responds to a cytokine called IL-2.

Interleukin-6 (IL-6)

An interleukin that acts as both a pro-inflammatory and anti-inflammatory cytokine.

Interleukin 8 (I- 8)

A cytokine produced by macrophages and other cell types such as epithelial cells and is one of the major mediators of

the inflammatory response.

Intermediate-density lipoproteins (IDL)

Is one of the five major groups of lipoproteins (chylomicrons, VLDL, IDL, LDL and HDL) that enable fats and cholesterol to move within the water-based solution of the bloodstream. IDL is further degraded to form LDL particles and, like LDL, can also promote the growth of atheroma and increase cardiovascular diseases.

Intermittent claudication

An aching, crampy, tired and sometimes burning pain in the legs that comes and goes, caused by peripheral vascular disease. It usually occurs with walking and disappears after rest.

Interoceptive

Relating to stimuli arising from within the body.

Interstitium

The space between cells in a tissue.

Interstitial

Pertaining to the interstitium.

Intertrigo

An inflammation (rash) caused by microbial infection in skin folds.

Intima

Innermost layer of an artery or vein.

Intimal hyperplasia

The thickening of the tunica intima of a blood vessel as a complication of a reconstruction procedure.

Intoxicant

Substance that produces drunkenness or intoxication.

Intracavernosal

Within the corpus cavernosum, columns of erectile tissues forming the body of the penis.

Intraperitoneal (i.p.)

The term used when a chemical is contained within or administered through the peritoneum (the thin, transparent membrane that lines the walls of the abdomen).

Intrathecal (i.t.)

Through the theca of the spinal cord into the subarachnoid space.

Intromission

The act of putting one thing into another.

Intubation

Refers to the placement of a tube into an external or internal orifice of the body.

Iodine (I)

Is an essential chemical element that is important for hormone development in the human body. Lack of iodine can lead to an enlarged thyroid gland (goitre) or other iodine deficiency disorders including mental retardation and stunted growth in babies and children. Iodine is found in dairy products, seafood, kelp, seaweeds, eggs, some vegetables and iodised salt.

IP

See intraperitoneal.

IP3R3

(Inositol 1,4,5-triphosphate receptor type 3) is an intracellular calcium release channel that mediates calcium release from the endoplasmic reticulum.

Iron (Fe)

Is essential to most life forms and to normal human physiology. In humans, iron is an essential component of proteins involved in oxygen transport and for haemoglobin. It is also essential for the regulation of cell

growth and differentiation. A deficiency of iron limits oxygen delivery to cells, resulting in fatigue, poor work performance and decreased immunity. Conversely, excess amounts of iron can result in toxicity and even death. Dietary sources include certain cereals, dark green leafy vegetables, dried fruit, legumes, seafood, poultry and meat.

Ischaemia

An insufficient supply of blood to an organ, usually due to a blocked artery.

Ischuria

Retention or suppression of urine.

Isoflavones

A sub-group of flavonoids in which the basic structure is a 3-phenyl chromane skeleton. They act as phytoestrogens in mammals. See flavonoids.

Isomers

Substances that are composed of the same elements in the same proportions and hence have the same molecular formula but differ in properties because of differences in the arrangement of atoms.

Isoprostanes

Unique prostaglandin-like compounds generated in-vivo from the free radical–catalysed peroxidation of essential fatty acids.

Jamu

Traditional Indonesian herbal medicine.

Janus kinase (JAK)-signal transducer and activator of transcription (STAT) signalling

Are essential molecules in cytokine signal transduction pathways involved in cancer development and progression.

Jaundice

Refers to the yellow colour of the skin and whites of the eyes caused by excess bilirubin in the blood.

JNK

(Jun N-terminal kinase), also known as stress-activated protein kinase (SAPK), belongs to the family of MAP kinases.

Jurkat cells

A line of T lymphocyte cells that are used to study acute T-cell leukaemia.

KB cell

A cell line derived from a human carcinoma of the nasopharynx, used as an assay for anti-neoplastic (anti-tumour) agents.

Kainate receptors

Or KARs, are non-NMDA (N-methyl-d-aspartate) ionotropic receptors which respond to the neurotransmitter glutamate.

Kaliuresis

The presence of excess potassium in the urine.

Kallikreins

Peptidases (enzymes that cleave peptide bonds in proteins), a subgroup of the serine protease family; they liberate kinins from kininogens. Kallikreins are targets of active investigation by drug researchers as possible biomarkers for cancer.

Kaposi sarcoma

A cancerous tumour of the connective tissues caused by the human herpesvirus 8 and often associated with AIDS.

Kaposi sarcoma herpes virus (KSHV)

Also known as human herpesvirus-8, is a gamma 2 herpesvirus or rhadinovirus. It plays an important role in the pathogenesis of Kaposi sarcoma (KS), multicentric Castleman disease (MCD) of the plasma cell type and primary effusion lymphoma and occurs in HIV patients.

Karyolysis

Dissolution and disintegration of the nucleus when a cell dies.

Karyorrhexis

Destructive fragmentation of the nucleus of a dying cell whereby its chromatin disintegrates into formless granules.

Keloids

Benign dermal tumours characterised by fibroblastic proliferation and excessive accumulation of collagen.

Keratin

A sulphur-containing protein which is a major component in skin, hair, nails, hooves, horns and teeth.

Keratinocyte

Is the major constituent of the epidermis, constituting 95 % of the cells found there.

Keratinophilic

Having an affinity for keratin.

Keratitis

Inflammation of the cornea.

Keratoconjunctivitis sicca

Also called keratitis sicca, xerophthalmia or dry eye syndrome (DES), is an eye disease characterised by a deficiency of aqueous tear film over the surface of the eye and in the lining of the lids.

Keratolysis

Softening and separation of the horny layer of the epidermis.

Keratolytic

Pertaining to keratolysis.

Keratomalacia

An eye disorder that leads to a dry cornea.

Kidney stones

Calculi, are hardened mineral deposits that form in the kidney.

Kinin

Is any of various structurally related polypeptides, such as bradykinin, that act locally to induce vasodilation and contraction of smooth muscle.

Kininogen

Either of two plasma α 2-globulins that are kinin precursors.

Ki-67

Human protein associated with cell proliferation.

Knockout

Gene knockout is a genetic technique in which an organism is engineered to carry genes that have been made inoperative.

Kunitz protease inhibitors

A type of protein contained in legume seeds which functions as a protease inhibitor.

Kupffer cells

Are resident macrophages of the liver and play an important role in its normal physiology and homeostasis as well as participating in the acute and chronic responses of the liver to toxic compounds.

L -Dopa

(L -3,4-dihydroxyphenylalanine) is an amino acid that is formed in the liver and converted into dopamine in the brain.

Labour

Process of childbirth involving muscular contractions.

Lacrimation

Secretion and discharge of tears.

Lactagogue

An agent that increases or stimulates milk flow or production. Also called a galactagogue.

Lactate dehydrogenase (LDH)

Enzyme that catalyses the conversion of lactate to pyruvate.

Lactation

Secretion and production of milk.

Lactic acidosis

Is a condition caused by the build-up of lactic acid in the body.
It leads to acidification of the blood (acidosis) and is considered a distinct form of metabolic acidosis.

LAK cell

A lymphokine-activated killer cell, i.e. a white blood cell that has been stimulated to kill tumour cells.

Lamella

In cell biology, refers to numerous plate or disc-like structures at both a tissue and a cellular level.

Laminin

A glycoprotein component of connective tissue basement membrane that promotes cell adhesion.

Laparotomy

A surgical procedure involving an incision through the abdominal wall to gain access into the abdominal cavity.
adj. laparotomised.

Larvacidal

An agent which kills insect or parasite larva.

Laryngitis

Is an inflammation of the larynx.

Laxation

Bowel movement.

Laxatives

Substances that are used to promote bowel movement.

LC 50

Median lethal concentration, see LD 50.

LD 50

Median lethal dose – the dose required to kill half the members of a tested population. Also called LC 50 (median lethal concentration).

LDL

See low-density lipoprotein.

LDL Cholesterol

See low-density lipoprotein.

LDL receptor (LDLr)

A low-density lipoprotein receptor gene.

Lectins

Are sugar-binding proteins that are highly specific for their sugar moieties, that agglutinate cells and/or precipitate glycoconjugates. They play a role in biological recognition phenomena involving cells and proteins.

Leishmaniasis

A disease caused by protozoan parasites that belong to the genus *Leishmania* and transmitted by the bite of certain species of sand fly.

Lenitive

Palliative; easing pain or discomfort.

Lenticular opacity

Also known as or related to cataract.

Leprosy

A chronic bacterial disease of the skin and nerves in the hands and feet and, in some cases, the lining of the nose. It is caused by the *Mycobacterium leprae* . Also called Hansen's disease.

Leptin

Is a 16 kDa protein hormone with important effects in regulating body weight, metabolism and reproductive function.

Lequesne algofunctional index

Is a widespread international instrument (10-question survey) and recommended by the World Health Organisation (WHO) for outcome measurement in hip and knee diseases such as osteoarthritis.

Leucocyte

White blood corpuscles, colourless, without haemoglobin, that help to combat infection.

Leucoderma

A skin abnormality characterised by white spots, bands and patches on the skin; they can also be caused by fungus and tinea. Also see vitiligo.

Leucorrhoea

Commonly known as whites, refers to a whitish discharge from the female genitals.

Leukaemia

A cancer of the blood or bone marrow and characterised by an abnormal proliferation (production by multiplication) of blood cells, usually white blood cells (leukocytes).

Leukemogenic

Relating to leukaemia, causing leukaemia.

Leukocytopenia

Abnormal decrease in the number of leukocytes (white blood cells) in the blood.

Leukocytosis

Increase in white blood cell count above its normal range.

Leukomyelopathy

Any diseases involving the white matter of the spinal cord.

Leukopenia

A decrease in the number of circulating white blood cells.

Leukoplakia

Condition characterised by white spots or patches on mucous membranes, especially of the mouth and vulva.

Leukotriene

A group of hormones that cause the inflammatory symptoms of hay-fever and asthma.

Leydig cells

Also called interstitial cells of Leydig, are found adjacent to the seminiferous tubules in the testicle. They produce testosterone in response to luteinising hormone.

Levarterenol

See Norepinephrine.

LexA repressor

Or repressor LexA, is a repressor enzyme that represses SOS response genes coding for DNA polymerases required for repairing DNA damage.

Libido

Sexual urge.

Lichen planus

A chronic mucocutaneous disease that affects the skin, tongue and oral mucosa.

Ligroin

A volatile, inflammable fraction of petroleum, obtained by distillation and used as a solvent.

Limbic system

Complex set of brain structures, including the hypothalamus, amygdala, hippocampus, anterior thalamic nuclei, septum, limbic cortex and fornix that control various functions such as emotion, behaviour, motivation, memory and olfaction.

Liniment

Liquid preparation rubbed on skin, used to relieve muscular aches and pains.

Linterised starch

Starch that has undergone prolonged acid treatment.

Lipodiatic

Having lipid- and lipoprotein-lowering property.

Lipodystrophy

A medical condition characterised by abnormal or degenerative conditions of the body's adipose tissue.

Lipogenesis

Is the process by which acetyl-CoA is converted to fats; adj. lipogenic.

Lipolysis

Is the breakdown of fat stored in fat cells in the body.

Liposomes

Artificially prepared vesicles made of lipid bilayer.

Lipotoxicity

Refers to tissue diseases that may occur when fatty acids spill over in excess of the oxidative needs of those tissues and enhances metabolic flux into harmful pathways of non-oxidative metabolism.

Lipotropic

Refers to compounds that help catalyse the breakdown of fat during metabolism in the body. e.g. chlorine and lecithin.

Lipoxygenase

A family of iron-containing enzymes that catalyse the dioxygenation of polyunsaturated fatty acids in lipids containing a cis,cis-1,4- pentadiene structure.

Lithiasis

Formation of urinary calculi (stones) in the renal system (kidneys, ureters, urinary bladder, urethra), can be of any one of several compositions.

Lithogenic

Promoting the formation of calculi (stones).

Lithontripic

Removes stones from kidney and gall bladder.

Liver X receptors

Nuclear hormones that function as central transcriptional regulators for lipid homeostasis.

Lochia

Vaginal discharge containing blood, mucus and uterine tissues during the postpartum period.

Lotion

A liquid suspension or dispersion of chemicals for external application to the body.

Lovo cells

Colon cancer cells.

Low-density lipoprotein (LDL)

Is a type of lipoprotein that transports cholesterol and triglycerides from the liver to peripheral tissues. High levels of LDL cholesterol can signal medical problems like cardiovascular disease, and it is sometimes called ‘bad cholesterol’.

LRP1

Low-density lipoprotein receptor–related protein-1, plays a role in intracellular signalling functions as well as in lipid metabolism.

LTB4

A type of leukotriene, a major metabolite in neutrophil polymorphonuclear leukocytes. It stimulates polymorphonuclear cell function (degranulation, formation of oxygen-centred free radicals, arachidonic acid release and metabolism). It induces skin inflammation.

Luciferase

Is a generic name for enzymes commonly used in nature for bioluminescence.

Lumbago

Is the term used to describe general lower-back pain.

Lung abscess

Necrosis of the pulmonary tissue and formation of cavities containing necrotic debris or fluid caused by microbial infections.

Lusitropic

An agent that affects diastolic relaxation.

Lutein

A carotenoid, occurs naturally as yellow or orange pigment in some fruit and leafy vegetables. It is one of the two carotenoids contained within the retina of the eye. Within the central macula, zeaxanthin predominates, whereas in the peripheral retina, lutein predominates. Lutein is necessary for good vision and may also help prevent or slow down atherosclerosis, the thickening of arteries, which is a major risk for cardiovascular disease.

Luteinising hormone (LH)

A hormone produced by the anterior pituitary gland. In females, it triggers ovulation. In males, it stimulates the production of testosterone to aid sperm maturation.

Luteolysis

Is the structural and functional degradation of the corpus luteum (CL) that occurs at the end of the luteal phase of both the oestrous and menstrual cycles in the absence of pregnancy. *adj* . luteolytic.

Luteotropic

Stimulating the formation of the corpus luteum.

Lymphadenitis

The inflammation or enlargement of a lymph node caused by microbial infection.

Lymphadenitis-cervical

Inflammation of the lymph nodes in the neck, usually caused by an infection.

Lymphatitis

Inflammation of lymph vessels and nodes.

Lymphadenopathy

A term meaning 'disease of the lymph nodes' – lymph node enlargement.

Lymphadenomegaly

Is the enlargement of the lymph node/nodes.

Lymphangitis

An inflammation or bacterial infection of lymphatic channels, mostly commonly caused by the bacterium *Streptococcus pyogenes* in humans.

Lymphoblastic

Pertaining to the production of lymphocytes.

Lymphocyte

A small white blood cell (leucocyte) that plays a large role in defending the body against disease. Lymphocytes are responsible for **immune** responses. There are two main types of lymphocytes: **B cells** and **T cells**. Lymphocytes secrete products (lymphokines) that modulate the functional activities of many other types of cells and are often present at sites of **chronic inflammation**.

Lymphocyte B cells

B cells make antibodies that attack bacteria and toxins.

Lymphocyte T cells

T cells attack body cells themselves when they have been taken over by viruses or have become cancerous.

Lymphoma

A type of cancer involving cells of the immune system called lymphocytes.

Lymphopenia

Abnormally low number of lymphocytes in the blood.

Lysosomes

Are small, spherical organelles containing digestive enzymes (acid hydrolases) and other proteases (cathepsins).

mTOR, the mammalian (or mechanistic) target of rapamycin

Regulates a wide range of cellular and developmental processes by coordinating signalling responses to mitogens, nutrients and various stresses.

Maceration

Softening or separating of parts by soaking in a liquid.

Macrophage

A type of large leukocyte that travels in the blood but can leave the bloodstream and enter tissue; like other leukocytes, it protects the body by digesting debris and foreign cells.

Macular degeneration

A disease that gradually destroys the macula, the central portion of the retina, reducing central vision.

Macules

Small circumscribed changes in the colour of skin that are neither raised (elevated) nor depressed.

Maculopapular

Describes a rash characterised by raised, spotted lesions.

Magnesium (Mg)

Is the fourth most abundant mineral in the body and is essential to good health. It is important for normal muscle and nerve function, steady heart rhythm, immune system and strong bones. Magnesium also helps regulate blood sugar levels, promotes normal blood pressure and is known to be involved in energy metabolism and protein synthesis and plays a role in preventing and managing disorders such as hypertension, cardiovascular disease and diabetes.

Dietary sources include legumes (e.g. soya bean and by-products), nuts, whole unrefined grains, fruit (e.g. banana, apricots), okra and green leafy vegetables.

MAK cell

Macrophage-activated killer cell, activated macrophage that is much more phagocytic than monocytes.

Malaise

A feeling of weakness, lethargy or discomfort as of impending illness.

Malaria

Is an infection of the blood by *Plasmodium* parasite that is carried from person to person by mosquitoes. There are four species of malaria parasites that infect man:

Plasmodium falciparum , so-called 'malignant tertian fever', is the most serious disease, *Plasmodium vivax* , causing a relapsing form of the disease, *Plasmodium malariae* , and *Plasmodium ovale* .

Malassezia

A fungal genus (previously known as *Pityrosporum*) classified as yeasts, naturally found on skin surfaces of many animals including humans. It can cause hypopigmentation on the chest or back if it becomes an opportunistic infection.

Mammalian target of rapamycin (mTOR)

Pathway that regulates mitochondrial oxygen consumption and oxidative capacity.

Mammogram

An x-ray of the breast to detect tumours.

Mandibular

Relating to the mandible, the human jaw bone.

Manganese

Is an essential element for health. It is an important constituent of some enzymes and an activator of other enzymes in

physiological processes. Manganese superoxide dismutase (MnSOD) is the principal antioxidant enzyme in the mitochondria. Manganese-activated enzymes play important roles in the metabolism of carbohydrates, amino acids and cholesterol. Manganese is the preferred cofactor of enzymes called glycosyltransferases, which are required for the synthesis of proteoglycans that are needed for the formation of healthy cartilage and bone. Dietary sources include whole grains, fruit, legumes (soybean and by-products), green leafy vegetables, beetroot and tea.

MAO activity

Monoamine oxidase activity.

MAPK (mitogen-activated protein kinase)

These kinases are strongly activated in cells subjected to osmotic stress, UV radiation, disregulated K^+ currents, RNA-damaging agents and a multitude of other stresses as well as inflammatory cytokines, endotoxin and withdrawal of a trophic factor. The stress-responsive MAPKs mediate a plethora of cellular responses to such stressful stimuli, including apoptosis and production of inflammatory and immunoregulatory cytokines in diverse cell systems.

Marasmus

Is one of the three forms of serious protein energy malnutrition.

Mastectomy

Surgery to remove a breast.

Masticatory

A substance chewed to increase salivation. Also called sialogue.

Mastitis

A bacterial infection of the breast which usually occurs in breastfeeding mothers.

Matrix metalloproteinases (MMP)

A member of a group of enzymes that can break down proteins, such as collagen, that are normally found in spaces between cells in tissues (i.e. extracellular matrix proteins). Matrix metalloproteinases are involved in wound healing, angiogenesis and tumour cell metastasis. See also metalloproteinase.

MBC

Minimum bacterial concentration – the lowest concentration of antibiotic required to kill an organism.

MCP-1

Monocyte chemotactic protein-1, plays a role in the recruitment of monocytes to sites of infection and injury. It is a member of small inducible gene (SIG) family.

MDA

Malondialdehyde is one of the most frequently used indicators of lipid peroxidation.

Measles

An acute, highly communicable rash illness due to a virus transmitted by direct contact with infectious droplets or, less commonly, by airborne spread.

Mechanonociceptors

Sensory neurons that are mechanically sensitive, found in all the paraspinal connective tissues including ligament, joint capsule, annulus fibrosus of the intervertebral disk, muscle, tendon and skin. They respond to a noxious (damaging) mechanical load.

Medial preoptic area

Is located at the rostral end of the hypothalamus, it is important for the regulation of male sexual behaviour.

Megaloblastic anaemia

An anaemia that results from inhibition of DNA synthesis in red blood cell production, often due to a deficiency of vitamin B12 or folate and characterised by many large

immature and dysfunctional red blood cells (megaloblasts) in bone marrow.

Melaene (melena)

Refers to the black, 'tarry' feces that are associated with gastrointestinal haemorrhage.

Melanogenesis

Production of melanin by living cells.

Melanoma

Malignant tumour of melanocytes which are found predominantly in skin but also in the bowel and the eye and appear as pigmented lesions.

Melatonin

A hormone produced in the brain by the pineal gland, it is important in the regulation of the circadian rhythms of several biological functions.

Menarche

The first menstrual cycle, or first menstrual bleeding, in female human beings.

Menorrhagia

Heavy or prolonged menstruation, too frequent menstrual periods.

Menopausal

Refers to permanent cessation of menstruation.

Menses

See menstruation.

Menstruation

The approximately monthly discharge of blood from the womb in women of childbearing age who are not pregnant. Also called menses. *adj* . menstrual.

Mesangial cells

Are specialised cells around blood vessels in the kidneys, at the mesangium.

Mesothelioma

Is an aggressive cancer affecting the membrane lining of the lungs and abdomen.

Metabolic syndrome (MetS)

Represents a combination of cardiometabolic risk factors, including visceral obesity, glucose intolerance or type 2 diabetes, elevated triglycerides, reduced HDL cholesterol and hypertension.

Metabonome

Complete set of metabolologically regulated elements in cells.

Metabolomics

Is the scientific study of chemical processes involving metabolites.

Metalloproteinase

Enzymes that break down proteins requiring zinc or calcium atoms for proper function.

Metallothionein (MT)

A family of cysteine-rich, low-molecular weight (500–14,000 Da) proteins.

Meta-analysis

A statistical procedure that combines the results of several studies that address a set of related research hypotheses.

Metaphysis

Is the portion of a long bone between the epiphyses and the diaphysis of the femur.

Metaphyseal

Pertaining to the metaphysis.

Metaplasia

Transformation of one mature differentiated cell type into another mature differentiated cell type.

Metastasis

Is the movement or spreading of cancer cells from one organ or tissue to another.

Metetrus

The quiescent period of sexual inactivity between oestrus cycles.

Methemoglobinemia

Is a disorder characterised by the presence of a higher-than-normal level of methemoglobin (ferric $[\text{Fe}^{3+}]$ rather than ferrous $[\text{Fe}^{2+}]$ haemoglobin) in red blood cells. This results in a decreased availability of oxygen to tissues.

Metropathy

Any disease of the uterus, especially of the myometrium.

Metroptosis

The slipping or falling out of place of an organ (as the uterus).

Metrorrhagia

Uterine bleeding at irregular intervals, particularly between the expected menstrual periods.

Mevinolin

A potent inhibitor of 3-hydroxy-3-methylglutaryl coenzyme A reductase (HMG-CoA reductase).

MHC

Acronym for major histocompatibility complex, a large cluster of genes found on the short arm of chromosome 6 in most vertebrates that encodes MHC molecules. MHC molecules play an important role in the immune system and autoimmunity.

MHC II molecules

Class II MHC molecules belong to a group of molecules known as the immunoglobulin supergene family, which

includes immunoglobulins, T-cell receptors, CD4, CD8 and others.

MIC

Minimum inhibitory concentration – lowest concentration of an antimicrobial that will inhibit the visible growth of a microorganism.

Micelle

A submicroscopic aggregation of molecules.

Micellisation

Formation process of micelles.

Microangiopathy

Or microvascular disease, is an angiopathy affecting small blood vessels in the body.

Microfilaria

A pre-larval parasitic worm of the family *Onchocercidae* , found in the vector and in the blood or tissue fluid of human hosts.

Micronuclei

Small particles consisting of acentric fragments of chromosomes or entire chromosomes, which lag behind at anaphase of cell division.

Microphthalmia-associated transcription factor (MITF)

A basic helix-loop-helix leucine zipper transcription factor protein that plays a role in the development, survival and function of melanocytes and osteoclast.

Microsomal PGE2 synthase

Is the enzyme that catalyses the final step in prostaglandin E2 (PGE2) biosynthesis.

Microvasculature

The finer vessels of the body, as the arterioles, capillaries and venules.

Micturition

Urination, act of urinating.

Migraine

A neurological syndrome characterised by altered bodily perceptions, severe painful headaches and nausea.

Mimosine

Is an alkaloid, β -3-hydroxy-4 pyridone amino acid, it is a toxic non-protein free amino acid and is an antinutrient.

Mineral apposition rate

MAR, rate of addition of new layers of mineral on the trabecular surfaces of bones.

Miscarriage

Spontaneous abortion.

Mitochondrial complex I

The largest enzyme in the mitochondrial respiratory oxidative phosphorylation system.

Mitochondrial permeability transition (MPT)

Is an increase in the permeability of the mitochondrial membranes to molecules of less than 1,500 Da in molecular weight. MPT is one of the major causes of cell death in a variety of conditions.

Mitogen

An agent that triggers mitosis, elicits all the signals necessary to induce cell proliferation.

Mitogenic

Able to induce mitosis or transformation.

Mitogenicity

Process of induction of mitosis.

Mitomycin

A chemotherapy drug that is given as a treatment for several different types of cancer, including breast, stomach, oesophagus and bladder cancers.

Mitosis

Cell division in which the nucleus divides into nuclei containing the same number of chromosomes.

MMP

Matrix metalloproteinases, a group of peptidases involved in degradation of the extracellular matrix (ECM).

Mnestic

Pertaining to memory.

Molecular docking

Is a key tool in structural molecular biology and computer-assisted drug design.

Molluscidal

Destroying molluscs like snails.

Molt 4 cells

MOLT4 cells are lymphoblast-like in morphology and are used for studies of apoptosis, tumour cytotoxicity, tumorigenicity as well as for anti-tumour testing.

Molybdenum (Mo)

Is an essential element that forms part of several enzymes such as xanthine oxidase involved in the oxidation of xanthine to uric acid and use of iron. Molybdenum concentrations also affect protein synthesis, metabolism and growth. Dietary sources include meat, green beans, eggs, sunflower seeds, wheat flour, lentils and cereal grain.

Monoamine oxidase A (MAOA)

Is an isozyme of monoamine oxidase. It preferentially deaminates norepinephrine (noradrenaline), epinephrine (adrenaline), serotonin and dopamine.

Monoaminergic

Of or pertaining to neurons that secrete monoamine neurotransmitters (e.g., dopamine, serotonin).

Monoclonal antibodies

Are produced by fusing single antibody-forming cells to tumour cells grown in culture.

Monocyte

Large white blood cell that ingests microbes, other cells and foreign matter.

Monogalactosyl diglyceride

Are the major lipid components of chloroplasts.

Monorrhagia

Is heavy bleeding that is usually defined as periods lasting longer than 7 days or excessive bleeding.

Morbidity

A diseased state or symptom, or can refer either to the incidence rate or to the prevalence rate of a disease.

Morelloflavone

A biflavonoid extracted from *Garcinia dulcis* , has shown antioxidative, antiviral and anti-inflammatory properties.

Morphine

The major alkaloid of opium and a potent narcotic analgesic.

MTTP

Microsomal triglyceride transfer protein that is required for the assembly and secretion of triglyceride-rich lipoproteins from both enterocytes and hepatocytes.

MUC 5AC

Mucin 5AC, a secreted gel-forming protein mucin with a high molecular weight of about 641 kDa.

Mucositis

Painful inflammation and ulceration of the mucous membranes lining the digestive tract.

Mucous

Relating to mucus.

Mucolytic

Capable of reducing the viscosity of mucus or an agent that so acts.

Mucus

Viscid secretion of the mucous membrane.

Multidrug resistance (MDR)

Ability of a living cell to show resistance to a wide variety of structurally and functionally unrelated compounds.

Muscarinic receptors

Are G protein-coupled acetylcholine receptors found in the plasma membranes of certain neurons and other cells.

Musculotropic

Affecting or acting upon muscular tissue.

Mutagen

An agent that induces genetic mutation by causing changes in the DNA.

Mutagenic

Capable of inducing mutation (used mainly for extracellular factors such as X-rays or chemical pollution).

Myalgia

Muscle pain.

Myc

Codes for a protein that binds to the DNA of other genes and is therefore a transcription factor, found on chromosome 8 in humans.

Mycosis

An infection or disease caused by a fungus.

Mydriasis

Abnormal, excessive dilation of the pupil caused by disease or drug.

Myelocyte

Is a young cell of the granulocytic series, occurring normally in bone marrow but not in circulating blood.

Myeloid leukaemia (chronic)

A type of cancer that affects the blood and bone marrow, characterised by excessive number of white blood cells.

Myeloma

Cancer that arises in the plasma cells, a type of white blood cells.

Myeloperoxidase (MPO)

Is a peroxidase enzyme most abundantly present in neutrophil granulocytes (a sub-type of white blood cells). It is an inflammatory enzyme produced by activated leukocytes that predicts risk of coronary heart disease.

Myeloproliferative disorder

Disease of the bone marrow in which excess cells are produced.

Myelosuppressive

Causing bone marrow suppression.

Myelotoxicity

State of being toxic to myeloid tissues, the bone marrow.

Myiasis

Parasitic infestation of the body of a live mammal by fly larvae.

Myocardial

Relating to heart muscle tissues.

Myocardial infarction (MI)

Is the rapid development of myocardial necrosis caused by a critical imbalance between oxygen supply and demand of the myocardium.

Myocardial ischaemia

An intermediate condition in coronary artery disease during which the heart tissue is slowly or suddenly starved of oxygen and other nutrients.

Myocardial lipidosis

Is the accumulation of fat droplets in myocardial fibres.

Myoclonus

Brief, involuntary twitching of a muscle or a group of muscles.

Myogenesis

The formation of muscular tissue, especially during embryonic development.

Myopathy

A muscular disease wherein the muscle fibres do not function for any one of many reasons, resulting in muscular weakness.

Myopia

Near – or short-sightedness.

Myosarcoma

A malignant muscle tumour.

Myotonia dystrophica

An inherited disorder of the muscles and other body systems characterised by progressive muscle weakness, prolonged muscle contractions (myotonia), clouding of the lens of the eye (cataracts), cardiac abnormalities, balding and infertility.

Myotube

A developing skeletal muscle fibre or cell with a tubular appearance and a centrally located nucleus.

Myringosclerosis

Also known as tympanosclerosis or intratympanic tympanosclerosis, is a condition caused by calcification of collagen tissues in the tympanic membrane of the middle ear.

Mytonia

A symptom of certain neuromuscular disorders characterised by the slow relaxation of the muscles after voluntary contraction or electrical stimulation.

N-nitrosomorpholine

A human carcinogen.

N-nitrosoproline

An indicator for N-nitrosation of amines.

Nicotinamide adenine dinucleotide phosphate (NADP)

A coenzyme comprising nicotinamide mononucleotide coupled by pyrophosphate linkage to adenosine 2',5'-bisphosphate; it acts as an electron carrier in numerous reactions, being alternately oxidised (NADP⁺) and reduced (NADPH).

NADPH

The reduced form of nicotinamide adenine dinucleotide phosphate that serves as an electron carrier.

NAFLD

Non-alcoholic fatty liver disease.

Narcotic

An agent that produces narcosis; in moderate doses, it dulls the senses, relieves pain and induces sleep; in excessive dose, it causes stupor, coma, convulsions and death.

Nasopharynx

Upper part of the alimentary continuous with the nasal passages.

Natriorexia

Excessive intake of sodium evoked by sodium depletion. *adj* . natriorexic, natriorexigenic.

Natriuresis

The discharge of excessive large amounts of sodium through urine. *adj* . natriuretic.

Natural killer cells (NK cells)

A type of cytotoxic lymphocyte that constitute a major component of the innate immune system.

Natural killer T (NKT) cells

A heterogeneous group of T cells that share properties of both T cells and natural killer (NK) cells.

Nausea

Sensation of unease and discomfort in the stomach with an urge to vomit.

Necropsy

See autopsy.

Necrosis

Morphological changes that follow cell death, usually involving nuclear and cytoplasmic changes.

Neointima

A new or thickened layer of arterial intima formed especially on a prosthesis or in atherosclerosis by migration and proliferation of cells from the media.

Neonatal

Adj . Of or relating to newborn infants or an infant.

Neoplasia

Abnormal growth of cells, which may lead to a neoplasm or tumour.

Neoplasm

Tumour; any new and abnormal growth, specifically one in which cell multiplication is uncontrolled and progressive. Neoplasms may be benign or malignant.

Neoplastic transformation

Conversion of a tissue with a normal growth pattern into a malignant tumour.

Neovascularisation

Is the development of tiny, abnormal, leaky blood vessels inside the eye.

Neovasculature

Formation of new blood vessels.

Nephrectomised

Kidneys surgically removed.

Nephrectomy

Surgical removal of the kidney.

Nephric

Relating to or connected with a kidney.

Nephrin

Is a protein necessary for the proper functioning of the renal filtration barrier.

Nephritic syndrome

Is a collection of signs (known as a syndrome) associated with disorders affecting the kidneys, more specifically glomerular disorders.

Nephritis

Is inflammation of the kidney.

Nephrolithiasis

Process of forming a kidney stone in the kidney or lower urinary tract.

Nephropathy

A disorder of the kidney.

Nephrotic syndrome

Non-specific disorder in which the kidneys are damaged, causing them to leak large amounts of protein from the blood into the urine.

Nephrotoxicity

Poisonous effect of some substances, both toxic chemicals and medication, on the kidney.

Nerve growth factor (NGF)

A small protein that induces the differentiation and survival of particular target neurons (nerve cells).

Nervine

A nerve tonic that acts therapeutically upon the nerves, particularly in the sense of a sedative that serves to calm ruffled nerves.

Neural tube defects (NTDs)

Are common birth defects of the brain and spinal cord.

NEU 4 sialidase

This protein belongs to a family of glycohydrolytic enzymes, which remove terminal sialic acid residues from various sialo derivatives, such as glycoproteins, glycolipids, oligosaccharides and gangliosides.

Neuralgia

Is a sudden, severe painful disorder of the nerves.

Neuraminidase

Glycoside hydrolase enzyme that cleaves the glycosidic linkages of neuraminic acids.

Neuraminidase inhibitors

A class of antiviral drugs targeted at the influenza viruses whose mode of action consists of blocking the function of the viral neuraminidase protein, thus preventing the virus from reproducing.

Neurasthenia

A condition with symptoms of fatigue, anxiety, headache, impotence and neuralgia.

Neurasthenic

A substance used to treat nerve pain and/or weakness (i.e. neuralgia, sciatica, etc.).

Neurectomy

Surgical cutting through or removal of a nerve or a section of a nerve.

Neurite

Refers to any projection from the cell body of a neuron.

Neuritis

An inflammation of the nerve characterised by pain, sensory disturbances and impairment of reflexes. *adj* . neuritic.

Neuritogenesis

The formation of neuritis. *a dj* . neuritogenic.

Neuroblastoma

A common extracranial cancer that forms in nerve tissues, common in infancy.

Neuroendocrine

Adj . Of, relating to or involving the interaction between the nervous system and the hormones of the endocrine glands.

Neurogenesis

Process by which neurons are generated from neural stem and progenitor cells.

Neurogenic

Originating from the nerves of the nervous system.

Neurolathyrism

Is a neurodegenerative disease that is caused by heavy consumption of *Lathyrus* legumes, resulting in weakness and paralysis of the legs.

Neuroleptic

Refers to the effects on cognition and behaviour of antipsychotic drugs that reduce confusion, delusions, hallucinations and psychomotor agitation in patients with psychoses.

Neuroma

Is a growth or tumour of nerve tissue.

Neuropathy

A collection of disorders that occurs when the peripheral nervous systems are damaged causing pain and numbness in the hands and feet.

Neuropharmacological

Relating to the effects of drugs on the neurosystem.

Neuroradiology

Is a subspecialty of radiology focusing on the diagnosis and characterisation of abnormalities of the central and peripheral nervous system. *adj* . neuroradiologic.

Neurotrophic

Relating to the nutrition and maintenance of nervous tissue (neurons).

Neutropenia

A disorder of the blood, characterised by abnormally low levels of neutrophils.

Neutrophil

Type of white blood cell, specifically a form of granulocyte.

Neutrophin

Protein that induces the survival, development and function of neurons.

NF-kappa B (NF-kB)

Nuclear factor kappa B, is an ubiquitous rapid-response transcription factor in cells involved in immune and inflammatory reactions.

Niacin

Vitamin B3. See vitamin B3.

Niacinamide

An amide of niacin, also known as nicotinamide. See vitamin B3.

NIH3T3 cells

A mouse embryonic fibroblast cell line used in the cultivation of keratinocytes.

Nidation

Implantation.

Niosomes

Are novel, vesicular drug delivery systems composed of non-ionic surfactants instead of phospholipids; they are capable of entrapping hydrophilic and hydrophobic drugs.

Nitrogen (N)

Is an essential building block of amino and nucleic acids and proteins and is essential to all living organisms. Protein-rich vegetables like legumes are rich food sources of nitrogen.

NK cells

Natural killer cells, a type of cytotoxic lymphocyte that constitute a major component of the innate immune system.

NK1.1+ T (NKT) cells

A type of natural killer T (NKT) cells. See natural killer T cells.

NMDA receptor

N-methyl- D -aspartate receptor, the predominant molecular device for controlling synaptic plasticity and memory function. A brain receptor activated by the amino acid glutamate, which, when excessively stimulated, may cause cognitive defects in Alzheimer's disease.

Nociceptive

Causing pain, responding to a painful stimulus.

Nociceptors

Specialised peripheral sensory neurons that respond to potentially damaging stimuli by sending nerve signals to the spinal cord and brain.

Non-osteogenic

Fibromata of bone, a benign tumour of bone which shows no evidence of ossification.

Non-alcoholic fatty liver disease

One cause of a fatty liver, occurring when fat is deposited (steatosis) in the liver not due to excessive alcohol use.

Nootropics

Are substances which are claimed to boost human cognitive abilities (the functions and capacities of the brain). Also popularly referred to as 'smart drugs', 'smart nutrients', 'cognitive enhancers' and 'brain enhancers'.

Noradrenalin

See Norepinephrine.

Norepinephrine

A substance, both a hormone and neurotransmitter, secreted by the adrenal medulla and the nerve endings of the sympathetic nervous system to cause vasoconstriction and increases in heart rate, blood pressure and the sugar level of the blood. Also called levarterenol, noradrenalin.

Normoglycaemic

Having the normal amount of glucose in the blood.

Normotensive

Having normal blood pressure.

Nosebo

A harmless substance that, when taken by a patient, is associated with unpleasant or harmful effects due to negative expectations or the psychological state of the person.

Nosocomial infections

Infections which are a result of treatment in a hospital or a health-care service unit but secondary to the patient's original condition.

NPC1L1

Niemann–Pick C1-Like 1 gene that plays a major role in cholesterol homeostasis. It is critical for the uptake of cholesterol across the plasma membrane of the intestinal enterocyte.

Nrf2

Nuclear erythroid 2-related factor 2, a transcription factor that activates ARE-containing genes.

Nrf2/ARE pathway

Plays an important role in inducing phase II detoxifying enzymes and antioxidant proteins and has been considered a potential target for cancer chemoprevention because it eliminates harmful reactive oxygen species or reactive intermediates generated from carcinogens.

Nuclear factor erythroid 2-related factor 2 (Nrf2)

A transcription factor that plays a major role in response to oxidative stress by binding to antioxidant-responsive elements that regulate many hepatic phase I and II enzymes as well as hepatic efflux transporters.

Nucleosomes

Fundamental repeating sub-units of all eukaryotic chromatin, consisting of a DNA chain coiled around a core of histones.

Nulliparous

Term used to describe a woman who has never given birth.

Nyctalopia

Night blindness, impaired vision in dim light and in the dark, due to impaired function of certain specialised vision cells.

Nystagmus

Fast, involuntary movements of the eyes.

Nycturia

Excessive urination at night; especially common in older men.

Obsessive–compulsive disorder (OCD)

A common psychiatric disorder defined by the presence of obsessive thoughts and repetitive compulsive actions; self-grooming.

Occludin

A novel integral membrane protein localising at tight junctions. *cf.* tight junction.

Occlusion

Closure or blockage (as of a blood vessel).

Occlusive peripheral arterial disease (PAOD)

Also known as peripheral vascular disease (PVD) or peripheral arterial disease (PAD), refers to the obstruction of large arteries not within the coronary, aortic arch vasculature or brain. PVD can result from atherosclerosis, inflammatory processes leading to stenosis, an embolism or thrombus formation.

Oculomotor nerve

The third of twelve paired cranial nerves.

Odds ratio

A statistical measure of effect size, describing the strength of association or non-independence between two binary data values.

Odontalgia

Toothache. *adj.* odontalgic.

Odontopathy

Any disease of the teeth.

Oedema

See edema.

Oligoarthritis

An inflammation of two, three or four joints.

Oligoasthenoteratozoospermia

Male infertility, refers to the inability of a male to achieve a pregnancy in a fertile female.

Oligonucleosome

A series of nucleosomes.

Oligospermia or oligozoospermia

Refers to semen with a low concentration of sperm, commonly associated with male infertility.

Oliguria

Decreased production of urine.

Oligoanuria

Insufficient urine volume to allow for administration of necessary fluids, etc.

Omega 3 fatty acids

Are essential polyunsaturated fatty acids that have in common a final carbon–carbon double bond in the $n - 3$ position. Dietary sources of omega-3 fatty acids include fish oil and certain plant/nut oils. The three most nutritionally important omega 3 fatty acids are alpha-linolenic acid, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). Research indicates that omega 3 fatty acids are important in health promotion and disease and can help prevent a wide range of medical problems, including cardiovascular disease, depression, asthma and rheumatoid arthritis.

Omega 6 fatty acids

Are essential polyunsaturated fatty acids that have in common a final carbon–carbon double bond in the $n - 6$ position. Omega-6 fatty acids are considered essential fatty acids (EFAs) found in vegetable oils, nuts and seeds. They are essential to human health but cannot be made in the body. Omega-6 fatty acids – found in vegetable oils, nuts and seeds – are a beneficial part of a heart-healthy eating. Omega-6 and omega-3 PUFA play a crucial role in heart and brain function and in normal growth and development. Linoleic acid (LA) is the main omega-6 fatty acid in foods,

accounting for 85–90 % of the dietary omega-6 PUFA. Other omega 6 acids include gamma-linolenic acid or GLA, sometimes called gamoleic acid, eicosadienoic acid, arachidonic acid and docosadienoic acid.

Omega 9 fatty acids

Are not essential polyunsaturated fatty acids that have in common a final carbon–carbon double bond in the $n - 9$ position. Some $n - 9$ s are common components of animal fat and vegetable oil. Two $n - 9$ fatty acids important in industry are oleic acid (18:1, $n - 9$), which is a main component of olive oil, and erucic acid (22:1, $n - 9$), which is found in rapeseed, wallflower seed and mustard seed.

Oncogenes

Genes carried by tumour viruses that are directly and solely responsible for the neoplastic (tumorous) transformation of host cells.

Oncosis

Accidental cell death, also referred to swelling necrosis.

Ophthalmia

Severe inflammation of eyes or the conjunctiva or deeper structures of the eye. Also called ophthalmitis.

Ophthalmia (sympathetic)

Inflammation of both eyes following trauma to one eye.

Ophthalmopathy

An autoimmune disease where the thyroid gland is overactive leading to ocular manifestations.

Opiate

Drug derived from the opium plant.

Opioid receptors

A group of G-protein-coupled receptors located in the brain and various organs that bind opiates or opioid substances.

Oppilation

Obstruction, particularly of the lower intestines.

Optic placode

An ectodermal placode from which the lens of the embryonic eye develops; also called lens placode.

ORAC (oxygen radical absorbance capacity)

A method of measuring antioxidant capacities in biological samples.

Oral submucous fibrosis

A chronic debilitating disease of the oral cavity characterised by inflammation and progressive fibrosis of the sub-mucosa tissues.

Oral thrush

An infection of yeast fungus, *Candida albicans* , in the mucous membranes of the mouth.

Orchidectomy

Surgery to remove one or both testicles.

Orchidectomised

With testis removed.

Orchitis

An acute painful inflammatory reaction of the testis secondary to infection by different bacteria and viruses.

Orexigenic

Increasing or stimulating the appetite.

Orofacial dyskinesia

Abnormal involuntary movements involving muscles of the face, mouth, tongue, eyes and, occasionally, the neck – may be unilateral or bilateral and constant or intermittent.

Oropharyngeal

Relating to the oropharynx.

Oropharynx

Part of the pharynx between the soft palate and the epiglottis.

Osmophobia

A fear, aversion or psychological hypersensitivity to odours.

Ostalgia, ostealgia

Pain in the bones. Also called osteodynia.

Osteoarthritis

Is the deterioration of the joints that becomes more common with age.

Osteoarthrosis

Chronic non-inflammatory bone disease.

Osteoblast

A mononucleate cell that is responsible for bone formation.

Osteoblastic

Relating to osteoblasts.

Osteocalcin

A non-collagenous protein found in bone and dentin, also referred to as bone gamma-carboxyglutamic acid-containing protein.

Osteoclasts

A kind of bone cell that removes bone tissue by removing its mineralised matrix.

Osteoclastogenesis

The production of osteoclasts.

Osteodynia

Pain in the bone.

Osteogenic

Derived from or composed of any tissue concerned in bone growth or repair.

Osteomalacia

Refers to the softening of the bones due to defective bone mineralisation.

Osteomyelofibrosis

A myeloproliferative disorder in which fibrosis and sclerosis finally lead to bone marrow obliteration.

Osteopenia

Reduction in bone mass, usually caused by a lowered rate of formation of new bone that is insufficient to keep up with the rate of bone destruction.

Osteoporosis

A disease of bone that leads to an increased risk of fracture.

Osteoprotegerin

Also called osteoclastogenesis inhibitory factor (OCIF), a cytokine which can inhibit the production of osteoclasts.

Osteosarcoma

A malignant bone tumour. Also called osteogenic sarcoma.

Otalgia

Earache, pain in the ear.

Otic placode

A thickening of the ectoderm on the outer surface of a developing embryo from which the ear develops.

Otitis

Inflammation of the inner or outer parts of the ear.

Otitis media

Inflammation of the middle ear.

Otorrhoea

Running drainage (discharge) exiting the ear.

Otopathy

Disease of the ear.

Ovariectomised

With one or two ovaries removed.

Ovariectomy

Surgical removal of one or both ovaries.

Oxidation

The process of adding oxygen to a compound, dehydrogenation or increasing the electro-negative charge.

Oxidoreductase activity

Catalysis of an oxidation–reduction (redox) reaction, a reversible chemical reaction. One substrate acts as a hydrogen or electron donor and becomes oxidised, while the other acts as hydrogen or electron acceptor and becomes reduced.

Oxygen radical absorbance capacity (ORAC)

A method of measuring antioxidant capacities in biological samples.

Oxytocic

Adj . Hastening or facilitating childbirth, especially by stimulating contractions of the uterus.

Oxytocin

Is a mammalian **hormone** that also acts as a **neurotransmitter** in the **brain** . It is best known for its roles in female reproduction: It is released in large amounts after distension of the **cervix** and **vagina** during labour and after stimulation of the **nipples** , facilitating **birth** and **breastfeeding** , respectively.

Oxyuriasis

Infestation by pinworms.

Ozoena

Discharge of the nostrils caused by chronic inflammation of the nostrils.

p.o.

Per os, oral administration.

P-glycoprotein (P-gp, ABCB1, MDR1)

A cell membrane-associated drug-exporting protein that transports a variety of drug substrates from cancer cells.

P-selectin

Also known as CD62P, GMP-140, LSECAM-3, PADGEM, a member of the selectin family. It is expressed by activated platelets and endothelial cells.

P65 transcription factor

Is a protein that in humans is encoded by the RELA gene. Its alternative name is nuclear factor NF-kappa-B p65 sub-unit.

P300/CBP

Are transcriptional co-activators that play critical roles in integrating multiple signal-dependent transcription events and may have specific roles in tumour suppression pathways.

p21waf1/cip1

Encodes a cyclin-dependent kinase inhibitor that is transcriptionally activated by the p53 tumour suppressor gene, transforming growth factor beta 1 (TGF-beta 1), AP2 and other pathways, all regulating apoptosis and the cell cycle.

Palliative

Relieving pain without alleviating the underlying problem.

Palinostmia

Olfactory preservation.

Palpebral ptosis

The abnormal drooping of the upper lid, caused by partial or total reduction in levator muscle function.

Palpitation

Rapid pulsation or throbbing of the heart.

Paludism

State of having symptoms of malaria characterised by high fever and chills.

Pancreatectomised

Having undergone a pancreatectomy.

Pancreatectomy

Surgical removal of all or part of the pancreas.

Pancreatitis

Inflammation of the pancreas.

Pancytopenia

A haematological condition in which there is a reduction in the number of red and white blood cells as well as platelets.

Pantothenic acid

Vitamin B5. See vitamin B5.

Papain

A protein-degrading enzyme used medicinally and to tenderise meat.

Papilloma

A benign epithelial tumour growing outwardly like in finger-like fronds.

Papule

A small, solid, usually inflammatory elevation of the skin that does not contain pus.

Paradontosis

Is the inflammation of gums and other deeper structures, including the bone.

Parageusia

Abnormal sense of taste.

Paralytic

Person affected with paralysis, pertaining to paralysis.

Paraoxonase

An enzyme that protects against oxidation of low-density lipoprotein and affects the risk of coronary artery disease.

Paraplegia

An impairment in motor or sensory function of the lower extremities.

Parasitemia

Presence of parasites in blood. *adj* . parasitemic.

Parasympathetic nervous system

Sub-system of the nervous system that slows the heart rate, increases intestinal and gland activity and relaxes the sphincter muscles.

Parasympathomimetic

Having an action resembling that caused by stimulation of the parasympathetic nervous system.

Parenteral administration

Administration by intravenous, subcutaneous or intramuscular routes .

Paresis

A condition characterised by partial loss of movement or impaired movement.

Paresthesia

A sensation of tingling, burning, pricking or numbness of a person's skin with no apparent long-term physical effect. Also known as 'pins and needles'.

Parotitis

Inflammation of salivary glands.

Paroxysm

A sudden outburst of emotion or action, a sudden attack, recurrence or intensification of a disease.

Paroxysmic

Relating to an abnormal event of the body with an abrupt onset and an equally sudden return to normal.

PARP

See poly (ADP-ribose) polymerase.

Pars compacta

Is a portion of the substantia nigra (a brain structure located in the midbrain).

Parturition

Act of childbirth.

Pathognomonic

Distinctively characteristic of a particular disease.

PCAF

P300/CBP-associated factor, a histone acetyl transferase (HAT) that plays an important role in the remodelling of chromatin and the regulation of gene expression, transcription, cell cycle progression and differentiation.

PCE/PCN ratio

Polychromatic erythrocyte/normochromatic erythrocyte ratio use as a measure of cytotoxic effects.

PCNA

Proliferating cell nuclear antigen, an auxiliary protein of DNA polymerase delta involved in modulating eukaryotic DNA replication.

pCREB

Phosphorylated cAMP (adenosine 3'5' cyclic monophosphate)-response element binding protein.

PDEF

Acronym for prostate-derived ETS factor, an ETS (epithelial-specific E26 transforming sequence) family member that has been identified as a potential tumour suppressor.

PDGR receptor (platelet-derived growth factor receptor)

Are cell surface tyrosine kinase receptors for members of the platelet-derived growth factor (PDGF) family.

PDGFs

Platelet-derived growth factors constitute a group of growth factors that play a significant role in blood vessel formation and the growth of blood vessels.

Pectoral

Pertaining to or used for the chest and respiratory tract.

pERK

Phosphorylated extracellular signal-regulated kinase, protein kinases involved in many cell functions.

P53

Also known as protein 53 or tumour protein 53, is a tumour suppressor protein that in humans is encoded by the TP53 gene.

Peliosis

See purpura.

Pellagra

Is a systemic nutritional wasting disease caused by a deficiency of vitamin B3 (niacin).

Pemphigus

Describes a group of autoimmune disorders in which there is blistering of the skin and/or mucosal surfaces.

Pemphigus neonatorum

Staphylococcal scalded skin syndrome, a bacterial disease of infants, characterised by elevated vesicles or blebs on a normal or reddened skin.

Peptic ulcer

A sore in the lining of the stomach or duodenum, the first part of the small intestine.

Peptide YY

A short (36 amino acid) pancreatic protein released by cells in the ileum and colon in response to feeding.

Percutaneous

Pertains to a medical procedure where access to inner organs or tissues is via needle puncture of the skin.

Perfusion

To force fluid through the lymphatic system or blood vessels to an organ or tissue.

Periapical periodontitis

Is the inflammation of the tissue adjacent to the tip of the tooth's root.

Perifuse

To flush a fresh supply of bathing fluid around all of the outside surfaces of a small piece of tissue immersed in it.

Perilipins

Highly phosphorylated adipocyte proteins that are localised at the surface of the lipid droplet.

Perimenopause

Is the phase before menopause actually takes place, when ovarian hormone production is declining and fluctuating.
adj . perimenopausal.

Perineum

The region between the thighs inferior to the pelvic diaphragm.

Perineal

Pertaining to the perineum.

Periodontal ligament (PDL)

Is a group of specialised connective tissue fibres that essentially attach a tooth to the bony socket.

Periodontitis

Is a severe form of gingivitis in which the inflammation of the gums extends to the supporting structures of the tooth.
Also called pyorrhoea.

Perioral paresthesias

Are sensations of numbness and tingling around the mouth.

Peripheral arterial disease (PAD)

Is a disease in which plaque builds up in the arteries that carry blood to your head, organs and limbs.

Peripheral neuropathy

Refers to damage to nerves of the peripheral nervous system.

Peripheral neuropathic pain (PNP)

Refers to situations where nerve roots or peripheral nerve trunks have been damaged by mechanical and/or chemical stimuli that exceeded the physical capabilities of the nervous system. Symptoms may include pain, paresthesia, dysesthesia, spasm, weakness, hypoesthesia or anesthesia.

Peripheral vascular disease (PVD)

See peripheral artery occlusive disease.

Peristalsis

A series of organised, wave-like muscle contractions that occur throughout the digestive tract.

PERK

A trans-membrane protein kinase of the PEK family resident in the endoplasmic reticulum (ER) membrane and linked to insulin processing.

Perlingual

Through or by way of the tongue.

Perniosis

An abnormal reaction to cold that occurs most frequently in women, children and the elderly. Also called chilblains.

Per os (P.O.)

Oral administration.

Peroxisome proliferator-activated receptors (PPARs)

A family of nuclear receptors that are involved in lipid metabolism, differentiation, proliferation, cell death and inflammation.

Peroxisome proliferator-activated receptor alpha (PPAR-alpha)

A nuclear receptor protein, transcription factor and a major regulator of lipid metabolism in the liver.

Peroxisome proliferator-activated receptor gamma (PPAR- γ)

A type-II nuclear receptor protein that regulates fatty acid storage and glucose metabolism.

Pertussis

Whooping cough, severe cough.

Peyers patches

Patches of lymphoid tissue or lymphoid nodules on the walls of the ileal-small intestine.

PGE-2

Prostaglandin E2, a hormone-like substance that is released by blood vessel walls in response to infection or inflammation that acts on the brain to induce fever.

Phagocytes

Are the white blood cells that protect the body by ingesting (phagocytosing) harmful foreign particles, bacteria and dead or dying cells. *adj* . phagocytic.

Phagocytosis

Is process the human body uses to destroy dead or foreign cells.

Phantosmia

A form of olfactory hallucination.

Pharmacognosis

The branch of pharmacology that studies the composition, use and history of drugs.

Pharmacodynamics

Branch of pharmacology dealing with the effects of drugs and the mechanism of their action.

Pharmacokinetics

Branch of pharmacology concerned with the movement of drugs within the body including processes of absorption, distribution, metabolism and excretion in the body.

Pharmacopoeia

Authoritative treatise containing directions for the identification of drug samples and the preparation of compound medicines and published by the authority of a government or a medical or pharmaceutical society and in a broader sense a general reference work for pharmaceutical drug specifications.

Pharyngitis, pharyngolaryngitis

Inflammation of the pharynx and the larynx.

Pharyngolaryngeal

Pertaining to the pharynx and larynx.

Phase-II drug-metabolising enzymes

Play an important role in biotransformation of endogenous compounds and xenobiotics to more easily excretable forms as well as in the metabolic inactivation of pharmacologically active compounds. Phase-II drug-metabolising enzymes are mainly transferases.

Phenolics

Class of chemical compounds consisting of a hydroxyl group (-OH) bonded directly to an aromatic hydrocarbon group.

Pheochromocytoma

Is a rare neuroendocrine tumour that usually originates from the adrenal glands' chromaffin cells, causing

overproduction of catecholamines, powerful hormones that induce high blood pressure and other symptoms.

Phlebitis

Is an inflammation of a vein, usually in the legs.

Phlegm

Abnormally viscid mucus secreted by the mucosa of the respiratory passages during certain infectious processes.

Phlegmon

A spreading, diffuse inflammation of the soft or connective tissue due to infection by *Streptococci* bacteria.

Phonophobia

Fear of loud sound.

Phoroglucinol

A white, crystalline compound used as an antispasmodic, analytical reagent and decalcifier of bone specimens for microscopic examination.

Phosphatidylglycerol

Is a glycerophospholipid found in pulmonary active surface lipoprotein and consists of a L -glycerol 3-phosphate backbone ester-bonded to either saturated or unsaturated fatty acids on carbons 1 and 2.

Phosphatidylinositol 3-kinases (PI 3-kinases or PI3Ks)

A group of enzymes involved in cellular functions such as cell growth, proliferation, differentiation, motility, survival and intracellular trafficking, which in turn are involved in cancer.

Phosphatidylserine

A phosphoglyceride phospholipid that is one of the key building blocks of cellular membranes, particularly in the nervous system. It is derived from soy lecithin.

Phosphaturia

A urinary tract condition of excessive urine phosphorus, causing urine to appear cloudy or murky coloured; also called hypophosphatemia.

Phosphodiesterases

A diverse family of enzymes that hydrolyse cyclic nucleotides and thus play a key role in regulating intracellular levels of the second messengers cAMP and cGMP and hence cell function.

Phosphoenolpyruvate C kinase (PEPCK)

An enzyme in the lyase family used in the metabolic pathway of gluconeogenesis.

Phospholipase

An enzyme that hydrolyses phospholipids into fatty acids and other lipophilic substances.

Phospholipase A2 (PLA2)

A small lipolytic enzyme that releases fatty acids from the second carbon group of glycerol. Plays an essential role in the synthesis of prostaglandins and leukotrienes.

Phospholipase C

Enzyme that cleaves phospholipase.

Phospholipase C gamma (PLC gamma)

Enzyme that cleaves phospholipase in cellular proliferation and differentiation, and its enzymatic activity is upregulated by a variety of growth factors and hormones.

Phosphorus (P)

Is an essential mineral that makes up 1 % of a person's total body weight and is found in the bones and teeth. It plays an important role in the body's utilisation of carbohydrates and fats in the synthesis of protein for the growth, maintenance and repair of cells and tissues. It is also crucial for the production of ATP, a molecule the body uses to store energy. Main sources are meat and milk; fruits and vegetables provide small amounts.

Photoaging

Is the term that describes damage to the skin caused by intense and chronic exposure to sunlight resulting in premature aging of the skin.

Photocarcinogenesis

Represents the sum of a complex of simultaneous and sequential biochemical events that ultimately lead to the occurrence of skin cancer caused by exposure to the sun.

Photodermatoses

Skin disorders caused by exposure to sunlight.

Photophobia

Abnormal visual intolerance to light.

Photopsia

An affection of the eye in which the patient perceives luminous rays, flashes, coruscations, etc.

Photosensitivity

Sensitivity towards light.

Phthisis

An archaic name for tuberculosis.

Phytohaemagglutinin

A lectin found in plants that is involved in the stimulation of lymphocyte proliferation.

Phytonutrients

Certain organic components of plants that are thought to promote human health. Fruit, vegetables, grains, legumes, nuts and teas are rich sources of phytonutrients. Phytonutrients are not 'essential' for life. Also called phytochemicals.

Phytosterols

A group of steroid alcohols, cholesterol-like phytochemicals naturally occurring in plants like vegetable oils, nuts and legumes.

Pica

The persistent eating of substances with no nutrition, such as dirt, chalk, sand, ice, clay or paint.

Piebaldism

Rare autosomal dominant disorder of melanocyte development characterised by distinct patches of skin and hair that contain no pigment.

Piles

See haemorrhoids.

PI3K

Phosphoinositide 3-kinase.

PI3K/AKT signalling pathways

Are involved in the modulation of cell survival, cell cycle progression and cellular growth in cancer.

Pityriasis lichenoides

Is a rare skin disorder of unknown aetiology characterised by multiple papules and plaques.

PKC

Protein kinase C, a membrane-bound enzyme that phosphorylates different intracellular proteins and raises intracellular Ca levels.

PKC delta inhibitors

Protein kinase C delta inhibitors that induce apoptosis of haematopoietic cell lines.

Placebo

A sham or simulated medical intervention.

Placode

A platelike epithelial thickening in the embryo where some organ or structure later develops.

Plantar verruca

Wart occurring on the sole of the foot.

Plasma

The yellow-coloured liquid component of blood in which blood cells are suspended.

Plasma kallikrein

A serine protease, synthesised in the liver and circulating in the plasma.

Plasmalemma

Plasma membrane.

Plasmin

A proteinase enzyme that is responsible for digesting fibrin in blood clots.

Plasminogen

The proenzyme of plasmin, whose primary role is the degradation of fibrin in the vasculature.

Plasminogen activator inhibitor-1 (PAI-1)

Also known as endothelial plasminogen activator inhibitor or serpin E1, is a serine protease inhibitor (serpin) that functions as the principal inhibitor of tissue plasminogen activator (tPA) and urokinase (uPA), the activators of plasminogen and hence fibrinolysis (the physiological breakdown of blood clots).

Plaster

Poultice.

Platelet-activating factor (PAF)

Is an acetylated derivative of glycerophosphorylcholine, released by basophils and mast cells in immediate hypersensitive reactions and macrophages and neutrophils in other inflammatory reactions. One of its main effects is to induce platelet aggregation.

Platelet-derived growth factor (PDGF)

Is one of the numerous growth factors or proteins that regulate cell growth and division.

PLC gamma

Phospholipase C gamma plays a central role in signal transduction.

Pleurisy

Is an inflammation of the pleura, the lining of the pleural cavity surrounding the lungs, which can cause painful respiration and other symptoms. Also known as pleuritis.

Pneumonia

An inflammatory illness of the lung caused by bacteria or viruses.

Pneumotoxicity

Damage to lung tissues.

Poliomyelitis

Is a highly infectious viral disease that may attack the central nervous system and is characterised by symptoms that range from a mild non-paralytic infection to total paralysis in a matter of hours; also called polio or infantile paralysis.

Poly (ADP-ribose) polymerase (PARP)

A protein involved in a number of cellular processes, especially DNA repair and programmed cell death.

Polyarthritis

Is any type of arthritis which involves five or more joints.

Polychromatic erythrocyte (PCE)

An immature red blood cell containing RNA that can be differentiated by appropriate staining techniques from a normochromatic erythrocyte (NCE) which lacks RNA.

Polycystic kidney disease

Is a kidney disorder passed down through families in which multiple cysts form on the kidneys, causing them to become enlarged.

Polycystic ovary syndrome

Imbalance of woman's sex hormone; this imbalance may cause changes in menstrual cycle, skin changes, small cysts in the ovary and problems in getting pregnant.

Polycythaemia

A type of blood disorder characterised by the production of too many red blood cells.

Polymorphonuclear

Having a lobed nucleus. Used especially of neutrophilic white blood cells.

Polyneuritis

Widespread inflammation of the nerves.

Polyneuritis gallinarum

A nervous disorder in birds and poultry.

Polyneuropathy

Simultaneous malfunction of many peripheral nerves throughout the body.

Polyp

A growth that protrudes from a mucous membrane.

Polyphagia

Medical term for excessive hunger or eating.

Polyposis

Describes a condition where there are a lot of polyps.

PolyQ disease

Polyglutamine repeat diseases are neurodegenerative ailments elicited by glutamine-encoding CAG nucleotide expansions within endogenous human genes.

Polyuria

A condition characterised by the passage of large volumes of urine with an increase in urinary frequency.

Pomade

A thick oily dressing.

Porphyria

A disorder wherein the body cannot convert naturally occurring compounds (prophyrins) into haem, which contains iron.

Porphyrin

Any of a class of water-soluble, nitrogenous biological pigments, derivatives of which include the haemoproteins.

Postherpetic neuralgia (PHN)

Is neuralgia (pain in the nerves) caused by the varicella herpes zoster virus. The pain may last for more than a month or more after a shingles infection occurred.

Postpartum depression

Depression after pregnancy; also called postnatal depression.

Postprandial

After mealtime.

Potassium (K)

Is an element that's essential for the body's growth and maintenance. It's necessary to keep a normal water balance between the cells and body fluids for cellular enzyme activities and plays an essential role in the response of nerves to stimulation and in the contraction of muscles. Potassium is found in many plant foods and fish (tuna, halibut): chard, mushrooms, spinach, fennel, kale, mustard greens, Brussels sprouts, broccoli, cauliflower, cabbage, winter squash, eggplant, cantaloupe, tomatoes, parsley, cucumber, bell pepper, turmeric, ginger root, apricots, strawberries, avocado and banana.

Poultice

Is a soft moist mass, often heated and medicated, that is spread on cloth over the skin to treat an aching, inflamed or painful part of the body. Also called cataplasm.

PPARs

Peroxisome proliferator-activated receptors – a group of nuclear receptor proteins that function as transcription factors regulating the expression of genes.

PR interval

Is the time (in seconds) from the beginning of the P wave (onset of atrial depolarisation) to the beginning of the QRS complex.

Prebiotics

A category of functional food, defined as non-digestible food ingredients that beneficially affect the host by selectively stimulating the growth and/or activity of one or a limited number of bacteria in the colon and thus improve host health. *cf.* probiotics.

Pre-eclampsia

Toxic condition of pregnancy characterised by high blood pressure, abnormal weight gain, proteinuria and oedema.

Prenidatory phase

Pre-implantation phase.

Prepubertal

Before puberty; pertaining to the period of accelerated growth preceding gonadal maturity.

Pregnane X receptor (PXR; NR1I2)

Is a ligand-activated transcription factor that plays a role not only in drug metabolism and transport but also in various other biological processes.

Pregnenolone

A steroid hormone produced by the adrenal glands, involved in the steroidogenesis of other steroid hormones like progesterone, mineralocorticoids, glucocorticoids, androgens and oestrogens.

Prenidatory

Referring to the time period between fertilisation and implantation.

Prenylated flavones

Flavones with an isoprenyl group in the 8-position, has been reported to have good anti-inflammatory properties.

Presyncopal sensation

State consisting of lightheadedness, muscular weakness, blurred vision and feeling faint.

Primiparous

Relating to a woman who has given birth once.

Proangiogenic

Promote angiogenesis (formation and development of new blood vessels).

Probiotication

Enhancement with beneficial probiotic bacteria such as *Lactobacillus* species that can prevent the growth of intestinal pathogenic microflora.

Probiotics

Are dietary supplements and live microorganisms containing potentially beneficial bacteria or yeasts that are taken into the alimentary system for healthy intestinal functions. *cf.* prebiotics.

Proctitis

An inflammation of the rectum that causes discomfort, bleeding and, occasionally, a discharge of mucus or pus.

Procyanidin

Also known as proanthocyanidin, oligomeric proanthocyanidin, leukocyanidin, leucoanthocyanin, is a class of flavanols found in many plants. It has antioxidant activity and plays a role in the stabilisation of collagen and maintenance of elastin.

Progestational

Of or relating to the phase of the menstrual cycle immediately following ovulation, characterised by secretion of progesterone.

Proglottid

One of the segments of a tapeworm.

Prognosis

Medical term to describe the likely outcome of an illness.

Prokinetic

Or gastroprokinetic, substance that enhances gastrointestinal motility by increasing the frequency of contractions in the small intestine or making them stronger.

Prolactin

A hormone produced by the pituitary gland, it stimulates the breasts to produce milk in pregnant women. It is also present in males, but its role is not well understood.

Prolapse

A common condition where the bladder, uterus and/or bowel protrudes into the vagina.

Prolapsus

To fall or slip out of place.

Prolapsus ani

Eversion of the lower portion of the rectum and protruding through the anus, common in infancy and old age.

Proliferating cell nuclear antigen (PCNA)

A new marker to study human colonic cell proliferation.

Proliferative vitreoretinopathy (PVR)

A most common cause of failure in retinal reattachment surgery, characterised by the formation of cellular membrane on both surfaces of the retina and in the vitreous.

Prolyl-4-hydroxylase (P4H)

Key enzyme in collagen synthesis.

Promastigote

The flagellate stage in the development of trypanosomatid protozoa, characterised by a free anterior flagellum.

Promyelocytic leukaemia

A subtype of acute myelogenous leukaemia (AML), a cancer of the blood and bone marrow.

Pro-oxidants

Chemicals that induce oxidative stress, either through creating reactive oxygen species or inhibiting antioxidant systems.

Prophylaxis

Prevention or protection against disease.

Proptosis

See exophthalmos.

Prostacyclin

A prostaglandin that is a metabolite of arachidonic acid, inhibits platelet aggregation and dilates blood vessels.

Prostaglandins

A family of C 20 lipid compounds found in various tissues, associated with muscular contraction and the inflammation response such as swelling, pain, stiffness, redness and warmth.

Prostaglandin E2 (PEG -2)

One of the prostaglandins, a group of hormone-like substances that participate in a wide range of body functions such as the contraction and relaxation of smooth muscle, the dilation and constriction of blood vessels, control of blood pressure and modulation of inflammation.

Prostaglandin E synthase

An enzyme that in humans is encoded by the glutathione-dependent PTGES gene.

Prostanoids

Term used to describe a sub-class of eicosanoids (products of COX pathway) consisting of the prostaglandins (mediators

of inflammatory and anaphylactic reactions), the thromboxanes (mediators of vasoconstriction) and the prostacyclins (active in the resolution phase of inflammation.)

Prostanoid EP 4

A prostaglandin receptor that may be involved in the neonatal adaptation of circulatory system, osteoporosis as well as initiation of skin immune responses.

Prostate

A gland that surrounds the urethra at the bladder in the male.

Prostate cancer

A disease in which cancer develops in the prostate, a gland in the male reproductive system. Symptoms include pain, difficulty in urinating, erectile dysfunction and other symptoms.

Prostate-specific antigen (PSA)

A protein produced by the cells of the prostate gland.

Protein kinase C (PKC)

A family of enzymes involved in controlling the function of other proteins through the phosphorylation of hydroxyl groups of serine and threonine amino acid residues on these proteins. PKC enzymes play important roles in several signal transduction cascades.

Protein tyrosine phosphatase (PTP)

A group of enzymes that remove phosphate groups from phosphorylated tyrosine residues on proteins.

Proteinase

A protease (enzyme) involved in the hydrolytic breakdown of proteins, usually by splitting them into polypeptide chains.

Proteinuria

Means the presence of an excess of serum proteins in the urine.

Proteolysis

Cleavage of the peptide bonds in protein forming smaller polypeptides. *adj* . proteolytic.

Proteomics

The large-scale study of proteins, particularly their structures and functions.

Prothrombin

Blood-clotting protein that is converted to the active form, factor IIa, or thrombin, by cleavage.

Prothyroid

Good for thyroid function.

Protheolithic

Proteolytic, see proteolysis.

Proto-oncogene

A normal gene which, when altered by mutation, becomes an oncogene that can contribute to cancer.

Prurigo

A general term used to describe itchy eruptions of the skin.

Pruritis

Defined as an unpleasant sensation on the skin that provokes the desire to rub or scratch the area to obtain relief; itch, itching. *adj* . pruritic.

PSA

Prostate-specific antigen, a protein which is secreted into ejaculate fluid by the healthy prostate. One of its functions is to aid sperm movement.

Psoriasis

A common chronic, non-contagious autoimmune dermatosis that affects the skin and joints.

Psychoactive

Having effects on the mind or behaviour.

Psychonautics

Exploration of the psyche by means of approaches such as meditation, prayer, lucid dreaming, brain wave entrainment, etc.

Psychotomimetic

Hallucinogenic.

Psychotropic

Capable of affecting the mind, emotions and behaviour.

PTEN

Phosphatase and tensin homologue, a tumour suppressor gene.

Ptosis

Also known as drooping eyelid; caused by weakness of the eyelid muscle and damage to the nerves that control the muscles or looseness of the skin of the upper eyelid.

P13-K

Is a lipid kinase enzyme involved in the regulation of a number of cellular functions such as cell growth, proliferation, differentiation, motility, survival and intracellular trafficking, which in turn are involved in cancer.

P13-K/AKT signalling pathway

Shown to be important for an extremely diverse array of cellular activities – most notably cellular proliferation and survival.

Pthysis

Silicosis with tuberculosis.

Ptosis

Drooping of the upper eye lid.

PTP

Protein tyrosine phosphatase.

PTPIB

Protein tyrosine phosphatase 1B.

P21

Also known as cyclin-dependent kinase inhibitor 1 or CDK-interacting protein 1, is a potent cyclin-dependent kinase inhibitor.

Puerperal

Pertaining to childbirth.

Puerperium

Post-partum period.

Pulmonary embolism

A blockage (blood clot) of the main artery of the lung.

Purgative

A substance used to cleanse or purge, especially causing the immediate evacuation of the bowel.

Purpura

Is the appearance of red or purple discolorations on the skin that do not blanch on applying pressure. Also called peliosis.

Purulent

Containing pus discharge.

Purulent sputum

Sputum containing or consisting of pus.

Pustule

Small, inflamed, pus-filled lesions.

Pyelitis

Acute inflammation of the pelvis of the kidney caused by bacterial infection.

Pyelonephritis

An ascending urinary tract infection that has reached the pyelum (pelvis) of the kidney.

Pyoderma

Bacterial skin infection.

Pyodermatitis

Refers to inflammation of the skin.

Pyorrhoea

See periodontitis.

Pyretic

Referring to fever.

Pyrexia

Fever of unknown origin.

Pyridoxal

A chemical form of vitamin B6. See vitamin B6.

Pyridoxamine

A chemical form of vitamin B6. See vitamin B6.

Pyridoxine

A chemical form of vitamin B6. See vitamin B6.

Pyrolysis

Decomposition or transformation of a compound caused by heat. *adj* . pyrolytic.

PYY peptide

A 36 amino acid peptide secreted by L cells of the distal small intestine and colon that inhibits gastric and pancreatic secretion.

QSR complex

Series of deflections in an electrocardiogram that represent electrical activity generated by ventricular depolarisation prior to contraction of the ventricle.

QT interval

Is a measure of the time between the start of the Q wave and the end of the T wave in the heart's electrical cycle. A

prolonged QT interval is a biomarker for ventricular tachyarrhythmias and a risk factor for sudden death.

Quorum sensing (QS)

The control of gene expression in response to cell density, is used by both gram-negative and gram-positive bacteria to regulate a variety of physiological functions.

Radiculitis

Inflammation of the radicle of a nerve.

Radiodermatitis

A skin disease associated with prolonged exposure to ionising radiation.

Radiolysis

The dissociation of molecules by radiation.

Radioprotective

Serving to protect or aiding in protecting against the injurious effect of radiations.

RAD23B

UV excision repair protein RAD23 homologue B.

RAGE

Is the receptor for advanced glycation end products, a multiligand receptor that propagates cellular dysfunction in several inflammatory disorders, in tumours and in diabetes.

RAS

See renin-angiotensin system or recurrent aphthous stomatitis.

Rash

A temporary eruption on the skin, see urticaria.

Reactive oxygen species

Species such as superoxide, hydrogen peroxide and hydroxyl radical. At low levels, these species may function in cell signalling processes. At higher levels, these species may

damage cellular macromolecules (such as DNA and RNA) and participate in apoptosis (programmed cell death).

Rec A

Is a 38 kDa *Escherichia coli* protein essential for the repair and maintenance of DNA.

Receptor for advanced glycation end products (RAGE)

Is a member of the immunoglobulin superfamily of cell surface molecules; mediates neurite outgrowth and cell migration upon stimulation with its ligand, amphoterin.

Reticulocyte

Non-nucleated stage in the development of the red blood cell.

Reticulocyte lysate

Cell lysate produced from reticulocytes, used as an in-vitro translation system.

Reticuloendothelial system

Part of the immune system, consists of the phagocytic cells located in reticular connective tissue, primarily monocytes and macrophages.

Recurrent aphthous stomatitis, or RAS

Is a common, painful condition in which recurring ovoid or round ulcers affect the oral mucosa.

Redox homeostasis

Is considered as the cumulative action of all free-radical reactions and antioxidant defenses in different tissues.

Refrigerant

A medicine or an application for allaying heat, fever or its symptoms.

Renal calculi

Kidney stones.

Renal interstitial fibrosis

Damage sustained by the kidneys' renal tubules and interstitial capillaries due to accumulation of extracellular waste in the wall of the small arteries and arterioles.

Renal resistive index (RRI)

Measures the resistance of renal arterial flow to the kidney.

Renin

Also known as an angiotensinogenase, is an enzyme that participates in the body's renin-angiotensin system (RAS).

Renin-angiotensin system (RAS)

Also called the renin-angiotensin-aldosterone system (RAAS), is a hormone system that regulates blood pressure and water (fluid) balance.

Reperfusion

The restoration of blood flow to an organ or tissue that has had its blood supply cut off, as after a heart attack.

Reporter gene

A transfected gene that produces a signal, such as green fluorescence, when it is expressed.

Resistin

A cysteine-rich protein secreted by adipose tissue of mice and rats.

Resolutive

A substance that induces subsidence of inflammation.

Resolvent

Reduces inflammation or swelling.

Respiratory burst

Is the rapid release of reactive oxygen species (superoxide radical and hydrogen peroxide) from different cells.

Resorb

To absorb or assimilate a product of the body such as an exudate or cellular growth.

Restenosis

Is the reoccurrence of stenosis, a narrowing of a blood vessel, leading to restricted blood flow.

Resveratrol

Is a phytoalexin produced naturally by several plants when under attack by pathogens such as bacteria or fungi. It is a potent antioxidant found in red grapes and other plants.

Reticuloendothelial system

Part of the immune system that consists of the phagocytic cells located in reticular connective tissue. Also called macrophage system or mononuclear phagocyte system.

Retinal ischaemia

Is a common cause of visual impairment and blindness.

Retinitis pigmentosa (RP)

An inherited, degenerative eye disease that causes severe vision impairment and may lead to blindness.

Retinol

A form of vitamin A, see vitamin A.

Retinoblastoma protein

A tumour suppressor protein that is dysfunctional in several major cancers.

Retinopathy

A general term that refers to some form of non-inflammatory damage to the retina of the eye.

Revulsive

Counter-irritant, used for swellings.

Reye's syndrome

A potentially fatal disease that has numerous detrimental effects on many organs, especially the brain and liver, occurs commonly in children after a viral infection.

Rhabdomyolysis

Breakdown of muscle fibres leading to the release of muscle fibre content (myoglobin) into the bloodstream.

Rheumatic

Pertaining to rheumatism or to abnormalities of the musculoskeletal system.

Rheumatism, rheumatic disorder, rheumatic diseases

Refers to various painful medical conditions which affect bones, joints, muscles, tendons. Rheumatic diseases are characterised by the signs of inflammation – redness, heat, swelling and pain.

Rheumatoid arthritis (RA)

Is a chronic, systemic autoimmune disorder that most commonly causes inflammation and tissue damage in joints (arthritis) and tendon sheaths, together with anaemia.

Rhinitis

Irritation and inflammation of some internal areas of the nose; the primary symptom of rhinitis is a runny nose.

Rhinopathy

Disease or malformation of the nose.

Rhinoplasty

Is surgery to repair or reshape the nose.

Rhinorrhoea

Commonly known as a runny nose, characterised by an unusually significant amount of nasal discharge.

Rhinosinusitis

Inflammation of the nasal cavity and sinuses.

Rho GTPases

Rho-guanosine triphosphate hydrolase enzymes are molecular switches that regulate many essential cellular processes, including actin dynamics, gene transcription, cell cycle progression and cell adhesion.

Ribosome inactivating proteins

Proteins that are capable of inactivating ribosomes.

Rickets

Is a softening of the bones in children potentially leading to fractures and deformity.

Ringworm

Dermatophytosis, a skin infection caused by fungus.

Roborant

Restoring strength or vigour, a tonic.

Rotavirus

The most common cause of infectious diarrhoea (gastroenteritis) in young children and infants, one of several viruses that causes infections called stomach flu.

Rubefacient

A substance for external application that produces redness of the skin e.g. by causing dilation of the capillaries and an increase in blood.

Ryanodine receptor

Intracellular Ca ++ channels in animal tissues like muscles and neurons.

S.C.

Abbreviation for sub-cutaneous, beneath the layer of skin.

S-T segment

The portion of an electrocardiogram between the end of the QRS complex and the beginning of the T wave. Elevation or depression of the S-T segment is the characteristic of myocardial ischaemia or injury and coronary artery disease.

Salve

Medical ointment used to soothe the head or body surface.

Sapraemia

See septicaemia.

Sarcoma

Cancer of the connective or supportive tissue (bone, cartilage, fat, muscle, blood vessels) and soft tissues.

Sarcopenia

Degenerative loss of skeletal muscle mass and strength associated with ageing.

Sarcoplasmic reticulum

A special type of smooth endoplasmic reticulum found in smooth and striated muscle.

SARS

Severe acute respiratory syndrome, the name of a potentially fatal new respiratory disease in humans which is caused by the SARS coronavirus (SARS-CoV).

Satiety

State of feeling satiated, fully satisfied (appetite or desire).

Scabies

A transmissible ectoparasite skin infection characterised by superficial burrows, intense pruritus (itching) and secondary infection.

Scarlatina

Scarlet fever, an acute, contagious disease caused by infection with group A streptococcal bacteria.

Schwann cells

Or neurolemmocytes, are the principal supporting cells of the peripheral nervous system; they form the myelin sheath of a nerve fibre.

Schistosomiasis

Is a parasitic disease caused by several species of fluke of the genus *Schistosoma*. Also known as bilharzia, bilharziosis or snail fever.

Schizophrenia

A psychotic disorder (or a group of disorders) marked by severely impaired thinking, emotions and behaviours.

Sciatica

A condition characterised by pain deep in the buttock often radiating down the back of the leg along the sciatic nerve.

Scleroderma

A disease of the body's connective tissue. The most common symptom is a thickening and hardening of the skin, particularly of the hands and face.

Scrofula

A tuberculous infection of the skin on the neck caused by the bacterium *Mycobacterium tuberculosis* .

Scrophulosis

See scrofula.

Scurf

Abnormal skin condition in which small flakes or sales become detached.

Scurvy

A state of dietary deficiency of vitamin C (ascorbic acid), which is required for the synthesis of collagen in humans.

Secretagogue

A substance that causes another substance to be secreted.

Sedative

Having a soothing, calming or tranquilising effect; reducing or relieving stress, irritability or excitement.

Seizure

The physical findings or changes in behaviour that occur after an episode of abnormal electrical activity in the brain.

Selectins

Are a family of cell adhesion molecules; e.g. selectin-E, selectin –L, selectin P.

Selenium (Se)

A trace mineral that is essential to good health but required only in tiny amounts; it is incorporated into proteins to make selenoproteins, which are important antioxidant enzymes. It is found in avocado, brazil nut, lentils, sunflower seeds, tomato, whole-grain cereals, seaweed, seafood and meat.

Sensorineural bradyacusia

Hearing impairment of the inner ear resulting from damage to the sensory hair cells or to the nerves that supply the inner ear.

Sepsis

Potentially fatal whole-body inflammation caused by severe infection.

Sequela

An abnormal pathological condition resulting from a disease, injury or trauma.

Serine proteinase

Peptide hydrolases which have an active centre histidine and serine involved in the catalytic process.

Serotonergic

Liberating, activated by or involving serotonin in the transmission of nerve impulses.

Serotonin

A monoamine neurotransmitter synthesised in serotonergic neurons in the central nervous system.

Sepsis

Is a potentially fatal medical condition characterised by a whole-body inflammatory response (called a systemic inflammatory response syndrome or SIRS) that is triggered by an infection.

Septicaemia

A systemic disease associated with the presence and persistence of pathogenic microorganisms or their toxins in the blood.

Sequelae

A pathological condition resulting from a prior disease, injury or attack.

Sexual potentiator

Increases sexual activity and potency and enhances sexual performance due to increased blood flow and efficient metabolism.

Sexually transmitted diseases (STD)

Infections that are transmitted through sexual activity.

SGOT, serum glutamic oxaloacetic transaminase

An enzyme that is normally present in liver and heart cells. SGOT is released into blood when the liver or heart is damaged. Also called aspartate transaminase (AST).

SGPT, serum glutamic pyruvic transaminase

An enzyme normally present in serum and body tissues, especially in the liver; it is released into the serum as a result of tissue injury, also called alanine transaminase (ALT).

Shiga-like toxin

A toxin produced by the bacterium *Escherichia coli* which disrupts the function of ribosomes, also known as verotoxin.

Shiga toxigenic Escherichia coli (STEC)

Comprises a diverse group of organisms capable of causing severe gastrointestinal disease in humans.

Shiga toxin

A toxin produced by the bacterium *Shigella dysenteriae*, which disrupts the function of ribosomes.

Shingles

Skin rash caused by the zoster virus (same virus that causes chickenpox) and is medically termed herpes zoster.

Sialogogue

Salivation promoter, a substance used to increase or promote the excretion of saliva.

Sialoproteins

Glycoproteins that contain sialic acid as one of their carbohydrates.

Sialorrhoea

Excessive production of saliva.

Sialylation

Reaction with sialic acid or its derivatives; used especially with oligosaccharides.

Sialyltransferases

Enzymes that transfer sialic acid to nascent oligosaccharides.

Sickle-cell disease

Is an inherited blood disorder that affects red blood cells.

People with sickle-cell disease have red blood cells that contain mostly haemoglobin S, an abnormal type of haemoglobin. Sometimes, these red blood cells become sickle shaped (crescent shaped) and have difficulty passing through small blood vessels.

Side stitch

Is an intense stabbing pain under the lower edge of the ribcage that occurs while exercising.

Signal transduction cascade

Refers to a series of sequential events that transfer a signal through a series of intermediate molecules until final regulatory molecules, such as transcription factors, are modified in response to the signal.

Silicon (Si)

Is required in minute amounts by the body and is important for the development of healthy hair and the prevention of nervous disorders. Lettuce is the best natural source of silicon.

Sinapism

Signifies an external application, in the form of a soft plaster, or poultice.

Sinusitis

Inflammation of the nasal sinuses.

SIRC cells

Statens seruminstitut rabbit cornea (SIRC) cell line.

SIRT 1

Stands for sirtuin (silent mating type information regulation 2 homologue) 1. It is an enzyme that deacetylates proteins that contribute to cellular regulation.

Sirtuin

Also called Sir2 proteins, a class of proteins that possess either histone deacetylase or mono-ribosyltransferase activity.

6-Keto-PGF1 alpha

A physiologically active and stable hydrolysis product of epoprostenol, found in nearly all mammalian tissues.

Sjögren's syndrome

An autoimmune disease that mainly affects the eyes and salivary glands but can affect different parts of the body.

Skp1

(S-phase kinase-associated protein 1) is a core component of SCF ubiquitin ligases and mediates protein degradation.

Smads

A family of intracellular proteins that mediate signalling by members of the TGF-beta (transforming growth factor beta) super-family.

Smad2/3

A key signalling molecule for TGF-beta.

Smad7

A TGFβ type 1 receptor antagonist.

Smallpox

Is an acute, contagious and devastating disease in humans caused by *Variola* virus and has resulted in high mortality over the centuries.

Snuff

Powder inhaled through the nose.

SOCE (store-operated Ca²⁺ entry)

Is a receptor-regulated Ca²⁺ entry pathway.

SOD

Super-oxide dismutase, is an enzyme that repairs cells and reduces the damage done to them by superoxide, the most common free radical in the body.

Sodium (Na)

Is an essential nutrient required for health. Sodium cations are important in neuron (brain and nerve) function and in influencing osmotic balance between cells and the interstitial fluid and in maintenance of total body fluid homeostasis. Extra intake may cause a harmful effect on health. Sodium is naturally supplied by salt intake with food.

Soleus muscle

Smaller calf muscle lower down the leg and under the gastrocnemius muscle.

Somites

Mesodermal structures formed during embryonic development that give rise to segmented body parts such as the muscles of the body wall.

Soporific

A sleep-inducing drug.

SOS response

A global response to DNA damage in which the cell cycle is arrested and DNA repair and mutagenesis are induced.

Soyasapogenins

Triterpenoid products obtained from the acid hydrolysis of soyasaponins, designated soyasapogenols A, B, C, D and E.

Soyasaponins

Bioactive saponin compounds found in many legumes.

Spasmogenic

Inducing spasm.

Spasmolytic

Checking spasms, see antispasmodic.

Spermatogenic

Giving rise to sperms.

Spermatorrhoea

Medically, an involuntary ejaculation/drooling of semen, usually nocturnal emissions.

Spermidine

An important polyamine in DNA synthesis and gene expression.

Spina bifida

A congenital birth defect caused by the incomplete closing of the embryonic neural tube.

Sphingolipid

A member of a class of lipids derived from the aliphatic amino alcohol sphingosine.

Spinocerebellar ataxia (SCA)

Is a progressive, degenerative genetic disease with multiple types.

Spleen

Organ that filters blood and prevents infection.

Spleen tyrosine kinase (SYK)

Is an enigmatic protein tyrosine kinase functional in a number of diverse cellular processes such as the regulation of immune and inflammatory responses.

Splenitis

Inflammation of the spleen.

Splenocyte

Is a monocyte, one of the five major types of white blood cell, and is characteristically found in the splenic tissue.

Splenomegaly

Is an enlargement of the spleen.

Sprain

To twist a ligament or muscle of a joint without dislocating the bone.

Sprue

Is a chronic disorder of the small intestine caused by sensitivity to gluten, a protein found in wheat and rye and to a lesser extent in oats and barley. It causes poor absorption by the intestine of fat, protein, carbohydrates, iron, water and vitamins A, D, E and K.

Sputum

Matter coughed up and usually ejected from the mouth, including saliva, foreign material and substances such as mucus or phlegm from the respiratory tract.

SREBP-1

See sterol regulatory element-binding protein-1.

Stanch

To stop or check the flow of a bodily fluid like blood from a wound.

Statin

A type of lipid-lowering drug.

STAT3

Signal transducer and activator of transcription 3, a transcription factor, plays a key role in many cellular processes such as cell growth and apoptosis.

Status epilepticus

Refers to a life-threatening condition in which the brain is in a state of persistent seizure.

STD

Sexually transmitted disease.

Steatorrhoea

Is the presence of excess fat in faeces which appear frothy and foul smelling and float because of the high fat content.

Steatohepatitis

Liver disease, characterised by inflammation of the liver with fat accumulation in the liver.

Steatosis

Refers to the deposition of fat in the interstitial spaces of an organ like the liver, fatty liver disease.

Stereotypy

Excessive repetitive or ritualistic movement, posture or utterance.

Sterility

Inability to produce offspring, also called asepsis.

Steroidogenic

Relating to steroidogenesis.

Steroidogenesis

The production of steroids, as by the adrenal glands.

Sterol-regulatory element-binding protein-1 (SREBP1)

Is a key regulator of the transcription of numerous genes that function in the metabolism of cholesterol and fatty acids.

Stimulant

A substance that promotes the activity of a body system or function.

Stomachic

Digestive stimulant, an agent that stimulates or strengthens the activity of the stomach; used as a tonic to improve the appetite and digestive processes.

Stomatitis

Oral inflammation and ulcers, may be mild and localised or severe, widespread and painful.

Stomatology

Medical study of the mouth and its diseases.

Stool

Faeces.

Strangury

Is the painful passage of small quantities of urine which are expelled slowly by straining with severe urgency; it is usually accompanied with the unsatisfying feeling of a remaining volume inside and a desire to pass something that will not pass.

Straub tail

Condition in which an animal carries its tail in an erect (vertical or nearly vertical) position.

STREPs

Sterol-regulatory element-binding proteins, a family of transcription factors that regulate lipid homeostasis by controlling the expression of a range of enzymes required for endogenous cholesterol, fatty acid, triacylglycerol and phospholipid synthesis.

Stria terminalis

A structure in the brain consisting of a band of fibres running along the lateral margin of the ventricular surface of the thalamus.

Striae gravidarum

A cutaneous condition characterised by stretch marks on the abdomen during and following pregnancy.

Stricture

An abnormal constriction of the internal passageway within a tubular structure such as a vessel or duct.

Strongyloidiasis

An intestinal parasitic infection in humans caused by two species of the parasitic nematode *Strongyloides*. The nematodes or roundworms are also called threadworms.

Styptic

A short stick of medication, usually anhydrous aluminum sulphate (a type of alum) or titanium dioxide, which is used for stanching blood by causing blood vessels to contract at the site of the wound. Also called haemostatic pencil, see antihæmorrhagic.

Subarachnoid hæmorrhage

Is bleeding in the area between the brain and the thin tissues that cover the brain.

Substance P

A neuropeptide that functions as a neurotransmitter and neuromodulator and is associated with the sensation of pain.

Substantia nigra

Is a dark-coloured brain structure located in the midbrain that plays an important role in reward, addiction and movement.

Sudatory

Medicine that causes or increases sweating. Also see sudorific.

Sudorific

A substance that causes sweating.

Sulphur

Sulphur is an essential component of all living cells. Sulphur is important for the synthesis of sulphur-containing amino acids, all polypeptides, proteins and enzymes such as glutathione an important sulphur-containing tripeptide which plays a role in cells as a source of chemical reduction potential. Sulphur is also important for hair formation. Good plant sources are garlic, onion, leeks and other alliaceous vegetables, brassicaceous vegetables like cauliflower, cabbages, Brussels sprout, kale; legumes – beans, green and red gram, soybeans; horseradish, water cress and wheat germ.

Superior mesenteric artery (SMA)

Arises from the anterior surface of the abdominal aorta, just inferior to the origin of the celiac trunk, and supplies the intestine from the lower part of the duodenum to the left colic flexure and the pancreas.

Superoxide mutase (SOD)

Antioxidant enzyme.

Suppuration

The formation of pus, the act of becoming converted into and discharging pus.

Supraorbital

Located above the orbit of the eye.

Sural nerve

Sensory nerve comprising collateral branches off the common tibial and common fibular nerve.

SYK, spleen tyrosine kinase

Is a human protein and gene. Syk plays a similar role in transmitting signals from a variety of cell surface receptors including CD74, Fc receptor and integrins.

Sympathetic nervous system

The part of the autonomic nervous system originating in the thoracic and lumbar regions of the spinal cord that in general inhibits or opposes the physiological effects of the parasympathetic nervous system, as in tending to reduce digestive secretions or speed up the heart.

Sympathomimetic

Mimicking the effects of impulses conveyed by adrenergic post-ganglionic fibres of the sympathetic nervous system.

Synaptic plasticity

The ability of neurons to change the number and strength of their synapses.

Synaptogenesis

The formation of synapses.

Synaptoneuroosomes

Purified synapses containing the pre- and post-synaptic termini.

Synaptosomes

Isolated terminal of a neuron.

Syncope

Fainting, sudden loss of consciousness followed by the return of wakefulness.

Syndactyly

Webbed toes, a condition where two or more digits are fused together.

Syneresis

Expulsion of liquid from a gel, as contraction of a blood clot and expulsion of liquid.

Syngeneic

Genetically identical or closely related, so as to allow tissue transplant; immunologically compatible.

Synovial

Lubricating fluid secreted by synovial membranes, as those of the joints.

Synoviocyte

Located in the synovial membrane; there are two types. Type A cells are more numerous, have phagocytic characteristics and produce degradative enzymes. Type B cells produce synovial fluid, which lubricates the joint and nurtures and nourishes the articular cartilage.

Syphilis

Is perhaps the best known of all the STDs. Syphilis is transmitted by direct contact with infection sores, called chancres, syphitic skin rashes or mucous patches on the tongue and mouth during kissing, necking, petting or sexual intercourse. It can also be transmitted from a pregnant woman to a fetus after the fourth month of pregnancy.

System lupus erythematosus

A long-term autoimmune disorder that may affect the skin, joints, kidneys, brain and other organs. Symptoms may include chest pain, fatigue, fever, hair loss, mailaise, mouth sores, sensitivity to sunlight and skin rash (butterfly rash).

Systolic

The blood pressure when the heart is contracting. It is specifically the maximum arterial pressure during contraction of the left ventricle of the heart.

T cells

Or T lymphocytes, a type of white blood cell that play a key role in the immune system.

Tachyarrhythmia

Any disturbance of the heart rhythm in which the heart rate is abnormally increased.

Tachycardia

A false heart rate applied to adults to rates over 100 beats per minute.

Tachykinins

Neuropeptide transmitters that are widely distributed and active in the central nervous system and periphery, rapidly acting secretagogues and cause smooth muscle contraction and vasodilation (hypotension).

Tachyphylaxia

A decreased response to a medicine given over a period of time so that larger doses are required to produce the same response.

Tachypnea

Abnormally fast breathing.

Taenia

A parasitic apeworm or flatworm of the genus *Taenia* .

Taeniocide

An agent that kills tapeworms.

Tardive dyskinesia

A disorder characterised by repetitive, involuntary, purposeless movements in the body such as grimacing, tongue protrusion, lip smacking, puckering and pursing of the lips and rapid eye blinking. Rapid, involuntary movements of the limbs, torso and fingers may also occur.

Tau

Is a class of microtubule-associated protein (MAP) in neuronal and glial cells.

Tau-1 (Ser198/199/202), pS396 (Ser396) and pS214 (Ser214) epitopes

Serine phosphorylation sites of tau-1.

Tau phosphorylation

Plays an important role in neuro-degenerative diseases and is regulated by protein kinases and phosphatases.

TBARS

See thiobarbituric acid reactive substances.

T cell

A type of white blood cell that attacks virus-infected cells, foreign cells and cancer cells.

TCA cycle

See tricarboxylic acid cycle.

TCID₅₀

Median tissue culture infective dose; that amount of a pathogenic agent that will produce pathological change in 50 % of cell cultures.

Telencephalon

The cerebral hemispheres, the largest divisions of the human brain.

Teletherapy

A non-invasive procedure using external beam radiotherapy treatments.

Telomerase

Enzyme that acts on parts of chromosomes known as telomeres.

Temporomandibular joint disorder (TMJD or TMD syndrome)

A disorder characterised by acute or chronic inflammation of the temporomandibular joint that connects the mandible to the skull.

Tendonitis

Is inflammation of a tendon.

Tenesmus

A strong desire to defaecate.

Teratogen

Is an agent that can cause malformations of an embryo or fetus. *adj* . teratogenic.

Testicular torsion

Twisting of the spermatic cord, which cuts off the blood supply to the testicle and surrounding structures within the scrotum.

Tetanus

An acute, potentially fatal disease caused by tetanus bacilli multiplying at the site of an injury and producing an exotoxin that reaches the central nervous system producing prolonged contraction of skeletal muscle fibres. Also called lockjaw.

Tete

Acute dermatitis caused by both bacterial and fungal infection.

Tetter

Any of a number of skin diseases.

TGF-beta

Transforming growth factor beta is a protein that controls proliferation, cellular differentiation and other functions in most cells.

Th cells or T helper cells

A sub-group of lymphocytes that helps other white blood cells in immunological processes.

Th 1 cells

Helper cells that play an important role in the immune system.

Th 17 cells

A sub-set of T helper cells producing interleukin 17.

Thalassemia major

Is a genetic blood disorder that causes the body to manufacture an abnormal form of haemoglobin.

Thelarche

The beginning of secondary (postnatal) breast development, usually occurring at the beginning of puberty in girls.

Thermogenic

Tending to produce heat, applied to drugs or food (fat-burning food).

Thermogenesis

Is the process of heat production in organisms.

Thermonociceptors

Or thermal nociceptors, sensory receptors that are stimulated by noxious heat or cold at various temperatures.

Thiobarbituric acid reactive substances (TBARS)

A well-established method for screening and monitoring lipid peroxidation.

Thixotropy

The property exhibited by certain gels of becoming fluid when stirred or shaken and returning to the semisolid state upon standing.

Thoracodynia

Pain in the chest.

3- β -HSD

(Or 3- β -hydroxysteroid dehydrogenase/ δ -5-4 isomerase) is an enzyme that catalyses the synthesis of progesterone from pregnenolone.

3-nitrotyrosine (3-NT) protein

Used as a marker for oxidative damage or nitrosative stress.

Thrombocythaemia

A blood condition characterised by a high number of platelets in the blood.

Thrombocytopenia

A condition when the bone marrow does not produce enough platelets (thrombocytes) like in leukaemia.

Thromboembolism

Formation in a blood vessel of a clot (thrombus) that breaks loose and is carried by the bloodstream to plug another vessel. *cf.* deep-vein thrombosis.

Thrombogenesis

Formation of a thrombus or blood clot.

Thrombophlebitis

Occurs when there is inflammation and clot in a surface vein.

Thromboplastin

An enzyme liberated from blood platelets that converts prothrombin into thrombin as blood starts to clot, also called thrombokinase.

Thrombosis

The formation or presence of a thrombus (clot).

Thromboxanes

Any of several compounds, originally derived from prostaglandin precursors in platelets that stimulate aggregation of platelets and constriction of blood vessels.

Thromboxane B₂

The inactive product of thromboxane.

Thrombus

A fibrinous clot formed in a blood vessel or in a chamber of the heart.

Thrush

A common mycotic infection caused by yeast, *Candida albicans*, in the digestive tract or vagina. In children, it is characterised by white spots on the tongue.

Thymocytes

Are T-cell precursors which develop in the thymus.

Thyrotoxicosis

Or hyperthyroidism – an overactive thyroid gland, producing excessive circulating free thyroxine, free triiodothyronine or both.

Tight junction

Associated areas of two cells whose membranes join together forming a virtually impermeable barrier to fluid.

TIMP-3

A human gene belonging to the tissue inhibitor of matrix metalloproteinases (MMP) gene family. See MMP.

Tincture

Solution of a drug in alcohol.

Tinea

Ringworm, fungal infection on the skin.

Tinea favosa

See favus.

Tinea cruris

Ringworm of the groin.

Tinea imbricata

(Also called Tokelau) an eruption characterised by concentric rings of overlapping scales forming papulosquamous patches scattered over the body; it occurs in tropical climates especially prevalent in southwest Polynesia and is caused by the fungus *Trichophyton concentricum* .

Tinea pedis

Fungal infection of the foot, also called athletes' foot.

Tinnitus

A noise in the ears, as ringing, buzzing, roaring, clicking, etc.

Tisane

A herbal infusion used as tea or for medicinal purposes.

Tissue plasminogen activator (t-PA)

A serine protease involved in the breakdown of blood clots.

TNF alpha

Cachexin or cachectin and formally known as tumour necrosis factor-alpha, a cytokine involved in systemic inflammation. The primary role of TNF is in the regulation of immune cells. TNF is also able to induce apoptotic cell death, to induce inflammation and to inhibit tumorigenesis and viral replication.

Tocolytics

Medications used to suppress premature labour.

Tocopherol

Fat-soluble organic compound belonging to vitamin E group.
See vitamin E.

Tocotrienol

Fat-soluble organic compound belonging to vitamin E group.
See vitamin E.

Tolerogenic

Producing immunological tolerance.

Toll-like receptors (TLRs)

A class of proteins that play a key role in the innate immune system.

Tonic

Substance that acts to restore, balance, tone, strengthen or invigorate a body system without overt stimulation or depression.

Tonic clonic seizure

A type of generalised seizure that affects the entire brain.

Tonsillitis

An inflammatory condition of the tonsils due to bacteria, allergies or respiratory problems.

TOP2A

Topoisomerase II alpha enzyme.

Topoisomerases

A class of enzymes involved in the regulation of DNA supercoiling.

Topoisomerase inhibitors

A new class of anti-cancer agents with a mechanism of action aimed at interrupting DNA replication in cancer cells.

Total parenteral nutrition (TPN)

Is a method of feeding that bypasses the gastrointestinal tract.

Toxemia

Is the presence of abnormal substances in the blood, but the term is also used for a serious condition in pregnancy that involves hypertension and proteinuria. Also called pre-eclampsia.

Tracheitis

Is a bacterial infection of the trachea; also known as bacterial tracheitis or acute bacterial tracheitis.

Trachoma

A contagious disease of the conjunctiva and cornea of the eye, producing painful sensitivity to strong light and excessive tearing.

TRAIL

Acronym for tumour necrosis factor-related apoptosis-inducing ligand, is a cytokine that preferentially induces apoptosis in tumour cells.

Tranquiliser

A substance drug used in calming a person suffering from nervous tension or anxiety.

Transaminase

Also called aminotransferase, is an enzyme that catalyses a type of reaction between an amino acid and an α -keto acid.

Transaminitis

Increase in alanine aminotransferase (ALT) and/or aspartate aminotransferase (AST) to >5 times the upper limit of normal.

Transcatheter arterial chemoembolisation (TACE)

Is an interventional radiology procedure involving percutaneous access to the hepatic artery and passing a catheter through the abdominal artery aorta followed by radiology. It is used extensively in the palliative treatment of unresectable hepatocellular carcinoma (HCC).

Transcriptional activators

Are proteins that bind to DNA and stimulate transcription of nearby genes.

Transcriptional co-activator PGC-1

A potent transcriptional co-activator that regulates oxidative metabolism in a variety of tissues.

Transcriptome profiling

To identify genes involved in peroxisome assembly and function.

Transforming growth factor beta (TGF- β)

A protein that controls proliferation, cellular differentiation and other functions in most cells.

Transient receptor potential ankyrin 1 (TRPA1)

Is a Ca(2+)-permeant, non-selective cationic channel that may play a role in nociception.

Transient receptor potential vanilloid 1 (TRPV1)

Receptor also known as capsaicin receptor and vanilloid receptor, is a Ca²⁺ permeable non-selective cation channel localised on a sub-set of primary sensory neurons that can be activated by physical and chemical stimuli.

TRAP 6

Thrombin receptor activating peptide with six amino acids.

Tremorine

A chemical that produces a tremor resembling Parkinsonian tremor.

Tremulous

Marked by trembling, quivering or shaking.

Triacylglycerol

Or triacylglyceride, is a glyceride in which the glycerol is esterified with three fatty acids.

Tricarboxylic acid cycle (TCA cycle)

A series of enzymatic reactions in aerobic organisms involving oxidative metabolism of acetyl units and producing high-energy phosphate compounds, which serve as the main source of cellular energy. Also called citric acid cycle, Krebs cycle.

Trichophytosis

Infection by fungi of the genus *Trichophyton* .

Trigeminal neuralgia (TN)

Is a neuropathic disorder of one or both of the facial trigeminal nerves, also known as prosopalgia.

Triglycerides

A type of fat (lipids) found in the bloodstream.

Trismus

Continuous contraction of the muscles of the jaw, specifically as a symptom of tetanus, or lockjaw; inability to open the mouth fully.

TrKB receptor

Also known as TrKB tyrosine kinase, a protein in humans that acts as a catalytic receptor for several neutrophins.

Trolox equivalent

Measures the antioxidant capacity of a given substance, as compared to the standard; Trolox is also referred to as TEAC (Trolox equivalent antioxidant capacity).

Trypanocidal

Destructive to trypanosomes.

Trypanosomes

Protozoan of the genus *Trypanosoma* .

Trypanosomiasis

Human disease or an infection caused by a trypanosome.

Trypsin

An enzyme of pancreatic juice that hydrolyses proteins into smaller polypeptide units.

Trypsin inhibitor

Small protein synthesised in the exocrine pancreas which prevents conversion of trypsinogen to trypsin, so protecting itself against trypsin digestion.

TRPV1

See transient receptor potential vanilloid 1.

Tuberculosis (TB)

Is a bacterial infection of the lungs caused by a bacterium called *Mycobacterium tuberculosis* , characterised by the formation of lesions (tubercles) and necrosis in the lung tissues and other organs.

Tumorigenesis

Formation or production of tumours.

Tumour

An abnormal swelling of the body other than that caused by direct injury.

Tussis

A cough.

Tympanic membrane

Ear drum.

Tympanitis

Infection or inflammation of the inner ear.

Tympanophonia

Increased resonance of one's own voice, breath sounds, arterial murmurs, etc., noted especially in disease of the middle ear.

Tympanosclerosis

See myringosclerosis.

Tyrosinase

A copper-containing enzyme found in animals and plants that catalyses the oxidation of phenols (such as tyrosine) and the production of melanin and other pigments from tyrosine by oxidation.

Ubiquitin ligase

Also called an E3 ubiquitin ligase, is a protein that targets other proteins to be broken down (degraded) within cells.

UCP1

An uncoupling protein found in the mitochondria of brown adipose tissue used to generate heat by non-shivering thermogenesis.

UCP – 2 enzyme

Uncoupling protein 2 enzyme, a mitochondrial protein expressed in adipocytes.

Ulcer

An open sore on an external or internal body surface usually accompanied by disintegration of tissue and pus.

Ulcerative colitis

Is one of two types of inflammatory bowel disease – a condition that causes the bowel to become inflamed and red.

Ulemorrhagia

Bleeding of the gums.

Ulitis

Inflammation of the gums.

Unguent

Ointment.

Unilateral ureteral obstruction

Unilateral blockage of urine flow through the ureter of one kidney, resulting in a backup of urine, distension of the renal pelvis and calyces and hydronephrosis.

Uraemia

An excess in the blood of urea, creatinine and other nitrogenous end products of protein and amino acid metabolism, more correctly referred to as azotaemia.

Urethra

Tube conveying urine from the bladder to the external urethral orifice.

Urethritis

Is an inflammation of the urethra caused by infection.

Uricemia

An excess of uric acid or urates in the blood.

Uricosuric

Promoting the excretion of uric acid in urine.

Urinary

Pertaining to the passage of urine.

Urinary incontinence

Sudden and strong need to urinate because of poor bladder control.

Urinogenital

Relating to genital and urinary organs or functions.

Urodynia

Pain on urination.

Urokinase

Also called urokinase-type plasminogen (u-PA), is a serine protease enzyme in human urine that catalyses the conversion of plasminogen to plasmin. It is used clinically as a thrombolytic agent.

Urokinase-type plasminogen (u-PA)

Plays a key role in tumour invasion and metastasis, also see Urokinase.

Urolithiasis

Formation of stones in the urinary tract (kidney, bladder or urethra).

Urticant

A substance that causes wheals to form.

Urticaria

Or hives, is a skin condition, commonly caused by an allergic reaction, that is characterised by raised red skin welts.

Uterine

Relating to the uterus.

Uterine myomas

Also called fibroids, tumours that grow from the uterine wall.

Uterine prolapse

Occurs when weakened or damaged muscles and ligaments allow the uterus to slip into the vagina.

Uterine relaxant

An agent that relaxes the muscles in the uterus.

Uterine stimulant

An agent that stimulates the uterus (and often employed during active childbirth).

Uterotonic

Giving muscular tone to the uterus.

Uterotrophic

Causing an effect on the uterus.

Uterus

Womb.

Vaginal dystrophy

A condition in which the outer part of the vagina becomes dry and the skin thickens or thins.

Vaginitis

Infectious or non-infectious inflammation of the vaginal mucosa.

Vaginopathy

Any disease of the vagina.

Vagotomy

The surgical cutting of the vagus nerve to reduce acid secretion in the stomach.

Vagus nerve

A cranial nerve, that is, a nerve connected to the brain. The vagus nerve has branches to most of the major organs in the body, including the larynx, throat, windpipe, lungs, heart and most of the digestive system.

Variola

Or smallpox, a contagious disease unique to humans, caused by either of two virus variants, *Variola major* and *Variola minor*. The disease is characterised by fever, weakness and skin eruption with pustules that form scabs that leave scars.

Varicose veins

Are veins that have become enlarged and twisted.

Vasa vasorum

Is a network of small blood vessels that supply large blood vessels. *plur* . vasa vasori.

Vascular endothelial growth factor (VEGF)

A polypeptide chemical produced by cells that stimulates the growth of new blood vessels.

Vasculitis

Group of disorders that destroy blood vessels by inflammation.

Vasculogenesis

The process of blood vessel formation occurring by a de novo production of endothelial cells.

Vasoconstrictor

Drug that causes constriction of blood vessels.

Vasodilator

Drug that causes dilation or relaxation of blood vessels.

Vasodilatory

Causing the widening of the lumen of blood vessels.

Vasomotor symptoms

Menopausal symptoms characterised by hot flushes and night sweats.

Vasospasm

Refers to a condition in which blood vessels spasm, leading to vasoconstriction and subsequently to tissue ischaemia and death (necrosis).

VCAM-1 (vascular cell adhesion molecule-1)

Also known as CD106, contains six or seven immunoglobulin domains and is expressed on both large and small vessels only after the endothelial cells are stimulated by cytokines.

VEGF

Vascular endothelial growth factor.

Venereal disease (VD)

Term given to the diseases syphilis and gonorrhoea.

Venule

A small vein, especially one joining capillaries to larger veins.

Vermifuge

A substance used to expel worms from the intestines.

Verotoxin

A Shiga-like toxin produced by *Escherichia coli*, which disrupts the function of ribosomes, causing acute renal failure.

Verruca

A contagious and painful wart on the sole of the foot.

Verruca plana

Is a reddish-brown or flesh-coloured, slightly raised, flat-surfaced, well-demarcated papule on the hand and face, also called flat wart.

Verruca vulgaris

Small painless warts on the skin caused by the human papillomavirus.

Vertigo

An illusory, sensory perception that the surroundings or one's own body are revolving; dizziness.

Very-low-density lipoprotein (VLDL)

A type of lipoprotein made by the liver. VLDL is one of the five major groups of lipoproteins (chylomicrons, VLDL, intermediate-density lipoprotein, low-density lipoprotein, high-density lipoprotein (HDL)) that enable fats and cholesterol to move within the water-based solution of the bloodstream. VLDL is converted in the bloodstream to low-density lipoprotein (LDL).

Vesical calculus

Calculi (stones) in the urinary bladder.

Vesicant

A substance that causes tissue blistering.

Vestibular

Relating to the sense of balance.

Vestibular disorders

Includes symptoms of dizziness, vertigo and imbalance; it can result from or be worsened by genetic or environmental conditions.

Vestibular schwannoma

Also called acoustic neuroma, is a benign tumour that may develop from an overproduction of Schwann cells that press on the hearing and balance nerves in the inner ear.

Vestibular system

Includes parts of the inner ear and brain that process sensory information involved with controlling balance and eye movement.

Vibrissa

Stiff hairs that are located especially about the nostrils.

Vimentin

A type III intermediate filament protein that is expressed in mesenchymal cells.

Viremia

A medical condition where viruses enter the bloodstream and hence have access to the rest of the body.

Visceral fat

Intra-abdominal fat, is located inside the peritoneal cavity, packed in between internal organs and torso.

Visual entopia

Visual disturbances.

Vitamin

Any complex organic compound found in various foods or sometimes synthesised in the body, required in tiny amounts and essential for the regulation of metabolism, normal growth and function of the body.

Vitamin A

Retinol, fat-soluble vitamins that play an important role in vision, bone growth, reproduction, cell division and cell differentiation, helps regulate the immune system in preventing or fighting off infections. Vitamin A that is found in colourful fruit and vegetables is called provitamin A carotenoid. They can be made into retinol in the body. Deficiency of vitamin A results in night blindness and keratomalacia.

Vitamin B1

Also called thiamine, water-soluble vitamins, dissolve easily in water and, in general, are readily excreted from the body; they are not readily stored; consistent daily intake is important. It functions as co-enzyme in the metabolism of carbohydrates and branched-chain amino acids and other cellular processes. Deficiency results in beriberi disease.

Vitamin B2

Also called riboflavin, an essential water-soluble vitamin that functions as co-enzyme in redox reactions. Deficiency causes ariboflavinosis.

Vitamin B3

Comprises niacin and niacinamide, water-soluble vitamins that function as co-enzyme or co-substrate for many redox reactions, and is required for energy metabolism. Deficiency causes pellagra.

Vitamin B5

Also called pantothenic acid, a water-soluble vitamin that functions as co-enzyme in fatty acid metabolism. Deficiency causes paresthesia.

Vitamin B6

Water-soluble vitamin, exists in three major chemical forms: pyridoxine, pyridoxal and pyridoxamine. Vitamin B6 is needed in enzymes involved in protein metabolism, red blood cell metabolism, efficient functioning of nervous and immune systems and haemoglobin formation. Deficiency causes anaemia and peripheral neuropathy.

Vitamin B7

Also called biotin or vitamin H, an essential water-soluble vitamin, is involved in the synthesis of fatty acids, amino acids and glucose in energy metabolism. Biotin promotes normal health of sweat glands, bone marrow, male gonads, blood cells, nerve tissue, skin and hair. Deficiency causes dermatitis and enteritis.

Vitamin B9

Also called folic acid, an essential water-soluble vitamin. Folate is especially important during periods of rapid cell division and growth such as infancy and pregnancy. Deficiency during pregnancy is associated with birth defects such as neural tube defects. Folate is also important for production of red blood cells and prevent anaemia. Folate is needed to make DNA and RNA, the building blocks of cells. It also helps prevent changes to DNA that may lead to cancer.

Vitamin B12

A water-soluble vitamin, also called cobalamin as it contains the metal cobalt. It helps maintain healthy nerve cells and red blood cells and DNA production. Vitamin B12 is bound to the protein in food. Deficiency causes megaloblastic anaemia.

Vitamin C

Also known as ascorbic acid, is an essential water-soluble vitamin. It functions as co-factor for reactions requiring reduced copper or iron metalloenzyme and as a protective anti-oxidant. Deficiency of vitamin C causes scurvy.

Vitamin D

A group of fat-soluble, pro-hormone vitamin, the two major forms of which are vitamin D2 (or ergocalciferol) and vitamin D3 (or cholecalciferol). Vitamin D obtained from sun exposure, food and supplements is biologically inert and must undergo two hydroxylations in the body for activation. Vitamin D is essential for promoting calcium absorption in the gut and maintaining adequate serum

calcium and phosphate concentrations to enable normal growth and mineralisation of bone and prevent hypocalcemic tetany. Deficiency causes rickets and osteomalacia. Vitamin D has other roles in human health, including modulation of neuromuscular and immune function, reduction of inflammation and modulation of many genes encoding proteins that regulate cell proliferation, differentiation and apoptosis.

Vitamin E

Is the collective name for a group of fat-soluble compounds and exists in eight chemical forms (alpha-, beta-, gamma- and delta-tocopherol and alpha-, beta-, gamma- and delta-tocotrienol). It has pronounced antioxidant activities stopping the formation of reactive oxygen species when fat undergoes oxidation and help prevent or delay the chronic diseases associated with free radicals. Besides its antioxidant activities, vitamin E is involved in immune function, cell signalling, regulation of gene expression and other metabolic processes. Deficiency is very rare but can cause mild haemolytic anaemia in newborn infants.

Vitamin K

A group of fat-soluble vitamins consisting of vitamin K₁, which is also known as phyloquinone or phytomenadione (also called phytonadione), and vitamin K₂ (menaquinone, menatetrenone). Vitamin K plays an important role in blood clotting. Deficiency is very rare but can cause bleeding diathesis.

Vitamin P

A substance or mixture of substances obtained from various plant sources, identified as citrin or a mixture of bioflavonoids, thought to but not proven to be useful in reducing the extent of haemorrhage.

Vitiligo

A chronic skin disease that causes loss of pigment, resulting in irregular pale patches of skin. It occurs when the

melanocytes, cells responsible for skin pigmentation, die or are unable to function. Also called leucoderma.

Vitreoretinopathy

See proliferative vitreoretinopathy.

VLA-4

Very late antigen-4, expressed by most leucocytes, but it is observed on neutrophils under special conditions.

VLDL

See very-low-density lipoproteins.

Vomitive

Substance that causes vomiting.

Vulnerary

Wound healer, a substance used to heal wounds and promote tissue formation.

Vulva-vaginal erythema

Abnormal redness and inflammation of the skin in the vagina.

Wart

An infectious skin tumour caused by a viral infection.

Welt

See wheal.

Wheal

A firm, elevated swelling of the skin. Also called a weal or welt.

White fat

White adipose tissue (WAT) in mammals, store of energy. *cf.* brown fat.

Whitlow

Painful infection of the hand involving one or more fingers that typically affects the terminal phalanx.

Whooping cough

Acute infectious disease usually in children caused by a *Bacillus* bacterium and accompanied by catarrh of the respiratory passages and repeated bouts of coughing.

Wnt signalling pathway

Is a network of proteins involved in embryogenesis and cancer and also in normal physiological processes.

X-linked agammaglobulinemia

Also known as X-linked hypogammaglobulinemia, XLA, Bruton-type agammaglobulinemia, Bruton syndrome, or sex-linked agammaglobulinemia; a rare x-linked genetic disorder that affects the body's ability to fight infection.

Xanthine oxidase

A flavoprotein enzyme containing a molybdenum co-factor (Moco) and (Fe₂S₂) clusters, involved in purine metabolism. In humans, inhibition of xanthine oxidase reduces the production of uric acid and prevents hyperuricemia and gout.

Xanthones

Unique class of biologically active phenol compounds with the molecular formula C₁₃H₈O₂ possessing antioxidant properties, discovered in the mangosteen fruit.

Xenobiotics

A chemical (as a drug, pesticide or carcinogen) that is foreign to a living organism.

Xenograft

A surgical graft of tissue from one species to an unlike species.

Xerophthalmia

A medical condition in which the eye fails to produce tears.

Xerostomia

Dryness in the mouth due to lack of saliva production.

Yaws

An infectious tropical infection of the skin, bones and joints caused by the spirochete bacterium *Treponema pertenue*, characterised by papules and pappiloma with subsequent deformation of the skins, bone and joints; also called framboesia.

yGCN5

A histone acetyl transferase (HAT) that plays a role in regulation of transcriton, cell cycle progression and differentiation.

Yellow fever

Is a viral disease that is transmitted to humans through the bite of infected mosquitoes. Illness ranges in severity from an influenza-like syndrome to severe hepatitis and haemorrhagic fever. Yellow fever virus (YFV) is maintained in nature by mosquito-borne transmission between non-human primates.

Zeaxanthin

A common carotenoid, found naturally as coloured pigments in many fruit vegetables and leafy vegetables. It is important for good vision and is one of the two carotenoids contained within the retina of the eye. Within the central macula, zeaxanthin predominates, whereas in the peripheral retina, lutein predominates.

Zinc (Zn)

Is an essential mineral for health. It is involved in numerous aspects of cellular metabolism: catalytic activity of enzymes, immune function, protein synthesis, wound healing, DNA synthesis and cell division. It also supports normal growth and development during pregnancy, childhood and adolescence and is required for proper sense of taste and smell. Dietary sources include beans, nuts, pumpkin seeds, sunflower seeds, whole wheat bread and animal sources.

ZK1

Krueppel-type zinc finger protein – bind DNA and, through this binding, regulate gene transcription.

ZOI protein

A high-molecular weight tight junction-associated protein.

Scientific Glossary

Abaxial

Facing away from the axis, as of the surface of an organ.

Abortive

Imperfectly formed.

Abscission

Shedding of leaves, flowers or fruit following the formation of the abscission zone.

Acaulescent

Lacking a stem or stem very much reduced.

Accrescent

Increasing in size after flowering or with age.

Achene

A dry, small, one-seeded, indehiscent one-seeded fruit formed from a superior ovary of one carpel as in sunflower.

Acid soil

Soil that maintains a pH of less than 7.0.

Acidulous

Acid or sour in taste.

Actinomorphic

Having radial symmetry, capable of being divided into symmetrical halves by any plane, refers to a flower, calyx or corolla.

Aculeate

Having sharp prickles.

Acuminate

Tapering gradually to a sharp point.

Acute

(Botany) tapering at an angle of less than 90° before terminating in a point as of leaf apex and base.

Adaxial

Side closest to the stem axis.

Aldephous

Having stamens united together by their filaments.

Adherent

Touching without organic fusion as of floral parts of different whorls.

Adnate

United with another unlike part as of stamens attached to petals.

Adpressed

Lying close to another organ but not fused to it.

Adventitious

Arising in abnormal positions, e.g. roots arising from the stem, branches or leaves, buds arising elsewhere than in the axils of leaves.

Adventive

Not native to and not fully established in a new habitat or environment; locally or temporarily naturalised. e.g. an adventive weed.

Aestivation

Refers to positional arrangement of the floral parts in the bud before it opens.

Akinete

A thick-walled dormant cell derived from the enlargement of a vegetative cell. It serves as a survival structure.

Alfisols

Soil with a clay-enriched subsoil and relatively high native fertility, having undergone only moderate leaching, containing aluminium, iron and with at least 35 % base saturation, meaning that calcium, magnesium and potassium are relatively abundant.

Alkaline soil

Soil that maintains a pH above 7.0, usually containing large amounts of calcium, sodium and magnesium, and is less soluble than acidic soils.

Alkaloids

Naturally occurring bitter, complex organic-chemical compounds containing basic nitrogen and oxygen atoms and having various pharmacological effects on humans and other animals.

Alternate

Leaves or buds that are spaced along opposite sides of stem at different levels.

Allomorphic

With a shape or form different from the typical.

Alluvial soil

A fine-grained fertile soil deposited by water flowing over flood plains or in river beds.

Alluvium

Soil or sediments deposited by a river or other running water.

Amplexicaul

Clasping the stem as base of certain leaves.

Anatomising

Interconnecting network as applied to leaf veins.

Andisols

Are soils formed in volcanic ash and containing high proportions of glass and amorphous colloidal materials.

Androdioecious

With male flowers and bisexual flowers on separate plants.

Androecium

Male parts of a flower; comprising the stamens of one flower.

Androgynophore

A stalk bearing both the androecium and gynoecium above the perianth of the flower.

Androgynous

With male and female flowers in distinct parts of the same inflorescence.

Andromonoecious

Having male flowers and bisexual flowers on the same plant.

Angiosperm

A division of seed plants with the ovules borne in an ovary.

Annual

A plant which completes its life cycle within a year.

Annular

Shaped like or forming a ring.

Annulus

Circle or ring-like structure or marking; the portion of the corolla which forms a fleshy, raised ring.

Anthelate

An open, paniculate cyme.

Anther

The part of the stamen containing pollen sac which produces the pollen.

Antheriferous

Containing anthers.

Anthesis

The period between the opening of the bud and the onset of flower withering.

Anthocarp

A false fruit consisting of the true fruit and the base of the perianth.

Anthocyanidins

Are common plant pigments. They are the sugar-free counterparts of anthocyanins.

Anthocyanins

A subgroup of antioxidant flavonoids, are glucosides of anthocyanidins. They occur as water-soluble vacuolar pigments that may appear red, purple or blue according to pH in plants.

Antipetala

situated opposite petals.

Antisepala

Situated opposite sepals.

Antrorse

Directed forward upwards.

Apetalous

Lacking petals as of flowers with no corolla.

Apical meristem

Active growing point. A zone of cell division at the tip of the stem or the root.

Apically

Towards the apex or tip of a structure.

Apiculate

Ending abruptly in a short, sharp, small point.

Apiculum

A short, pointed, flexible tip.

Apocarpous

carpels separate in single individual pistils.

Apopetalous

With separate petals, not united to other petals.

Aposepalous

With separate sepals, not united to other sepals.

Appressed

Pressed closely to another structure but not fused or united.

Aquatic

A plant living in or on water for all or a considerable part of its life span.

Arachnoid

(Botany) formed of or covered with long, delicate hairs or fibers.

Arborescent

Resembling a tree; applied to non-woody plants attaining tree height and to shrubs tending to become tree-like in size.

Arbuscular mycorrhiza (AM)

A type of mycorrhiza in which the fungus (of the phylum Glomeromycota) penetrates the cortical cells of the roots of a vascular plant and form unique structures such as arbuscules and vesicles. These fungi help plants to capture nutrients such as phosphorus and micronutrients from the soil.

Archegonium

A flask-shaped female reproductive organ in mosses, ferns and other related plants.

Areolate

With areolea.

Areole

(Botany) a small, specialised, cushion-like area on a cactus from which hairs, glochids, spines, branches or flowers may arise; an irregular angular spaces marked out on a surface e.g. fruit surface. *pl* . areolea.

Aril

Specialised outgrowth from the funiculus (attachment point of the seed) (or hilum) that encloses or is attached to the seed.
adj . arillate.

Arillode

A false aril; an aril originating from the micropyle instead of from the funicle or chalaza of the ovule, e.g. mace of nutmeg.

Aristate

Bristle-like part or appendage, e.g. awns of grains and grasses.

Aristulate

Having a small, stiff, bristle-like part or appendage; a diminutive of aristate.

Articulate

Jointed; usually breaking easily at the nodes or point of articulation into segments.

Ascending

Arched upwards in the lower part and becoming erect in the upper part.

Ascospore

Spore produced in the ascus in Ascomycete fungi.

Ascus

Is the sexual spore-bearing cell produced in Ascomycete fungi.
pl . asci.

Asperulous

Refers to a rough surface with short, hard projections.

Attenuate

Tapered or tapering gradually to a point.

Auricle

An ear-like appendage that occurs at the base of some leaves or corolla.

Auriculate

Having auricles.

Awn

A hair-like or bristle-like appendage on a larger structure.

Axil

Upper angle between a lateral organ, such as a leaf petiole and the stem that bears it.

Axile

Situated along the central axis of an ovary having two or more locules, as in axile placentation.

Axillary

Arising or growing in an axil.

Baccate

Beery-like, pulpy or fleshy.

Barbate

Bearded, having tufts of hairs.

Barbellae

Short, stiff, hair-like bristles. *adj* . barbellate.

Bark

Is the outermost layers of stems and roots of woody plants.

Basal

Relating to, situated at, arising from or forming the base.

Basaltic soil

Soil derived from basalt, a common extrusive volcanic rock.

Basidiospore

A reproductive spore produced by Basidiomycete fungi.

Basidium

A microscopic, spore-producing structure found on the hymenophore of fruiting bodies of Basidiomycete fungi.

Basifixed

Attached by the base, as certain anthers are to their filaments.

Basionym

The synonym of a scientific name that supplies the epithet for the correct name.

Beak

A prominent apical projection, especially of a carpel or fruit.
adj . beaked.

Bearded

Having a tuft of hairs.

Berry

A fleshy or pulpy indehiscent fruit from a single ovary with the seed(s) embedded in the fleshy tissue of the pericarp.

Biconvex

Convex on both sides.

Biennial

Completing the full cycle from germination to fruiting in more than one, but not more than 2 years.

Bifid

Forked, divided into two parts.

Bifoliolate

Having two leaflets.

Bilabiate

Having two lips as of a corolla or calyx with segments fused into an upper and lower lip.

Bipinnate

Twice pinnate; the primary leaflets being again divided into secondary leaflets.

Bipinnatisect

Refers to a pinnately compound leaf, in which each leaflet is again divided into pinnae.

Biserrate

Doubly serrate; with smaller regular, asymmetric teeth on the margins of larger teeth.

Bisexual

Having both sexes, as in a flower bearing both stamens and pistil, hermaphrodite or perfect.

Biternate

Twice ternate; with three pinnae each divided into three pinnules.

Blade

Lamina; part of the leaf above the sheath or petiole.

Blotched

See variegated.

Bole

Main trunk of tree from the base to the first branch.

Brachyblast

A short, axillary, densely crowded branchlet or shoot of limited growth, in which the internodes elongate little or not at all.

Bracket fungus

Shelf fungus.

Bract

A leaf-like structure, different in form from the foliage leaves, associated with an inflorescence or flower. *adj* . bracteate.

Bracteate

Possessing bracts.

Bracteolate

Having bracteoles.

Bracteole

A small, secondary, bract-like structure borne singly or in a pair on the pedicel or calyx of a flower. *adj* . bracteolate.

Bran

Hard outer layer of grain and comprises the aleurone and pericarp. It contains important antioxidant, vitamins and fibre.

Bristle

A stiff hair.

Bulb

A modified underground axis that is short and crowned by a mass of usually fleshy, imbricate scales. *adj* . bulbous.

Bulbil

A small bulb or bulb-shaped body, especially one borne in the leaf axil or an inflorescence, and usually produced for asexual reproduction.

Bullate

Puckered, blistered.

Burr

Type of seed or fruit with short, stiff bristles or hooks or may refer to a deformed type of wood in which the grain has been misformed.

Bush

Low, dense shrub without a pronounced trunk.

Buttress

Supporting, projecting outgrowth from base of a tree trunk as in some Rhizophoraceae and Moraceae.

Caducous

Shedding or falling early before maturity, refers to sepals and petals.

Caespitose

Growing densely in tufts or clumps; having short, closely packed stems.

Calcareous

Composed of or containing lime or limestone.

Calcrete

A hardpan consisting gravel and sand cemented by calcium.

Callus

A condition of thickened raised mass of hardened tissue on leaves or other plant parts often formed after an injury but sometimes a normal feature. A callus also can refer to an undifferentiated plant cell mass grown on a culture medium. *n* . callosity. *pl* . calli, callosities. *adj* . callose.

Calyptra

The protective cap or hood covering the spore case of a moss or related plant.

Calyptrate

Operculate, having a calyptra.

Calyx

Outer floral whorl usually consisting of free sepals or fused sepals (calyx tube) and calyx lobes. It encloses the flower while it is still a bud. *adj* . calycine.

Calyx lobe

One of the free upper parts of the calyx which may be present when the lower part is united into a tube.

Calyx tube

The tubular fused part of the calyx, often cup shaped or bell shaped, when it is free from the corolla.

Campanulate

Shaped like a bell refers to calyx or corolla.

Canaliculate

Having groove or grooves.

Candelabrifform

Having the shape of a tall branched candle-stick.

Canescent

Covered with short, fine whitish or grayish hairs or down.

Canopy

Uppermost leafy stratum of a tree.

Cap

See pileus.

Capitate

Growing together in a head. Also means enlarged and globular at the tip.

Capitulum

A flower head or inflorescence having a dense cluster of sessile or almost sessile, flowers or florets.

Capsule

A dry, dehiscent fruit formed from two or more united carpels and dehiscing at maturity by sections called valves to release the seeds. *adj* . capsular.

Carinate

Keeled.

Carpel

A simple pistil consisting of ovary, ovules, style and stigma. *adj* . carpellary.

Carpogonium

Female reproductive organ in red algae. *pl* . carpogonia.

Carpophore

Part of the receptacle which is lengthened between the carpels as a central axis; any fruiting body or fruiting structure of a fungus.

Cartilaginous

Sinewy, having a firm, tough, flexible texture (in respect of leaf margins).

Caruncle

(Bot) fleshy structure attached to the seed of certain plants.

Caryopsis

A simple dry, indehiscent fruit formed from a single ovary with the seed coat united with the ovary wall as in grasses and cereals.

Cataphyll

A reduced or scarcely developed leaf at the start of a plant's life (i.e. cotyledons) or in the early stages of leaf development.

Catkin

A slim, cylindrical, pendulous flower spike usually with unisexual flowers.

Caudate

Having a narrow, tail-like appendage.

Caudex

Thickened, usually underground base of the stem.

Caulescent

Having a well developed aerial stem.

Cauliflory

Botanical term referring to plants which flower and fruit from their main stems or woody trunks. *adj* . cauliflorous.

Cauline

Borne on the aerial part of a stem.

Chaffy

Having thin, membranous scales in the inflorescence as in the flower heads of the sunflower family.

Chalaza

The basal region of the ovule where the stalk is attached.

Chamaephyte

A low-growing perennial plant whose dormant overwintering buds are borne at or just above the surface of the ground.

Chartaceous

Papery, of paper-like texture.

Chasmogamous

Describing flowers in which pollination takes place while the flower is open.

Chatoyant

Having a velvety sheen or lustre.

Chloroplast

A chlorophyll-containing organelle (plastid) that gives the green colour to leaves and stems. Plastids harness light energy that is used to fix carbon dioxide in the process called photosynthesis.

Chromoplast

Plastid containing colored pigments apart from chlorophyll.

Chromosomes

Thread-shaped structures that occur in pairs in the nucleus of a cell, containing the genetic information of living organisms.

Cilia

Hairs along the margin of a leaf or corolla lobe.

Ciliate

With a fringe of hairs on the margin as of the corolla lobes or leaf.

Ciliolate

Minutely ciliate.

Cilium

A straight, usually erect hair on a margin or ridge. *pl* . cilia.

Cincinnus

A monochasial cyme in which the lateral branches arise alternately on opposite sides of the false axis.

Circinnate

Spirally coiled, with the tip innermost.

Circumscissile

Opening by a transverse line around the circumference as of a fruit.

Cladode

The modified photosynthetic stem of a plant whose foliage leaves are much reduced or absent. *cf* . cladophyll, phyllode.

Cladophyll

A photosynthetic branch or portion of a stem that resembles and functions as a leaf, like in asparagus. *cf* . cladode, phyllode.

Clamp connection

In the Basidiomycetes fungi, a lateral connection or outgrowth formed between two adjoining cells of a hypha and arching over the septum between them.

Clavate

Club shaped thickened at one end refer to fruit or other organs.

Claw

The conspicuously narrowed basal part of a flat structure.

Clay

A naturally occurring material composed primarily of fine-grained minerals like kaolinite, montmorillonite-smectite or illite which exhibit plasticity through a variable range of water content and which can be hardened when dried and/or fired.

Clayey

Resembling or containing a large proportion of clay.

Cleft

Incised halfway down.

Cleistogamous

Refers to a flower in which fertilisation occurs within the bud, i.e. without the flower opening. *cf.* chasmogamous.

Climber

Growing more or less upwards by leaning or twining around another structure.

Clone

All the plants reproduced, vegetatively, from a single parent thus having the same genetic make-up as the parent.

Coccus

One of the sections of a distinctly lobed fruit which becomes separate at maturity; sometimes called a mericarp. *pl.* cocci.

Coenocarpium

A fleshy, multiple pseudocarp formed from an inflorescence rather than a single flower.

Coherent

Touching without organic fusion, referring to parts normally together, e.g. floral parts of the same whorl. *cf.* adherent, adnate, connate.

Collar

Boundary between the above- and below ground parts of the plant axis.

Colliculate

Having small elevations.

Column

A structure formed by the united style, stigma and stamen(s) as in Asclepiadaceae and Orchidaceae.

Comose

Tufted with hairs at the ends as of seeds.

Composite

Having two types of florets as of the flowers in the sunflower family, Asteraceae.

Compost

Organic matter (like leaves, mulch, manure, etc.) that breaks down in soil releasing its nutrients.

Compound

Describe a leaf that is further divided into leaflets or pinnae or flower with more than a single floret.

Compressed

Flattened in one plane.

Conceptacles

Specialised cavities of marine algae that contain the reproductive organs.

Concolorous

Uniformly coloured, as in upper and lower surfaces. *cf.* discolorous.

Conduplicate

Folded together lengthwise.

Cone

A reproductive structure composed of an axis (branch) bearing sterile bract-like organs and seed or pollen bearing structures. Applied to Gymnospermae, Lycopodiaceae, Casuarinaceae and also in some members of Proteaceae.

Conic

Cone shaped, attached at the broader end.

Conic-capitate

A cone-shaped head of flowers.

Connate

Fused to another structure of the same kind. *cf.* adherent, adnate, coherent.

Connective

The tissue separating two lobes of an anther.

Connivent

Converging.

Conspecific

Within or belonging to the same species.

Contorted

Twisted.

Convolute

Refers to an arrangement of petals in a bud where each has one side overlapping the adjacent petal.

Cordate

Heart-shaped as of leaves.

Core

Central part.

Coriaceous

Leathery texture as of leaves.

Corm

A short, swollen, fleshy, underground plant stem that serves as a food storage organ used by some plants to survive winter or other adverse conditions.

Cormel

A miniature, new corm produced on a mature corm.

Corn silk

The long, filamentous styles that grow as a silky tuft or tassel at the tip of an ear of corn.

Corolla

The inner floral whorl of a flower, usually consisting of free petals or a petals fused forming a corolla tube and corolla lobes. *adj* . corolline.

Corona

A crown-like section of the staminal column, usually with the inner and outer lobes as in the **Stapelieae** .

Coroniform

Crown shaped, as in the pappus of Asteraceae.

Cortex

The outer of the stem or root of a plant, bounded on the outside by the epidermis and on the inside by the endodermis containing undifferentiated cells.

Corymb

A flat-topped, short, broad inflorescence, in which the flowers, through unequal pedicels, are in one horizontal plane and the youngest in the centre. *adj* . corymbose

Costa

A thickened, linear ridge or the midrib of the pinna in ferns. *adj* . costate.

Costapalmate

Having definite costa (midrib) unlike the typical palmate leaf, but the leaflets are arranged radially like in a palmate leaf.

Cotyledon

The primary seed leaf within the embryo of a seed.

Cover crop

Crop grown in between trees or in fields primarily to protect the soil from erosion, to improve soil fertility and to keep off weeds.

Crenate

Round-toothed or scalloped as of leaf margins.

Crenulate

Minutely crenate, very strongly scalloped.

Crested

Frilled and ruffled edge.

Crispate

Weakly undulating edge.

Crisped

With a curled or twisted edge.

Cristate

Having or forming a crest or crista.

Crozier

Shaped like a shepherd's crook.

Crustaceous

Like a crust; having a hard crust or shell.

Cucullate

Having the shape of a cowl or hood, hooded.

Culm

The main aerial stem of the Graminae (grasses, sedges, rushes and other monocots).

Culm sheath

The plant casing (similar to a leaf) that protects the young bamboo shoot during growth, attached at each node of culm.

Cultigen

Plant species or race known only in cultivation.

Cultivar

Cultivated variety; an assemblage of cultivated individuals distinguished by any characters significant for the purposes of agriculture, forestry or horticulture and which, when reproduced, retains its distinguishing features.

Cuneate

Wedge-shaped, obtriangular.

Cupular

Cup-shaped, havin a cupule.

Cupule

A small cup-shaped structure or organ, like the cup at the base of an acorn.

Cusp

An elongated, usually rigid, acute point. *cf.* mucro.

Cuspidate

Terminating in or tipped with a sharp firm point or cusp. *cf.* mucronate.

Cuspidulate

Constricted into a minute cusp. *cf.* cuspidate.

Cyathiform

In the form of a cup, a little widened at the top.

Cyathium

A specialised type of inflorescence of plants in the genus Euphorbia and Chamaesyce in which the unisexual flowers are clustered together within a bract-like envelope. *pl.* cyathia.

Cylindric

Tubular or rod shaped.

Cylindric-acuminate

Elongated and tapering to a point.

Cymbiform

Boat shaped, elongated and having the upper surface decidedly concave.

Cyme

An inflorescence in which the lateral axis grows more strongly than the main axis with the oldest flower in the centre or at

the ends. *adj.* cymose.

Cymule

A small cyme or one or a few flowers.

Cystidium

A relatively large cell found on the hymenium of a Basidiomycete, for example, on the surface of a mushroom.

Cystocarp

Fruitlike structure (sporocarp) developed after fertilisation in the red algae.

Deciduous

Falling off or shedding at maturity or a specific season or stage of growth.

Decorticate

To remove the bark, rind or husk from an organ; to strip off its bark; to come off as a skin.

Decompound

As of a compound leaf; consisting of divisions that are themselves compound.

Decumbent

Prostrate, laying or growing on the ground but with ascending tips. *cf.* ascending, procumbent.

Decurrent

Having the leaf base tapering down to a narrow wing that extends to the stem.

Decussate

Having paired organs with successive pairs at right angles to give four rows as of leaves.

Deflexed

Bent downwards.

Degumming

Removal of gum deposits (phosphatides, entrained oil and meal particles) from crude edible oils traditionally done with water. Water degumming process also remove hydrophilic substances such as sugars from the oil.

Dehisce

To split open at maturity, as in a capsule.

Dehiscent

Splitting open at maturity to release the contents. *cf.* indehiscent.

Deltate

Triangular shape.

Deltoid

Shaped like an equilateral triangle.

Dendritic

Branching from a main stem or axis like the branches of a tree.

Dentate

With sharp, rather coarse teeth perpendicular to the margin.

Denticulate

Finely toothed.

Diageotropic

The tendency of growing parts, such as roots, to grow at right angle to the line of gravity.

Diadelphous

Having stamens in two bundles as in Papilionaceae flowers.

Dichasium

A cymose inflorescence in which the branches are opposite and approximately equal. *pl.* dichasia. *adj.* dichasial.

Dichotomous

Divided into two parts.

Dicotyledon

Angiosperm with two cotyledons.

Didymous

Arranged or occurring in pairs as of anthers, having two lobes.

Digitate

Having digits or fingerlike projections.

Dikaryophyses

Or dendrophydia, irregularly, strongly branched terminal hyphae in the Hymenomycetes (class of Basidiomycetes) fungi.

Dimorphic

Having or occurring in two forms, as of stamens of two different lengths or a plant having two kinds of leaves.

Dioecious

With male and female unisexual flowers on separate plants. *cf.* monoecious.

Diploid

A condition in which the chromosomes in the nucleus of a cell exist as pairs, one set being derived from the female parent and the other from the male.

Diplobiontic life cycle

Life cycle that exhibits alternation of generations, which features of spore-producing multicellular sporophytes and gamete-producing multicellular gametophytes. mitoses occur in both the diploid and haploid phases.

Diplontic life cycle

Or gametic meiosis, wherein instead of immediately dividing meiotically to produce haploid cells, the zygote divides mitotically to produce a multicellular diploid individual or a group of more diploid cells.

Diplochory

Seed dispersal involving two or more modes.

Dipterocarpous

Trees of the family Dipterocarpaceae, with two-winged fruit found mainly in tropical lowland rainforest.

Disc

(Botany) refers to the usually disc shaped receptacle of the flower head in Asteraceae; also the fleshy nectariferous organ usually between the stamens and ovary; also used for the enlarged style-end in Proteaceae.

Disc floret

The central, tubular 4 or 5-toothed or lobed floret on the disc of an inflorescence, as of flower head of Asteraceae.

Disciform

Flat and rounded in shaped. *cf.* discoid, radiate.

Discoid

Resembling a disc; having a flat, circular form; disk-shaped *cf.* disciform, radiate.

Discolorous

Having two colours, as of a leaf which has different colors on the two surfaces. *cf.* concolorous.

Disomic

Having one or more chromosomes present twice but without the entire genome doubled.

Dispersal

Dissemination of seeds.

Distal

Site of any structure farthest from the point of attachment. *cf.* proximal.

Distichous

Referring to two rows of upright leaves in the same plane.

Dithecous

Having two thecae.

Divaricate

Diverging at a wide angle.

Domatium

A part of a plant (e.g. a leaf) that has been modified to provide protection for other organisms. *pl.* domatia.

Dormancy

A resting period in the life of a plant during which growth slows or appears to stop.

Dorsal

Referring to the back surface.

Dorsifixed

Attached to the back as of anthers.

Drupaceous

Resembling a drupe.

Drupe

A fleshy fruit with a single seed enclosed in a hard shell (endocarp) which is tissue embedded in succulent tissue (mesocarp) surrounded by a thin outer skin (epicarp). *adj.* drupaceous.

Drupelet

A small drupe.

Ebracteate

Without bracts.

Echinate

Bearing stiff, stout, bristly, prickly hairs.

Edaphic

Refers to plant communities that are distinguished by soil conditions rather than by climate.

Eglandular

Without glands. *cf.* glandular.

Elaeoplasts

A type of leucoplast that is specialised for the storage of lipids in plants.

Elaiosome

Fleshy lipid-rich structures that are attached to the seeds of many plant species.

Ellipsoid

A 3-dimensional shape; elliptic in outline.

Elliptic

Having a 2-dimensional shape of an ellipse or flattened circle.

Elongate

Extended, stretched out.

Emarginate

Refers to leaf with a broad, shallow notch at the apex. *cf.* retuse.

Embryo

(Botany) a minute rudimentary plant contained within a seed or an archegonium, composed of the embryonic axis (shoot end and root end).

Endemic

Prevalent in or peculiar to a particular geographical locality or region.

Endocarp

The hard innermost layer of the pericarp of many fruit.

Endosperm

Tissue that surrounds and nourishes the embryo in the angiosperm seed. It contains starchy carbohydrates, proteins and small amounts of vitamins and minerals.

Endospermous

Refers to seeds having an endosperm.

Ensiform

Shaped like the blade of a sword, long and narrow with sharp edges and a pointed tip.

Endotrophic

As of mycorrhiza obtaining nutrients from inside.

Ensilage

The process of preserving green food for livestock in an undried condition in airtight conditions. Also called silaging.

Entire

Having a smooth, continuous margin without any incisions or teeth as of a leaf.

Entisols

Soils that do not show any profile development other than an A horizon.

Ephemeral

Transitory, short-lived.

Epicalyx

A whorl of bracts, subtending and resembling a calyx.

Epicarp

Outermost layer of the pericarp of a fruit.

Epicormic

Attached to the corm.

Epicotyl

The upper portion of the embryonic axis, above the cotyledons and below the first true leaves.

Epigeal

Above ground with cotyledons raised above ground.

Epiparasite

An organism parasitic on another that parasitises a third.

Epipetalous

Borne on the petals, as of stamens.

Epiphyte

A plant growing on, but not parasitic on, another plant, deriving its moisture and nutrients from the air and rain e.g. some Orchidaceae. *adj.* epiphytic.

Epithet

Name.

Equitant

In a loose fan pattern.

Erect

Upright, vertical.

Essential oils

Volatile products obtained from a natural source; refers to volatile products obtained by steam or water distillation in a strict sense.

Etiolation

To cause (a plant) to develop without chlorophyll by preventing exposure to sunlight.

Eutrophic

Having waters rich in mineral and organic nutrients that promote a proliferation of plant life, especially algae, which reduces the dissolved oxygen content and often causes the extinction of other organisms.

Excentric

Off the true centre.

Excrecence

Abnormal outgrowth.

Excurrent

Projecting beyond the tip, as the midrib of a leaf or bract.

Exserted

Sticking out, protruding beyond some enclosing organ, as of stamens which project beyond the corolla or perianth.

Exstipulate

Without stipules. *cf.* stipulate.

Extra-floral

Outside the flower.

Extrose

Turned outwards or away from the axis as of anthers. *cf.* introrse, latrorse.

Falcate

Sickle-shaped, crescent-shaped.

Fascicle

A cluster or bundle of stems, flowers, stamens. *adj.* fasciculate.

Fasciclude

Staminode bundles.

Fastigate

A tree in which the branches grow almost vertically.

Ferrosols

Soils with an iron oxide content of greater than 5 %.

Ferruginous

Rust coloured, reddish-brown.

Fertile

Having functional sexual parts which are capable of fertilisation and seed production. *cf.* sterile.

Filament

The stalk of a stamen supporting and subtending the anther.

Filiform

Having the form of or resembling a thread or filament.

Fimbriate

Fringed.

Fixed oils

Non volatile oils, triglycerides of fatty acids.

Flaccid

Limp and weak.

Flag leaf

The uppermost leaf on the stem.

Flaky

In the shape of flakes or scales.

Flexuous

Zig-zagging, sinuous, bending, as of a stem.

Floccose

Covered with tufts of soft woolly hairs.

Floral tube

A flower tube usually formed by the basal fusion of the perianth and stamens.

Floret

One of the small individual flowers of sunflower family or the reduced flower of the grasses, including the lemma and palea.

Flower

The sexual reproductive organ of flowering plants, typically consisting of gynoecium, androecium and perianth or calyx and/or corolla and the axis bearing these parts.

Fluted

As of a trunk with grooves and folds.

Fodder

Plant material, fresh or dried fed to animals.

Foliaceous

Leaf-like.

Foliage

Leaves of the plant.

Foliar

Pertaining to a leaf.

Foliolate

Pertaining to leaflets, used with a number prefix to denote the number of leaflets.

Foliose

Leaf-like.

Follicle

(Botany) a dry fruit, derived from a single carpel and dehiscing along one suture.

Forb

Any herb that is not grass or grass-like.

Foveolate

Surface pitted with shallow depressions.

Free central placentation

The arrangement of ovules on a central column that is not connected to the ovary wall by partitions, as in the ovaries of the carnation and primrose.

Frond

The leaf of a fern or cycad.

Fruit

Ripened ovary with adnate parts.

Frutescent

Shrubby.

Fugacious

Shedding off early.

Fulvous

Yellow, tawny.

Funiculus

(Botany) short stalk which attaches the ovule to the ovary wall.

Fuscescent

Dusky.

Fusiform

A 3-dimensional shape; spindle shaped, i.e. broad in the centre and tapering at both ends thick, but tapering at both ends.

Gall-flowers

Short styled flowers that do not develop into a fruit but are adapted for the development of a specific wasp within the fruit e.g. in the fig.

Gamete

A reproductive cell that fuses with another gamete to form a zygote. Gametes are haploid, (they contain half the normal (diploid) number of chromosomes); thus when two fuse, the diploid number is restored.

Gametophyte

The gamete-producing phase in a plant characterised by alternation of generations.

Gamosepalous

With sepals united or partially united.

Genome

Complete set of genetic material of an organism.

Geniculate

Bent like a knee, refer to awns and filaments.

Geocarpic

Where the fruit are pushed into the soil by the gynophore and mature.

Geophyte

A plant that stores food in an underground storage organ e.g. a tuber, bulb or rhizome and has subterranean buds which form aerial growth.

Geotextile

Are permeable fabrics which, when used in association with soil, have the ability to separate, filter, reinforce, protect or drain.

Germ

Of cereal is the embryo of the seed or kernel. It contains vitamins B, E, folic acid, some protein, minerals and polyunsaturated fats.

Glabrescent

Becoming glabrous.

Glabrous

Smooth, hairless without pubescence.

Gland

A secretory organ, e.g. a nectary, extra-floral nectary or a gland tipped, hair-like or wart-like organ. *adj.* glandular. *cf.* eglandular.

Glaucous

Pale blue-green in colour, covered with a whitish bloom that rubs off readily.

Gley soils

A hydric soil which exhibits a greenish-blue-grey soil color due to wetland conditions.

Globose

Spherical in shape.

Globular

A three-dimensional shape; spherical or orbicular; circular in outline.

Glochids

Tiny, finely barbed hair-like spines found on the areoles of some cacti and other plants.

Glochidiate

Having glochids.

Glochidote

Plant having glochids.

Glume

One of the two small, sterile bracts at the base of the grass spikelet, called the lower and upper glumes, due to their position on the rachilla. Also used in Apiaceae, Cyperaceae for the very small bracts on the spikelet in which each flower is subtended by one floral glume. *adj.* glumaceous.

Grits

Consist of coarsely ground corn or sometimes alkali-treated corn.

Groats

Hulled, whole grains of various cereals, such as oats, wheat, barley or buckwheat, it includes the cereal germ, fiber-rich bran portion and endosperm of the grain.

Guttation

The appearance of drops of xylem sap on the tips or edges of leaves of some vascular plants, such as grasses and bamboos.

Guttule

Small droplet.

Gymnosperm

A group of spermatophyte seed-bearing plants with ovules on scales, which are usually arranged in cone-like structures and not borne in an ovary. *cf.* angiosperm.

Gynoecium

The female organ of a flower; a collective term for the pistil, carpel or carpels.

Gynomonoecious

Having female flowers and bisexual flowers on the same plant.
cf. andromonoecious.

Gynophore

Stalk that bears the pistil/carpel.

Habit

The general growth form of a plant, comprising its size, shape, texture and stem orientation, the locality in which the plant grows.

Halophyte

A plant adapted to living in highly saline habitats. Also, a plant that accumulates high concentrations of salt in its tissues. *adj.* halophytic.

Hapaxanthic

Refer to palms which flowers only once and then dies. *c.f.* pleonanthic.

Haploid

Condition where nucleus or cell has a single set of unpaired chromosomes, the haploid number is designated as n .

Haplontic life cycle

Or zygotic meiosis wherein meiosis of a zygote immediately after karyogamy, produces haploid cells which produces more or larger haploid cells ending its diploid phase.

Hastate

Having the shape of an arrowhead but with the basal lobes pointing outward at right angles as of a leaf.

Hastula

A piece of plant material at the junction of the petiole and the leaf blade; the hastula can be found on the top of the leaf, adaxial or the bottom, abaxial or both sides.

Heartwood

Wood from the inner portion of a tree.

Heliophilous

Sun-loving, tolerates high level of sunlight.

Heliotropic

Growing towards sunlight.

Herb

A plant which is non-woody or woody at the base only, the above ground stems usually being ephemeral. *adj.* herbaceous.

Herbaceous

Resembling a herb, having a habit of a herb.

Hermaphrodite

Bisexual, bearing flowers with both androecium and gynoecium in the same flower. *adj.* hermaphroditic.

Heterocyst

A differentiated cyanobacterial cell that carries out nitrogen fixation.

Heterogamous

Bearing separate male and female flowers, bisexual and female flowers or florets in an inflorescence or flower head, e.g. some Asteraceae in which the ray florets may be neuter or unisexual and the disk florets may be bisexual. *cf.* homogamous.

Heteromorphous

Having two or more distinct forms. *cf.* homomorphous.

Heterophyllous

Having leaves of different form.

Heterosporous

Producing spores of two sizes, the larger giving rise to megagametophytes (female), the smaller giving rise to

microgametophytes (male). Refer to the ferns and fern allies. *cf.* homosporous.

Heterostylous

Having styles of two different lengths or forms.

Heterostyly

The condition in which flowers on polymorphous plants have styles of different lengths, thereby facilitating cross-pollination.

Hilar

Of or relating to a hilum.

Hilum

The scar on a seed, indicating the point of attachment to the funiculus.

Hirsute

Bearing long coarse hairs.

Hispid

Bearing stiff, short, rough hairs or bristles.

Hispidulous

Minutely hispid.

Histosol

Soil comprising primarily of organic materials, having 40 cm or more of organic soil material in the upper 80 cm.

Hoary

Covered with a greyish layer of very short, closely interwoven hairs.

Holdfast

An organ or structure of attachment, especially the basal, root-like formation by which certain seaweeds or other algae are attached to a substrate.

Holocarpic

Having the entire thallus developed into a fruiting body or sporangium.

Homochromous

Having all the florets of the same colour in the same flower head *cf.* heterochromous.

Homogamous

Bearing flowers or florets that do not differ sexually *cf.* heterogamous.

Homogenous endosperm

Endosperm with even surface that lacks invaginations or infoldings of the surrounding tissue.

Homogonium

A part of a filament of a cyanobacterium that detaches and grows by cell division into a new filament. *pl.* homogonia.

Homomorphous

Uniform, with only one form. *cf.* heteromorphous.

Homosporous

Producing one kind of spores. Refer to the ferns and fern allies. *cf.* heterosporous.

Hurd fibre

Long pith fibre of the stem.

Hyaline

Colourless, almost transparent.

Hybrid

The first generation progeny of the sexual union of plants belonging to different taxa.

Hybridisation

The crossing of individuals from different species or taxa.

Hydathode

A type of secretory tissue in leaves, usually of Angiosperms, that secretes water through pores in the epidermis or margin of the leaf.

Hydrophilous

Water loving; requiring water in order to be fertilised, referring to many aquatic plants.

Hygrochastic

Applied to plants in which the opening of the fruit is caused by the absorption of water.

Hygrophilous

Living in water or moist places.

Hymenial cystidia

The cells of the hymenium develop into basidia or asci, while in others some cells develop into sterile cells called cystidia.

Hymenium

Spore-bearing layer of cells in certain fungi containing asci (Ascomycetes) or basidia (Basidiomycetes).

Hypanthium

Cup-like receptacles of some dicotyledonous flowers formed by the fusion of the calyx, corolla and androecium that surrounds the ovary which bears the sepals, petals and stamens. Adj. relating to or of the nature of a hypanthium.

Hypha

Is a long, branching filamentous cell of a fungus and also of unrelated Actinobacteria. *pl.* hyphae.

Hypocotyl

The portion of the stem below the cotyledons.

Hypodermis

The cell layer beneath the epidermis of the pericarp.

Hypogeal

Below ground as of germination of seed.

Hysteresis

Refers to systems that may exhibit path dependence.

Imbricate

Closely packed and overlapping. *cf.* valvate.

Imparipinnate

Pinnately compound with a single terminal leaflet and hence with an odd number of leaflets. *cf.* paripinnate.

Inceptisols

Old soils that have no accumulation of clays, iron, aluminium or organic matter.

Incised

Cut jaggedly with very deep teeth.

Included

Referring to stamens which do not project beyond the corolla or to valves which do not extend beyond the rim of a capsular fruit. *cf.* exserted.

Incurved

Curved inwards; curved towards the base or apex.

Indefinite

Numerous and variable in number.

Indehiscent

Not opening or splitting to release the contents at maturity as of fruit. *cf.* dehiscent.

Indumentum

Covering of fine hairs or bristles commonly found on external parts of plants.

Indurate

To become hard, often the hardening developed only at maturity.

Indusium

An enclosing membrane, covering the sorus of a fern. Also used for the modified style end or pollen-cup of some Goodeniaceae (including Brunoniaceae). *adj.* indusiate.

Inferior

Said of an ovary or fruit that has sepals, petals and stamens above the ovary. *cf.* superior.

Inflated

Enlarged and hollow except in the case of a fruit which may contain a seed. *cf.* swollen.

Inflexed

Bent or curved inward or downward, as petals or sepals.

Inflorescence

A flower cluster or the arrangement of flowers in relation to the axis and to each other on a plant.

Infracoliar

Located below the leaves.

Infraspecific

Referring to any taxon below the species rank.

Infructescence

The fruiting stage of an inflorescence.

Infundibulum

Funnel shaped cavity or structure.

Inrolled

Curved inwards.

Integuments

Two distinct tissue layers that surround the nucellus of the ovule, forming the testa or seed coat when mature.

Intercalary

Of growth, between the apex and the base; of cells, spores, etc., between two cells.

Interfoliar

Inter leaf.

Internode

Portion of the stem, culm, branch or rhizome between two nodes or points of attachment of the leaves.

Interpetiolar

As of stipules positioned between petioles of opposite leaves.

Intrastaminal

Within the stamens.

Intricate

Entangled, complex.

Introduced

Not indigenous; not native to the area in which it now occurs.

Introrse

Turned inwards or towards the axis or pistil as of anthers. *cf.* extrorse, latrorse.

Involucre

A whorl of bracts or leaves that surround one to many flowers or an entire inflorescence.

Involute

Having the margins rolled inwards, referring to a leaf or other flat organ.

Jugate

Of a pinnate leaf; having leaflets in pairs.

Juvenile

Young or immature, used here for leaves formed on a young plant which are different in morphology from those formed on an older plant.

Keel

A longitudinal ridge at the back of the leaf. Also, the two lower fused petals of a 'pea' flower in the Papilionaceae, which form a boat-like structure around the stamens and styles, also called carina. *adj.* keeled. *cf.* standard, wing.

Labellum

The modified lowest of the three petals forming the corolla of an orchid, usually larger than the other two petals and often spurred.

Lacerate

Irregularly cleft.

Laciniate

Fringed; having a fringe of slender, narrow, pointed lobes cut into narrow lobes.

Lamella

A gill-shaped structure: fine sheets of material held adjacent to one another.

Lamina

The blade of the leaf or frond.

Lanate

Woolly, covered with long hairs which are loosely curled together like wool.

Lanceolate

Lance-shaped in outline, tapering from a broad base to the apex.

Landrace

Plants adapted to the natural environment in which they grow, developing naturally with minimal assistance or guidance from humans and usually possess more diverse phenotypes and genotypes. They have not been improved by formal breeding programs.

Laterite

Reddish–coloured soils rich in iron oxide, formed by weathering of rocks under oxidising and leaching conditions, commonly found in tropical and subtropical regions. *adj.* lateritic.

Latex

A milky, clear or sometimes coloured sap of diverse composition exuded by some plants.

Latrorse

Turned sideways, i.e. not towards or away from the axis as of anthers dehiscing longitudinally on the side. *cf.* extrorse, introse.

Lax

Loose or limp, not densely arranged or crowded.

Leaflet

One of the ultimate segments of a compound leaf.

Lectotype

A specimen chosen after the original description to be the type.

Lemma

The lower of two bracts (scales) of a grass floret, usually enclosing the palea, lodicules, stamens and ovary.

Lenticel

Is a lens shaped opening that allows gases to be exchanged between air and the inner tissues of a plant, commonly found on young bark, or the surface of the fruit.

Lenticellate

Dotted with lenticels.

Lenticular

Shaped like a biconvex lens. *cf.* lentiform.

Lentiform

Shaped like a biconvex lens, *cf.* lenticular.

Leptomorphic

Temperate, running bamboo rhizome; usually thinner than the culms they support and the internodes are long and hollow.

Liane

A woody climbing or twining plant.

Ligneous

Woody.

Lignotuber

A woody, usually underground, tuberous rootstock often giving rise to numerous aerial stems.

Ligulate

Small and tongue shaped or with a little tongue shaped appendage or ligule, star shaped as of florets of Asteraceae.

Ligule

A strap-shaped corolla in the flowers of Asteraceae; also a thin membranous outgrowth from the inner junction of the grass leaf sheath and blade. *cf.* ligulate.

Limb

The expanded portion of the calyx tube or the corolla tube or the large branch of a tree.

Linear

A 2-dimensional shape, narrow with nearly parallel sides.

Linguiform

Tongue shaped *cf.* ligulate.

Lipotubuloids

Are cytoplasmic domains containing aggregates of lipid bodies surrounded by a network of microtubules, which join one lipid body with the others.

Lithosol

A kind of shallow soils lacking well-defined horizons and composed of imperfectly weathered fragments of rock.

Littoral

Of or on a shore, especially seashore.

Loam

A type of soil made up of sand, silt and clay in relative concentration of 40-40-20 % respectively.

Lobed

Divided but not to the base.

Loculicidal

Opening into the cells, when a ripe capsule splits along the back.

Loculus

Cavity or chamber of an ovary. *pl.* loculi.

Lodicules

Two small structures below the ovary which, at flowering, swell up and force open the enclosing bracts, exposing the stamens and carpel.

Lorate

Strap-shaped with obtuse tip.

Lyrate

Pinnately lobed, with a large terminal lobe and smaller lateral ones which become progressively smaller towards the base.

Macronutrients

Chemical elements which are needed in large quantities for growth and development by plants and include nitrogen, phosphorus, potassium and magnesium.

Maculate

Spotted.

Mallee

A growth habit in which several to many woody stems arise separately from a lignotuber; usually applied to certain low-growing species of *Eucalyptus*.

Mangrove

A distinctive vegetation type of trees and shrubs with modified roots, often viviparous, occupying the saline coastal habitats that are subject to periodic tidal inundation.

Marcescent

Withering or to decay without falling off.

Margin

The edge of the leaf blade.

Medulla

The pith in the stems or roots of certain plants; or the central portion of a thallus in certain lichens.

Megasporangium

The sporangium containing megaspores in fern and fern allies. *cf.* microsporangium.

Megaspore

The large spore which may develop into the female gametophyte in heterosporous ferns and fern allies. *cf.* microspore.

Megasporophyll

A leaflike structure that bears megasporangia.

Megastrobilus

Female cone, seed cone or ovulate cone, contains ovules within which, when fertilised by pollen, become seeds. The female cone structure varies more markedly between the different conifer families.

Meiosis

The process of cell division that results in the formation of haploid cells from diploid cells to produce gametes.

Mericarp

A 1-seeded portion of an initially syncarpous fruit (schizocarp) which splits apart at maturity. *cf.* coccus.

Meristem

The region of active cell division in plants, from which permanent tissue is derived. *adj.* meristematic.

Merous

Used with a number prefix to denote the basic number of the three outer floral whorls, e.g. a 5-merous flower may have five sepals, ten petals and 15 stamens.

Mesic

Moderately wet.

Mesocarp

The middle layer of the fruit wall derived from the middle layer of the carpel wall. *cf.* endocarp, exocarp, pericarp.

Mesophytes

Terrestrial plants which are adapted to neither a particularly dry nor particularly wet environment.

Micropyle

The small opening in a plant ovule through which the pollen tube passes in order to effect fertilisation.

Microsporangium

The sporangium containing microspores in petridophytes. *cf.* megasporangium.

Microspore

A small spore which gives rise to the male gametophyte in heterosporous pteridophytes. Also for a pollen grain. *cf.* megaspore.

Midvein

The main vascular supply of a simple leaf blade or lamina. Also called mid-rib.

Mitosis

Is a process of cell division which results in the production of two daughter cells from a single parent cell.

Mollisols

Soils with deep, high organic matter, nutrient-enriched surface soil (A horizon), typically between 60 and 80 cm thick.

Monadelphous

Applied to stamens united by their filaments into a single bundle.

Monocarpic

Refer to plants that flower, set seeds and then die.

Monochasial

A cyme having a single flower on each axis.

Monocotyledon

Angiosperm having one cotyledon.

Monoecious

Having both male and female unisexual flowers on the same individual plant. *cf.* dioecious.

Monoembryonic seed

The seed contains only one embryo, a true sexual (zygotic) embryo. polyembryonic seed.

Monolete

A spore that has a simple linear scar.

Monopodial

With a main terminal growing point producing many lateral branches progressively. *cf.* sympodial.

Monostichous

Forming one row.

Monotypic

Of a genus with one species or a family with one genus; in general, applied to any taxon with only one immediately

subordinate taxon.

Montane

Refers to highland areas located below the subalpine zone.

Mucilage

A soft, moist, viscous, sticky secretion. *adj.* mucilaginous.

Mucous

(Botany) slimy.

Mucro

A sharp, pointed part or organ, especially a sharp terminal point, as of a leaf.

Mucronate

Ending with a short, sharp tip or mucro, resembling a spine. *cf* . cuspidate, muticous.

Mucronulate

With a very small mucro; a diminutive of mucronate.

Mulch

Protective cover of plant (organic) or non-plant material placed over the soil, primarily to modify and improve the effects of the local microclimate and to control weeds.

Multiple fruit

A fruit that is formed from a cluster of flowers.

Muricate

Covered with numerous short hard outgrowths. *cf* . papillose.

Muriculate

With numerous minute hard outgrowths; a diminutive of muricate.

Muticous

Blunt, lacking a sharp point. *cf* . mucronate.

MYB proteins

Are a superfamily of transcription factors that play regulatory roles in developmental processes and defense responses in plants.

Mycorrhiza

The mutualistic symbiosis (non-pathogenic association) between soil-borne fungi with the roots of higher plants.

Mycorrhiza (vesicular arbuscular)

Endomycorrhiza living in the roots of higher plants producing inter-and intracellular fungal growth in root cortex and forming specific fungal structures, referred to as vesicles and arbuscles. *abbrev.* VAM.

Myrmecochory

Seed dispersal by ants.

Native

A plant indigenous to the locality or region.

Naviculate

Boat-shaped.

Necrotic

Applied to dead tissue.

Nectariferous

Having one or more nectaries.

Nectary

A nectar-secretory gland; commonly in a flower, sometimes on leaves, fronds or stems.

Nervation

Venation, a pattern of veins or nerves as of leaf.

Nixtamalisation

Refers to a process for the preparation of maize (corn) or other grain, in which the grains are soaked and cooked in an alkaline solution, usually limewater, and hulled.

Node

The joint between segments of a culm, stem, branch or rhizome; the point of the stem that gives rise to the leaf and bud.

Nodule

A small knoblike outgrowth, as those found on the roots of many leguminous, that containing *Rhizobium* bacteria which fixes nitrogen in the soil.

Nom. ambig.

Nomen ambiguum (Latin) ambiguous name used in different senses which has become a long-persistent source of error.

Nom. cons.

Nomen nonservandum (Latin) name conserved in International Code of Botanical Nomenclature.

Nom. dub.

Nomen dubium (Latin) an invalid proposed taxonomic name because it is not accompanied by a definition or description of the taxon to which it applies.

Nom. illeg.

Nomen illegitimum (Latin) illegitimate taxon deemed as superfluous at its time of publication either because the taxon to which it was applied already has a name or because the name has already been applied to another plant.

Nom. invalid.

Nomen invalidum (Latin) invalid name according to International Code of Botanical Nomenclature.

Nom. nud.

Nomen nudum (Latin) the name of a taxon which has never been validated by a description.

Nom. rej.

Nomen rejiciendum (Latin) name rejected in International Code of Botanical Nomenclature.

Notho-

(Subsp. or var.) prefix to the rank of a hybrid taxon below the rank of species.

Nucellus

Central portion of an ovule in which the embryo sac develops.

Nucellar embryony

A form of seed reproduction in which the nucellar tissue which surrounds the embryo sac can produce additional embryos (polyembryony) which are genetically identical to the parent plant. This is found in many citrus species and in mango.

Nut

A dry indehiscent 1-celled fruit with a hard pericarp.

Nutlet

A small. 1-seeded, indehiscent lobe of a divided fruit.

Ob-

Prefix meaning inverse or opposite to.

Obconic

A 3-dimensional shape; inversely conic; cone shaped, conic with the vertex pointing downward.

Obcordate

Inversely cordate, broad and notched at the tip; heart shaped but attached at the pointed end.

Obdeltate

Inversely deltate; deltate with the broadest part at the apex.

Ob lanceolate

Inversely lanceolate, lance-shaped but broadest above the middle and tapering toward the base as of leaf.

Oblate

Having the shape of a spheroid with the equatorial diameter greater than the polar diameter; being flattened at the poles.

Oblong

Longer than broad with sides nearly parallel to each other.

Obovate

Inversely ovate, broadest above the middle.

Obpyramidal

Resembling a 4-sided pyramid attached at the apex with the square base facing away from the attachment.

Obpyriform

Inversely pyriform, resembling a pear which is attached at the narrower end. *cf.* pyriform.

Obspathulate

Inversely spathulate; resembling a spoon but attached at the broadest end. *cf.* spathulate.

Obtriangular

Inversely triangular; triangular but attached at the apex. *cf.* triangular.

Obtrullate

Inversely trullate; resembling a trowel blade with the broadest axis above the middle. *cf.* trullate.

Obtuse

With a blunt or rounded tip, the converging edges separated by an angle greater than 90°.

-oid

Suffix denoting a 3-dimensional shape, e.g. spheroid.

Ochraceous

A dull yellow color.

Ocreate

Having a tube-like covering around some stems, formed of the united stipules; sheathed.

Oleaginous

Oily.

Oligotrophic

Lacking in plant nutrients and having a large amount of dissolved oxygen throughout.

Operculum

A lid or cover that becomes detached at maturity by abscission, e.g. in *Eucalyptus* , also a cap or lid covering the bud and formed by fusion or cohesion of sepals and/or petals. *adj.* operculate.

Opposite

Describing leaves or other organs which are borne at the same level but on opposite sides of the stem. *cf.* alternate.

Orbicular

Of circular outline, disc-like.

Order

A taxonomic rank between class and family used in the classification of organisms, i.e. a group of families believed to be closely related.

Orifice

An opening or aperture.

Organosols

Soils not regularly inundated by marine waters and containing a specific thickness of organic materials within the upper part of the profile.

Orth. Var.

Orthographic variant, i.e. an incorrect alternate spelling of a name.

Ovary

The female part of the pistil of a flower which contains the ovules (immature seeds).

Ovate

Egg-shaped, usually with reference to two dimensions.

Ovoid

Egg-shaped, usually with reference to three dimensions.

Ovule

The young, immature seed in the ovary which becomes a seed after fertilisation. *adj.* ovular.

Ovulode

A sterile reduced ovule borne on the placenta, commonly occurring in Myrtaceae.

Oxisols

Refer to ferralsols.

Pachymorphic

Describes the short, thick rhizomes of clumping bamboos with short, thick and solid inter-node (except the bud-bearing internodes, which are more elongated). *cf.* sympodial.

Palate

(Botany) a raised appendage on the lower lip of a corolla which partially or completely closes the throat.

Palea

The upper of the two membranous bracts of a grass floret, usually enclosing the lodicules, stamens and ovary. *pl.* paleae. *adj.* paleal. *cf.* lemma.

Paleate

Having glumes.

Palm heart

Refers to soft, tender inner core and growing bud of certain palm trees which are eaten as vegetables. Also called heart of palm, palmito, burglar's thigh, chonta or swamp cabbage.

Palmate

Describing a leaf which is divided into several lobes or leaflets which arise from the same point. *adj.* palmately.

Palmito

See palm heart.

Palustrial

Paludal, swampy, marshy.

Palustrine

Marshy, swampy.

Palustrine herb

Vegetation that is rooted below water but grows above the surface in wetland system.

Panduriform

Fiddle shaped, usually with reference to two dimensions.

Panicle

A compound, indeterminate, racemose inflorescence in which the main axis bears lateral racemes or spikes. *adj.* paniculate.

Pantropical

Distributed through-out the tropics.

Papilionaceous

Butterfly-like, said of the pea flower or flowers of Papilionaceae, flowers which are zygomorphic with imbricate petals, one broad upper one, two narrower lateral ones and two narrower lower ones.

Papilla

A small, superficial protuberance on the surface of an organ being an outgrowth of one epidermal cell. *pl.* papillae. *adj.* papillose.

Papillate

Having papillae.

Papillose

Covered with papillae.

Pappus

A tuft (or ring) of hairs, bristles or scales borne above the ovary and outside the corolla as in Asteraceae often persisting as a tuft of hairs on a fruit. *adj.* pappose.

Papyraceous

Resembling parchment or paper.

Parenchyma

Undifferentiated plant tissue composed of more or less uniform cells.

Parietal

Describes the attachment of ovules to the outer walls of the ovaries.

Paripinnate

Pinnate with an even number of leaflets and without a terminal leaflet. *cf.* imparipinnate.

-partite

Divided almost to the base into segments, the number of segments written as a prefix.

Patelliform

Shaped like a limpet shell; cap-shaped and without whorls.

Patent

Diverging from the axis almost at right angles.

Peat

Is an accumulation of partially decayed vegetation matter.

Pectin

A group of water-soluble colloidal carbohydrates of high molecular weight found in certain ripe fruit.

Pectinate

Pinnatifid with narrow segments resembling the teeth of a comb.

Pedicel

The stalk of the flower or stalk of a spikelet in Poaceae. *adj.* pedicellate.

Pedicellate

Having pedicel.

Peduncle

A stalk supporting an inflorescence. *adj.* pedunculate.

Pellucid

Allowing the passage of light; transparent or translucent.

Pellucid-dotted

Copiously dotted with immersed, pellucid, resinous glands.

Peltate

With the petiole attached to the lower surface of the leaf blade.

Pendant

Hanging down.

Pendulous

Drooping, as of ovules.

Penniveined or penni-nerved

Pinnately veined.

Pentamerous

In five parts.

Perennial

A plant that completes its life cycle or lives for more than two years. *cf.* annual, biennial.

Perfoliate

A leaf with the basal lobes united around—and apparently pierced by—the stem.

Pergamentaceous

Parchment-like.

Perianth

The two outer floral whorls of the Angiosperm flower; commonly used when the calyx and the corolla are not readily distinguishable (as in monocotyledons).

Pericarp

(Botany). The wall of a ripened ovary; fruit wall composed of the exocarp, mesocarp and endocarp.

Persistent

Remaining attached; not falling off. *cf.* caduceus.

Petal

Free segment of the corolla. *adj.* petaline. *cf.* lobe.

Petiole

Relating to the petiole.

Petiolate

Having petiole.

Petiole

Leaf stalk. *adj.* petiolate.

Petiolulate

Supported by its own petiolule.

Petiolule

The stalk of a leaflet in a compound leaf. *adj.* petiolulate.

pH

Is a measure of the acidity or basicity of a solution. It is defined as the cologarithm of the activity of dissolved hydrogen ions (H⁺).

Phenology

The study of periodic plant life cycle events as influenced by seasonal and interannual variations in climate.

Phyllary

A bract of the involucre of a composite plant, term for one of the scale-like bracts beneath the flower-head in Asteraceae.

Phylloclade

A flattened, photosynthetic branch or stem that resembles or performs the function of a leaf, with the true leaves represented by scales.

Phyllode

A petiole that function as a leaf. *adj.* phyllodineous. *cf.* cladode.

Phyllopodia

Refer to the reduced, scale-like leaves found on the outermost portion of the corm where they seem to persist longer than typical sporophylls as in the fern *Isoetes*.

Phytoremediation

Describes the treatment of environmental problems (bioremediation) through the use of plants which mitigate the environmental problem without the need to excavate the contaminant material and dispose of it elsewhere.

Pileus

(Botany) cap of mushroom.

Piliferous

(Botany) bearing or producing hairs, as of an organ with the apex having long, hair-like extensions.

Pilose

Covered with fine soft hairs.

Pinna

A primary division of the blade of a compound leaf or frond.
pl. pinnae.

Pinnate

Bearing leaflets on each side of a central axis of a compound leaf; divided into pinnae.

Pinnatifid, pinnatilobed

A pinnate leaf parted approximately halfway to midrib; when divided to almost to the mid rib described as deeply pinnatifid or pinnatisect.

Pinnatisect

Lobed or divided almost to the midrib.

Pinnule

A leaflet of a bipinnate compound leaf.

Pistil

Female part of the flower comprising the ovary, style and stigma.

Pistillate

Having one or more pistils; having pistils but no stamens.

Placenta

The region within the ovary to which ovules are attached. *pl.* placentae.

Placentation

The arrangement of the placentae and ovules in the ovary.

Plano-

A prefix meaning level or flat.

Pleonanthic

Refer to palms in which the stem does not die after flowering.

Plicate

Folded like a fan.

Plumose

Feather-like, with fine hairs arising laterally from a central axis; feathery.

Pneumatophore

Modified root which allows gaseous exchange in mud-dwelling shrubs, e.g. mangroves.

Pod

A dry 1 to many-seeded dehiscent fruit, as applied to the fruit of Fabaceae, i.e. Caesalpiniaceae, Mimosaceae and Papilionaceae.

Podzol, Podsolic soil

Any of a group of acidic, zonal soils having a leached, light-coloured, gray and ashy appearance. Also called spodosol.

Pollen cone

Male cone or microstrobilus or pollen cone is structurally similar across all conifers, extending out from a central axis are microsporophylls (modified leaves). Under each microsporophyll is one or several microsporangia (pollen sacs).

Pollinia

The paired, waxy pollen masses of flowers of orchids and milkweeds.

Polyandrous

(Botany) having an indefinite number of stamens.

Polyembryonic seed

Seeds contain many embryos, most of which are asexual (nucellar) in origin and genetically identical to the maternal parent.

Polygamous

With unisexual and bisexual flowers on the same or on different individuals of the same species.

Polymorphic

With different morphological variants.

Polypetalous

(Botany) having a corolla composed of distinct, separable petals.

Pome

A fleshy fruit where the succulent tissues are developed from the receptacle.

Pore

A tiny opening.

Premorse

Abruptly truncated, as though bitten or broken off as of a leaf.

Procumbent

Trailing or spreading along the ground but not rooting at the nodes, referring to stems. *cf.* ascending, decumbent, erect.

Pro hyb.

(Latin) as a hybrid.

Pro parte

(Latin) in part.

Pro Parte majore

(Latin) for the greater part.

Pro parte minore

(Latin) for a small part.

Pro sp.

(Latin) as a species.

Pro subsp.

(Latin) as a subspecies.

Pro syn.

(Latin) as a synonym.

Prophyll

A plant structure that resembles a leaf.

Prostrate

Lying flat on the ground.

Protandous

Relating to a flower in which the anthers release their pollen before the stigma of the same flower becomes receptive.

Proximal

End of any structure closest to the point of attachment. *cf.* distal.

Pruinose

Having a thick, waxy, powdery coating or bloom.

Pseudocarp

A false fruit, largely made up of tissue that is not derived from the ovary but from floral parts such as the receptacle and calyx.

Pseudostem

The false, herbaceous stem of a banana plant composed of overlapping leaf bases.

Pteridophyte

A vascular plant which reproduces by spores; the ferns and fern allies.

Puberulent

Covered with minute hairs or very fine down; finely pubescent.

Puberulous

Covered with a minute down.

Pubescent

Covered with short, soft hairs.

Pulvinate

Having a swelling, pulvinus at the base as a leaf stalk.

Pulvinus

Swelling at the base of leaf stalk.

Pulviniform

Swelling or bulging.

Punctate

Marked with translucent dots or glands.

Punctiform

Marked by or composed of points or dots.

Punctulate

Marked with minute dots; a diminutive of punctate.

Purpurascent

Purple or becoming purple.

Pusticulate

Characterised by small pustules.

Pyrene

The stone or pit of a drupe, consisting of the hardened endocarp and seed.

Pyriform

Pear-shaped, a 3-dimensional shape; attached at the broader end. *cf.* obpyriform.

Pyxidium

Seed capsule having a circular lid (operculum) which falls off to release the seed.

Raceme

An indeterminate inflorescence with a simple, elongated axis and pedicellate flowers, youngest at the top. *adj.* racemose.

Rachilla

The main axis of a grass spikelet.

Rachis

The main axis of the spike or other inflorescence of grasses or a compound leaf.

Radiate

Arranged around a common centre, as of an inflorescence of Asteraceae with marginal, female or neuter, ligulate ray-

florets and central, perfect or functionally male, tubular, disc florets. *cf.* disciform, discoid.

Radical

Arising from the root or its crown or the part of a plant embryo that develops into a root.

Ray

The marginal portion of the inflorescence of Asteraceae and Apiaceae when distinct from the disc. Also, the spreading branches of a compound umbel.

Receptacle

The region at the end of a pedicel or on an axis which bears one or more flowers. *adj.* receptacular.

Recurved

Curved downwards or backwards.

Reflexed

Bent or turned downward.

Regosol

Soil that is young and undeveloped, characterised by medium to fine-textured unconsolidated parent material that maybe alluvial in origin and lacks a significant horizon layer formation.

Reniform

Kidney shaped in outline.

Repand

With slightly undulate margin.

Replicate

Folded back, as in some corolla lobes.

Resinous

Producing sticky resin.

Resupinate

Twisted through 180°.

Reticulate

Having the appearance of a network.

Retorse

Bent or directed downwards or backwards. *cf.* antrorse.

Retuse

With a very blunt and slightly notched apex. *cf.* emarginated.

Revolute

With the margins inrolled on the lower (abaxial) surface.

Rhizine

A root-like filament or hair growing from the stems of mosses or on lichens.

Rhizoid

Root-like filaments in a moss, fern, fungus, etc. that attach the plant to the substratum.

Rhizome

A prostrate or underground stem consisting of a series of nodes and internodes with adventitious roots and which generally grows horizontally.

Rhizophore

A stilt-like outgrowth of the stem which branches into roots on contact with the substrate.

Rhombic

Shaped like a rhombus.

Rhomboid

Shaped like a rhombus.

Rib

A distinct vein or linear marking, often raised as a linear ridge.

Riparian

Along the river margins, interface between land and a stream.

Rosette

A tuft of leaves or other organs arranged spirally like petals in a rose, ranging in form from a hemispherical tuft to a flat whorl. *adj.* rosetted, rosulate.

Rostrate

Beaked; the apex tapered into a slender, usually obtuse point.

Rostrum

A beak-like extension.

Rosulate

Having a rosette.

Rotate

Wheel shaped; refers to a corolla with a very short tube and a broad upper part which is flared at right angles to the tube. *cf.* salverform.

Rotundate

Rounded; especially at the end or ends.

Rugae

Refers to a series of ridges produced by folding of the wall of an organ.

Rugose

Deeply wrinkled.

Rugulose

Finely wrinkled.

Ruminate

(Animal) chew repeatedly over an extended period.

Ruminate endosperm

Uneven endosperm surface that is often highly enlarged by ingrowths or infoldings of the surrounding tissue. *cf.* homogenous endosperm.

Rz value

Is a numerical reference to the mesh/emulsion equalisation on the screen.

Saccate

Pouched.

Sagittate

Shaped like an arrow head.

Saline soils

Soils that contain excessive levels of salts that reduce plant growth and vigour by altering water uptake and causing ion-specific toxicities or imbalances.

Salinity

Is characterised by high electrical conductivities and low sodium ion concentrations compared to calcium and magnesium.

Salverform

Applies to a gamopetalous corolla having a slender tube and an abruptly expanded limb.

Samara

An indehiscent, winged, dry fruit.

Sand

A naturally occurring granular material composed of finely divided rock and mineral particles range in diameter from 0.0625 μm to 2 mm. *adj.* sandy.

Saponins

Are plant glycosides with a distinctive foaming characteristic. They are found in many plants, but get their name from the soapwort plant (*Saponaria*).

Saprophytic

Living on and deriving nourishment from dead organic matter.

Sapwood

Outer woody layer of the tree just adjacent to and below the bark.

Sarcotesta

Outermost fleshy covering of Cycad seeds below which is the sclerotesta.

Scabrid

Scurfy, covered with surface abrasions, irregular projections or delicate scales.

Scabrous

Rough to the touch because of scattered rough hairs.

Scale

Dry bract or leaf.

Scandent

Refer to plants, climbing.

Scape

Erect flowering stem, usually leafless, rising from the crown or roots of a plant. *adj.* scapose.

Scapigerous

With a scape.

Scarious

Dry, thin and membranous.

Schizocarp

A dry fruit which splits into longitudinally multiple parts called mericarps or cocci. *adj.* schizocarpous.

Sclerotesta

The innermost fleshy coating of cycad seeds, usually located directly below the sarcotesta.

Scorpoid

Refers to a cymose inflorescence in which the main axis appears to coil.

Scutellum

(Botany) any of various parts shaped like a shield.

Secondary venation

Arrangement of the lateral veins arising from the midrib in the leaf lamina.

Secund

With the flowers all turned in the same direction.

Sedge

A plant of the family Apiaceae, Cyperaceae.

Segmented

Constricted into divisions.

Seminal root

Or seed root originate from the scutellar node located within the seed embryo and are composed of the radicle and lateral seminal roots.

Senescence

Refers to the biological changes which take place in plants as they age.

Sepal

Free segment of the calyx. *adj.* sepaline.

Septum

A partition or cross wall. *pl.* septa. *adj.* septate.

Seriate

Arranged in rows.

Sericeous

Silky; covered with close-pressed, fine, straight silky hairs.

Serrate

Toothed like a saw; with regular, asymmetric teeth pointing forward.

Serrated

Toothed margin.

Serratures

Serrated margin.

Serrulate

With minute teeth on the margin.

Sessile

Without a stalk.

Seta

A bristle or stiff hair. *pl.* setae. *adj.* setose, setaceous.

Setaceous

Bristle-like.

Setate

With bristles.

Setiform

Bristle shaped.

Setulose

With minute bristles.

Sheathing

Clasping or enveloping the stem.

Shrub

A woody plant usually less than 5 m high and many-branched without a distinct main stem except at ground level.

Silicula

A broad, dry, usually dehiscent fruit derived from two or more carpels which usually dehisce along two sutures. *cf.* siliqua.

Siliqua

A silicula which is at least twice as long as broad.

Silt

Is soil or rock derived granular material of a grain size between sand and clay, grain particles ranging from 0.004 to 0.06 mm in diameter. *adj.* silty.

Simple

Refer to a leaf or other structure that is not divided into parts.
cf. compound.

Sinuate

With deep wavy margin.

Sinuous

Wavy.

Sinus

An opening or groove, as occurs between the bases of two petals.

Sodicity

Is characterised by low electrical conductivities and high sodium ion concentrations compared to calcium and magnesium.

Sodic soils

Contains high levels of sodium salts that affects soil structure, inhibits water movement and causes poor germination and crop establishment and plant toxicity.

Soil pH

Is a measure of the acidity or basicity of the soil. See pH.

Solitary

Usually refer to flowers which are borne singly and not grouped into an inflorescence or clustered.

Sorocarp

Fruiting body formed by some cellular slime moulds, has both stalk and spore mass.

Sorophore

Stalk bearing the sorocarp.

Sorosis

Fleshy multiple fruit formed from flowers that are crowded together on a fleshy stem e.g. pineapple and mulberry.

Sorus

A discrete aggregate of sporangia in ferns. *pl.* sori.

Spadix

Fleshy spike-like inflorescence with an unbranched, usually thickened axis and small embedded flowers often surrounded by a spathe. *pl.* spadices.

Spathe

A large bract ensheathing an inflorescence or its peduncle. *adj.* spathaceous.

Spatheate

Like or with a spathe.

Spathulate

Spatula or spoon shaped; broad at the tip and narrowed towards the base.

Spicate

Borne in or forming a spike.

Spiculate

Spikelet-bearing.

Spike

An unbranched, indeterminate inflorescence with sessile flowers or spikelets. *adj.* spicate, spiciform.

Spikelet

A small or secondary spike characteristics of the grasses and sedges and, generally composed of two glumes and one or more florets. Also applied to the small spike-like inflorescence or inflorescence units commonly found in Apiaceae.

Spine

A stiff, sharp, pointed structure, formed by modification of a plant organ. *adj.* spinose.

Spinescent

Ending in a spine; modified to form a spine.

Spinulate

Covered with small spines.

Spinulose

With small spines over the surface.

Spodosol

See podsol.

Sporidia

Asexual spores of smut fungi.

Sporangium

A spore bearing structure found in ferns, fern allies and gymnosperms. *pl.* sporangia. *adj.* sporangial.

Sporocarp

A stalked specialised fruiting structure formed from modified sporophylls, containing sporangia or spores as found in ferns and fern allies.

Sporophore

A spore-bearing structure, especially in fungi.

Sporophyll

A leaf or bract which bears or subtends sporangia in the fern allies, ferns and gymnosperms.

Sporophyte

The spore-producing phase in the life cycle of a plant that exhibits alternation of generations.

Spreading

Bending or spreading outwards and horizontally.

Spur

A tubular or saclike extension of the corolla or calyx of a flower.

Squama

Structure shaped like a fish scale. *pl.* squamae.

Squamous

Covered in scales.

Squarrose

Having rough or spreading scale-like processes.

Stamen

The male part of a flower, consisting typically of a stalk (filament) and a pollen-bearing portion (anther). *adj.* staminal, staminate.

Staminate

Unisexual flower bearing stamens but no functional pistils.

Staminode

A sterile or abortive stamen, often reduced in size and lacking anther. *adj.* staminodial.

Standard

Refers to the adaxial petal in the flower of Papilionaceae. *cf.* keel, wing.

Starch

A polysaccharide carbohydrate consisting of a large number of glucose units joined together by glycosidic bonds α -1-4 linkages.

Stellate

Star shaped, applies to hairs.

Stem

The main axis of a plant, developed from the plumule of the embryo and typically bearing leaves.

Sterile

Lacking any functional sexual parts which are capable of fertilisation and seed production.

Stigma

The sticky receptive tip of an ovary with or without a style which is receptive to pollen.

Stilt root

A supporting root arising from the stem some distance above the ground as in some mangroves, sometimes also known as a prop root.

Stipe

A stalk that support some other structure like the frond, ovary or fruit.

Stipule

Secondary stipule at the base of a leaflet. *pl.* stipellae. *adj.* stipellate.

Stipitate

Having a stalk or stipe, usually of an ovary or fruit.

Stipulated

Having stipules.

Stipule

Small leaf-like, scale-like or bristle-like appendages at the base of the leaf or on the petiole. *adj.* stipulate.

Stolon

A horizontal, creeping stem rooting at the nodes and giving rise to another plant at its tip.

Stoloniferous

Bearing stolon or stolons.

Stoma

A pore in the epidermis of the leaf or stem for gaseous exchange. *pl.* stomata.

Stone

The hard endocarp of a drupe, containing the seed or seeds.

Stramineous

Chaffy; straw-liked.

Striae

Parallel longitudinal lines or ridges. *adj.* striate.

Striate

Marked with fine longitudinal parallel lines or ridges.

Strigose

Bearing stiff, straight, closely appressed hair; often the hairs have swollen bases.

Strobilus

A cone-like structure formed from sporophylls or sporangiophores. *pl.* strobili.

Strophile

An appendage at the hilum of certain plant seeds.

Strophiolate

Furnished with a strophile or caruncle.

Style

The part of the pistil between the stigma and ovary.

Sub-

A prefix meaning nearly or almost, as in subglobose or subequal.

Subcarnose

Nearly fleshy.

Sub-family

Taxonomic rank between the family and tribe.

Subglobose

Nearly spherical in shape.

Subretuse

Faintly notched at the apex.

Subsessile

Nearly stalkless or sessile.

Subshrub

Intermediate between a herb and shrub.

Subspecies

A taxonomic rank subordinate to species.

Substrate

Surface on which a plant or organism grows or attached to.

Subtend

Attached below something.

Subulate

Narrow and tapering gradually to a fine point, awl-shaped.

Succulent

Fleshy, juicy, soft in texture and usually thickened.

Suckers

Young plants sprouting from the underground roots of a parent plant and appearing around the base of the parent plant.

Suffrutescent stem

Stem woody at the base.

Sulcate

Grooved longitudinally with deep furrows.

Sulcus

A groove or depression running along the internodes of culms or branches.

Superior

Refers to the ovary is free and mostly above the level of insertion of the sepals and petals. *cf.* inferior.

Suture

Line of dehiscence.

Swidden

Slash-and-burn or shifting cultivation.

Syconium

A type of pseudocarp formed from a hollow receptacle with small flowers attached to the inner wall. After fertilisation the ovaries of the female flowers develop into one-seeded achenes, e.g. fig.

Symbiosis

Describes close and often long-term mutualistic and beneficial interactions between different organisms.

Sympetalous

Having petals united.

Sympodial

Refers to a specialised lateral growth pattern in which the apical meristem. *cf* monopodial.

Synangium

An organ composed of united sporangia, divided internally into cells, each containing spores. *pl.* synangia.

Syncarp

An aggregate or multiple fruit formed from two or more united carpels with a single style. *adj.* syncarpous.

Syncarpous

Carpels fused forming a compound pistil.

Synteny

Presence of two or more genetic loci on the same chromosome.

Tannins

Group of plant-derived phenolic compounds.

Taxon

The taxonomic group of plants of any rank. e.g. a family, genus, species or any infraspecific category. *pl.* taxa.

Tendrill

A slender, threadlike organ formed from a modified stem, leaf or leaflet which, by coiling around objects, supports a climbing plant.

Tepal

A segment of the perianth in a flower in which all the perianth segments are similar in appearance and are not differentiated into calyx and corolla; a sepal or petal.

Tetrasporangium

A sporangium containing four haploid spores as found in some algae.

Terete

Having a circular shape when cross-sectioned or a cylindrical shape that tapers at each end.

Terminal

At the apex or distal end.

Ternate

In threes as of leaf with three leaflets.

Testa

A seed coat, outer integument of a seed.

Thallus

Plant body of algae, fungi and other lower organisms.

Thyrse

A dense, panicle-like inflorescence, as of the lilac, in which the lateral branches terminate in cymes.

Tomentose

Refers to plant hairs that are bent and matted forming a wooly coating.

Tomentellose

Mildly tomentose.

Torus

Receptacle of a flower.

Transpiration

Evaporation of water from the plant through leaf and stem pores.

Tree

That has many secondary branches supported clear of the ground on a single main stem or trunk.

Triangular

Shaped like a triangle, 3-angled and 3-sided.

Tribe

A category intermediate in rank between subfamily and genus.

Trichome

A hair-like outgrowth of the epidermis.

Trichotomous

Divided almost equally into three parts or elements.

Tridentate

Three toothed or three pronged.

Trifid

Divided or cleft into three parts or lobes.

Trifoliate

Having three leaves.

Trifoliolate

A leaf having three leaflets.

Trifurcate

Having three forks or branches.

Trigonous

Obtusely three-angled; triangular in cross-section with plane faces.

Tripartite

Consisting of three parts.

Tripinnate

Relating to leaves, pinnately divided three times with pinnate pinnules.

Tripliveined

Main laterals arising above base of lamina.

Triploid

Describing a nucleus or cell that has three times ($3n$) the haploid number (n) of chromosomes.

Triveined

Main laterals arising at the base of lamina.

Triquetrous

Three-edged; acutely 3-angled.

Trullate

With the widest axis below the middle and with straight margins; ovate but margins straight and angled below middle, trowel-shaped, angular ovate.

Truncate

With an abruptly transverse end as if cut off.

Tuber

A stem, usually underground, enlarged as a storage organ and with minute scale-like leaves and buds. *adj.* tuberous.

Tubercle

A wart-like protuberance. *adj.* tuberculate.

Tuberculate

Bearing tubercles; covered with warty lumps.

Tuberisation

Formation of tubers in the soil.

Tuft

A densely packed cluster arising from an axis. *adj.* tufted.

Turbinate

Having the shape of a top; cone-shaped, with the apex downward, inversely conic.

Turgid

Distended by water or other liquid.

Turion

The tender young, scaly shoot such as asparagus, developed from an underground bud without branches or leaves.

Turnery

Articles made by the process of turning.

Twining

Winding spirally.

Ultisols

Mineral soils with no calcareous material, have less than 10 % weatherable minerals in the extreme top layer of soil and with less than 35 % base saturation throughout the soil.

Umbel

An inflorescence of pedicellate flowers of almost equal length arising from one point on top of the peduncle. *adj.* umbellate.

Umbellet

A secondary umbel of a compound umbel. *cf.* umbellule.

Umbellule

An, a secondary umbel of a compound umbel. *cf.* umbellet.

Uncinate

Bent at the end like a hook; unciform.

Undershrub

Subshrub; a small, usually sparsely branched woody shrub less than 1 m high. *cf.* shrub.

Undulate

With an edge/margin or edges wavy in a vertical plane; may vary from weakly to strongly undulate or crisped. *cf.* crisped.

Unifoliolate

A compound leaf which has been reduced to a single, usually terminal leaflet.

Uniform

With one form, e.g. having stamens of a similar length or having one kind of leaf. *cf.* dimorphic.

Uniseriate

Arranged in one row or at one level.

Unisexual

With one sex only, either bearing the anthers with pollen or an ovary with ovules, referring to a flower, inflorescence or individual plant. *cf.* bisexual.

Urceolate

Shaped like a jug, urn or pitcher.

Utricle

A small bladdery pericarp.

Vaginate

Forming or enclosed in a sheath.

Valvate

Meeting without overlapping, as of sepals or petals in bud. *cf.* imbricate.

Valve

One of the sections or portions into which a capsule separates when ripe.

Variant

Any definable individual or group of individuals which may or may not be regarded as representing a formal taxon after examination.

Variegate, variegated

Diverse in colour or marked with irregular patches of different colours, blotched.

Variety

A taxonomic rank below that of sub-species.

Vein

(Botany) a strand of vascular bundle tissue.

Veinlets

Small veins.

Velum

A flap of tissue covering the sporangium in the fern, Isoetes.

Velutinous

Having the surface covered with a fine and dense silky pubescence of short fine hairs; velvety. *cf.* sericeous.

Venation

Distribution or arrangement of veins in a leaf.

Veneer

Thin sheet of wood.

Ventral

(Botany) facing the central axis, opposed to dorsal.

Vernation

The arrangement of young leaves or fronds in a bud or at a stem apex. *cf.* circinnate.

Verrucose

Warty.

Verticil

A circular arrangement, as of flowers, leaves or hairs, growing about a central point; a whorl.

Verticillaster

False whorl composed of a pair of opposite cymes as in Lamiaceae.

Verticillate

Whorled, arranged in one or more whorls.

Vertisol

A soil with a high content of expansive montmorillonite clay that forms deep cracks in drier seasons or years.

Vertosols

Soils that both contain more than 35 % clay and possess deep cracks wider than 5 mm during most years.

Vesicle

A small bladdery sac or cavity filled with air or fluid. *adj.* vesicular.

Vestigial

The remaining trace or remnant of an organ which seemingly lost all or most of its original function in a species through evolution.

Vestiture

Covering; the type of hairiness, scaliness or other covering commonly found on the external parts of plants. *cf.* indumentums.

Vibratile

Capable of to and fro motion.

Villose

Covered with long, fine, soft hairs, finer than in pilose.

Villous

Covered with soft, shaggy unmatted hairs.

Vine

A climbing or trailing plant.

Violaxanthin

Is a natural xanthophyll pigment with an orange color found in a variety of plants like pansies.

Viscid

Sticky, being of a consistency that resists flow.

Viviparous

Describes seeds or fruit which sprout before they fall from the parent plant.

Whorl

A ringlike arrangement of leaves, sepals, stamens or other organs around an axis.

Winged

Having a flat, often membranous expansion or flange, e.g. on a seed, stem or one of the two lateral petals of a Papilionaceous flower or one of the petal-like sepals of Polygalaceae. *cf.* keel, standard.

Xanthophylls

Are yellow, carotenoid pigments found in plants. They are oxidised derivatives of carotenes.

Xeromorphic

Plant with special modified structure to help the plant to adapt to dry conditions.

Xerophyte

A plant which naturally grows in dry regions and is often structurally modified to withstand dry conditions.

Zygomorphic

Having only one plane of symmetry, usually the vertical plane, referring to a flower, calyx or corolla. *cf.* actinomorphic.

Zygote

The first cell formed by the union of two gametes in sexual reproduction. *adj.* zygotic.
